Density, distribution function, quantile function and random generation for the chi-squared (χ^2) distribution with `df` degrees of freedom and optional non-centrality parameter `ncp`.

Usage

```
dchisq(x, df, ncp=0, log = FALSE)
pchisq(q, df, ncp=0, lower.tail = TRUE, log.p = FALSE)
qchisq(p, df, ncp=0, lower.tail = TRUE, log.p = FALSE)
rchisq(n, df, ncp=0)
```

Arguments

<code>x</code> , <code>q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>df</code>	degrees of freedom (non-negative, but can be non-integer).
<code>ncp</code>	non-centrality parameter (non-negative).
<code>log</code> , <code>log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The chi-squared distribution with `df` = $n \geq 0$ degrees of freedom has density

$$f_n(x) = \frac{1}{2^{n/2} \Gamma(n/2)} x^{n/2-1} e^{-x/2}$$

for $x > 0$. The mean and variance are n and $2n$.

The non-central chi-squared distribution with `df` = n degrees of freedom and non-centrality parameter `ncp` = λ has density

$$f(x) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} f_{n+2r}(x)$$

for $x \geq 0$. For integer n , this is the distribution of the sum of squares of n normals each with variance one, λ being the sum of squares of the normal means; further, $E(X) = n + \lambda$, $Var(X) = 2(n + 2 * \lambda)$, and $E((X - E(X))^3) = 8(n + 3 * \lambda)$.

Note that the degrees of freedom `df` = n , can be non-integer, and also $n = 0$ which is relevant for non-centrality $\lambda > 0$, see Johnson et al. (1995, chapter 29).

Note that `ncp` values larger than about $1e5$ may give inaccurate results with many warnings for `pchisq` and `qchisq`.

Value

`dchisq` gives the density, `pchisq` gives the distribution function, `qchisq` gives the quantile function, and `rchisq` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

Source

The central cases are computed via the gamma distribution.

The non-central `dchisq` and `rchisq` are computed as a Poisson mixture central of chi-squares (Johnson et al, 1995, p.436).

The non-central `pchisq` is for `ncp < 80` computed from the Poisson mixture of central chi-squares and for larger `ncp` based on a C translation of

Ding, C. G. (1992) Algorithm AS275: Computing the non-central chi-squared distribution function. *Appl.Statist.*, **41** 478–482.

which computes the lower tail only (so the upper tail suffers from cancellation).

The non-central `qchisq` is based on inversion of `pchisq`.

          all.equal(p.0, exp(-lam/2)))

```

clearNames

Remove the Names from an Object

Description

This function sets the names attribute of object to NULL and returns the object.

Usage

```
clearNames(object)
```

Arguments

object an object that may have a names attribute

Value

An object similar to object but without names.

Author(s)

Douglas Bates and Saikat DebRoy

See Also

[setNames](#)

Examples

```

lapply( women, mean )                            # has a names attribute
clearNames( lapply( women, mean ) )           # removes the names

```

Description

Classical multidimensional scaling of a data matrix. Also known as *principal coordinates analysis* (Gower, 1966).

Usage

```
cmdscale(d, k = 2, eig = FALSE, add = FALSE, x.ret = FALSE)
```

Arguments

d	a distance structure such as that returned by <code>dist</code> or a full symmetric matrix containing the dissimilarities.
k	the dimension of the space which the data are to be represented in; must be in $\{1, 2, \dots, n - 1\}$.
eig	indicates whether eigenvalues should be returned.
add	logical indicating if an additive constant c^* should be computed, and added to the non-diagonal dissimilarities such that all $n - 1$ eigenvalues are non-negative.
x.ret	indicates whether the doubly centred symmetric distance matrix should be returned.

Details

Multidimensional scaling takes a set of dissimilarities and returns a set of points such that the distances between the points are approximately equal to the dissimilarities.

The functions `isoMDS` and `sammon` in package **MASS** provide alternative ordination techniques.

When `add = TRUE`, an additive constant c^* is computed, and the dissimilarities $d_{ij} + c^*$ are used instead of the original d_{ij} 's.

Whereas `S` (Becker *et al.*, 1988) computes this constant using an approximation suggested by Torgerson, `R` uses the analytical solution of Cailliez (1983), see also Cox and Cox (1994).

Value

If `eig = FALSE` and `x.ret = FALSE` (default), a matrix with `k` columns whose rows give the coordinates of the points chosen to represent the dissimilarities.

Otherwise, a list containing the following components.

points	a matrix with <code>k</code> columns whose rows give the coordinates of the points chosen to represent the dissimilarities.
eig	the $n - 1$ eigenvalues computed during the scaling process if <code>eig</code> is true.
x	the doubly centered distance matrix if <code>x.ret</code> is true.
GOF	a numeric vector of length 2, equal to say (g_1, g_2) , where $g_i = (\sum_{j=1}^k \lambda_j) / (\sum_{j=1}^n T_i(\lambda_j))$, where λ_j are the eigenvalues (sorted decreasingly), $T_1(v) = v $, and $T_2(v) = \max(v, 0)$.

text(x, y, rownames(loc), cex=0.8)

cmdsE <- cmdscale(eurodist, k=20, add = TRUE, eig = TRUE, x.ret = TRUE)
utils::str(cmdsE)
```

coef

Extract Model Coefficients

Description

`coef` is a generic function which extracts model coefficients from objects returned by modeling functions. `coefficients` is an *alias* for it.

Usage

```
coef(object, ...)
coefficients(object, ...)
```

Arguments

`object` an object for which the extraction of model coefficients is meaningful.

`...` other arguments.

Details

All object classes which are returned by model fitting functions should provide a `coef` method or use the default one. (Note that the method is for `coef` and not `coefficients`.)

Class "aov" has a `coef` method that does not report aliased coefficients (see [alias](#)).

Value

Coefficients extracted from the model object `object`.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

[fitted.values](#) and [residuals](#) for related methods; [glm](#), [lm](#) for model fitting.

Examples

```
x <- 1:5; coef(lm(c(1:3, 7, 6) ~ x))
```

`complete.cases` *Find Complete Cases*

Description

Return a logical vector indicating which cases are complete, i.e., have no missing values.

Usage

```
complete.cases(...)
```

Arguments

... a sequence of vectors, matrices and data frames.

Value

A logical vector specifying which observations/rows have no missing values across the entire sequence.

See Also

[is.na](#), [na.omit](#), [na.fail](#).

Examples

```
x <- airquality[, -1] # x is a regression design matrix
y <- airquality[, 1] # y is the corresponding response

stopifnot(complete.cases(y) != is.na(y))
ok <- complete.cases(x, y)
sum(!ok) # how many are not "ok" ?
x <- x[ok,]
y <- y[ok]
```

 confint

Confidence Intervals for Model Parameters

Description

Computes confidence intervals for one or more parameters in a fitted model. There is a default and a method for objects inheriting from class "lm".

Usage

```
confint(object, parm, level = 0.95, ...)
```

Arguments

object	a fitted model object.
parm	a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
level	the confidence level required.
...	additional argument(s) for methods.

Details

confint is a generic function. The default method assumes asymptotic normality, and needs suitable `coef` and `vcov` methods to be available. The default method can be called directly for comparison with other methods.

For objects of class "lm" the direct formulae based on t values are used.

There are stub methods for classes "glm" and "nls" which invoke those in package MASS which are based on profile likelihoods.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as $(1-level)/2$ and $1 - (1-level)/2$ in % (by default 2.5% and 97.5%).

See Also

`confint.glm` and `confint.nls` in package MASS.

Examples

```
fit <- lm(100/mpg ~ disp + hp + wt + am, data=mtcars)
confint(fit)
confint(fit, "wt")

## from example(glm) (needs MASS to be present on the system)
counts <- c(18,17,15,20,10,20,25,13,12)
outcome <- gl(3,1,9); treatment <- gl(3,3)
glm.D93 <- glm(counts ~ outcome + treatment, family=poisson())
confint(glm.D93)
confint.default(glm.D93) # based on asymptotic normality
```

constrOptim	<i>Linearly constrained optimisation</i>
-------------	--

Description

Minimise a function subject to linear inequality constraints using an adaptive barrier algorithm.

Usage

```
constrOptim(theta, f, grad, ui, ci, mu = 1e-04, control = list(),
            method = if(is.null(grad)) "Nelder-Mead" else "BFGS",
            outer.iterations = 100, outer.eps = 1e-05, ...)
```

Arguments

theta	Starting value: must be in the feasible region.
f	Function to minimise (see below).
grad	Gradient of f, or NULL (see below).
ui	Constraints (see below).
ci	Constraints (see below).
mu	(Small) tuning parameter.
control	Passed to optim .
method	Passed to optim .
outer.iterations	Iterations of the barrier algorithm.
outer.eps	Criterion for relative convergence of the barrier algorithm.
...	Other arguments passed to optim , which will pass them to f and grad if it does not use them.

Details

The feasible region is defined by $ui \%*\% theta - ci \geq 0$. The starting value must be in the interior of the feasible region, but the minimum may be on the boundary.

A logarithmic barrier is added to enforce the constraints and then [optim](#) is called. The barrier function is chosen so that the objective function should decrease at each outer iteration. Minima in the interior of the feasible region are typically found quite quickly, but a substantial number of outer iterations may be needed for a minimum on the boundary.

The tuning parameter `mu` multiplies the barrier term. Its precise value is often relatively unimportant. As `mu` increases the augmented objective function becomes closer to the original objective function but also less smooth near the boundary of the feasible region.

Any `optim` method that permits infinite values for the objective function may be used (currently all but "L-BFGS-B").

The objective function `f` takes as first argument the vector of parameters over which minimisation is to take place. It should return a scalar result. Optional arguments `...` will be passed to `optim` and then (if not used by `optim`) to `f`. As with `optim`, the default is to minimise, but maximisation can be performed by setting `control$fnscale` to a negative value.

The gradient function `grad` must be supplied except with `method="Nelder-Mead"`. It should take arguments matching those of `f` and return a vector containing the gradient.

Value

As for `optim`, but with two extra components: `barrier.value` giving the value of the barrier function at the optimum and `outer.iterations` gives the number of outer iterations (calls to `optim`)

See Also

`optim`, especially `method="L-BFGS-B"` which does box-constrained optimisation.

Examples

```
## from optim
fr <- function(x) { ## Rosenbrock Banana function
  x1 <- x[1]
  x2 <- x[2]
  100 * (x2 - x1 * x1)^2 + (1 - x1)^2
}
grr <- function(x) { ## Gradient of 'fr'
  x1 <- x[1]
  x2 <- x[2]
  c(-400 * x1 * (x2 - x1 * x1) - 2 * (1 - x1),
    200 * (x2 - x1 * x1))
}

optim(c(-1.2,1), fr, grr)
#Box-constraint, optimum on the boundary
constrOptim(c(-1.2,0.9), fr, grr, ui=rbind(c(-1,0),c(0,-1)), ci=c(-1,-1))
# x<=0.9, y-x>0.1
constrOptim(c(.5,0), fr, grr, ui=rbind(c(-1,0),c(1,-1)), ci=c(-0.9,0.1))

## Solves linear and quadratic programming problems
## but needs a feasible starting value
#
# from example(solve.QP) in 'quadprog'
# no derivative
fQP <- function(b) {-sum(c(0,5,0)*b)+0.5*sum(b*b)}
Amat <- matrix(c(-4,-3,0,2,1,0,0,-2,1),3,3)
bvec <- c(-8,2,0)
```

```

constrOptim(c(2,-1,-1), fQP, NULL, ui=t(Amat), ci=bvec)
# derivative
gQP <- function(b) {-c(0,5,0)+b}
constrOptim(c(2,-1,-1), fQP, gQP, ui=t(Amat), ci=bvec)

## Now with maximisation instead of minimisation
hQP <- function(b) {sum(c(0,5,0)*b)-0.5*sum(b*b)}
constrOptim(c(2,-1,-1), hQP, NULL, ui=t(Amat), ci=bvec,
            control=list(fnscale=-1))

```

contrast

Contrast Matrices

Description

Return a matrix of contrasts.

Usage

```

contr.helmert(n, contrasts = TRUE)
contr.poly(n, scores = 1:n, contrasts = TRUE)
contr.sum(n, contrasts = TRUE)
contr.treatment(n, base = 1, contrasts = TRUE)
contr.SAS(n, contrasts = TRUE)

```

Arguments

n	a vector of levels for a factor, or the number of levels.
contrasts	a logical indicating whether contrasts should be computed.
scores	the set of values over which orthogonal polynomials are to be computed.
base	an integer specifying which group is considered the baseline group. Ignored if contrasts is FALSE.

Details

These functions are used for creating contrast matrices for use in fitting analysis of variance and regression models. The columns of the resulting matrices contain contrasts which can be used for coding a factor with *n* levels. The returned value contains the computed contrasts. If the argument *contrasts* is FALSE a square indicator matrix (the dummy coding) is returned **except** for *contr.poly* (which include the 0-degree, i.e. constant, polynomial when *contrasts* = FALSE).

contr.helmert returns Helmert contrasts, which contrast the second level with the first, the third with the average of the first two, and so on. *contr.poly* returns contrasts based on orthogonal polynomials. *contr.sum* uses 'sum to zero contrasts'.

contr.treatment contrasts each level with the baseline level (specified by *base*): the baseline level is omitted. Note that this does not produce 'contrasts' as defined in the standard theory for linear models as they are not orthogonal to the intercept.

contr.SAS is a wrapper for *contr.treatment* that sets the base level to be the last level of the factor. The coefficients produced when using these contrasts should be equivalent to those produced by many (but not all) SAS procedures.

Value

A matrix with n rows and k columns, with $k=n-1$ if `contrasts` is `TRUE` and $k=n$ if `contrasts` is `FALSE`.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical models*. Chapter 2 of *Statistical Models in S* eds J. M. Chambers and T. J. Hastie, Wadsworth & Brooks/Cole.

See Also

`contrasts`, `C`, and `aov`, `glm`, `lm`.

Examples

```
(cH <- contr.helmert(4))
apply(cH, 2, sum) # column sums are 0!
crossprod(cH) # diagonal -- columns are orthogonal
contr.helmert(4, contrasts = FALSE) # just the 4 x 4 identity matrix

(cT <- contr.treatment(5))
all(crossprod(cT) == diag(4)) # TRUE: even orthonormal

(cT. <- contr.SAS(5))
all(crossprod(cT.) == diag(4)) # TRUE

(cP <- contr.poly(3)) # Linear and Quadratic
zapsmall(crossprod(cP), digits=15) # orthonormal up to fuzz
```

`contrasts`

Get and Set Contrast Matrices

Description

Set and view the contrasts associated with a factor.

Usage

```
contrasts(x, contrasts = TRUE)
contrasts(x, how.many) <- value
```

Arguments

<code>x</code>	a factor or a logical variable.
<code>contrasts</code>	logical. See ‘Details’.
<code>how.many</code>	How many contrasts should be made. Defaults to one less than the number of levels of <code>x</code> . This need not be the same as the number of columns of <code>value</code> .
<code>value</code>	either a numeric matrix whose columns give coefficients for contrasts in the levels of <code>x</code> , or the (quoted) name of a function which computes such matrices.

Details

If contrasts are not set for a factor the default functions from `options("contrasts")` are used.

A logical vector `x` is converted into a two-level factor with levels `c(FALSE, TRUE)` (regardless of which levels occur in the variable).

The argument `contrasts` is ignored if `x` has a matrix `contrasts` attribute set. Otherwise if `contrasts = TRUE` it is passed to a contrasts function such as `contr.treatment` and if `contrasts = FALSE` an identity matrix is returned.

If `value` supplies more than `how.many` contrasts, the first `how.many` are used. If too few are supplied, a suitable contrast matrix is created by extending `value` after ensuring its columns are contrasts (orthogonal to the constant term) and not collinear.

`C`, `contr.helmert`, `contr.poly`, `contr.sum`, `contr.treatment`; `glm`, `aov`, `lm`.

Examples

```
utils::example(factor)
fff <- ff[, drop=TRUE] # reduce to 5 levels.
contrasts(fff) # treatment contrasts by default
contrasts(C(fff, sum))
contrasts(fff, contrasts = FALSE) # the 5x5 identity matrix

contrasts(fff) <- contr.sum(5); contrasts(fff) # set sum contrasts
contrasts(fff, 2) <- contr.sum(5); contrasts(fff) # set 2 contrasts
# supply 2 contrasts, compute 2 more to make full set of 4.
contrasts(fff) <- contr.sum(5)[,1:2]; contrasts(fff)
```

convolve

Fast Convolution

Description

Use the Fast Fourier Transform to compute the several kinds of convolutions of two sequences.

Usage

```
convolve(x, y, conj = TRUE, type = c("circular", "open", "filter"))
```

Arguments

`x, y` numeric sequences *of the same length* to be convolved.
`conj` logical; if `TRUE`, take the complex *conjugate* before back-transforming (default, and used for usual convolution).

type character; one of "circular", "open", "filter" (beginning of word is ok). For circular, the two sequences are treated as *circular*, i.e., periodic. For open and filter, the sequences are padded with 0s (from left and right) first; "filter" returns the middle sub-vector of "open", namely, the result of running a weighted mean of x with weights y .

Details

The Fast Fourier Transform, `fft`, is used for efficiency.

The input sequences x and y must have the same length if `circular` is true.

Note that the usual definition of convolution of two sequences x and y is given by `convolve(x, rev(y), type = "o")`.

Value

If `r <- convolve(x, y, type = "open")` and `n <- length(x)`, `m <- length(y)`, then

$$r_k = \sum_i x_{k-m+i} y_i$$

where the sum is over all valid indices i , for $k = 1, \dots, n + m - 1$

If `type == "circular"`, $n = m$ is required, and the above is true for $i, k = 1, \dots, n$ when $x_j := x_{n+j}$ for $j < 1$.

References

See Also

`fft`, `nextn`, and particularly `filter` (from the `stats` package) which may be more appropriate.

Examples

```
require(graphics)

x <- c(0,0,0,100,0,0,0)
y <- c(0,0,1, 2 ,1,0,0)/4
zapsmall(convolve(x,y)) # *NOT* what you first thought.
zapsmall(convolve(x, y[3:5], type="f")) # rather
x <- rnorm(50)
y <- rnorm(50)
# Circular convolution *has* this symmetry:
all.equal(convolve(x,y, conj = FALSE), rev(convolve(rev(y),x)))

n <- length(x <- -20:24)
y <- (x-10)^2/1000 + rnorm(x)/8

Han <- function(y) # Hanning
  convolve(y, c(1,2,1)/4, type = "filter")

plot(x,y, main="Using convolve(.) for Hanning filters")
lines(x[-c(1 , n) ], Han(y), col="red")
lines(x[-c(1:2, (n-1):n)], Han(Han(y)), lwd=2, col="dark blue")
```

`cophenetic`*Cophenetic Distances for a Hierarchical Clustering*

Description

Computes the cophenetic distances for a hierarchical clustering.

Usage

```
cophenetic(x)
## Default S3 method:
cophenetic(x)
## S3 method for class 'dendrogram':
cophenetic(x)
```

Arguments

`x` an R object representing a hierarchical clustering. For the default method, an object of class `hclust` or with a method for `as.hclust()` such as `agnes`.

Details

The cophenetic distance between two observations that have been clustered is defined to be the intergroup dissimilarity at which the two observations are first combined into a single cluster. Note that this distance has many ties and restrictions.

It can be argued that a dendrogram is an appropriate summary of some data if the correlation between the original distances and the cophenetic distances is high. Otherwise, it should simply be viewed as the description of the output of the clustering algorithm.

`cophenetic` is a generic function. Support for classes which represent hierarchical clusterings (total indexed hierarchies) can be added by providing an `as.hclust()` or, more directly, a `cophenetic()` method for such a class.

The method for objects of class "`dendrogram`" requires that all leaves of the dendrogram object have non-null labels.

Value

An object of class `dist`.

Author(s)

Robert Gentleman

cor(d0, d.coph) # 0.9911
```

cor

Correlation, Variance and Covariance (Matrices)

Description

`var`, `cov` and `cor` compute the variance of `x` and the covariance or correlation of `x` and `y` if these are vectors. If `x` and `y` are matrices then the covariances (or correlations) between the columns of `x` and the columns of `y` are computed.

`cov2cor` scales a covariance matrix into the corresponding correlation matrix *efficiently*.

Usage

```
var(x, y = NULL, na.rm = FALSE, use)

cov(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

cor(x, y = NULL, use = "everything",
    method = c("pearson", "kendall", "spearman"))

cov2cor(V)
```

Arguments

<code>x</code>	a numeric vector, matrix or data frame.
<code>y</code>	NULL (default) or a vector, matrix or data frame with compatible dimensions to <code>x</code> . The default is equivalent to <code>y = x</code> (but more efficient).
<code>na.rm</code>	logical. Should missing values be removed?
<code>use</code>	an optional character string giving a method for computing covariances in the presence of missing values. This must be (an abbreviation of) one of the strings "everything", "all.obs", "complete.obs", "na.or.complete", or "pairwise.complete.obs".

method	a character string indicating which correlation coefficient (or covariance) is to be computed. One of "pearson" (default), "kendall", or "spearman", can be abbreviated.
V	symmetric numeric matrix, usually positive definite such as a covariance matrix.

Details

For `cov` and `cor` one must *either* give a matrix or data frame for x *or* give both x and y .

`var` is just another interface to `cov`, where `na.rm` is used to determine the default for use when that is unspecified. If `na.rm` is TRUE then the complete observations (rows) are used (`use = "na.or.complete"`) to compute the variance. Otherwise, by default `use = "everything"`.

If `use` is "everything", NAs will propagate conceptually, i.e., a resulting value will be NA whenever one of its contributing observations is NA.

If `use` is "all.obs", then the presence of missing observations will produce an error. If `use` is "complete.obs" then missing values are handled by casewise deletion (and if there are no complete cases, that gives an error).

"na.or.complete" is the same unless there are no complete cases, that gives NA. Finally, if `use` has the value "pairwise.complete.obs" then the correlation or covariance between each pair of variables is computed using all complete pairs of observations on those variables. This can result in covariance or correlation matrices which are not positive semi-definite, as well as NA entries if there are no complete pairs for that pair of variables. For `cov` and `var`, "pairwise.complete.obs" only works with the "pearson" method. Note that (the equivalent of) `var(double(0), use=*)` gives NA for `use = "everything"` and "na.or.complete", and gives an error in the other cases.

The denominator $n - 1$ is used which gives an unbiased estimator of the (co)variance for i.i.d. observations. These functions return NA when there is only one observation (whereas S-PLUS has been returning NaN), and fail if x has length zero.

For `cor()`, if `method` is "kendall" or "spearman", Kendall's τ or Spearman's ρ statistic is used to estimate a rank-based measure of association. These are more robust and have been recommended if the data do not necessarily come from a bivariate normal distribution.

For `cov()`, a non-Pearson method is unusual but available for the sake of completeness. Note that "spearman" basically computes `cor(R(x), R(y))` (or `cov(., .)`) where `R(u) := rank(u, na.last="keep")`. In the case of missing values, the ranks are calculated depending on the value of `use`, either based on complete observations, or based on pairwise completeness with reranking for each pair.

Scaling a covariance matrix into a correlation one can be achieved in many ways, mathematically most appealing by multiplication with a diagonal matrix from left and right, or more efficiently by using `sweep(., FUN = "/")` twice. The `cov2cor` function is even a bit more efficient, and provided mostly for didactical reasons.

Value

For `r <- cor(*, use = "all.obs")`, it is now guaranteed that `all(r <= 1)`.

symnum(cor(swM, method = "kendall", use = "complete"))
## Kendall's tau doesn't change much:
symnum(cor(swiss, method = "kendall"))
```

Description

Test for association between paired samples, using one of Pearson's product moment correlation coefficient, Kendall's τ or Spearman's ρ .

Usage

```
cor.test(x, ...)

## Default S3 method:
cor.test(x, y,
         alternative = c("two.sided", "less", "greater"),
         method = c("pearson", "kendall", "spearman"),
         exact = NULL, conf.level = 0.95, ...)

## S3 method for class 'formula':
cor.test(formula, data, subset, na.action, ...)
```

Arguments

<code>x</code> , <code>y</code>	numeric vectors of data values. <code>x</code> and <code>y</code> must have the same length.
<code>alternative</code>	indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. "greater" corresponds to positive association, "less" to negative association.
<code>method</code>	a character string indicating which correlation coefficient is to be used for the test. One of "pearson", "kendall", or "spearman", can be abbreviated.
<code>exact</code>	a logical indicating whether an exact p-value should be computed. Used for Kendall's τ and Spearman's ρ . See 'Details' for the meaning of NULL (the default).
<code>conf.level</code>	confidence level for the returned confidence interval. Currently only used for the Pearson product moment correlation coefficient if there are at least 4 complete pairs of observations.
<code>formula</code>	a formula of the form $\sim u + v$, where each of <code>u</code> and <code>v</code> are numeric variables giving the data values for one sample. The samples must be of the same length.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

The three methods each estimate the association between paired samples and compute a test of the value being zero. They use different measures of association, all in the range $[-1, 1]$ with 0 indicating no association. These are sometimes referred to as tests of no *correlation*, but that term is often confined to the default method.

If `method` is "pearson", the test statistic is based on Pearson's product moment correlation coefficient `cor(x, y)` and follows a t distribution with `length(x) - 2` degrees of freedom if the

samples follow independent normal distributions. If there are at least 4 complete pairs of observation, an asymptotic confidence interval is given based on Fisher's Z transform.

If method is "kendall" or "spearman", Kendall's τ or Spearman's ρ statistic is used to estimate a rank-based measure of association. These tests may be used if the data do not necessarily come from a bivariate normal distribution.

For Kendall's test, by default (if `exact` is NULL), an exact p-value is computed if there are less than 50 paired samples containing finite values and there are no ties. Otherwise, the test statistic is the estimate scaled to zero mean and unit variance, and is approximately normally distributed.

For Spearman's test, p-values are computed using algorithm AS 89.

Value

A list with class "htest" containing the following components:

statistic	the value of the test statistic.
parameter	the degrees of freedom of the test statistic in the case that it follows a t distribution.
p.value	the p-value of the test.
estimate	the estimated measure of association, with name "cor", "tau", or "rho" corresponding to the method employed.
null.value	the value of the association measure under the null hypothesis, always 0.
alternative	a character string describing the alternative hypothesis.
method	a character string indicating how the association was measured.
data.name	a character string giving the names of the data.
conf.int	a confidence interval for the measure of association. Currently only given for Pearson's product moment correlation coefficient in case of at least 4 complete pairs of observations.

         exact = FALSE) # using large sample approximation
## => p=0.04765

## Compare this to
cor.test(x, y, method = "spearm", alternative = "g")
cor.test(x, y,          alternative = "g")

## Formula interface.
require(graphics)
pairs(USJudgeRatings)
cor.test(~ CONT + INTG, data = USJudgeRatings)

```

cov.wt

Weighted Covariance Matrices

Description

Returns a list containing estimates of the weighted covariance matrix and the mean of the data, and optionally of the (weighted) correlation matrix.

Usage

```

cov.wt(x, wt = rep(1/nrow(x), nrow(x)), cor = FALSE, center = TRUE,
       method = c("unbiased", "ML"))

```

Arguments

<code>x</code>	a matrix or data frame. As usual, rows are observations and columns are variables.
<code>wt</code>	a non-negative and non-zero vector of weights for each observation. Its length must equal the number of rows of <code>x</code> .
<code>cor</code>	a logical indicating whether the estimated correlation weighted matrix will be returned as well.
<code>center</code>	either a logical or a numeric vector specifying the centers to be used when computing covariances. If <code>TRUE</code> , the (weighted) mean of each variable is used, if <code>FALSE</code> , zero is used. If <code>center</code> is numeric, its length must equal the number of columns of <code>x</code> .
<code>method</code>	string specifying how the result is scaled, see ‘Details’ below.

Details

By default, `method = "unbiased"`, The covariance matrix is divided by one minus the sum of squares of the weights, so if the weights are the default ($1/n$) the conventional unbiased estimate of the covariance matrix with divisor $(n - 1)$ is obtained. This differs from the behaviour in S-PLUS which corresponds to `method = "ML"` and does not divide.

Value

A list containing the following named components:

<code>cov</code>	the estimated (weighted) covariance matrix
<code>center</code>	an estimate for the center (mean) of the data.
<code>n.obs</code>	the number of observations (rows) in <code>x</code> .
<code>wt</code>	the weights used in the estimation. Only returned if given as an argument.
<code>cor</code>	the estimated correlation matrix. Only returned if <code>cor</code> is TRUE.

cov.wt(xy, wt = w1) # i.e. method = "unbiased"
cov.wt(xy, wt = w1, method = "ML", cor = TRUE)
```

cpgram

Plot Cumulative Periodogram

Description

Plots a cumulative periodogram.

Usage

```
cpgram(ts, taper = 0.1,
       main = paste("Series: ", deparse(substitute(ts))),
       ci.col = "blue")
```

Arguments

<code>ts</code>	a univariate time series
<code>taper</code>	proportion tapered in forming the periodogram
<code>main</code>	main title
<code>ci.col</code>	colour for confidence band.

Value

None.

Side Effects

Plots the cumulative periodogram in a square plot.

Note

From package **MASS**.

Examples

```
require(graphics)

par(pty = "s", mfrow = c(1,2))
cpgram(lh)
lh.ar <- ar(lh, order.max = 9)
cpgram(lh.ar$resid, main = "AR(3) fit to lh")

cpgram(ldeaths)
```

cutree

Cut a tree into groups of data

Description

Cuts a tree, e.g., as resulting from [hclust](#), into several groups either by specifying the desired number(s) of groups or the cut height(s).

Usage

```
cutree(tree, k = NULL, h = NULL)
```

Arguments

tree	a tree as produced by hclust . <code>cutree()</code> only expects a list with components <code>merge</code> , <code>height</code> , and <code>labels</code> , of appropriate content each.
k	an integer scalar or vector with the desired number of groups
h	numeric scalar or vector with heights where the tree should be cut.

At least one of `k` or `h` must be specified, `k` overrides `h` if both are given.

Value

`cutree` returns a vector with group memberships if `k` or `h` are scalar, otherwise a matrix with group memberships is returned where each column corresponds to the elements of `k` or `h`, respectively (which are also used as column names).

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[hclust](#), [dendrogram](#) for cutting trees themselves.

Examples

```
hc <- hclust(dist(USArrests))

cutree(hc, k=1:5) #k = 1 is trivial
cutree(hc, h=250)

## Compare the 2 and 3 grouping:
g24 <- cutree(hc, k = c(2,4))
table(g24[, "2"], g24[, "4"])
```

decompose

*Classical Seasonal Decomposition by Moving Averages***Description**

Decompose a time series into seasonal, trend and irregular components using moving averages. Deals with additive or multiplicative seasonal component.

Usage

```
decompose(x, type = c("additive", "multiplicative"), filter = NULL)
```

Arguments

x	A time series.
type	The type of seasonal component. Can be abbreviated.
filter	A vector of filter coefficients in reverse time order (as for AR or MA coefficients), used for filtering out the seasonal component. If NULL, a moving average with symmetric window is performed.

Details

The additive model used is:

$$Y_t = T_t + S_t + e_t$$

The multiplicative model used is:

$$Y_t = T_t S_t e_t$$

The function first determines the trend component using a moving average (if `filter` is NULL, a symmetric window with equal weights is used), and removes it from the time series. Then, the seasonal figure is computed by averaging, for each time unit, over all periods. The seasonal figure is then centered. Finally, the error component is determined by removing trend and seasonal figure (recycled as needed) from the original time series.

Value

An object of class "decomposed.ts" with following components:

seasonal	The seasonal component (i.e., the repeated seasonal figure)
figure	The estimated seasonal figure only
trend	The trend component
random	The remainder part
type	The value of <code>type</code>

Note

The function `stl` provides a much more sophisticated decomposition.

Examples

```
require(graphics)

m <- decompose(co2)
m$figure
plot(m)
```

delete.response *Modify Terms Objects*

Description

`delete.response` returns a terms object for the same model but with no response variable.
`drop.terms` removes variables from the right-hand side of the model. There is also a "`[.terms`" method to perform the same function (with `keep.response=TRUE`).
`reformulate` creates a formula from a character vector.

Usage

```
delete.response(termobj)

reformulate(termlabels, response = NULL)

drop.terms(termobj, dropx = NULL, keep.response = FALSE)
```

Arguments

<code>termobj</code>	A terms object
<code>termlabels</code>	character vector giving the right-hand side of a model formula. Cannot be zero-length.
<code>response</code>	character string, symbol or call giving the left-hand side of a model formula, or NULL.
<code>dropx</code>	vector of positions of variables to drop from the right-hand side of the model.
<code>keep.response</code>	Keep the response in the resulting object?

Value

`delete.response` and `drop.terms` return a terms object.
`reformulate` returns a formula.

See Also

[terms](#)

Examples

```
ff <- y ~ z + x + w
tt <- terms(ff)
tt
delete.response(tt)
drop.terms(tt, 2:3, keep.response = TRUE)
tt[-1]
tt[2:3]
reformulate(attr(tt, "term.labels"))

## keep LHS :
reformulate("x*w", ff[[2]])
fS <- surv(ft, case) ~ a + b
reformulate(c("a", "b*f"), fS[[2]])

stopifnot(identical(      ~ var, reformulate("var")),
          identical(~ a + b + c, reformulate(letters[1:3])),
          identical( y ~ a + b, reformulate(letters[1:2], "y"))
          )
```

dendrapply

Apply a Function to All Nodes of a Dendrogram

Description

Apply function FUN to each node of a [dendrogram](#) recursively. When `y <- dendrapply(x, fn)`, then `y` is a dendrogram of the same graph structure as `x` and for each node, `y.node[j] <- FUN(x.node[j], ...)` (where `y.node[j]` is an (invalid!) notation for the `j`-th node of `y`).

Usage

```
dendrapply(X, FUN, ...)
```

Arguments

`X` an object of class "[dendrogram](#)".
`FUN` an R function to be applied to each dendrogram node, typically working on its [attributes](#) alone, returning an altered version of the same node.
`...` potential further arguments passed to FUN.

Value

Usually a dendrogram of the same (graph) structure as X. For that, the function must be conceptually of the form `FUN <- function(X) { attributes(X) <-; X }`, i.e. returning the node with some attributes added or changed.

Note

this is still somewhat experimental, and suggestions for enhancements (or nice examples of usage) are very welcome.

Author(s)

Martin Maechler

[as.dendrogram](#), [lapply](#) for applying a function to each component of a list, [rapply](#) for doing so to each non-list component of a nested list.

Examples

```
require(graphics)

## a smallish simple dendrogram
dhc <- as.dendrogram(hc <- hclust(dist(USArrests), "ave"))
(dhc21 <- dhc[[2]][[1]])

## too simple:
dendrapply(dhc21, function(n) utils::str(attributes(n)))

## toy example to set colored leaf labels :
local({
  colLab <-<- function(n) {
    if(is.leaf(n)) {
      a <- attributes(n)
      i <-<- i+1
      attr(n, "nodePar") <-
        c(a$nodePar, list(lab.col = mycols[i], lab.font= i%3))
    }
    n
  }
  mycols <- grDevices::rainbow(attr(dhc21,"members"))
  i <- 0
})
dL <- dendrapply(dhc21, colLab)
op <- par(mfrow=2:1)
plot(dhc21)
plot(dL) ## --> colored labels!
par(op)
```

Description

Class "dendrogram" provides general functions for handling tree-like structures. It is intended as a replacement for similar functions in hierarchical clustering and classification/regression trees, such that all of these can use the same engine for plotting or cutting trees.

The code is still in testing stage and the API may change in the future.

Usage

```
as.dendrogram(object, ...)
## S3 method for class 'hclust':
as.dendrogram(object, hang = -1, ...)

## S3 method for class 'dendrogram':
plot(x, type = c("rectangle", "triangle"),
     center = FALSE,
     edge.root = is.leaf(x) || !is.null(attr(x, "edgetext")),
     nodePar = NULL, edgePar = list(),
     leaflab = c("perpendicular", "textlike", "none"),
     dLeaf = NULL, xlab = "", ylab = "", xaxt = "n", yaxt = "s",
     horiz = FALSE, frame.plot = FALSE, xlim, ylim, ...)

## S3 method for class 'dendrogram':
cut(x, h, ...)

## S3 method for class 'dendrogram':
print(x, digits, ...)

## S3 method for class 'dendrogram':
rev(x)

## S3 method for class 'dendrogram':
str(object, max.level = NA, digits.d = 3,
     give.attr = FALSE, wid = getOption("width"),
     nest.lev = 0, indent.str = "", stem = "--", ...)

is.leaf(object)
```

Arguments

object	any R object that can be made into one of class "dendrogram".
x	object of class "dendrogram".
hang	numeric scalar indicating how the <i>height</i> of leaves should be computed from the heights of their parents; see <code>plot.hclust</code> .
type	type of plot.
center	logical; if TRUE, nodes are plotted centered with respect to the leaves in the branch. Otherwise (default), plot them in the middle of all direct child nodes.

<code>edge.root</code>	logical; if true, draw an edge to the root node.
<code>nodePar</code>	a list of plotting parameters to use for the nodes (see points) or NULL by default which does not draw symbols at the nodes. The list may contain components named <code>pch</code> , <code>cex</code> , <code>col</code> , and/or <code>bg</code> each of which can have length two for specifying separate attributes for <i>inner</i> nodes and <i>leaves</i> .
<code>edgePar</code>	a list of plotting parameters to use for the edge segments and labels (if there's an <code>edgetext</code>). The list may contain components named <code>col</code> , <code>lty</code> and <code>lwd</code> (for the segments), <code>p.col</code> , <code>p.lwd</code> , and <code>p.lty</code> (for the polygon around the text) and <code>t.col</code> for the text color. As with <code>nodePar</code> , each can have length two for differentiating leaves and inner nodes.
<code>leaflab</code>	a string specifying how leaves are labeled. The default "perpendicular" write text vertically (by default). "textlike" writes text horizontally (in a rectangle), and "none" suppresses leaf labels.
<code>dLeaf</code>	a number specifying the distance in user coordinates between the tip of a leaf and its label. If NULL as per default, 3/4 of a letter width or height is used.
<code>horiz</code>	logical indicating if the dendrogram should be drawn <i>horizontally</i> or not.
<code>frame.plot</code>	logical indicating if a box around the plot should be drawn, see plot.default .
<code>h</code>	height at which the tree is cut.
<code>xlim, ylim</code>	optional x- and y-limits of the plot, passed to plot.default . The defaults for these show the full dendrogram.
<code>..., xlab, ylab, xaxt, yaxt</code>	graphical parameters, or arguments for other methods.
<code>digits</code>	integer specifying the precision for printing, see print.default .
<code>max.level, digits.d, give.attr, wid, nest.lev, indent.str</code>	arguments to <code>str</code> , see str.default() . Note that <code>give.attr = FALSE</code> still shows <code>height</code> and <code>members</code> attributes for each node.
<code>stem</code>	a string used for <code>str()</code> specifying the <i>stem</i> to use for each dendrogram branch.

Details

Warning: This documentation is preliminary.

The dendrogram is directly represented as a nested list where each component corresponds to a branch of the tree. Hence, the first branch of tree `z` is `z[[1]]`, the second branch of the corresponding subtree is `z[[1]][[2]]` etc.. Each node of the tree carries some information needed for efficient plotting or cutting as attributes, of which only `members`, `height` and `leaf` for leaves are compulsory:

members total number of leaves in the branch

height numeric non-negative height at which the node is plotted.

midpoint numeric horizontal distance of the node from the left border (the leftmost leaf) of the branch (unit 1 between all leaves). This is used for `plot(*, center=FALSE)`.

label character; the label of the node

x.member for `cut()$upper`, the number of *former* members; more generally a substitute for the `members` component used for 'horizontal' (when `horiz = FALSE`, else 'vertical') alignment.

edgetext character; the label for the edge leading to the node

nodePar a named list (of length-1 components) specifying node-specific attributes for `points` plotting, see the `nodePar` argument above.

edgePar a named list (of length-1 components) specifying attributes for `segments` plotting of the edge leading to the node, and drawing of the `edgetext` if available, see the `edgePar` argument above.

leaf logical, if `TRUE`, the node is a leaf of the tree.

`cut.dendrogram()` returns a list with components `$upper` and `$lower`, the first is a truncated version of the original tree, also of class `dendrogram`, the latter a list with the branches obtained from cutting the tree, each a `dendrogram`.

There are `[[`, `print`, and `str` methods for "dendrogram" objects where the first one (extraction) ensures that selecting sub-branches keeps the class.

Objects of class "hclust" can be converted to class "dendrogram" using method `as.dendrogram`.

`rev.dendrogram` simply returns the dendrogram `x` with reversed nodes, see also `reorder.dendrogram`.

`is.leaf(object)` is logical indicating if `object` is a leaf (the most simple dendrogram). `plotNode()` and `plotNodeLimit()` are helper functions.

Warning

Some operations on dendrograms (including plotting) make use of recursion. For very deep trees It may be necessary to increase `options("expressions")`: if you do you are likely to need to set the C stack size larger than the OS default if possible (which it is not on Windows).

Note

When using `type = "triangle"`, `center = TRUE` often looks better.

See Also

`order.dendrogram` also on the `labels` method for dendrograms.

Examples

```
require(graphics); require(utils)

hc <- hclust(dist(USArrests), "ave")
(dend1 <- as.dendrogram(hc)) # "print()" method
str(dend1)                   # "str()" method
str(dend1, max = 2) # only the first two sub-levels

op <- par(mfrow= c(2,2), mar = c(5,2,1,4))
plot(dend1)
## "triangle" type and show inner nodes:
plot(dend1, nodePar=list(pch = c(1,NA), cex=0.8, lab.cex = 0.8),
      type = "t", center=TRUE)
plot(dend1, edgePar=list(col = 1:2, lty = 2:3),

plot(d3e, nodePar= nP, leaflab = "textlike")

```

Description

The (S3) generic function `density` computes kernel density estimates. Its default method does so with the given kernel and bandwidth for univariate observations.

Usage

```

density(x, ...)
## Default S3 method:
density(x, bw = "nrd0", adjust = 1,
        kernel = c("gaussian", "epanechnikov", "rectangular",
                  "triangular", "biweight",
                  "cosine", "optcosine"),
        weights = NULL, window = kernel, width,
        give.Rkern = FALSE,
        n = 512, from, to, cut = 3, na.rm = FALSE, ...)

```

Arguments

`x` the data from which the estimate is to be computed.

<code>bw</code>	the smoothing bandwidth to be used. The kernels are scaled such that this is the standard deviation of the smoothing kernel. (Note this differs from the reference books cited below, and from S-PLUS.) <code>bw</code> can also be a character string giving a rule to choose the bandwidth. See bw.nrd . The specified (or computed) value of <code>bw</code> is multiplied by <code>adjust</code> .
<code>adjust</code>	the bandwidth used is actually <code>adjust*bw</code> . This makes it easy to specify values like ‘half the default’ bandwidth.
<code>kernel, window</code>	a character string giving the smoothing kernel to be used. This must be one of "gaussian", "rectangular", "triangular", "epanechnikov", "biweight", "cosine" or "optcosine", with default "gaussian", and may be abbreviated to a unique prefix (single letter). "cosine" is smoother than "optcosine", which is the usual ‘cosine’ kernel in the literature and almost MSE-efficient. However, "cosine" is the version used by S.
<code>weights</code>	numeric vector of non-negative observation weights, hence of same length as <code>x</code> . The default NULL is equivalent to <code>weights = rep(1/nx, nx)</code> where <code>nx</code> is the length of (the finite entries of) <code>x[]</code> .
<code>width</code>	this exists for compatibility with S; if given, and <code>bw</code> is not, will set <code>bw</code> to <code>width</code> if this is a character string, or to a kernel-dependent multiple of <code>width</code> if this is numeric.
<code>give.Rkern</code>	logical; if true, <i>no</i> density is estimated, and the ‘canonical bandwidth’ of the chosen kernel is returned instead.
<code>n</code>	the number of equally spaced points at which the density is to be estimated. When <code>n > 512</code> , it is rounded up to the next power of 2 for efficiency reasons (fft).
<code>from,to</code>	the left and right-most points of the grid at which the density is to be estimated; the defaults are <code>cut * bw</code> outside of <code>range(x)</code> .
<code>cut</code>	by default, the values of <code>from</code> and <code>to</code> are <code>cut</code> bandwidths beyond the extremes of the data. This allows the estimated density to drop to approximately zero at the extremes.
<code>na.rm</code>	logical; if TRUE, missing values are removed from <code>x</code> . If FALSE any missing values cause an error.
<code>...</code>	further arguments for (non-default) methods.

Details

The algorithm used in `density.default` disperses the mass of the empirical distribution function over a regular grid of at least 512 points and then uses the fast Fourier transform to convolve this approximation with a discretized version of the kernel and then uses linear approximation to evaluate the density at the specified points.

The statistical properties of a kernel are determined by $\sigma_K^2 = \int t^2 K(t) dt$ which is always = 1 for our kernels (and hence the bandwidth `bw` is the standard deviation of the kernel) and $R(K) = \int K^2(t) dt$.

MSE-equivalent bandwidths (for different kernels) are proportional to $\sigma_K R(K)$ which is scale invariant and for our kernels equal to $R(K)$. This value is returned when `give.Rkern = TRUE`. See the examples for using exact equivalent bandwidths.

Infinite values in `x` are assumed to correspond to a point mass at $+/-\text{Inf}$ and the density estimate is of the sub-density on $(-\text{Inf}, +\text{Inf})$.

Value

If `give.Rkern` is true, the number $R(K)$, otherwise an object with class "density" whose underlying structure is a list containing the following components.

<code>x</code>	the <code>n</code> coordinates of the points where the density is estimated.
<code>y</code>	the estimated density values. These will be non-negative, but can be zero.
<code>bw</code>	the bandwidth used.
<code>n</code>	the sample size after elimination of missing values.
<code>call</code>	the call which produced the result.
<code>data.name</code>	the deparsed name of the <code>x</code> argument.
<code>has.na</code>	logical, for compatibility (always FALSE).

The `print` method reports `summary` values on the `x` and `y` components.

```

Description

Compute derivatives of simple expressions, symbolically.

Usage

```
D (expr, name)
deriv(expr, ...)
deriv3(expr, ...)

## Default S3 method:
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
      hessian = FALSE, ...)
## S3 method for class 'formula':
deriv(expr, namevec, function.arg = NULL, tag = ".expr",
      hessian = FALSE, ...)

## Default S3 method:
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
       hessian = TRUE, ...)
## S3 method for class 'formula':
deriv3(expr, namevec, function.arg = NULL, tag = ".expr",
       hessian = TRUE, ...)
```

Arguments

<code>expr</code>	A expression or call or (except <code>D</code>) a formula with no lhs.
<code>name, namevec</code>	character vector, giving the variable names (only one for <code>D()</code>) with respect to which derivatives will be computed.
<code>function.arg</code>	If specified and non-NULL, a character vector of arguments for a function return, or a function (with empty body) or TRUE, the latter indicating that a function with argument names <code>namevec</code> should be used.
<code>tag</code>	character; the prefix to be used for the locally created variables in result.
<code>hessian</code>	a logical value indicating whether the second derivatives should be calculated and incorporated in the return value.
<code>...</code>	arguments to be passed to or from methods.

Details

`D` is modelled after its `S` namesake for taking simple symbolic derivatives.

`deriv` is a *generic* function with a default and a [formula](#) method. It returns a [call](#) for computing the `expr` and its (partial) derivatives, simultaneously. It uses so-called *algorithmic derivatives*. If `function.arg` is a function, its arguments can have default values, see the `fx` example below. Currently, `deriv.formula` just calls `deriv.default` after extracting the expression to the right of `~`.

`deriv3` and its methods are equivalent to `deriv` and its methods except that `hessian` defaults to TRUE for `deriv3`.

The internal code knows about the arithmetic operators `+`, `-`, `*`, `/` and `^`, and the single-variable functions `exp`, `log`, `sin`, `cos`, `tan`, `sinh`, `cosh`, `sqrt`, `pnorm`, `dnorm`, `asin`, `acos`, `atan`, `gamma`, `lgamma`, `digamma` and `trigamma`, as well as `psigamma` for one or two arguments (but derivative only with respect to the first). (Note that only the standard normal distribution is considered.)

Value

D returns a call and therefore can easily be iterated for higher derivatives.

deriv and deriv3 normally return an `expression` object whose evaluation returns the function values with a "gradient" attribute containing the gradient matrix. If `hessian` is TRUE the evaluation also returns a "hessian" attribute containing the Hessian array.

If `function.arg` is not NULL, deriv and deriv3 return a function with those arguments rather than an expression.

  2) * (2 * x) + sin(x^2) * (2 * x) * 2)
## End(Not run)
```

deviance

Model Deviance

Description

Returns the deviance of a fitted model object.

Usage

```
deviance(object, ...)
```

Arguments

`object` an object for which the deviance is desired.
`...` additional optional argument.

Details

This is a generic function which can be used to extract deviances for fitted models. Consult the individual modeling functions for details on how to use this function.

Value

The value of the deviance extracted from the object `object`.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

[df.residual](#), [extractAIC](#), [glm](#), [lm](#).

<code>df.residual</code>	<i>Residual Degrees-of-Freedom</i>
--------------------------	------------------------------------

Description

Returns the residual degrees-of-freedom extracted from a fitted model object.

Usage

```
df.residual(object, ...)
```

Arguments

<code>object</code>	an object for which the degrees-of-freedom are desired.
<code>...</code>	additional optional arguments.

Details

This is a generic function which can be used to extract residual degrees-of-freedom for fitted models. Consult the individual modeling functions for details on how to use this function.

The default method just extracts the `df.residual` component.

Value

The value of the residual degrees-of-freedom extracted from the object `x`.

See Also

[deviance](#), [glm](#), [lm](#).

<code>diffinv</code>	<i>Discrete Integration: Inverse of Differencing</i>
----------------------	--

Description

Computes the inverse function of the lagged differences function [diff](#).

Usage

```
diffinv(x, ...)

## Default S3 method:
diffinv(x, lag = 1, differences = 1, xi, ...)
## S3 method for class 'ts':
diffinv(x, lag = 1, differences = 1, xi, ...)
```

Arguments

<code>x</code>	a numeric vector, matrix, or time series.
<code>lag</code>	a scalar lag parameter.
<code>differences</code>	an integer representing the order of the difference.
<code>xi</code>	a numeric vector, matrix, or time series containing the initial values for the integrals. If missing, zeros are used.
<code>...</code>	arguments passed to or from other methods.

Details

`diffinv` is a generic function with methods for class `"ts"` and `default` for vectors and matrices.

Missing values are not handled.

Value

A numeric vector, matrix, or time series (the latter for the `"ts"` method) representing the discrete integral of `x`.

dist

Distance Matrix Computation

Description

This function computes and returns the distance matrix computed by using the specified distance measure to compute the distances between the rows of a data matrix.

Usage

```
dist(x, method = "euclidean", diag = FALSE, upper = FALSE, p = 2)

as.dist(m, diag = FALSE, upper = FALSE)
## Default S3 method:
as.dist(m, diag = FALSE, upper = FALSE)

## S3 method for class 'dist':
```

```
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none",
      right = TRUE, ...)

## S3 method for class 'dist':
as.matrix(x, ...)
```

Arguments

<code>x</code>	a numeric matrix, data frame or "dist" object.
<code>method</code>	the distance measure to be used. This must be one of "euclidean", "maximum", "manhattan", "canberra", "binary" or "minkowski". Any unambiguous substring can be given.
<code>diag</code>	logical value indicating whether the diagonal of the distance matrix should be printed by <code>print.dist</code> .
<code>upper</code>	logical value indicating whether the upper triangle of the distance matrix should be printed by <code>print.dist</code> .
<code>p</code>	The power of the Minkowski distance.
<code>m</code>	An object with distance information to be converted to a "dist" object. For the default method, a "dist" object, or a matrix (of distances) or an object which can be coerced to such a matrix using <code>as.matrix()</code> . (Only the lower triangle of the matrix is used, the rest is ignored).
<code>digits, justify</code>	passed to <code>format</code> inside of <code>print()</code> .
<code>right, ...</code>	further arguments, passed to other methods.

Details

Available distance measures are (written for two vectors x and y):

euclidean: Usual square distance between the two vectors (2 norm).

maximum: Maximum distance between two components of x and y (supremum norm)

manhattan: Absolute distance between the two vectors (1 norm).

canberra: $\sum_i |x_i - y_i| / |x_i + y_i|$. Terms with zero numerator and denominator are omitted from the sum and treated as if the values were missing.

binary: (aka *asymmetric binary*): The vectors are regarded as binary bits, so non-zero elements are 'on' and zero elements are 'off'. The distance is the *proportion* of bits in which only one is on amongst those in which at least one is on.

minkowski: The p norm, the p th root of the sum of the p th powers of the differences of the components.

Missing values are allowed, and are excluded from all computations involving the rows within which they occur. Further, when `Inf` values are involved, all pairs of values are excluded when their contribution to the distance gave `NaN` or `NA`.

If some columns are excluded in calculating a Euclidean, Manhattan, Canberra or Minkowski distance, the sum is scaled up proportionally to the number of columns used. If all pairs are excluded when calculating a particular distance, the value is `NA`.

The "dist" method of `as.matrix()` and `as.dist()` can be used for conversion between objects of class "dist" and conventional distance matrices.

`as.dist()` is a generic function. Its default method handles objects inheriting from class "dist", or coercible to matrices using `as.matrix()`. Support for classes representing distances (also known as dissimilarities) can be added by providing an `as.matrix()` or, more directly, an `as.dist` method for such a class.

Value

`dist` returns an object of class "dist".

The lower triangle of the distance matrix stored by columns in a vector, say `do`. If `n` is the number of observations, i.e., `n <- attr(do, "Size")`, then for $i < j \leq n$, the dissimilarity between (row) i and j is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is $n*(n-1)/2$, i.e., of order n^2 .

The object has the following attributes (besides "class" equal to "dist"):

<code>Size</code>	integer, the number of observations in the dataset.
<code>Labels</code>	optionally, contains the labels, if any, of the observations of the dataset.
<code>Diag, Upper</code>	logicals corresponding to the arguments <code>diag</code> and <code>upper</code> above, specifying how the object should be printed.
<code>call</code>	optionally, the <code>call</code> used to create the object.
<code>method</code>	optionally, the distance method used; resulting from <code>dist()</code> , the <code>(match.arg())</code> ed method argument.

plot(hclust(dd)) # to see a dendrogram of clustered variables
```

```

## example of binary and canberra distances.
x <- c(0, 0, 1, 1, 1, 1)
y <- c(1, 0, 1, 1, 0, 1)
dist(rbind(x,y), method= "binary")
## answer 0.4 = 2/5
dist(rbind(x,y), method= "canberra")
## answer 2 * (6/5)

## To find the names
labels(eurodist)

## Examples involving "Inf" :
## 1)
x[6] <- Inf
(m2 <- rbind(x,y))
dist(m2, method="binary")# warning, answer 0.5 = 2/4
## These all give "Inf":
stopifnot(Inf == dist(m2, method= "euclidean"),
          Inf == dist(m2, method= "maximum"),
          Inf == dist(m2, method= "manhattan"))
## "Inf" is same as very large number:
x1 <- x; x1[6] <- 1e100
stopifnot(dist(cbind(x ,y), method="canberra") ==
          print(dist(cbind(x1,y), method="canberra")))

## 2)
y[6] <- Inf #-> 6-th pair is excluded
dist(rbind(x,y), method="binary") # warning; 0.5
dist(rbind(x,y), method="canberra") # 3
dist(rbind(x,y), method="maximum") # 1
dist(rbind(x,y), method="manhattan") # 2.4

```

dummy.coef

Extract Coefficients in Original Coding

Description

This extracts coefficients in terms of the original levels of the coefficients rather than the coded variables.

Usage

```

dummy.coef(object, ...)

## S3 method for class 'lm':
dummy.coef(object, use.na = FALSE, ...)

## S3 method for class 'aovlist':
dummy.coef(object, use.na = FALSE, ...)

```

Arguments

object a linear model fit.

`use.na` logical flag for coefficients in a singular model. If `use.na` is true, undetermined coefficients will be missing; if false they will get one possible value.

`...` arguments passed to or from other methods.

Details

A fitted linear model has coefficients for the contrasts of the factor terms, usually one less in number than the number of levels. This function re-expresses the coefficients in the original coding; as the coefficients will have been fitted in the reduced basis, any implied constraints (e.g., zero sum for `contr.helmert` or `contr.sum` will be respected. There will be little point in using `dummy.coef` for `contr.treatment` contrasts, as the missing coefficients are by definition zero.

The method used has some limitations, and will give incomplete results for terms such as `poly(x, 2)`. However, it is adequate for its main purpose, `aov` models.

Value

A list giving for each term the values of the coefficients. For a multistratum `aov` model, such a list for each stratum.

Warning

This function is intended for human inspection of the output: it should not be used for calculations. Use coded variables for all calculations.

The results differ from S for singular values, where S can be incorrect.

See Also

[aov, model.tables](#)

Examples

```
options(contrasts=c("contr.helmert", "contr.poly"))
## From Venables and Ripley (2002) p.165.
utils::data(npk, package="MASS")
npk.aov <- aov(yield ~ block + N*P*K, npk)
dummy.coef(npk.aov)

npk.aovE <- aov(yield ~ N*P*K + Error(block), npk)
dummy.coef(npk.aovE)
```

Description

Compute or plot an empirical cumulative distribution function.

Usage

```
ecdf(x)

## S3 method for class 'ecdf':
plot(x, ..., ylab="Fn(x)", verticals = FALSE,
      col.01line = "gray70", pch = 19)

## S3 method for class 'ecdf':
print(x, digits= getOption("digits") - 2, ...)

## S3 method for class 'ecdf':
summary(object, ...)
```

Arguments

<code>x</code> , <code>object</code>	numeric vector of the observations for <code>ecdf</code> ; for the methods, an object inheriting from class <code>"ecdf"</code> .
<code>...</code>	arguments to be passed to subsequent methods, e.g., <code>plot.stepfun</code> for the <code>plot</code> method.
<code>ylab</code>	label for the y-axis.
<code>verticals</code>	see <code>plot.stepfun</code> .

Details

The e.c.d.f. (empirical cumulative distribution function) F_n is a step function with jumps i/n at observation values, where i is the number of tied observations at that value. Missing values are ignored.

For observations $x = (x_1, x_2, \dots, x_n)$, F_n is the fraction of observations less or equal to t , i.e.,

$$F_n(t) = \#\{x_i \leq t\} / n = \frac{1}{n} \sum_{i=1}^n \mathbf{1}_{[x_i \leq t]}.$$

The function `plot.ecdf` which implements the `plot` method for `ecdf` objects, is implemented via a call to `plot.stepfun`; see its documentation.

Value

For `ecdf`, a function of class `"ecdf"`, inheriting from the `"stepfun"` class.

For the `summary` method, a summary of the knots of `object` with a `"header"` attribute.

Author(s)

```

`eff.aovlist`*Compute Efficiencies of Multistratum Analysis of Variance*

Description

Computes the efficiencies of fixed-effect terms in an analysis of variance model with multiple strata.

Usage

```
eff.aovlist(aovlist)
```

Arguments

`aovlist` The result of a call to `aov` with an `Error` term.

Details

Fixed-effect terms in an analysis of variance model with multiple strata may be estimable in more than one stratum, in which case there is less than complete information in each. The efficiency for a term is the fraction of the maximum possible precision (inverse variance) obtainable by estimating in just that stratum. Under the assumption of balance, this is the same for all contrasts involving that term.

This function is used to pick strata in which to estimate terms in `model.tables.aovlist` and `se.contrast.aovlist`.

In many cases terms will only occur in one stratum, when all the efficiencies will be one: this is detected and no further calculations are done.

The calculation used requires orthogonal contrasts for each term, and will throw an error if non-orthogonal contrasts (e.g. treatment contrasts or an unbalanced design) are detected.

Value

A matrix giving for each non-pure-error stratum (row) the efficiencies for each fixed-effect term in the model.

```

effects

*Effects from Fitted Model***Description**

Returns (orthogonal) effects from a fitted model, usually a linear model. This is a generic function, but currently only has a methods for objects inheriting from classes "lm" and "glm".

Usage

```

effects(object, ...)

## S3 method for class 'lm':
effects(object, set.sign = FALSE, ...)

```

Arguments

object	an R object; typically, the result of a model fitting function such as <code>lm</code> .
set.sign	logical. If TRUE, the sign of the effects corresponding to coefficients in the model will be set to agree with the signs of the corresponding coefficients, otherwise the sign is arbitrary.
...	arguments passed to or from other methods.

Details

For a linear model fitted by `lm` or `aov`, the effects are the uncorrelated single-degree-of-freedom values obtained by projecting the data onto the successive orthogonal subspaces generated by the QR decomposition during the fitting process. The first r (the rank of the model) are associated with coefficients and the remainder span the space of residuals (but are not associated with particular residuals).

Empty models do not have effects.

Value

A (named) numeric vector of the same length as `residuals`, or a matrix if there were multiple responses in the fitted model, in either case of class "coef".

The first r rows are labelled by the corresponding coefficients, and the remaining rows are unlabelled. Note that in rank-deficient models the corresponding coefficients will be in a different order if pivoting occurred.

# just the first is different
```

embed

Embedding a Time Series

Description

Embeds the time series x into a low-dimensional Euclidean space.

Usage

```
embed (x, dimension = 1)
```

Arguments

x a numeric vector, matrix, or time series.
 $dimension$ a scalar representing the embedding dimension.

Details

Each row of the resulting matrix consists of sequences $x[t]$, $x[t-1]$, ..., $x[t-dimension+1]$, where t is the original index of x . If x is a matrix, i.e., x contains more than one variable, then $x[t]$ consists of the t th observation on each variable.

Value

A matrix containing the embedded time series x .

Author(s)

A. Trapletti, B.D. Ripley

Examples

```
x <- 1:10
embed (x, 3)
```

expand.model.frame *Add new variables to a model frame*

Description

Evaluates new variables as if they had been part of the formula of the specified model. This ensures that the same `na.action` and `subset` arguments are applied and allows, for example, `x` to be recovered for a model using `sin(x)` as a predictor.

Usage

```
expand.model.frame(model, extras,
                   envir = environment(formula(model)),
                   na.expand = FALSE)
```

Arguments

<code>model</code>	a fitted model
<code>extras</code>	one-sided formula or vector of character strings describing new variables to be added
<code>envir</code>	an environment to evaluate things in
<code>na.expand</code>	logical; see below

Details

If `na.expand=FALSE` then NA values in the extra variables will be passed to the `na.action` function used in `model`. This may result in a shorter data frame (with `na.omit`) or an error (with `na.fail`). If `na.expand=TRUE` the returned data frame will have precisely the same rows as `model.frame(model)`, but the columns corresponding to the extra variables may contain NA.

Value

A data frame.

See Also

[model.frame](#), [predict](#)

Examples

```
model <- lm(log(Volume) ~ log(Girth) + log(Height), data=trees)
expand.model.frame(model, ~ Girth) # prints data.frame like

dd <- data.frame(x=1:5, y=rnorm(5), z=c(1,2,NA,4,5))
model <- glm(y ~ x, data=dd, subset=1:4, na.action=na.omit)
expand.model.frame(model, "z", na.expand=FALSE) # = default
expand.model.frame(model, "z", na.expand=TRUE)
```

Exponential

*The Exponential Distribution***Description**

Density, distribution function, quantile function and random generation for the exponential distribution with rate `rate` (i.e., mean $1/\text{rate}$).

Usage

```
dexp(x, rate = 1, log = FALSE)
pexp(q, rate = 1, lower.tail = TRUE, log.p = FALSE)
qexp(p, rate = 1, lower.tail = TRUE, log.p = FALSE)
rexp(n, rate = 1)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>rate</code>	vector of rates.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If `rate` is not specified, it assumes the default value of 1.

The exponential distribution with rate λ has density

$$f(x) = \lambda e^{-\lambda x}$$

for $x \geq 0$.

Value

`dexp` gives the density, `pexp` gives the distribution function, `qexp` gives the quantile function, and `rexp` generates random deviates.

Note

The cumulative hazard $H(t) = -\log(1 - F(t))$ is `-pexp(t, r, lower = FALSE, log = TRUE)`.

Source

`dexp`, `pexp` and `qexp` are all calculated from numerically stable versions of the definitions.

`rexp` uses

Ahrens, J. H. and Dieter, U. (1972). Computer methods for sampling from the exponential and normal distributions. *Communications of the ACM*, **15**, 873–882.

Examples

```
dexp(1) - exp(-1) #-> 0
```

extractAIC	<i>Extract AIC from a Fitted Model</i>
------------	--

Description

Computes the (generalized) Akaike An Information Criterion for a fitted parametric model.

Usage

```
extractAIC(fit, scale, k = 2, ...)
```

Arguments

fit	fitted model, usually the result of a fitter like <code>lm</code> .
scale	optional numeric specifying the scale parameter of the model, see <code>scale</code> in <code>step</code> . Currently only used in the "lm" method, where <code>scale</code> specifies the estimate of the error variance, and <code>scale = 0</code> indicates that it is to be estimated by maximum likelihood.
k	numeric specifying the 'weight' of the <i>equivalent degrees of freedom</i> (\equiv <code>edf</code>) part in the AIC formula.
...	further arguments (currently unused in base R).

Details

This is a generic function, with methods in base R for "aov", "coxph", "glm", "lm", "negbin" and "survreg" classes.

The criterion used is

$$AIC = -2 \log L + k \times \text{edf},$$

where L is the likelihood and `edf` the equivalent degrees of freedom (i.e., the number of free parameters for usual parametric models) of `fit`.

For linear models with unknown scale (i.e., for `lm` and `aov`), $-2 \log L$ is computed from the *deviance* and uses a different additive constant to `logLik` and hence `AIC`. If RSS denotes the (weighted) residual sum of squares then `extractAIC` uses for $-2 \log L$ the formulae $RSS/s - n$ (corresponding to Mallows' C_p) in the case of known scale s and $n \log(RSS/n)$ for unknown scale.

AIC only handles unknown scale and uses the formula $n \log(RSS/n) - n + n \log 2\pi - \sum \log w$ where w are the weights.

For `glm` fits the family's `aic()` function to compute the AIC: see the note under `logLik` about the assumptions this makes.

$k = 2$ corresponds to the traditional AIC, using $k = \log(n)$ provides the BIC (Bayesian IC) instead.

Value

A numeric vector of length 2, giving

<code>edf</code>	the ‘equivalent d egrees of f reedom’ for the fitted model <code>fit</code> .
<code>AIC</code>	the (generalized) Akaike Information Criterion for <code>fit</code> .

Note

This function is used in `add1`, `drop1` and `step` and similar functions in package **MASS** from which it was adopted.

factanal

Factor Analysis

Description

Perform maximum-likelihood factor analysis on a covariance matrix or data matrix.

Usage

```
factanal(x, factors, data = NULL, covmat = NULL, n.obs = NA,
         subset, na.action, start = NULL,
         scores = c("none", "regression", "Bartlett"),
         rotation = "varimax", control = NULL, ...)
```

Arguments

<code>x</code>	A formula or a numeric matrix or an object that can be coerced to a numeric matrix.
<code>factors</code>	The number of factors to be fitted.
<code>data</code>	An optional data frame (or similar: see <code>model.frame</code>), used only if <code>x</code> is a formula. By default the variables are taken from <code>environment(formula)</code> .
<code>covmat</code>	A covariance matrix, or a covariance list as returned by <code>cov.wt</code> . Of course, correlation matrices are covariance matrices.
<code>n.obs</code>	The number of observations, used if <code>covmat</code> is a covariance matrix.
<code>subset</code>	A specification of the cases to be used, if <code>x</code> is used as a matrix or formula.
<code>na.action</code>	The <code>na.action</code> to be used if <code>x</code> is used as a formula.
<code>start</code>	NULL or a matrix of starting values, each column giving an initial set of uniquenesses.
<code>scores</code>	Type of scores to produce, if any. The default is none, "regression" gives Thompson's scores, "Bartlett" gives Bartlett's weighted least-squares scores. Partial matching allows these names to be abbreviated.
<code>rotation</code>	character. "none" or the name of a function to be used to rotate the factors: it will be called with first argument the loadings matrix, and should return a list with component <code>loadings</code> giving the rotated loadings, or just the rotated loadings.
<code>control</code>	A list of control values, nstart The number of starting values to be tried if <code>start = NULL</code> . Default 1. trace logical. Output tracing information? Default FALSE. lower The lower bound for uniquenesses during optimization. Should be > 0. Default 0.005. opt A list of control values to be passed to <code>optim</code> 's <code>control</code> argument. rotate a list of additional arguments for the rotation function.
<code>...</code>	Components of <code>control</code> can also be supplied as named arguments to <code>factanal</code> .

Details

The factor analysis model is

$$x = \Lambda f + e$$

for a p -element row-vector x , a $p \times k$ matrix of *loadings*, a k -element vector of *scores* and a p -element vector of errors. None of the components other than x is observed, but the major restriction is that the scores be uncorrelated and of unit variance, and that the errors be independent with variances Φ , the *uniquenesses*. Thus factor analysis is in essence a model for the covariance matrix of x ,

$$\Sigma = \Lambda' \Lambda + \Psi$$

There is still some indeterminacy in the model for it is unchanged if Λ is replaced by $G\Lambda$ for any orthogonal matrix G . Such matrices G are known as *rotations* (although the term is applied also to non-orthogonal invertible matrices).

If `covmat` is supplied it is used. Otherwise `x` is used if it is a matrix, or a formula `x` is used with `data` to construct a model matrix, and that is used to construct a covariance matrix. (It makes no sense for the formula to have a response, and all the variables must be numeric.) Once a covariance

matrix is found or calculated from `x`, it is converted to a correlation matrix for analysis. The correlation matrix is returned as component `correlation` of the result.

The fit is done by optimizing the log likelihood assuming multivariate normality over the uniquenesses. (The maximizing loadings for given uniquenesses can be found analytically: Lawley & Maxwell (1971, p. 27).) All the starting values supplied in `start` are tried in turn and the best fit obtained is used. If `start = NULL` then the first fit is started at the value suggested by Jöreskog (1963) and given by Lawley & Maxwell (1971, p. 31), and then `control$nstart - 1` other values are tried, randomly selected as equal values of the uniquenesses.

The uniquenesses are technically constrained to lie in $[0, 1]$, but near-zero values are problematical, and the optimization is done with a lower bound of `control$lower`, default 0.005 (Lawley & Maxwell, 1971, p. 32).

Scores can only be produced if a data matrix is supplied and used. The first method is the regression method of Thomson (1951), the second the weighted least squares method of Bartlett (1937, 8). Both are estimates of the unobserved scores f . Thomson's method regresses (in the population) the unknown f on x to yield

$$\hat{f} = \Lambda' \Sigma^{-1} x$$

and then substitutes the sample estimates of the quantities on the right-hand side. Bartlett's method minimizes the sum of squares of standardized errors over the choice of f , given (the fitted) Λ .

If `x` is a formula then the standard NA-handling is applied to the scores (if requested): see [napredict](#).

Value

An object of class "factanal" with components

<code>loadings</code>	A matrix of loadings, one column for each factor. The factors are ordered in decreasing order of sums of squares of loadings, and given the sign that will make the sum of the loadings positive.
<code>uniquenesses</code>	The uniquenesses computed.
<code>correlation</code>	The correlation matrix used.
<code>criteria</code>	The results of the optimization: the value of the negative log-likelihood and information on the iterations used.
<code>factors</code>	The argument <code>factors</code> .
<code>dof</code>	The number of degrees of freedom of the factor analysis model.
<code>method</code>	The method: always "mle".
<code>scores</code>	If requested, a matrix of scores. <code>napredict</code> is applied to handle the treatment of values omitted by the <code>na.action</code> .
<code>n.obs</code>	The number of observations if available, or NA.
<code>call</code>	The matched call.
<code>na.action</code>	If relevant.
<code>STATISTIC, PVAL</code>	The significance-test statistic and P value, if it can be computed.

Note

There are so many variations on factor analysis that it is hard to compare output from different programs. Further, the optimization in maximum likelihood factor analysis is hard, and many other examples we compared had less good fits than produced by this function. In particular, solutions which are Heywood cases (with one or more uniquenesses essentially zero) are much often common than most texts and some other programs would lead one to believe.

factor.scope

Compute Allowed Changes in Adding to or Dropping from a Formula

Description

`add.scope` and `drop.scope` compute those terms that can be individually added to or dropped from a model while respecting the hierarchy of terms.

Usage

```
add.scope(terms1, terms2)

drop.scope(terms1, terms2)

factor.scope(factor, scope)
```

Arguments

terms1	the terms or formula for the base model.
terms2	the terms or formula for the upper (<code>add.scope</code>) or lower (<code>drop.scope</code>) scope. If missing for <code>drop.scope</code> it is taken to be the null formula, so all terms (except any intercept) are candidates to be dropped.
factor	the "factor" attribute of the terms of the base object.
scope	a list with one or both components <code>drop</code> and <code>add</code> giving the "factor" attribute of the lower and upper scopes respectively.

Details

`factor.scope` is not intended to be called directly by users.

Value

For `add.scope` and `drop.scope` a character vector of terms labels. For `factor.scope`, a list with components `drop` and `add`, character vectors of terms labels.

See Also

[add1](#), [drop1](#), [aov](#), [lm](#)

Examples

```
add.scope( ~ a + b + c + a:b, ~ (a + b + c)^3)
# [1] "a:c" "b:c"
drop.scope( ~ a + b + c + a:b)
# [1] "c" "a:b"
```

Description

Family objects provide a convenient way to specify the details of the models used by functions such as [glm](#). See the documentation for [glm](#) for the details on how such model fitting takes place.

Usage

```
family(object, ...)

binomial(link = "logit")
gaussian(link = "identity")
Gamma(link = "inverse")
inverse.gaussian(link = "1/mu^2")
poisson(link = "log")
quasi(link = "identity", variance = "constant")
quasibinomial(link = "logit")
quasipoisson(link = "log")
```

Arguments

link	<p>a specification for the model link function. This can be a name/expression, a literal character string, a length-one character vector or an object of class "link-glm" (such as generated by make.link) provided it is not specified <i>via</i> one of the standard names given next.</p> <p>The gaussian family accepts the links (as names) identity, log and inverse; the binomial family the links logit, probit, cauchit, (corresponding to logistic, normal and Cauchy CDFs respectively) log and cloglog (complementary log-log); the Gamma family the links inverse, identity and log; the poisson family the links log, identity, and sqrt and the inverse.gaussian family the links 1/mu², inverse, identity and log.</p> <p>The quasi family accepts the links logit, probit, cloglog, identity, inverse, log, 1/mu² and sqrt, and the function power can be used to create a power link function.</p>
variance	<p>for all families other than quasi, the variance function is determined by the family. The quasi family will accept the literal character string (or unquoted as a name/expression) specifications "constant", "mu(1-mu)", "mu", "mu²" and "mu³", a length-one character vector taking one of those values, or a list containing components varfun, validmu, dev.resids, initialize and name.</p>
object	<p>the function family accesses the family objects which are stored within objects created by modelling functions (e.g., glm).</p>
...	<p>further arguments passed to methods.</p>

Details

family is a generic function with methods for classes "glm" and "lm" (the latter returning gaussian()).

The quasibinomial and quasipoisson families differ from the binomial and poisson families only in that the dispersion parameter is not fixed at one, so they can model over-dispersion. For the binomial case see McCullagh and Nelder (1989, pp. 124–8). Although they show that there is (under some restrictions) a model with variance proportional to mean as in the quasi-binomial model, note that glm does not compute maximum-likelihood estimates in that model. The behaviour of S is closer to the quasi- variants.

Value

An object of class "family" (which has a concise print method). This is a list with elements

family	character: the family name.
link	character: the link name.
linkfun	function: the link.
linkinv	function: the inverse of the link function.
variance	function: the variance as a function of the mean.
dev.resids	function giving the deviance residuals as a function of (y, μ, wt) .
aic	function giving the AIC value if appropriate (but NA for the quasi- families). See logLik for the assumptions made about the dispersion parameter.
mu.eta	function: derivative function $(eta) d\mu/d\eta$.
initialize	expression. This needs to set up whatever data objects are needed for the family as well as <code>n</code> (needed for AIC in the binomial family) and <code>mustart</code> (see glm).
valid.mu	logical function. Returns TRUE if a mean vector <code>mu</code> is within the domain of variance.
valid.eta	logical function. Returns TRUE if a linear predictor <code>eta</code> is within the domain of <code>linkinv</code> .

Note

The `link` and `variance` arguments have rather awkward semantics for back-compatibility. The recommended way to supply them is as quoted character strings, but they can also be supplied unquoted (as names or expressions). In addition, they can also be supplied as a length-one character vector giving the name of one of the options, or as a list (for `link`, of class "link-glm"). The restrictions apply only to links given as names: when given as a character string all the links known to `make.link` are accepted.

This is potentially ambiguous: supplying `link=logit` could mean the unquoted name of a link or the value of object `logit`. It is interpreted if possible as the name of an allowed link, then as an object. (You can force the interpretation to always be the value of an object via `logit[1]`.)

Author(s)

The design was inspired by S functions of the same names described in Hastie & Pregibon (1992) (except `quasibinomial` and `quasipoisson`).

# needs to set a starting value for the next fit
glm(y ~x, family=quasi(variance="mu(1-mu)", link="logit"), start=c(0,1))
```

FDist

*The F Distribution***Description**

Density, distribution function, quantile function and random generation for the F distribution with `df1` and `df2` degrees of freedom (and optional non-centrality parameter `ncp`).

Usage

```
df(x, df1, df2, ncp, log = FALSE)
pf(q, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
qf(p, df1, df2, ncp, lower.tail = TRUE, log.p = FALSE)
rf(n, df1, df2, ncp)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>df1, df2</code>	degrees of freedom. Inf is allowed.
<code>ncp</code>	non-centrality parameter. If omitted the central F is assumed.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The F distribution with `df1 = n_1` and `df2 = n_2` degrees of freedom has density

$$f(x) = \frac{\Gamma(n_1/2 + n_2/2)}{\Gamma(n_1/2)\Gamma(n_2/2)} \left(\frac{n_1}{n_2}\right)^{n_1/2} x^{n_1/2-1} \left(1 + \frac{n_1x}{n_2}\right)^{-(n_1+n_2)/2}$$

for $x > 0$.

It is the distribution of the ratio of the mean squares of n_1 and n_2 independent standard normals, and hence of the ratio of two independent chi-squared variates each divided by its degrees of freedom. Since the ratio of a normal and the root mean-square of m independent normals has a Student's t_m distribution, the square of a t_m variate has a F distribution on 1 and m degrees of freedom.

The non-central F distribution is again the ratio of mean squares of independent normals of unit variance, but those in the numerator are allowed to have non-zero means and `ncp` is the sum of squares of the means. See [Chisquare](#) for further details on non-central distributions.

Value

`df` gives the density, `pf` gives the distribution function `qf` gives the quantile function, and `rf` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

Source

For `df`, and `ncp == 0`, computed via a binomial probability, code contributed by Catherine Loader (see [dbinom](#)); for `ncp != 0`, computed via a [dbeta](#), code contributed by Peter Ruckdeschel.

For `pf`, via [pbeta](#) (or for large `df2`, via [pchisq](#)).

For `qf`, via [qchisq](#) for large `df2`, else via [qbeta](#).

## the density of the square of a t_m is 2*dt(x, m)/(2*x)
# check this is the same as the density of F_{1,m}
x <- seq(0.001, 5, len=100)
all.equal(df(x^2, 1, 5), dt(x, 5)/x)

## Identity: qf(2*p - 1, 1, df) == qt(p, df)^2 for p >= 1/2
p <- seq(1/2, .99, length=50); df <- 10
rel.err <- function(x,y) ifelse(x==y, 0, abs(x-y)/mean(abs(c(x,y))))
quantile(rel.err(qf(2*p - 1, df1=1, df2=df), qt(p, df)^2), .90) # ~ = 7e-9
```

 fft

Fast Discrete Fourier Transform

Description

Performs the Fast Fourier Transform of an array.

Usage

```
fft(z, inverse = FALSE)
mvfft(z, inverse = FALSE)
```

Arguments

<code>z</code>	a real or complex array containing the values to be transformed.
<code>inverse</code>	if TRUE, the unnormalized inverse transform is computed (the inverse has a + in the exponent of <i>e</i> , but here, we do <i>not</i> divide by $1/\text{length}(x)$).

Value

When `z` is a vector, the value computed and returned by `fft` is the unnormalized univariate Fourier transform of the sequence of values in `z`. When `z` contains an array, `fft` computes and returns the multivariate (spatial) transform. If `inverse` is `TRUE`, the (unnormalized) inverse Fourier transform is returned, i.e., if `y <- fft(z)`, then `z` is `fft(y, inverse = TRUE) / length(y)`.

By contrast, `mvfft` takes a real or complex matrix as argument, and returns a similar shaped matrix, but with each column replaced by its discrete Fourier transform. This is useful for analyzing vector-valued series.

The FFT is fastest when the length of the series being transformed is highly composite (i.e., has many factors). If this is not the case, the transform may take a long time to compute and will use a large amount of memory.

fft(x)
fft(fft(x), inverse = TRUE)/length(x)
```

filter

Linear Filtering on a Time Series

Description

Applies linear filtering to a univariate time series or to each series separately of a multivariate time series.

Usage

```
filter(x, filter, method = c("convolution", "recursive"),
       sides = 2, circular = FALSE, init)
```

Arguments

<code>x</code>	a univariate or multivariate time series.
<code>filter</code>	a vector of filter coefficients in reverse time order (as for AR or MA coefficients).
<code>method</code>	Either "convolution" or "recursive" (and can be abbreviated). If "convolution" a moving average is used: if "recursive" an autoregression is used.

sides	for convolution filters only. If <code>sides=1</code> the filter coefficients are for past values only; if <code>sides=2</code> they are centred around lag 0. In this case the length of the filter should be odd, but if it is even, more of the filter is forward in time than backward.
circular	for convolution filters only. If <code>TRUE</code> , wrap the filter around the ends of the series, otherwise assume external values are missing (NA).
init	for recursive filters only. Specifies the initial values of the time series just prior to the start value, in reverse time order. The default is a set of zeros.

Details

Missing values are allowed in `x` but not in `filter` (where they would lead to missing values everywhere in the output).

Note that there is an implied coefficient 1 at lag 0 in the recursive filter, which gives

$$y_i = x_i + f_1 y_{i-1} + \dots + f_p y_{i-p}$$

No check is made to see if recursive filter is invertible: the output may diverge if it is not.

The convolution filter is

$$y_i = f_1 x_{i+o} + \dots + f_p x_{i+o-(p-1)}$$

where `o` is the offset: see `sides` for how it is determined.

Value

A time series object.

Note

`convolve(, type="filter")` uses the FFT for computations and so *may* be faster for long filters on univariate series, but it does not return a time series (and so the time alignment is unclear), nor does it handle missing values. `filter` is faster for a filter of length 100 on a series of length 1000, for example.

Examples

```
x <- 1:100
filter(x, rep(1, 3))
filter(x, rep(1, 3), sides = 1)
filter(x, rep(1, 3), sides = 1, circular = TRUE)

filter(presidents, rep(1,3))
```

fisher.test

*Fisher's Exact Test for Count Data***Description**

Performs Fisher's exact test for testing the null of independence of rows and columns in a contingency table with fixed marginals.

Usage

```
fisher.test(x, y = NULL, workspace = 200000, hybrid = FALSE,
           control = list(), or = 1, alternative = "two.sided",
           conf.int = TRUE, conf.level = 0.95,
           simulate.p.value = FALSE, B = 2000)
```

Arguments

<code>x</code>	either a two-dimensional contingency table in matrix form, or a factor object.
<code>y</code>	a factor object; ignored if <code>x</code> is a matrix.
<code>workspace</code>	an integer specifying the size of the workspace used in the network algorithm. In units of 4 bytes. Only used for non-simulated p-values larger than 2×2 tables.
<code>hybrid</code>	a logical. Only used for larger than 2×2 tables, in which cases it indicated whether the exact probabilities (default) or a hybrid approximation thereof should be computed. See 'Details'.
<code>control</code>	a list with named components for low level algorithm control. At present the only one used is "mult", a positive integer ≥ 2 with default 30 used only for larger than 2×2 tables. This says how many times as much space should be allocated to paths as to keys: see file 'fexact.c' in the sources of this package.
<code>or</code>	the hypothesized odds ratio. Only used in the 2×2 case.
<code>alternative</code>	indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2×2 case.
<code>conf.int</code>	logical indicating if a confidence interval should be computed (and returned).
<code>conf.level</code>	confidence level for the returned confidence interval. Only used in the 2×2 case if <code>conf.int = TRUE</code> .
<code>simulate.p.value</code>	a logical indicating whether to compute p-values by Monte Carlo simulation, in larger than 2×2 tables.
<code>B</code>	an integer specifying the number of replicates used in the Monte Carlo test.

Details

If `x` is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both `x` and `y` must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

For 2×2 cases, p-values are obtained directly using the (central or non-central) hypergeometric distribution. Otherwise, computations are based on a C version of the FORTRAN subroutine FEXACT which implements the network developed by Mehta and Patel (1986) and improved by Clarkson, Fan and Joe (1993). The FORTRAN code can be obtained from <http://www.netlib.org/toms/643>. Note this fails (with an error message) when the entries of the table are too large. (It transposes the table if necessary so it has no more rows than columns. One constraint is that the product of the row marginals be less than $2^{31} - 1$.)

For 2×2 tables, the null of conditional independence is equivalent to the hypothesis that the odds ratio equals one. 'Exact' inference can be based on observing that in general, given all marginal totals fixed, the first element of the contingency table has a non-central hypergeometric distribution with non-centrality parameter given by the odds ratio (Fisher, 1935). The alternative for a one-sided test is based on the odds ratio, so `alternative = "greater"` is a test of the odds ratio being bigger than `or`.

Two-sided tests are based on the probabilities of the tables, and take as 'more extreme' all tables with probabilities less than or equal to that of the observed table, the p-value being the sum of such probabilities.

For larger than 2×2 tables and `hybrid = TRUE`, asymptotic chi-squared probabilities are only used if the 'Cochran conditions' are satisfied, that is if no cell has count zero, and more than 80% of the cells have counts at least 5.

Simulation is done conditional on the row and column marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.)

Value

A list with class "htest" containing the following components:

<code>p.value</code>	the p-value of the test.
<code>conf.int</code>	a confidence interval for the odds ratio. Only present in the 2×2 case if argument <code>conf.int = TRUE</code> .
<code>estimate</code>	an estimate of the odds ratio. Note that the <i>conditional</i> Maximum Likelihood Estimate (MLE) rather than the unconditional MLE (the sample odds ratio) is used. Only present in the 2×2 case.
<code>null.value</code>	the odds ratio under the null, <code>or</code> . Only present in the 2×2 case.
<code>alternative</code>	a character string describing the alternative hypothesis.
<code>method</code>	the character string "Fisher's Exact Test for Count Data".
<code>data.name</code>	a character string giving the names of the data.

                             satisfaction=c("VeryD", "LittleD", "ModerateS", "VeryS")))
fisher.test(Job)
fisher.test(Job, simulate.p.value=TRUE, B=1e5)
```

Description

`fitted` is a generic function which extracts fitted values from objects returned by modeling functions. `fitted.values` is an alias for it.

All object classes which are returned by model fitting functions should provide a `fitted` method. (Note that the generic is `fitted` and not `fitted.values`.)

Methods can make use of `napredict` methods to compensate for the omission of missing values. The default and `nls` methods do.

Usage

```
fitted(object, ...)  
fitted.values(object, ...)
```

Arguments

<code>object</code>	an object for which the extraction of model fitted values is meaningful.
<code>...</code>	other arguments.

Value

Fitted values extracted from the object `x`.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

[coefficients](#), [glm](#), [lm](#), [residuals](#).

fivenum

Tukey Five-Number Summaries

Description

Returns Tukey's five number summary (minimum, lower-hinge, median, upper-hinge, maximum) for the input data.

Usage

```
fivenum(x, na.rm = TRUE)
```

Arguments

<code>x</code>	numeric, maybe including <code>NAs</code> and \pm <code>Infs</code> .
<code>na.rm</code>	logical; if <code>TRUE</code> , all <code>NA</code> and <code>NaNs</code> are dropped, before the statistics are computed.

Value

A numeric vector of length 5 containing the summary information. See `boxplot.stats` for more details.

See Also

`IQR`, `boxplot.stats`, `median`, `quantile`, `range`.

Examples

```
fivenum(c(rnorm(100), -1:1/0))
```

```
fligner.test
```

Fligner-Killeen Test of Homogeneity of Variances

Description

Performs a Fligner-Killeen (median) test of the null that the variances in each of the groups (samples) are the same.

Usage

```
fligner.test(x, ...)

## Default S3 method:
fligner.test(x, g, ...)

## S3 method for class 'formula':
fligner.test(formula, data, subset, na.action, ...)
```

Arguments

<code>x</code>	a numeric vector of data values, or a list of numeric data vectors.
<code>g</code>	a vector or factor object giving the group for the corresponding elements of <code>x</code> . Ignored if <code>x</code> is a list.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

If `x` is a list, its elements are taken as the samples to be compared for homogeneity of variances, and hence have to be numeric data vectors. In this case, `g` is ignored, and one can simply use `fligner.test(x)` to perform the test. If the samples are not yet contained in a list, use `fligner.test(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

The Fligner-Killeen (median) test has been determined in a simulation study as one of the many tests for homogeneity of variances which is most robust against departures from normality, see Conover, Johnson & Johnson (1981). It is a k -sample simple linear rank which uses the ranks of the absolute values of the centered samples and weights $a(i) = \text{qnorm}((1+i/(n+1))/2)$. The version implemented here uses median centering in each of the samples (F-K:med X^2 in the reference).

Value

A list of class "htest" containing the following components:

<code>statistic</code>	the Fligner-Killeen:med X^2 test statistic.
<code>parameter</code>	the degrees of freedom of the approximate chi-squared distribution of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>method</code>	the character string "Fligner-Killeen test of homogeneity of variances".
<code>data.name</code>	a character string giving the names of the data.

References

Examples

```
require(graphics)

plot(count ~ spray, data = InsectSprays)
fligner.test(InsectSprays$count, InsectSprays$spray)
fligner.test(count ~ spray, data = InsectSprays)
## Compare this to bartlett.test()
```

formula

*Model Formulae***Description**

The generic function `formula` and its specific methods provide a way of extracting formulae which have been included in other objects.

`as.formula` is almost identical, additionally preserving attributes when `object` already inherits from "formula". The default value of the `env` argument is used only when the formula would otherwise lack an environment.

Usage

```
formula(x, ...)
as.formula(object, env = parent.frame())
```

Arguments

<code>x, object</code>	R object.
<code>...</code>	further arguments passed to or from other methods.
<code>env</code>	the environment to associate with the result.

Details

The models fit by, e.g., the `lm` and `glm` functions are specified in a compact symbolic form. The `~` operator is basic in the formation of such models. An expression of the form `y ~ model` is interpreted as a specification that the response `y` is modelled by a linear predictor specified symbolically by `model`. Such a model consists of a series of terms separated by `+` operators. The terms themselves consist of variable and factor names separated by `:` operators. Such a term is interpreted as the interaction of all the variables and factors appearing in the term.

In addition to `+` and `:`, a number of other operators are useful in model formulae. The `*` operator denotes factor crossing: `a*b` interpreted as `a+b+a:b`. The `^` operator indicates crossing to the specified degree. For example `(a+b+c)^2` is identical to `(a+b+c)*(a+b+c)` which in turn expands to a formula containing the main effects for `a`, `b` and `c` together with their second-order interactions. The `%in%` operator indicates that the terms on its left are nested within those on the right. For example `a + b %in% a` expands to the formula `a + a:b`. The `-` operator removes the specified terms, so that `(a+b+c)^2 - a:b` is identical to `a + b + c + b:c + a:c`. It can also be used to remove the intercept term: `y ~ x - 1` is a line through the origin. A model with no intercept can be also specified as `y ~ x + 0` or `y ~ 0 + x`.

While formulae usually involve just variable and factor names, they can also involve arithmetic expressions. The formula `log(y) ~ a + log(x)` is quite legal. When such arithmetic expressions involve operators which are also used symbolically in model formulae, there can be confusion between arithmetic and symbolic operator use.

To avoid this confusion, the function `I()` can be used to bracket those portions of a model formula where the operators are used in their arithmetic sense. For example, in the formula `y ~ a + I(b+c)`, the term `b+c` is to be interpreted as the sum of `b` and `c`.

Variable names can be quoted by backticks `'like this'` in formulae, although there is no guarantee that all code using formulae will accept such non-syntactic names.

Most model-fitting functions accept formulae with right-hand-side including the function `offset` to indicate terms with a fixed coefficient of one. Some functions accept other ‘specials’ such as `strata` or `cluster` (see the `specials` argument of `terms.formula`).

There are two special interpretations of `.` in a formula. The usual one is in the context of a `data` argument of model fitting functions and means ‘all columns not otherwise in the formula’: see `terms.formula`. In the context of `update.formula`, **only**, it means ‘what was previously in this part of the formula’.

When `formula` is called on a fitted model object, either a specific method is used (such as that for class `"nls"`) or the default method. The default first looks for a `"formula"` component of the object (and evaluates it), then a `"terms"` component, then a `formula` parameter of the call (and evaluates its value) and finally a `"formula"` attribute.

There is a method for data frames. If there is only one column this forms the RHS with an empty LHS. For more columns, the first column is the LHS of the formula and the remaining columns separated by `+` form the RHS.

Value

All the functions above produce an object of class `"formula"` which contains a symbolic model formula.

Environments

A formula object has an associated environment, and this environment (rather than the parent environment) is used by `model.frame` to evaluate variables that are not found in the supplied `data` argument.

Formulas created with the `~` operator use the environment in which they were created. Formulas created with `as.formula` will use the `env` argument for their environment. Pre-existing formulas extracted with `as.formula` will only have their environment changed if `env` is given explicitly.

Examples

```
class(fo <- y ~ x1*x2) # "formula"
fo
typeof(fo) # R internal : "language"
terms(fo)

environment(fo)
environment(as.formula("y ~ x"))
environment(as.formula("y ~ x", env=new.env()))

## Create a formula for a model with a large number of variables:
xnam <- paste("x", 1:25, sep="")
(fmla <- as.formula(paste("y ~ ", paste(xnam, collapse= "+"))))
```

`formula.nls` *Extract Model Formula from nls Object*

Description

Returns the model used to fit `object`.

Usage

```
## S3 method for class 'nls':  
formula(x, ...)
```

Arguments

`x` an object inheriting from class "nls", representing a nonlinear least squares fit.
`...` further arguments passed to or from other methods.

Value

a formula representing the model used to obtain `object`.

Author(s)

Jose Pinheiro and Douglas Bates

[nls](#), [formula](#)

Examples

```
fml <- nls(circumference ~ A/(1+exp((B-age)/C)), Orange,  
          start = list(A=160, B=700, C = 350))  
formula(fml)
```

`friedman.test` *Friedman Rank Sum Test*

Description

Performs a Friedman rank sum test with unreplicated blocked data.

Usage

```
friedman.test(y, ...)  
  
## Default S3 method:  
friedman.test(y, groups, blocks, ...)  
  
## S3 method for class 'formula':  
friedman.test(formula, data, subset, na.action, ...)
```

Arguments

<code>y</code>	either a numeric vector of data values, or a data matrix.
<code>groups</code>	a vector giving the group for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.
<code>blocks</code>	a vector giving the block for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.
<code>formula</code>	a formula of the form <code>a ~ b c</code> , where <code>a</code> , <code>b</code> and <code>c</code> give the data values and corresponding groups and blocks, respectively.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

`friedman.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of `groups` and `blocks`) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of `blocks`, the location parameter of `y` is the same in each of the `groups`.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. NA's are not allowed in `groups` or `blocks`; if `y` contains NA's, corresponding blocks are removed.

Value

A list with class `"htest"` containing the following components:

<code>statistic</code>	the value of Friedman's chi-squared statistic.
<code>parameter</code>	the degrees of freedom of the approximate chi-squared distribution of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>method</code>	the character string <code>"Friedman rank sum test"</code> .
<code>data.name</code>	a character string giving the names of the data.

ftable

*Flat Contingency Tables***Description**

Create 'flat' contingency tables.

Usage

```
ftable(x, ...)

## Default S3 method:
ftable(..., exclude = c(NA, NaN), row.vars = NULL,
        col.vars = NULL)
```

Arguments

<code>x, ...</code>	R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, or a contingency table object of class "table" or "ftable".
<code>exclude</code>	values to use in the exclude argument of <code>factor</code> when interpreting non-factor objects.
<code>row.vars</code>	a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the rows of the flat contingency table.
<code>col.vars</code>	a vector of integers giving the numbers of the variables, or a character vector giving the names of the variables to be used for the columns of the flat contingency table.

Details

`ftable` creates ‘flat’ contingency tables. Similar to the usual contingency tables, these contain the counts of each combination of the levels of the variables (factors) involved. This information is then re-arranged as a matrix whose rows and columns correspond to unique combinations of the levels of the row and column variables (as specified by `row.vars` and `col.vars`, respectively). The combinations are created by looping over the variables in reverse order (so that the levels of the left-most variable vary the slowest). Displaying a contingency table in this flat matrix form (via `print.ftable`, the print method for objects of class "ftable") is often preferable to showing it as a higher-dimensional array.

`ftable` is a generic function. Its default method, `ftable.default`, first creates a contingency table in array form from all arguments except `row.vars` and `col.vars`. If the first argument is of class "table", it represents a contingency table and is used as is; if it is a flat table of class "ftable", the information it contains is converted to the usual array representation using `as.ftable`. Otherwise, the arguments should be R objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted, which are cross-tabulated using `table`. Then, the arguments `row.vars` and `col.vars` are used to collapse the contingency table into flat form. If neither of these two is given, the last variable is used for the columns. If both are given and their union is a proper subset of all variables involved, the other variables are summed out.

When the arguments are R expressions interpreted as factors, additional arguments will be passed to `table` to control how the variable names are displayed; see the last example below.

Function `ftable.formula` provides a formula method for creating flat contingency tables.

There are methods for `as.table` and `as.data.frame`.

Value

`ftable` returns an object of class "ftable", which is a matrix with counts of each combination of the levels of variables with information on the names and levels of the (row and columns) variables stored as attributes "row.vars" and "col.vars".

See Also

[ftable.formula](#) for the formula interface (which allows a `data = .` argument); [read.ftable](#) for information on reading, writing and coercing flat contingency tables; [table](#) for ordinary cross-tabulation; [xtabs](#) for formula-based cross-tabulation.

Examples

```
## Start with a contingency table.
ftable(Titanic, row.vars = 1:3)
ftable(Titanic, row.vars = 1:2, col.vars = "Survived")
ftable(Titanic, row.vars = 2:1, col.vars = "Survived")

## Start with a data frame.
x <- ftable(mtcars[c("cyl", "vs", "am", "gear")])
x
ftable(x, row.vars = c(2, 4))

## Start with expressions, use table()'s "dnn" to change labels
ftable(mtcars$cyl, mtcars$vs, mtcars$am, mtcars$gear, row.vars = c(2, 4),
       dnn = c("Cylinders", "V/S", "Transmission", "Gears"))
```

ftable.formula

*Formula Notation for Flat Contingency Tables***Description**

Produce or manipulate a flat contingency table using formula notation.

Usage

```
## S3 method for class 'formula':
ftable(formula, data = NULL, subset, na.action, ...)
```

Arguments

<code>formula</code>	a formula object with both left and right hand sides specifying the column and row variables of the flat table.
<code>data</code>	a data frame, list or environment (or similar: see model.frame) containing the variables to be cross-tabulated, or a contingency table (see below).
<code>subset</code>	an optional vector specifying a subset of observations to be used. Ignored if <code>data</code> is a contingency table.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Ignored if <code>data</code> is a contingency table.
<code>...</code>	further arguments to the default <code>ftable</code> method may also be passed as arguments, see ftable.default .

Details

This is a method of the generic function `ftable`.

The left and right hand side of `formula` specify the column and row variables, respectively, of the flat contingency table to be created. Only the `+` operator is allowed for combining the variables. A `.` may be used once in the formula to indicate inclusion of all the remaining variables.

If `data` is an object of class `"table"` or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. Otherwise, if it is not a flat contingency table (i.e., an object of class `"ftable"`), it should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, `na.action` is applied to the data to handle missing values, and, after possibly selecting a subset of the data as specified by the `subset` argument, a contingency table is computed from the variables.

The contingency table is then collapsed to a flat table, according to the row and column variables specified by `formula`.

Value

A flat contingency table which contains the counts of each combination of the levels of the variables, collapsed into a matrix for suitably displaying the counts.

See Also

`ftable`, `ftable.default`; `table`.

Examples

```
Titanic
x <- ftable(Survived ~ ., data = Titanic)
x
ftable(Sex ~ Class + Age, data = x)
```

Description

Density, distribution function, quantile function and random generation for the Gamma distribution with parameters `shape` and `scale`.

Usage

```
dgamma(x, shape, rate = 1, scale = 1/rate, log = FALSE)
pgamma(q, shape, rate = 1, scale = 1/rate, lower.tail = TRUE,
       log.p = FALSE)
qgamma(p, shape, rate = 1, scale = 1/rate, lower.tail = TRUE,
       log.p = FALSE)
rgamma(n, shape, rate = 1, scale = 1/rate)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>rate</code>	an alternative way to specify the scale.
<code>shape, scale</code>	shape and scale parameters. Must be positive, <code>scale</code> strictly.
<code>log, log.p</code>	logical; if TRUE, probabilities/densities p are returned as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If `scale` is omitted, it assumes the default value of 1.

The Gamma distribution with parameters `shape = α` and `scale = σ` has density

$$f(x) = \frac{1}{\sigma^\alpha \Gamma(\alpha)} x^{\alpha-1} e^{-x/\sigma}$$

for $x \geq 0$, $\alpha > 0$ and $\sigma > 0$. (Here $\Gamma(\alpha)$ is the function implemented by R's `gamma()` and defined in its help. Note that $a = 0$ corresponds to the trivial distribution with all mass at point 0.)

The mean and variance are $E(X) = \alpha\sigma$ and $Var(X) = \alpha\sigma^2$.

The cumulative hazard $H(t) = -\log(1 - F(t))$ is `-pgamma(t, ..., lower = FALSE, log = TRUE)`.

Note that for smallish values of `shape` (and moderate `scale`) a large parts of the mass of the Gamma distribution is on values of x so near zero that they will be represented as zero in computer arithmetic. So `rgamma` can well return values which will be represented as zero. (This will also happen for very large values of `scale` since the actual generation is done for `scale=1`.) Similarly, `qgamma` has a very hard job for small `scale`, and warns of potential unreliability for `scale < 1e-10`.

Value

`dgamma` gives the density, `pgamma` gives the distribution function, `qgamma` gives the quantile function, and `rgamma` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

Note

The S parametrization is via `shape` and `rate`: S has no `scale` parameter.

`pgamma` is closely related to the incomplete gamma function. As defined by Abramowitz and Stegun 6.5.1 (and by 'Numerical Recipes') this is

$$P(a, x) = \frac{1}{\Gamma(a)} \int_0^x t^{a-1} e^{-t} dt$$

$P(a, x)$ is `pgamma(x, a)`. Other authors (for example Karl Pearson in his 1922 tables) omit the normalizing factor, defining the incomplete gamma function as `pgamma(x, a) * gamma(a)`. A few use the 'upper' incomplete gamma function, the integral from x to ∞ which can be computed by `pgamma(x, a, lower=FALSE) * gamma(a)`, or its normalized version. See also http://en.wikipedia.org/wiki/Incomplete_gamma_function.

Source

`dgamma` is computed via the Poisson density, using code contributed by Catherine Loader (see [dbinom](#)).

`pgamma` uses an unpublished (and not otherwise documented) algorithm ‘mainly by Morten Welinder’.

`qgamma` is based on a C translation of

Best, D. J. and D. E. Roberts (1975). Algorithm AS91. Percentage points of the chi-squared distribution. *Applied Statistics*, **24**, 385–388.

plus a final Newton step to improve the approximation.

`rgamma` for `shape >= 1` uses

Ahrens, J. H. and Dieter, U. (1982). Generating gamma variates by a modified rejection technique. *Communications of the ACM*, **25**, 47–54,

and for $0 < \text{shape} < 1$ uses

Ahrens, J. H. and Dieter, U. (1974). Computer methods for sampling from gamma, beta, Poisson and binomial distributions. *Computing*, **12**, 223–246.

See Also

[gamma](#) for the gamma function, [dbeta](#) for the Beta distribution and [dchisq](#) for the chi-squared distribution which is a special case of the Gamma distribution.

Examples

```
-log(dgamma(1:4, shape=1))
p <- (1:9)/10
pgamma(qgamma(p, shape=2), shape=2)
1 - 1/exp(qgamma(p, shape=1))

# even for shape = 0.001 about half the mass is on numbers
# that cannot be represented accurately (and most of those as zero)
pgamma(.Machine$double.xmin, 0.001)
pgamma(5e-324, 0.001) # on most machines this is the smallest
                        # representable non-zero number
table(rgamma(1e4, 0.001) == 0)/1e4
```

Geometric

*The Geometric Distribution***Description**

Density, distribution function, quantile function and random generation for the geometric distribution with parameter `prob`.

Usage

```
dgeom(x, prob, log = FALSE)
pgeom(q, prob, lower.tail = TRUE, log.p = FALSE)
qgeom(p, prob, lower.tail = TRUE, log.p = FALSE)
rgeom(n, prob)
```

Arguments

<code>x</code> , <code>q</code>	vector of quantiles representing the number of failures in a sequence of Bernoulli trials before success occurs.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>prob</code>	probability of success in each trial. $0 < \text{prob} \leq 1$.
<code>log</code> , <code>log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The geometric distribution with `prob = p` has density

$$p(x) = p(1 - p)^x$$

for $x = 0, 1, 2, \dots, 0 < p \leq 1$.

If an element of `x` is not integer, the result of `pgeom` is zero, with a warning.

The quantile is defined as the smallest value x such that $F(x) \geq p$, where F is the distribution function.

Value

`dgeom` gives the density, `pgeom` gives the distribution function, `qgeom` gives the quantile function, and `rgeom` generates random deviates.

Invalid `prob` will result in return value `NaN`, with a warning.

Source

`dgeom` computes via `dbinom`, using code contributed by Catherine Loader (see [dbinom](#)).

`pgeom` and `qgeom` are based on the closed-form formulae.

`rgeom` uses the derivation as an exponential mixture of Poissons, see

Devroye, L. (1986) *Non-Uniform Random Variate Generation*. Springer-Verlag, New York. Page 480.

See Also

[dnbinom](#) for the negative binomial which generalizes the geometric distribution.

Examples

```
qgeom((1:9)/10, prob = .2)
Ni <- rgeom(20, prob = 1/4); table(factor(Ni, 0:max(Ni)))
```

getInitial

Get Initial Parameter Estimates

Description

This function evaluates initial parameter estimates for a nonlinear regression model. If `data` is a parameterized data frame or `pframe` object, its `parameters` attribute is returned. Otherwise the object is examined to see if it contains a call to a `selfStart` object whose `initial` attribute can be evaluated.

Usage

```
getInitial(object, data, ...)
```

Arguments

<code>object</code>	a formula or a <code>selfStart</code> model that defines a nonlinear regression model
<code>data</code>	a data frame in which the expressions in the formula or arguments to the <code>selfStart</code> model can be evaluated
<code>...</code>	optional additional arguments

Value

A named numeric vector or list of starting estimates for the parameters. The construction of many `selfStart` models is such that these "starting" estimates are, in fact, the converged parameter estimates.

Author(s)

Jose Pinheiro and Douglas Bates

```

glm

*Fitting Generalized Linear Models***Description**

glm is used to fit generalized linear models, specified by giving a symbolic description of the linear predictor and a description of the error distribution.

Usage

```
glm(formula, family = gaussian, data, weights, subset,
    na.action, start = NULL, etastart, mustart,
    offset, control = glm.control(...), model = TRUE,
    method = "glm.fit", x = FALSE, y = TRUE, contrasts = NULL,
    ...)
```

```
glm.fit(x, y, weights = rep(1, nobs),
        start = NULL, etastart = NULL, mustart = NULL,
        offset = rep(0, nobs), family = gaussian(),
        control = glm.control(), intercept = TRUE)
```

```
## S3 method for class 'glm':
weights(object, type = c("prior", "working"), ...)
```

Arguments

formula	an object of class "formula" (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under 'Details'.
family	a description of the error distribution and link function to be used in the model. This can be a character string naming a family function, a family function or the result of a call to a family function. (See family for details of family functions.)
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which glm is called.
weights	an optional vector of weights to be used in the fitting process. Should be NULL or a numeric vector.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of options , and is <code>na.fail</code> if that is unset. The 'factory-fresh' default is <code>na.omit</code> . Another possible value is NULL, no action. Value <code>na.exclude</code> can be useful.
start	starting values for the parameters in the linear predictor.
etastart	starting values for the linear predictor.
mustart	starting values for the vector of means.

<code>offset</code>	this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be <code>NULL</code> or a numeric vector of length either one or equal to the number of cases. One or more <code>offset</code> terms can be included in the formula instead or as well, and if both are specified their sum is used. See <code>model.offset</code> .
<code>control</code>	a list of parameters for controlling the fitting process. See the documentation for <code>glm.control</code> for details.
<code>model</code>	a logical value indicating whether <i>model frame</i> should be included as a component of the returned value.
<code>method</code>	the method to be used in fitting the model. The default method <code>"glm.fit"</code> uses iteratively reweighted least squares (IWLS). The only current alternative is <code>"model.frame"</code> which returns the model frame and does no fitting.
<code>x, y</code>	For <code>glm</code> : logical values indicating whether the response vector and model matrix used in the fitting process should be returned as components of the returned value. For <code>glm.fit</code> : <code>x</code> is a design matrix of dimension $n * p$, and <code>y</code> is a vector of observations of length <code>n</code> .
<code>contrasts</code>	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
<code>intercept</code>	logical. Should an intercept be included in the <i>null</i> model?
<code>object</code>	an object inheriting from class <code>"glm"</code> .
<code>type</code>	character, partial matching allowed. Type of weights to extract from the fitted model object.
<code>...</code>	For <code>glm</code> : arguments to be passed by default to <code>glm.control</code> : see argument <code>control</code> . For <code>weights</code> : further arguments passed to or from other methods.

Details

A typical predictor has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for `response`. For `binomial` and `quasibinomial` families the response can also be specified as a `factor` (when the first level denotes failure and all others success) or as a two-column matrix with the columns giving the numbers of successes and failures. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with duplicates removed. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a `terms` object as the formula.

A specification of the form `first:second` indicates the the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the *cross* of `first` and `second`. This is the same as `first + second + first:second`.

`glm.fit` is the workhorse function.

If more than one of `etastart`, `start` and `mustart` is specified, the first in the list will be used. It is often advisable to supply starting values for a `quasi` family, and also for families with unusual links such as `gaussian("log")`.

All of `weights`, `subset`, `offset`, `etastart` and `mustart` are evaluated in the same way as variables in `formula`, that is first in `data` and then in the environment of `formula`.

For the background to warning messages about ‘fitted probabilities numerically 0 or 1 occurred’ for binomial GLMs, see Venables & Ripley (2002, pp. 197–8).

Value

glm returns an object of class inheriting from "glm" which inherits from the class "lm". See later in this section.

The function `summary` (i.e., `summary.glm`) can be used to obtain or print a summary of the results and the function `anova` (i.e., `anova.glm`) to produce an analysis of variance table.

The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` can be used to extract various useful features of the value returned by `glm`.

`weights` extracts a vector of weights, one for each case in the fit (after subsetting and `na.action`).

An object of class "glm" is a list containing at least the following components:

<code>coefficients</code>	a named vector of coefficients
<code>residuals</code>	the <i>working</i> residuals, that is the residuals in the final iteration of the IWLS fit. Since cases with zero weights are omitted, their working residuals are NA.
<code>fitted.values</code>	the fitted mean values, obtained by transforming the linear predictors by the inverse of the link function.
<code>rank</code>	the numeric rank of the fitted linear model.
<code>family</code>	the <code>family</code> object used.
<code>linear.predictors</code>	the linear fit on link scale.
<code>deviance</code>	up to a constant, minus twice the maximized log-likelihood. Where sensible, the constant is chosen so that a saturated model has deviance zero.
<code>aic</code>	Akaike's <i>An Information Criterion</i> , minus twice the maximized log-likelihood plus twice the number of coefficients (so assuming that the dispersion is known).
<code>null.deviance</code>	The deviance for the null model, comparable with <code>deviance</code> . The null model will include the offset, and an intercept if there is one in the model. Note that this will be incorrect if the link function depends on the data other than through the fitted mean: specify a zero offset to force a correct calculation.
<code>iter</code>	the number of iterations of IWLS used.
<code>weights</code>	the <i>working</i> weights, that is the weights in the final iteration of the IWLS fit.
<code>prior.weights</code>	the case weights initially supplied.
<code>df.residual</code>	the residual degrees of freedom.
<code>df.null</code>	the residual degrees of freedom for the null model.
<code>y</code>	if requested (the default) the <code>y</code> vector used. (It is a vector even for a binomial model.)
<code>x</code>	(if requested, the model matrix.
<code>model</code>	(if requested (the default), the model frame.
<code>converged</code>	logical. Was the IWLS algorithm judged to have converged?
<code>boundary</code>	logical. Is the fitted value on the boundary of the attainable values?
<code>call</code>	the matched call.
<code>formula</code>	the formula supplied.
<code>terms</code>	the <code>terms</code> object used.

<code>data</code>	the <code>data</code> argument.
<code>offset</code>	the <code>offset</code> vector used.
<code>control</code>	the value of the <code>control</code> argument used.
<code>method</code>	the name of the fitter function used, currently always <code>"glm.fit"</code> .
<code>contrasts</code>	(where relevant) the contrasts used.
<code>xlevels</code>	(where relevant) a record of the levels of the factors used in fitting.
<code>na.action</code>	(where relevant) information returned by <code>model.frame</code> on the special handling of NAs.

In addition, non-empty fits will have components `qr`, `R` and `effects` relating to the final weighted linear fit.

Objects of class `"glm"` are normally of class `c("glm", "lm")`, that is inherit from class `"lm"`, and well-designed methods for class `"lm"` will be applied to the weighted linear model at the final iteration of IWLS. However, care is needed, as extractor functions for class `"glm"` such as `residuals` and `weights` do **not** just pick out the component of the fit with the same name.

If a `binomial` `glm` model was specified by giving a two-column response, the weights returned by `prior.weights` are the total numbers of cases (factored by the supplied case weights) and the component `y` of the result is the proportion of successes.

Author(s)

The original R implementation of `glm` was written by Simon Davies working for Ross Ihaka at the University of Auckland, but has since been extensively re-written by members of the R Core team.

The design was inspired by the S function of the same name described in Hastie & Pregibon (1992).

glm.control

*Auxiliary for Controlling GLM Fitting***Description**

Auxiliary function as user interface for `glm` fitting. Typically only used when calling `glm` or `glm.fit`.

Usage

```
glm.control(epsilon = 1e-8, maxit = 25, trace = FALSE)
```

Arguments

<code>epsilon</code>	positive convergence tolerance ϵ ; the iterations converge when $ dev - dev_{old} /(dev + 0.1) < \epsilon$.
<code>maxit</code>	integer giving the maximal number of IWLS iterations.
<code>trace</code>	logical indicating if output should be produced for each iteration.

Details

If `epsilon` is small, it is also used as the tolerance for the least squares solution.

When `trace` is true, calls to `cat` produce the output for each IWLS iteration. Hence, `options(digits = *)` can be used to increase the precision, see the example.

Value

A list with the arguments as components.

```

 glm.summaries

Accessing Generalized Linear Model Fits

Description

These functions are all [methods](#) for class `glm` or `summary.glm` objects.

Usage

```
## S3 method for class 'glm':
family(object, ...)

## S3 method for class 'glm':
residuals(object, type = c("deviance", "pearson", "working",
                          "response", "partial"), ...)
```

Arguments

<code>object</code>	an object of class <code>glm</code> , typically the result of a call to glm .
<code>type</code>	the type of residuals which should be returned. The alternatives are: "deviance" (default), "pearson", "working", "response", and "partial".
<code>...</code>	further arguments passed to or from other methods.

Details

The references define the types of residuals: Davison & Snell is a good reference for the usages of each.

The partial residuals are a matrix of working residuals, with each column formed by omitting a term from the model.

How `residuals` treats cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear, with residual value NA. See also [naresid](#).

For fits done with `y = FALSE` the response values are computed from other components.

hclust

Hierarchical Clustering

Description

Hierarchical cluster analysis on a set of dissimilarities and methods for analyzing it.

Usage

```
hclust(d, method = "complete", members=NULL)

## S3 method for class 'hclust':
plot(x, labels = NULL, hang = 0.1,
     axes = TRUE, frame.plot = FALSE, ann = TRUE,
     main = "Cluster Dendrogram",
     sub = NULL, xlab = NULL, ylab = "Height", ...)

plclust(tree, hang = 0.1, unit = FALSE, level = FALSE, hmin = 0,
        square = TRUE, labels = NULL, plot. = TRUE,
        axes = TRUE, frame.plot = FALSE, ann = TRUE,
        main = "", sub = NULL, xlab = NULL, ylab = "Height")
```

Arguments

<code>d</code>	a dissimilarity structure as produced by <code>dist</code> .
<code>method</code>	the agglomeration method to be used. This should be (an unambiguous abbreviation of) one of "ward", "single", "complete", "average", "mcquitty", "median" or "centroid".
<code>members</code>	NULL or a vector with length size of <code>d</code> . See the 'Details' section.
<code>x, tree</code>	an object of the type produced by <code>hclust</code> .
<code>hang</code>	The fraction of the plot height by which labels should hang below the rest of the plot. A negative value will cause the labels to hang down from 0.
<code>labels</code>	A character vector of labels for the leaves of the tree. By default the row names or row numbers of the original data are used. If <code>labels=FALSE</code> no labels at all are plotted.
<code>axes, frame.plot, ann</code>	logical flags as in <code>plot.default</code> .
<code>main, sub, xlab, ylab</code>	character strings for <code>title</code> . <code>sub</code> and <code>xlab</code> have a non-NULL default when there's a <code>tree\$call</code> .
<code>...</code>	Further graphical arguments.
<code>unit</code>	logical. If true, the splits are plotted at equally-spaced heights rather than at the height in the object.
<code>hmin</code>	numeric. All heights less than <code>hmin</code> are regarded as being <code>hmin</code> : this can be used to suppress detail at the bottom of the tree.
<code>level, square, plot.</code>	as yet unimplemented arguments of <code>plclust</code> for S-PLUS compatibility.

Details

This function performs a hierarchical cluster analysis using a set of dissimilarities for the n objects being clustered. Initially, each object is assigned to its own cluster and then the algorithm proceeds iteratively, at each stage joining the two most similar clusters, continuing until there is just a single cluster. At each stage distances between clusters are recomputed by the Lance–Williams dissimilarity update formula according to the particular clustering method being used.

A number of different clustering methods are provided. *Ward's* minimum variance method aims at finding compact, spherical clusters. The *complete linkage* method finds similar clusters. The *single linkage* method (which is closely related to the minimal spanning tree) adopts a 'friends of friends' clustering strategy. The other methods can be regarded as aiming for clusters with characteristics somewhere between the single and complete link methods. Note however, that methods "median" and "centroid" are *not* leading to a *monotone distance* measure, or equivalently the resulting dendrograms can have so called *inversions* (which are hard to interpret).

If `members!=NULL`, then `d` is taken to be a dissimilarity matrix between clusters instead of dissimilarities between singletons and `members` gives the number of observations per cluster. This way the hierarchical cluster algorithm can be 'started in the middle of the dendrogram', e.g., in order to reconstruct the part of the tree above a cut (see examples). Dissimilarities between clusters can be efficiently computed (i.e., without `hclust` itself) only for a limited number of distance/linkage combinations, the simplest one being squared Euclidean distance and centroid linkage. In this case the dissimilarities between the clusters are the squared Euclidean distances between cluster means.

In hierarchical cluster displays, a decision is needed at each merge to specify which subtree should go on the left and which on the right. Since, for n observations there are $n - 1$ merges, there are

$2^{(n-1)}$ possible orderings for the leaves in a cluster tree, or dendrogram. The algorithm used in `hclust` is to order the subtree so that the tighter cluster is on the left (the last, i.e., most recent, merge of the left subtree is at a lower value than the last merge of the right subtree). Single observations are the tightest clusters possible, and merges involving two observations place them in order by their observation sequence number.

Value

An object of class **hclust** which describes the tree produced by the clustering process. The object is a list with components:

<code>merge</code>	an $n - 1$ by 2 matrix. Row i of <code>merge</code> describes the merging of clusters at step i of the clustering. If an element j in the row is negative, then observation $-j$ was merged at this stage. If j is positive then the merge was with the cluster formed at the (earlier) stage j of the algorithm. Thus negative entries in <code>merge</code> indicate agglomerations of singletons, and positive entries indicate agglomerations of non-singletons.
<code>height</code>	a set of $n - 1$ non-decreasing real values. The clustering <i>height</i> : that is, the value of the criterion associated with the clustering <code>method</code> for the particular agglomeration.
<code>order</code>	a vector giving the permutation of the original observations suitable for plotting, in the sense that a cluster plot using this ordering and matrix <code>merge</code> will not have crossings of the branches.
<code>labels</code>	labels for each of the objects being clustered.
<code>call</code>	the call which produced the result.
<code>method</code>	the cluster method that has been used.
<code>dist.method</code>	the distance that has been used to create <code>d</code> (only returned if the distance object has a "method" attribute).

There are `print`, `plot` and `identify` (see `identify.hclust`) methods and the `rect.hclust()` function for `hclust` objects. The `plclust()` function is basically the same as the `plot` method, `plot.hclust`, primarily for back compatibility with S-plus. Its extra arguments are not yet implemented.

Author(s)

The `hclust` function is based on Fortran code contributed to STATLIB by F. Murtagh.

Examples

```
require(graphics)

hc <- hclust(dist(USArrests), "ave")
plot(hc)
plot(hc, hang = -1)

## Do the same with centroid clustering and squared Euclidean distance,
## cut the tree into ten clusters and reconstruct the upper part of the
## tree from the cluster centers.
hc <- hclust(dist(USArrests)^2, "cen")
memb <- cutree(hc, k = 10)
cent <- NULL
for(k in 1:10){
  cent <- rbind(cent, colMeans(USArrests[memb == k, , drop = FALSE]))
}
hcl <- hclust(dist(cent)^2, method = "cen", members = table(memb))
opar <- par(mfrow = c(1, 2))
plot(hc, labels = FALSE, hang = -1, main = "Original Tree")
plot(hcl, labels = FALSE, hang = -1, main = "Re-start from 10 clusters")
par(opar)
```

heatmap

Draw a Heat Map

Description

A heat map is a false color image (basically `image(t(x))`) with a dendrogram added to the left side and to the top. Typically, reordering of the rows and columns according to some set of values (row or column means) within the restrictions imposed by the dendrogram is carried out.

Usage

```
heatmap(x, Rowv=NULL, Colv=if(symm)"Rowv" else NULL,
        distfun = dist, hclustfun = hclust,
        reorderfun = function(d,w) reorder(d,w),
        add.expr, symm = FALSE, revC = identical(Colv, "Rowv"),
        scale=c("row", "column", "none"), na.rm = TRUE,
        margins = c(5, 5), ColSideColors, RowSideColors,
        cexRow = 0.2 + 1/log10(nr), cexCol = 0.2 + 1/log10(nc),
        labRow = NULL, labCol = NULL, main = NULL,
        xlab = NULL, ylab = NULL,
        keep.dendro = FALSE, verbose = getOption("verbose"), ...)
```

Arguments

<code>x</code>	numeric matrix of the values to be plotted.
<code>Rowv</code>	determines if and how the <i>row</i> dendrogram should be computed and reordered. Either a dendrogram or a vector of values used to reorder the row dendrogram or <code>NA</code> to suppress any row dendrogram (and reordering) or by default, <code>NULL</code> , see ‘Details’ below.
<code>Colv</code>	determines if and how the <i>column</i> dendrogram should be reordered. Has the same options as the <code>Rowv</code> argument above and <i>additionally</i> when <code>x</code> is a square matrix, <code>Colv = "Rowv"</code> means that columns should be treated identically to the rows.
<code>distfun</code>	function used to compute the distance (dissimilarity) between both rows and columns. Defaults to <code>dist</code> .
<code>hclustfun</code>	function used to compute the hierarchical clustering when <code>Rowv</code> or <code>Colv</code> are not dendrograms. Defaults to <code>hclust</code> . Should take as argument a result of <code>distfun</code> and return an object to which <code>as.dendrogram</code> can be applied.
<code>reorderfun</code>	function(<code>d,w</code>) of dendrogram and weights for reordering the row and column dendrograms. The default uses <code>reorder.dendrogram</code> .
<code>add.expr</code>	expression that will be evaluated after the call to <code>image</code> . Can be used to add components to the plot.
<code>symm</code>	logical indicating if <code>x</code> should be treated symmetrically ; can only be true when <code>x</code> is a square matrix.
<code>revC</code>	logical indicating if the column order should be reversed for plotting, such that e.g., for the symmetric case, the symmetry axis is as usual.
<code>scale</code>	character indicating if the values should be centered and scaled in either the row direction or the column direction, or none. The default is <code>"row"</code> if <code>symm</code> false, and <code>"none"</code> otherwise.
<code>na.rm</code>	logical indicating whether <code>NA</code> ’s should be removed.
<code>margins</code>	numeric vector of length 2 containing the margins (see <code>par(mar=*)</code>) for column and row names, respectively.
<code>ColSideColors</code>	(optional) character vector of length <code>ncol(x)</code> containing the color names for a horizontal side bar that may be used to annotate the columns of <code>x</code> .
<code>RowSideColors</code>	(optional) character vector of length <code>nrow(x)</code> containing the color names for a vertical side bar that may be used to annotate the rows of <code>x</code> .
<code>cexRow, cexCol</code>	positive numbers, used as <code>cex.axis</code> in for the row or column axis labeling. The defaults currently only use number of rows or columns, respectively.
<code>labRow, labCol</code>	character vectors with row and column labels to use; these default to <code>rownames(x)</code> or <code>colnames(x)</code> , respectively.
<code>main, xlab, ylab</code>	main, x- and y-axis titles; defaults to none.
<code>keep.dendro</code>	logical indicating if the dendrogram(s) should be kept as part of the result (when <code>Rowv</code> and/or <code>Colv</code> are not <code>NA</code>).
<code>verbose</code>	logical indicating if information should be printed.
<code>...</code>	additional arguments passed on to <code>image</code> , e.g., <code>col</code> specifying the colors.

Details

If either `Rowv` or `Colv` are dendrograms they are honored (and not reordered). Otherwise, dendrograms are computed as `dd <- as.dendrogram(hclustfun(distfun(X)))` where `X` is either `x` or `t(x)`.

If either is a vector (of ‘weights’) then the appropriate dendrogram is reordered according to the supplied values subject to the constraints imposed by the dendrogram, by `reorder(dd, Rowv)`, in the row case. If either is missing, as by default, then the ordering of the corresponding dendrogram is by the mean value of the rows/columns, i.e., in the case of rows, `Rowv <- rowMeans(x, na.rm=na.rm)`. If either is `NULL`, no reordering will be done for the corresponding side.

By default (`scale = "row"`) the rows are scaled to have mean zero and standard deviation one. There is some empirical evidence from genomic plotting that this is useful.

The default colors are not pretty. Consider using enhancements such as the **RColorBrewer** package, <http://cran.r-project.org/package=RColorBrewer>.

Value

Invisibly, a list with components

<code>rowInd</code>	row index permutation vector as returned by <code>order.dendrogram</code> .
<code>colInd</code>	column index permutation vector.
<code>Rowv</code>	the row dendrogram; only if input <code>Rowv</code> was not NA and <code>keep.dendro</code> is true.
<code>Colv</code>	the column dendrogram; only if input <code>Colv</code> was not NA and <code>keep.dendro</code> is true.

Note

Unless `Rowv = NA` (or `Colw = NA`), the original rows and columns are reordered *in any case* to match the dendrogram, e.g., the rows by `order.dendrogram(Rowv)` where `Rowv` is the (possibly `reorder()` ed) row dendrogram.

`heatmap()` uses `layout` and draws the `image` in the lower right corner of a 2x2 layout. Consequentially, it can **not** be used in a multi column/row layout, i.e., when `par(mfrow=*)` or `(mfcol=*)` has been called.

HoltWinters

Holt-Winters Filtering

Description

Computes Holt-Winters Filtering of a given time series. Unknown parameters are determined by minimizing the squared prediction error.

Usage

```

HoltWinters(x, alpha = NULL, beta = NULL, gamma = NULL,
           seasonal = c("additive", "multiplicative"),
           start.periods = 2, l.start = NULL, b.start = NULL,
           s.start = NULL,
           optim.start = c(alpha = 0.3, beta = 0.1, gamma = 0.1),
           optim.control = list())

```

Arguments

<code>x</code>	An object of class <code>ts</code>
<code>alpha</code>	<i>alpha</i> parameter of Holt-Winters Filter.
<code>beta</code>	<i>beta</i> parameter of Holt-Winters Filter. If set to 0, the function will do exponential smoothing.
<code>gamma</code>	<i>gamma</i> parameter used for the seasonal component. If set to 0, a non-seasonal model is fitted.

<code>seasonal</code>	Character string to select an "additive" (the default) or "multiplicative" seasonal model. The first few characters are sufficient. (Only takes effect if <code>gamma</code> is non-zero).
<code>start.periods</code>	Start periods used in the autodetection of start values. Must be at least 2.
<code>l.start</code>	Start value for level (<code>a[0]</code>).
<code>b.start</code>	Start value for trend (<code>b[0]</code>).
<code>s.start</code>	Vector of start values for the seasonal component (<code>s₁[0]...s_p[0]</code>)
<code>optim.start</code>	Vector with named components <code>alpha</code> , <code>beta</code> , and <code>gamma</code> containing the starting values for the optimizer. Only the values needed must be specified. Ignored in the one-parameter case.
<code>optim.control</code>	Optional list with additional control parameters passed to <code>optim</code> if this is used. Ignored in the one-parameter case.

Details

The additive Holt-Winters prediction function (for time series with period length `p`) is

$$\hat{Y}[t+h] = a[t] + hb[t] + s[t+1+(h-1) \bmod p],$$

where $a[t]$, $b[t]$ and $s[t]$ are given by

$$a[t] = \alpha(Y[t] - s[t-p]) + (1 - \alpha)(a[t-1] + b[t-1])$$

$$b[t] = \beta(a[t] - a[t-1]) + (1 - \beta)b[t-1]$$

$$s[t] = \gamma(Y[t] - a[t]) + (1 - \gamma)s[t-p]$$

The multiplicative Holt-Winters prediction function (for time series with period length `p`) is

$$\hat{Y}[t+h] = (a[t] + hb[t]) \times s[t+1+(h-1) \bmod p].$$

where $a[t]$, $b[t]$ and $s[t]$ are given by

$$a[t] = \alpha(Y[t]/s[t-p]) + (1 - \alpha)(a[t-1] + b[t-1])$$

$$b[t] = \beta(a[t] - a[t-1]) + (1 - \beta)b[t-1]$$

$$s[t] = \gamma(Y[t]/a[t]) + (1 - \gamma)s[t-p]$$

The function tries to find the optimal values of α and/or β and/or γ by minimizing the squared one-step prediction error if they are omitted. `optimize` will be used for the univariate case, and `optim` else.

For seasonal models, start values for `a`, `b` and `s` are detected by performing a simple decomposition in trend and seasonal component using moving averages (see function `decompose`) on the `start.periods` first periods (a simple linear regression on the trend component is used for starting level and trend.). For level/trend-models (no seasonal component), start values for `a` and `b` are `x[2]` and `x[2] - x[1]`, respectively. For level-only models (ordinary exponential smoothing), the start value for `a` is `x[1]`.

Value

An object of class "HoltWinters", a list with components:

fitted	A multiple time series with one column for the filtered series as well as for the level, trend and seasonal components, estimated contemporaneously (that is at time t and not at the end of the series).
x	The original series
alpha	alpha used for filtering
beta	beta used for filtering
gamma	gamma used for filtering
coefficients	A vector with named components a , b , s_1 , ..., s_p containing the estimated values for the level, trend and seasonal components
seasonal	The specified seasonal-parameter
SSE	The final sum of squared errors achieved in optimizing
call	The call used

Examples

```
require(graphics)

## Seasonal Holt-Winters
(m <- HoltWinters(co2))
plot(m)
plot(fitted(m))

(m <- HoltWinters(AirPassengers, seasonal = "mult"))
plot(m)

## Non-Seasonal Holt-Winters
x <- uspop + rnorm(uspop, sd = 5)
m <- HoltWinters(x, gamma = 0)
plot(m)

## Exponential Smoothing
m2 <- HoltWinters(x, gamma = 0, beta = 0)
lines(fitted(m2)[,1], col = 3)
```

Description

Density, distribution function, quantile function and random generation for the hypergeometric distribution.

Usage

```
dhyper(x, m, n, k, log = FALSE)
phyper(q, m, n, k, lower.tail = TRUE, log.p = FALSE)
qhyper(p, m, n, k, lower.tail = TRUE, log.p = FALSE)
rhyper(nn, m, n, k)
```

Arguments

<code>x</code> , <code>q</code>	vector of quantiles representing the number of white balls drawn without replacement from an urn which contains both black and white balls.
<code>m</code>	the number of white balls in the urn.
<code>n</code>	the number of black balls in the urn.
<code>k</code>	the number of balls drawn from the urn.
<code>p</code>	probability, it must be between 0 and 1.
<code>nn</code>	number of observations. If <code>length(nn) > 1</code> , the length is taken to be the number required.
<code>log</code> , <code>log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The hypergeometric distribution is used for sampling *without* replacement. The density of this distribution with parameters `m`, `n` and `k` (named Np , $N - Np$, and n , respectively in the reference below) is given by

$$p(x) = \binom{m}{x} \binom{n}{k-x} / \binom{m+n}{k}$$

for $x = 0, \dots, k$.

Value

`dhyper` gives the density, `phyper` gives the distribution function, `qhyper` gives the quantile function, and `rhyper` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

Source

dhyper computes via binomial probabilities, using code contributed by Catherine Loader (see [dbinom](#)).

phyper is based on calculating dhyper and $\text{phyper}(\dots) / \text{dhyper}(\dots)$ (as a summation), based on ideas of Ian Smith and Morten Welinder.

qhyper is based on inversion.

rhyper is based on a corrected version of

Kachitvichyanukul, V. and Schmeiser, B. (1985). Computer generation of hypergeometric random variates. *Journal of Statistical Computation and Simulation*, **22**, 127–145.

References

Johnson, N. L., Kotz, S., and Kemp, A. W. (1992) *Univariate Discrete Distributions*, Second Edition. New York: Wiley.

Examples

```
m <- 10; n <- 7; k <- 8
x <- 0:(k+1)
rbind(phyper(x, m, n, k), dhyper(x, m, n, k))
all(phyper(x, m, n, k) == cumsum(dhyper(x, m, n, k)))# FALSE
## but error is very small:
signif(phyper(x, m, n, k) - cumsum(dhyper(x, m, n, k)), digits=3)
```

identify.hclust *Identify Clusters in a Dendrogram*

Description

identify.hclust reads the position of the graphics pointer when the (first) mouse button is pressed. It then cuts the tree at the vertical position of the pointer and highlights the cluster containing the horizontal position of the pointer. Optionally a function is applied to the index of data points contained in the cluster.

Usage

```
## S3 method for class 'hclust':
identify(x, FUN = NULL, N = 20, MAXCLUSTER = 20, DEV.FUN = NULL,
        ...)
```

Arguments

x	an object of the type produced by hclust.
FUN	(optional) function to be applied to the index numbers of the data points in a cluster (see ‘Details’ below).
N	the maximum number of clusters to be identified.
MAXCLUSTER	the maximum number of clusters that can be produced by a cut (limits the effective vertical range of the pointer).
DEV.FUN	(optional) integer scalar. If specified, the corresponding graphics device is made active before FUN is applied.
...	further arguments to FUN.

Details

By default clusters can be identified using the mouse and an `invisible` list of indices of the respective data points is returned.

If `FUN` is not `NULL`, then the index vector of data points is passed to this function as first argument, see the examples below. The active graphics device for `FUN` can be specified using `DEV.FUN`.

The identification process is terminated by pressing any mouse button other than the first, see also `identify`.

Value

Either a list of data point index vectors or a list of return values of `FUN`.

See Also

`hclust`, `rect.hclust`

Examples

```
## Not run:
require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
(x <- identify(hca)) ## Terminate with 2nd mouse button !!

hci <- hclust(dist(iris[,1:4]))
plot(hci)
identify(hci, function(k) print(table(iris[k,5])))

# open a new device (one for dendrogram, one for bars):
get(getOption("device"))() # << make that narrow (& small)
                             # and *beside* 1st one
nD <- dev.cur()              # to be for the barplot
dev.set(dev.prev())# old one for dendrogram
plot(hci)
## select subtrees in dendrogram and "see" the species distribution:
identify(hci, function(k) barplot(table(iris[k,5]),col=2:4), DEV.FUN = nD)
## End(Not run)
```

influence.measures *Regression Deletion Diagnostics*

Description

This suite of functions can be used to compute some of the regression (leave-one-out deletion) diagnostics for linear and generalized linear models discussed in Belsley, Kuh and Welsch (1980), Cook and Weisberg (1982), etc.

Usage

```

influence.measures(model)

rstandard(model, ...)
## S3 method for class 'lm':
rstandard(model, infl = lm.influence(model, do.coef = FALSE),
          sd = sqrt(deviance(model)/df.residual(model)), ...)
## S3 method for class 'glm':
rstandard(model, infl = lm.influence(model, do.coef = FALSE),
          ...)

rstudent(model, ...)
## S3 method for class 'lm':
rstudent(model, infl = lm.influence(model, do.coef = FALSE),
          res = infl$wt.res, ...)
## S3 method for class 'glm':
rstudent(model, infl = influence(model, do.coef = FALSE), ...)

dffits(model, infl = , res = )

dfbeta(model, ...)
## S3 method for class 'lm':
dfbeta(model, infl = lm.influence(model, do.coef = TRUE), ...)

dfbetas(model, ...)
## S3 method for class 'lm':
dfbetas(model, infl = lm.influence(model, do.coef = TRUE), ...)

covratio(model, infl = lm.influence(model, do.coef = FALSE),
          res = weighted.residuals(model))

cooks.distance(model, ...)
## S3 method for class 'lm':
cooks.distance(model, infl = lm.influence(model, do.coef = FALSE),
              res = weighted.residuals(model),
              sd = sqrt(deviance(model)/df.residual(model)),
              hat = infl$hat, ...)
## S3 method for class 'glm':
cooks.distance(model, infl = influence(model, do.coef = FALSE),
              res = infl$pear.res,
              dispersion = summary(model)$dispersion,
              hat = infl$hat, ...)

hatvalues(model, ...)
## S3 method for class 'lm':
hatvalues(model, infl = lm.influence(model, do.coef = FALSE), ...)

hat(x, intercept = TRUE)

```

Arguments

model an R object, typically returned by `lm` or `glm`.

<code>infl</code>	influence structure as returned by <code>lm.influence</code> or <code>influence</code> (the latter only for the <code>glm</code> method of <code>rstudent</code> and <code>cooks.distance</code>).
<code>res</code>	(possibly weighted) residuals, with proper default.
<code>sd</code>	standard deviation to use, see default.
<code>dispersion</code>	dispersion (for <code>glm</code> objects) to use, see default.
<code>hat</code>	hat values H_{ii} , see default.
<code>x</code>	the X or design matrix.
<code>intercept</code>	should an intercept column be prepended to <code>x</code> ?
<code>...</code>	further arguments passed to or from other methods.

Details

The primary high-level function is `influence.measures` which produces a class "infl" object tabular display showing the DFBETAS for each model variable, DFFITS, covariance ratios, Cook's distances and the diagonal elements of the hat matrix. Cases which are influential with respect to any of these measures are marked with an asterisk.

The functions `dfbetas`, `dffits`, `covratio` and `cooks.distance` provide direct access to the corresponding diagnostic quantities. Functions `rstandard` and `rstudent` give the standardized and Studentized residuals respectively. (These re-normalize the residuals to have unit variance, using an overall and leave-one-out measure of the error variance respectively.)

Values for generalized linear models are approximations, as described in Williams (1987) (except that Cook's distances are scaled as F rather than as chi-square values). The approximations can be poor when some cases have large influence.

The optional `infl`, `res` and `sd` arguments are there to encourage the use of these direct access functions, in situations where, e.g., the underlying basic influence measures (from `lm.influence` or the generic `influence`) are already available.

Note that cases with `weights == 0` are *dropped* from all these functions, but that if a linear model has been fitted with `na.action = na.exclude`, suitable values are filled in for the cases excluded during fitting.

The function `hat()` exists mainly for S (version 2) compatibility; we recommend using `hatvalues()` instead.

Note

For `hatvalues`, `dfbeta`, and `dfbetas`, the method for linear models also works for generalized linear models.

stopifnot(all.equal(imI$infmat[, "cook.d"],
                    cooks.distance(lmI)))
```

integrate

Integration of One-Dimensional Functions

Description

Adaptive quadrature of functions of one variable over a finite or infinite interval.

Usage

```
integrate(f, lower, upper, ..., subdivisions=100,
          rel.tol = .Machine$double.eps^0.25, abs.tol = rel.tol,
          stop.on.error = TRUE, keep.xy = FALSE, aux = NULL)
```

Arguments

<code>f</code>	an R function taking a numeric first argument and returning a numeric vector of the same length. Returning a non-finite element will generate an error.
<code>lower, upper</code>	the limits of integration. Can be infinite.
<code>...</code>	additional arguments to be passed to <code>f</code> .
<code>subdivisions</code>	the maximum number of subintervals.
<code>rel.tol</code>	relative accuracy requested.
<code>abs.tol</code>	absolute accuracy requested.
<code>stop.on.error</code>	logical. If true (the default) an error stops the function. If false some errors will give a result with a warning in the <code>message</code> component.
<code>keep.xy</code>	unused. For compatibility with S.
<code>aux</code>	unused. For compatibility with S.

Details

Note that arguments after `...` must be matched exactly.

If one or both limits are infinite, the infinite range is mapped onto a finite interval.

For a finite interval, globally adaptive interval subdivision is used in connection with extrapolation by the Epsilon algorithm.

`rel.tol` cannot be less than $\max(50 \cdot \text{Machine\$double.eps}, 0.5e-28)$ if `abs.tol` ≤ 0 .

Value

A list of class "integrate" with components

<code>value</code>	the final estimate of the integral.
<code>abs.error</code>	estimate of the modulus of the absolute error.
<code>subdivisions</code>	the number of subintervals produced in the subdivision process.
<code>message</code>	"OK" or a character string giving the error message.
<code>call</code>	the matched call.

Note

Like all numerical integration routines, these evaluate the function on a finite set of points. If the function is approximately constant (in particular, zero) over nearly all its range it is possible that the result and error estimate may be seriously wrong.

When integrating over infinite intervals do so explicitly, rather than just using a large number as the endpoint. This increases the chance of a correct answer – any function whose integral over an infinite interval is finite must be near zero for most of that interval.

`f` must accept a vector of inputs and produce a vector of function evaluations at those points. The [Vectorize](#) function may be helpful to convert `f` to this form.

integrate(dnorm, 0, 20000) ## fails on many systems
integrate(dnorm, 0, Inf) ## works
```

interaction.plot *Two-way Interaction Plot*

Description

Plots the mean (or other summary) of the response for two-way combinations of factors, thereby illustrating possible interactions.

Usage

```
interaction.plot(x.factor, trace.factor, response, fun = mean,
               type = c("l", "p", "b"), legend = TRUE,
               trace.label = deparse(substitute(trace.factor)),
               fixed = FALSE,
```

```

xlab = deparse(substitute(x.factor)),
ylab = ylabel,
ylim = range(cells, na.rm=TRUE),
lty = nc:1, col = 1, pch = c(1:9, 0, letters),
xpd = NULL, leg.bg = par("bg"), leg.bty = "n",
xtick = FALSE, xaxt = par("xaxt"), axes = TRUE,
...)

```

Arguments

<code>x.factor</code>	a factor whose levels will form the x axis.
<code>trace.factor</code>	another factor whose levels will form the traces.
<code>response</code>	a numeric variable giving the response
<code>fun</code>	the function to compute the summary. Should return a single real value.
<code>type</code>	the type of plot: lines or points.
<code>legend</code>	logical. Should a legend be included?
<code>trace.label</code>	overall label for the legend.
<code>fixed</code>	logical. Should the legend be in the order of the levels of <code>trace.factor</code> or in the order of the traces at their right-hand ends?
<code>xlab, ylab</code>	the x and y label of the plot each with a sensible default.
<code>ylim</code>	numeric of length 2 giving the y limits for the plot.
<code>lty</code>	line type for the lines drawn, with sensible default.
<code>col</code>	the color to be used for plotting.
<code>pch</code>	a vector of plotting symbols or characters, with sensible default.
<code>xpd</code>	determines clipping behaviour for the <code>legend</code> used, see <code>par(xpd)</code> . Per default, the legend is <i>not</i> clipped at the figure border.
<code>leg.bg, leg.bty</code>	arguments passed to <code>legend()</code> .
<code>xtick</code>	logical. Should tick marks be used on the x axis?
<code>xaxt, axes, ...</code>	graphics parameters to be passed to the plotting routines.

Details

By default the levels of `x.factor` are plotted on the x axis in their given order, with extra space left at the right for the legend (if specified). If `x.factor` is an ordered factor and the levels are numeric, these numeric values are used for the x axis.

The response and hence its summary can contain missing values. If so, the missing values and the line segments joining them are omitted from the plot (and this can be somewhat disconcerting).

The graphics parameters `xlab`, `ylab`, `ylim`, `lty`, `col` and `pch` are given suitable defaults (and `xlim` and `xaxs` are set and cannot be overridden). The defaults are to cycle through the line types, use the foreground colour, and to use the symbols 1:9, 0, and the capital letters to plot the traces.

Note

Some of the argument names and the precise behaviour are chosen for S-compatibility.

Examples

```
require(graphics)

with(ToothGrowth, {
  interaction.plot(dose, supp, len, fixed=TRUE)
  dose <- ordered(dose)
  interaction.plot(dose, supp, len, fixed=TRUE, col = 2:3, leg.bty = "o")
  interaction.plot(dose, supp, len, fixed=TRUE, col = 2:3, type = "p")
})

with(OrchardSprays, {
  interaction.plot(treatment, rowpos, decrease)
  interaction.plot(rowpos, treatment, decrease, cex.axis=0.8)
  ## order the rows by their mean effect
  rowpos <- factor(rowpos,
                   levels = sort.list(tapply(decrease, rowpos, mean)))
  interaction.plot(rowpos, treatment, decrease, col = 2:9, lty = 1)
})

with(esoph, {
  interaction.plot(agegp, alcgp, ncases/ncontrols, main = "'esoph' Data")
  interaction.plot(agegp, tobgp, ncases/ncontrols, trace.label="tobacco",
                  fixed=TRUE, xaxt = "n")
})
## deal with NAs:
esoph[66,] # second to last age group: 65-74
esophNA <- esoph; esophNA$ncases[66] <- NA
with(esophNA, {
  interaction.plot(agegp, alcgp, ncases/ncontrols, col= 2:5)
  # doesn't show *last* group either
  interaction.plot(agegp, alcgp, ncases/ncontrols, col= 2:5, type = "b")
  ## alternative take non-NA's {"cheating"}
  interaction.plot(agegp, alcgp, ncases/ncontrols, col= 2:5,
                  fun = function(x) mean(x, na.rm=TRUE),
                  sub = "function(x) mean(x, na.rm=TRUE)")
})
rm(esophNA) # to clear up
```

 IQR

The Interquartile Range

Description

computes interquartile range of the x values.

Usage

```
IQR(x, na.rm = FALSE)
```

Arguments

`x` a numeric vector.
`na.rm` logical. Should missing values be removed?

Details

Note that this function computes the quartiles using the [quantile](#) function rather than following Tukey's recommendations, i.e., $IQR(x) = \text{quantile}(x, 3/4) - \text{quantile}(x, 1/4)$.

For normally $N(m, 1)$ distributed X , the expected value of $IQR(X)$ is $2 * \text{qnorm}(3/4) = 1.3490$, i.e., for a normal-consistent estimate of the standard deviation, use $IQR(x) / 1.349$.

References

Examples

```
IQR(rivers)
```

```
is.empty.model      Check if a Model is Empty
```

Description

R model notation allows models with no intercept and no predictors. These require special handling internally. `is.empty.model()` checks whether an object describes an empty model.

Usage

```
is.empty.model(x)
```

Arguments

`x` A `terms` object or an object with a `terms` method.

Value

TRUE if the model is empty

See Also

[lm,glm](#)

Examples

```
y <- rnorm(20)
is.empty.model(y ~ 0)
is.empty.model(y ~ -1)
is.empty.model(lm(y ~ 0))
```

isoreg

*Isotonic / Monotone Regression***Description**

Compute the isotonic (monotonely increasing nonparametric) least squares regression which is piecewise constant.

Usage

```
isoreg(x, y = NULL)
```

Arguments

`x`, `y` coordinate vectors of the regression points. Alternatively a single plotting structure can be specified: see [xy.coords](#).

Details

The algorithm determines the convex minorant $m(x)$ of the *cumulative* data (i.e., `cumsum(y)`) which is piecewise linear and the result is $m'(x)$, a step function with level changes at locations where the convex $m(x)$ touches the cumulative data polygon and changes slope.

`as.stepfun()` returns a [stepfun](#) object which can be more parsimonious.

Value

`isoreg()` returns an object of class `isoreg` which is basically a list with components

<code>x</code>	original (constructed) abscissa values <code>x</code> .
<code>y</code>	corresponding <code>y</code> values.
<code>yf</code>	fitted values corresponding to <i>ordered</i> <code>x</code> values.
<code>yc</code>	cumulative <code>y</code> values corresponding to <i>ordered</i> <code>x</code> values.
<code>iKnots</code>	integer vector giving indices where the fitted curve jumps, i.e., where the convex minorant has kinks.
<code>isOrd</code>	logical indicating if original <code>x</code> values were ordered increasingly already.
<code>ord</code>	<code>if(!isOrd)</code> : integer permutation <code>order(x)</code> of <i>original</i> <code>x</code> .
<code>call</code>	the <code>call</code> to <code>isoreg()</code> used.

Note

The code should be improved to accept *weights* additionally and solve the corresponding weighted least squares problem.

'Patches are welcome!'

the plotting method `plot.isoreg` with more examples; `isoMDS()` from the **MASS** package internally uses isotonic regression.

Examples

```
require(graphics)

(ir <- isoreg(c(1,0,4,3,3,5,4,2,0)))
plot(ir, plot.type = "row")

(ir3 <- isoreg(y3 <- c(1,0,4,3,3,5,4,2, 3)))# last "3", not "0"
(fi3 <- as.stepfun(ir3))
(ir4 <- isoreg(1:10, y4 <- c(5, 9, 1:2, 5:8, 3, 8)))
cat(sprintf("R^2 = %.2f\n",
           1 - sum(residuals(ir4)^2) / ((10-1)*var(y4))))

## If you are interested in the knots alone :
with(ir4, cbind(iKnots, yf[iKnots]))

## Example of unordered x[] with ties:
x <- sample((0:30)/8)
y <- exp(x)
x. <- round(x) # ties!
plot(m <- isoreg(x., y))
stopifnot(all.equal(with(m, yf[iKnots]),
                    as.vector(tapply(y, x., mean))))
```

 KalmanLike

Kalman Filtering

Description

Use Kalman Filtering to find the (Gaussian) log-likelihood, or for forecasting or smoothing.

Usage

```
KalmanLike(y, mod, nit = 0, fast=TRUE)
KalmanRun(y, mod, nit = 0, fast=TRUE)
KalmanSmooth(y, mod, nit = 0)
KalmanForecast(n.ahead = 10, mod, fast=TRUE)
makeARIMA(phi, theta, Delta, kappa = 1e6)
```

Arguments

<code>y</code>	a univariate time series.
<code>mod</code>	A list describing the state-space model: see ‘Details’.
<code>nit</code>	The time at which the initialization is computed. <code>nit = 0</code> implies that the initialization is for a one-step prediction, so <code>Pn</code> should not be computed at the first step.
<code>n.ahead</code>	The number of steps ahead for which prediction is required.

<code>phi, theta</code>	numeric vectors of length ≥ 0 giving AR and MA parameters.
<code>Delta</code>	vector of differencing coefficients, so an ARMA model is fitted to $y[t] - \text{Delta}[1]*y[t-1] - \dots$
<code>kappa</code>	the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model.
<code>fast</code>	If TRUE the <code>mod</code> object may be modified.

Details

These functions work with a general univariate state-space model with state vector a , transitions $a \leftarrow T a + R e$, $e \sim \mathcal{N}(0, \kappa Q)$ and observation equation $y = Z' a + \text{eta}$, ($\text{eta} \equiv \eta$), $\eta \sim \mathcal{N}(0, \kappa h)$. The likelihood is a profile likelihood after estimation of κ .

The model is specified as a list with at least components

T the transition matrix

Z the observation coefficients

h the observation variance

V RQR'

a the current state estimate

P the current estimate of the state uncertainty matrix

Pn the estimate at time $t - 1$ of the state uncertainty matrix

`KalmanSmooth` is the workhorse function for `tsSmooth`.

`makeARIMA` constructs the state-space model for an ARIMA model.

Value

For `KalmanLike`, a list with components `Lik` (the log-likelihood less some constants) and `s2`, the estimate of κ .

For `KalmanRun`, a list with components `values`, a vector of length 2 giving the output of `KalmanLike`, `resid` (the residuals) and `states`, the contemporaneous state estimates, a matrix with one row for each time.

For `KalmanSmooth`, a list with two components. Component `smooth` is a n by p matrix of state estimates based on all the observations, with one row for each time. Component `var` is a n by p by p array of variance matrices.

For `KalmanForecast`, a list with components `pred`, the predictions, and `var`, the unscaled variances of the prediction errors (to be multiplied by `s2`).

For `makeARIMA`, a model list including components for its arguments.

Warning

These functions are designed to be called from other functions which check the validity of the arguments passed, so very little checking is done.

In particular, `KalmanLike` alters the objects passed as the elements `a`, `P` and `Pn` of `mod`, so these should not be shared. Use `fast=FALSE` to prevent this.

kernapply

Apply Smoothing Kernel

Description

kernapply computes the convolution between an input sequence and a specific kernel.

Usage

```
kernapply(x, ...)  
  
## Default S3 method:  
kernapply(x, k, circular = FALSE, ...)  
## S3 method for class 'ts':  
kernapply(x, k, circular = FALSE, ...)  
## S3 method for class 'vector':  
kernapply(x, k, circular = FALSE, ...)  
  
## S3 method for class 'tskernel':  
kernapply(x, k, ...)
```

Arguments

x	an input vector, matrix, time series or kernel to be smoothed.
k	smoothing "tskernel" object.
circular	a logical indicating whether the input sequence to be smoothed is treated as circular, i.e., periodic.
...	arguments passed to or from other methods.

Value

A smoothed version of the input sequence.

Author(s)

A. Trapletti

Examples

```
## see 'kernel' for examples
```

kernel

*Smoothing Kernel Objects***Description**

The "tskernel" class is designed to represent discrete symmetric normalized smoothing kernels. These kernels can be used to smooth vectors, matrices, or time series objects.

There are `print`, `plot` and `[` methods for these kernel objects.

Usage

```
kernel(coef, m, r, name)

df.kernel(k)
bandwidth.kernel(k)
is.tskernel(k)
## S3 method for class 'tskernel':
plot(x, type = "h", xlab = "k", ylab = "W[k]",
      main = attr(x, "name"), ...)
```

Arguments

<code>coef</code>	the upper half of the smoothing kernel coefficients (including coefficient zero) <i>or</i> the name of a kernel (currently "daniell", "dirichlet", "fejer" or "modified.daniell").
<code>m</code>	the kernel dimension(s). When <code>m</code> has length larger than one, it means the convolution of kernels of dimension <code>m[j]</code> , for <code>j</code> in <code>1:length(m)</code> . Currently this is supported only for the named "*daniell" kernels.
<code>name</code>	the name the kernel will be called.
<code>r</code>	the kernel order for a Fejer kernel.
<code>k, x</code>	a "tskernel" object.
<code>type, xlab, ylab, main, ...</code>	arguments passed to <code>plot.default</code> .

Details

`kernel` is used to construct a general kernel or named specific kernels. The modified Daniell kernel halves the end coefficients (as used by S-PLUS).

The `[` method allows natural indexing of kernel objects with indices in $(-m) : m$. The normalization is such that for `k <- kernel(*)`, `sum(k[-k$m : k$m])` is one.

`df.kernel` returns the 'equivalent degrees of freedom' of a smoothing kernel as defined in Brockwell and Davis (1991), page 362, and `bandwidth.kernel` returns the equivalent bandwidth as defined in Bloomfield (1976), p. 201, with a continuity correction.

Value

`kernel()` returns an object of class "tskernel" which is basically a list with the two components `coef` and the kernel dimension `m`. An additional attribute is "name".

spectrum(sunspot.year, kernel=kernel("daniell", c(11,7,3)), log="no")
```

kmeans

K-Means Clustering

Description

Perform k-means clustering on a data matrix.

Usage

```
kmeans(x, centers, iter.max = 10, nstart = 1,
       algorithm = c("Hartigan-Wong", "Lloyd", "Forgy",
                     "MacQueen"))
```

Arguments

<code>x</code>	A numeric matrix of data, or an object that can be coerced to such a matrix (such as a numeric vector or a data frame with all numeric columns).
<code>centers</code>	Either the number of clusters or a set of initial (distinct) cluster centres. If a number, a random set of (distinct) rows in <code>x</code> is chosen as the initial centres.
<code>iter.max</code>	The maximum number of iterations allowed.
<code>nstart</code>	If <code>centers</code> is a number, how many random sets should be chosen?
<code>algorithm</code>	character: may be abbreviated.

Details

The data given by `x` is clustered by the k -means method, which aims to partition the points into k groups such that the sum of squares from points to the assigned cluster centres is minimized. At the minimum, all cluster centres are at the mean of their Voronoi sets (the set of data points which are nearest to the cluster centre).

The algorithm of Hartigan and Wong (1979) is used by default. Note that some authors use k -means to refer to a specific algorithm rather than the general method: most commonly the algorithm given by MacQueen (1967) but sometimes that given by Lloyd (1957) and Forgy (1965). The Hartigan–Wong algorithm generally does a better job than either of those, but trying several random starts is often recommended.

Except for the Lloyd–Forgy method, k clusters will always be returned if a number is specified. If an initial matrix of centres is supplied, it is possible that no point will be closest to one or more centres, which is currently an error for the Hartigan–Wong method.

Value

An object of class "kmeans" which is a list with components:

<code>cluster</code>	A vector of integers indicating the cluster to which each point is allocated.
<code>centers</code>	A matrix of cluster centres.
<code>withinss</code>	The within-cluster sum of squares for each cluster.
<code>size</code>	The number of points in each cluster.

There is a `print` method for this class.

Examples

```
require(graphics)

# a 2-dimensional example
x <- rbind(matrix(rnorm(100, sd = 0.3), ncol = 2),
           matrix(rnorm(100, mean = 1, sd = 0.3), ncol = 2))
colnames(x) <- c("x", "y")
(cl <- kmeans(x, 2))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:2, pch = 8, cex=2)

## random starts do help here with too many clusters
(cl <- kmeans(x, 5, nstart = 25))
plot(x, col = cl$cluster)
points(cl$centers, col = 1:5, pch = 8)
```

kruskal.test

*Kruskal-Wallis Rank Sum Test***Description**

Performs a Kruskal-Wallis rank sum test.

Usage

```
kruskal.test(x, ...)

## Default S3 method:
kruskal.test(x, g, ...)

## S3 method for class 'formula':
kruskal.test(formula, data, subset, na.action, ...)
```

Arguments

x	a numeric vector of data values, or a list of numeric data vectors.
g	a vector or factor object giving the group for the corresponding elements of x. Ignored if x is a list.
formula	a formula of the form lhs ~ rhs where lhs gives the data values and rhs the corresponding groups.
data	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula formula. By default the variables are taken from environment(formula).
subset	an optional vector specifying a subset of observations to be used.
na.action	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
...	further arguments to be passed to or from methods.

Details

`kruskal.test` performs a Kruskal-Wallis rank sum test of the null that the location parameters of the distribution of `x` are the same in each group (sample). The alternative is that they differ in at least one.

If `x` is a list, its elements are taken as the samples to be compared, and hence have to be numeric data vectors. In this case, `g` is ignored, and one can simply use `kruskal.test(x)` to perform the test. If the samples are not yet contained in a list, use `kruskal.test(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the Kruskal-Wallis rank sum statistic.
<code>parameter</code>	the degrees of freedom of the approximate chi-squared distribution of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>method</code>	the character string "Kruskal-Wallis rank sum test".
<code>data.name</code>	a character string giving the names of the data.

## Mucociliary efficiency from the rate of removal of dust in normal
## subjects, subjects with obstructive airway disease, and subjects
## with asbestosis.
x <- c(2.9, 3.0, 2.5, 2.6, 3.2) # normal subjects
y <- c(3.8, 2.7, 4.0, 2.4)     # with obstructive airway disease
z <- c(2.8, 3.4, 3.7, 2.2, 2.0) # with asbestosis
kruskal.test(list(x, y, z))
## Equivalently,
x <- c(x, y, z)
g <- factor(rep(1:3, c(5, 4, 5)),
            labels = c("Normal subjects",
                      "Subjects with obstructive airway disease",
                      "Subjects with asbestosis"))
kruskal.test(x, g)

## Formula interface.
require(graphics)
boxplot(Ozone ~ Month, data = airquality)
kruskal.test(Ozone ~ Month, data = airquality)
```

ks.test

Kolmogorov-Smirnov Tests

Description

Performs one or two sample Kolmogorov-Smirnov tests.

Usage

```
ks.test(x, y, ...,
        alternative = c("two.sided", "less", "greater"),
        exact = NULL)
```

Arguments

<code>x</code>	a numeric vector of data values.
<code>y</code>	either a numeric vector of data values, or a character string naming a cumulative distribution function or an actual cumulative distribution function such as <code>pnorm</code> .
<code>...</code>	parameters of the distribution specified (as a character string) by <code>y</code> .
<code>alternative</code>	indicates the alternative hypothesis and must be one of "two.sided" (default), "less", or "greater". You can specify just the initial letter of the value, but the argument name must be give in full. See 'Details' for the meanings of the possible values.
<code>exact</code>	NULL or a logical indicating whether an exact p-value should be computed. See 'Details' for the meaning of NULL. Not used for the one-sided two-sample case.

Details

If `y` is numeric, a two-sample test of the null hypothesis that `x` and `y` were drawn from the same *continuous* distribution is performed.

Alternatively, `y` can be a character string naming a continuous (cumulative) distribution function, or such a function. In this case, a one-sample test is carried out of the null that the distribution function which generated `x` is distribution `y` with parameters specified by `...`

The presence of ties generates a warning, since continuous distributions do not generate them.

The possible values "two.sided", "less" and "greater" of `alternative` specify the null hypothesis that the true distribution function of `x` is equal to, not less than or not greater than the hypothesized distribution function (one-sample case) or the distribution function of `y` (two-sample case), respectively. This is a comparison of cumulative distribution functions, and the test statistic is the maximum difference in value, with the statistic in the "greater" alternative being $D^+ = \max_u [F_x(u) - F_y(u)]$. Thus in the two-sample case `alternative="greater"` includes distributions for which `x` is stochastically *smaller* than `y` (the CDF of `x` lies above and hence to the left of that for `y`), in contrast to `t.test` or `wilcox.test`.

Exact p-values are not available for the one-sided two-sample case, or in the case of ties. If `exact = NULL` (the default), an exact p-value is computed if the sample size is less than 100 in the one-sample case, and if the product of the sample sizes is less than 10000 in the two-sample case. Otherwise, asymptotic distributions are used whose approximations may be inaccurate in small samples. In the one-sample two-sided case, exact p-values are obtained as described in Marsaglia,

Tsang & Wang (2003). The formula of Birnbaum & Tingey (1951) is used for the one-sample one-sided case.

If a single-sample test is used, the parameters specified in . . . must be pre-specified and not estimated from the data. There is some more refined distribution theory for the KS test with estimated parameters (see Durbin, 1973), but that is not implemented in `ks.test`.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>alternative</code>	a character string describing the alternative hypothesis.
<code>method</code>	a character string indicating what type of test was performed.
<code>data.name</code>	a character string giving the name(s) of the data.

[shapiro.test](#) which performs the Shapiro-Wilk test for normality.

Examples

```
require(graphics)

x <- rnorm(50)
y <- runif(30)
# Do x and y come from the same distribution?
ks.test(x, y)
# Does x come from a shifted gamma distribution with shape 3 and rate 2?
ks.test(x+2, "pgamma", 3, 2) # two-sided, exact
ks.test(x+2, "pgamma", 3, 2, exact = FALSE)
ks.test(x+2, "pgamma", 3, 2, alternative = "gr")

# test if x is stochastically larger than x2
x2 <- rnorm(50, -1)
plot(ecdf(x), xlim=range(c(x, x2)))
plot(ecdf(x2), add=TRUE, lty="dashed")
t.test(x, x2, alternative="g")
wilcox.test(x, x2, alternative="g")
ks.test(x, x2, alternative="l")
```

ksmooth

*Kernel Regression Smoother***Description**

The Nadaraya–Watson kernel regression estimate.

Usage

```
ksmooth(x, y, kernel = c("box", "normal"), bandwidth = 0.5,
        range.x = range(x),
        n.points = max(100, length(x)), x.points)
```

Arguments

<code>x</code>	input x values
<code>y</code>	input y values
<code>kernel</code>	the kernel to be used.
<code>bandwidth</code>	the bandwidth. The kernels are scaled so that their quartiles (viewed as probability densities) are at $\pm 0.25 \cdot \text{bandwidth}$.
<code>range.x</code>	the range of points to be covered in the output.
<code>n.points</code>	the number of points at which to evaluate the fit.
<code>x.points</code>	points at which to evaluate the smoothed fit. If missing, <code>n.points</code> are chosen uniformly to cover <code>range.x</code> .

Value

A list with components

<code>x</code>	values at which the smoothed fit is evaluated. Guaranteed to be in increasing order.
<code>y</code>	fitted values corresponding to <code>x</code> .

Note

This function is implemented purely for compatibility with S, although it is nowhere near as slow as the S function. Better kernel smoothers are available in other packages.

Examples

```
require(graphics)

with(cars, {
  plot(speed, dist)
  lines(ksmooth(speed, dist, "normal", bandwidth=2), col=2)
  lines(ksmooth(speed, dist, "normal", bandwidth=5), col=3)
})
```

`lag`*Lag a Time Series*

Description

Compute a lagged version of a time series, shifting the time base back by a given number of observations.

Usage

```
lag(x, ...)  
  
## Default S3 method:  
lag(x, k = 1, ...)
```

Arguments

<code>x</code>	A vector or matrix or univariate or multivariate time series
<code>k</code>	The number of lags (in units of observations).
<code>...</code>	further arguments to be passed to or from methods.

Details

Vector or matrix arguments `x` are coerced to time series.

`lag` is a generic function; this page documents its default method.

Value

A time series object.

Note

Note the sign of `k`: a series lagged by a positive `k` starts *earlier*.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[diff](#), [deltat](#)

Examples

```
lag(1deaths, 12) # starts one year earlier
```

lag.plot

*Time Series Lag Plots***Description**

Plot time series against lagged versions of themselves. Helps visualizing ‘auto-dependence’ even when auto-correlations vanish.

Usage

```
lag.plot(x, lags = 1, layout = NULL, set.lags = 1:lags,
        main = NULL, asp = 1,
        diag = TRUE, diag.col = "gray", type = "p", oma = NULL,
        ask = NULL, do.lines = (n <= 150), labels = do.lines,
        ...)
```

Arguments

x	time-series (univariate or multivariate)
lags	number of lag plots desired, see arg <code>set.lags</code> .
layout	the layout of multiple plots, basically the <code>mfrow</code> <code>par()</code> argument. The default uses about a square layout (see <code>n2mfrow</code> such that all plots are on one page.
set.lags	vector of positive integers allowing specification of the set of lags used; defaults to <code>1:lags</code> .
main	character with a main header title to be done on the top of each page.
asp	Aspect ratio to be fixed, see <code>plot.default</code> .
diag	logical indicating if the x=y diagonal should be drawn.
diag.col	color to be used for the diagonal if <code>(diag)</code> .
type	plot type to be used, but see <code>plot.ts</code> about its restricted meaning.
oma	outer margins, see <code>par</code> .
ask	logical or NULL; if true, the user is asked to confirm before a new page is started.
do.lines	logical indicating if lines should be drawn.
labels	logical indicating if labels should be used.
...	Further arguments to <code>plot.ts</code> . Several graphical parameters are set in this function and so cannot be changed: these include <code>xlab</code> , <code>ylab</code> , <code>mgp</code> , <code>col.lab</code> and <code>font.lab</code> : this also applies to the arguments <code>xy.labels</code> and <code>xy.lines</code> .

Details

If just one plot is produced, this is a conventional plot. If more than one plot is to be produced, `par(mfrow)` and several other graphics parameters will be set, so it is not (easily) possible to mix such lag plots with other plots on the same page.

If `ask = NULL`, `par(ask = TRUE)` will be called if more than one page of plots is to be produced and the device is interactive.

Note

It is more flexible and has different default behaviour than the S version. We use `main =` instead of `head =` for internal consistency.

Martin Maechler

See Also

`plot.ts` which is the basic work horse.

Examples

```
require(graphics)

lag.plot(nhtemp, 8, diag.col = "forest green")
lag.plot(nhtemp, 5, main="Average Temperatures in New Haven")
## ask defaults to TRUE when we have more than one page:
lag.plot(nhtemp, 6, layout = c(2,1), asp = NA,
         main = "New Haven Temperatures", col.main = "blue")

## Multivariate (but non-stationary! ...)
lag.plot(freeny.x, lags = 3)
## Not run:
no lines for long series :
lag.plot(sqrt(sunspots), set = c(1:4, 9:12), pch = ".", col = "gold")
## End(Not run)
```

line

Robust Line Fitting

Description

Fit a line robustly as recommended in *Exploratory Data Analysis*.

Usage

```
line(x, y)
```

Arguments

`x, y` the arguments can be any way of specifying x-y pairs.

Value

An object of class "tukeyline".

Methods are available for the generic functions `coef`, `residuals`, `fitted`, and `print`.

References

Tukey, J. W. (1977). *Exploratory Data Analysis*, Reading Massachusetts: Addison-Wesley.

See Also[lm](#).**Examples**

```
require(graphics)

plot(cars)
(z <- line(cars))
abline(coef(z))
## Tukey-Anscombe Plot :
plot(residuals(z) ~ fitted(z), main = deparse(z$call))
```

lm

*Fitting Linear Models***Description**

`lm` is used to fit linear models. It can be used to carry out regression, single stratum analysis of variance and analysis of covariance (although [aov](#) may provide a more convenient interface for these).

Usage

```
lm(formula, data, subset, weights, na.action,
   method = "qr", model = TRUE, x = FALSE, y = FALSE, qr = TRUE,
   singular.ok = TRUE, contrasts = NULL, offset, ...)
```

Arguments

<code>formula</code>	an object of class " formula " (or one that can be coerced to that class): a symbolic description of the model to be fitted. The details of model specification are given under ‘Details’.
<code>data</code>	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in <code>data</code> , the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>lm</code> is called.
<code>subset</code>	an optional vector specifying a subset of observations to be used in the fitting process.
<code>weights</code>	an optional vector of weights to be used in the fitting process. Should be <code>NULL</code> or a numeric vector. If non- <code>NULL</code> , weighted least squares is used with weights <code>weights</code> (that is, minimizing $\sum(w * e^2)$); otherwise ordinary least squares is used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of options , and is <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . Another possible value is <code>NULL</code> , no action. Value <code>na.exclude</code> can be useful.
<code>method</code>	the method to be used; for fitting, currently only <code>method = "qr"</code> is supported; <code>method = "model.frame"</code> returns the model frame (the same as with <code>model = TRUE</code> , see below).

<code>model, x, y, qr</code>	logicals. If <code>TRUE</code> the corresponding components of the fit (the model frame, the model matrix, the response, the QR decomposition) are returned.
<code>singular.ok</code>	logical. If <code>FALSE</code> (the default in <code>S</code> but not in <code>R</code>) a singular fit is an error.
<code>contrasts</code>	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
<code>offset</code>	this can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting. This should be <code>NULL</code> or a numeric vector of length either one or equal to the number of cases. One or more <code>offset</code> terms can be included in the formula instead or as well, and if both are specified their sum is used. See <code>model.offset</code> .
<code>...</code>	additional arguments to be passed to the low level regression fitting functions (see below).

Details

Models for `lm` are specified symbolically. A typical model has the form `response ~ terms` where `response` is the (numeric) response vector and `terms` is a series of terms which specifies a linear predictor for `response`. A terms specification of the form `first + second` indicates all the terms in `first` together with all the terms in `second` with duplicates removed. A specification of the form `first:second` indicates the set of terms obtained by taking the interactions of all terms in `first` with all terms in `second`. The specification `first*second` indicates the *cross* of `first` and `second`. This is the same as `first + second + first:second`.

If the formula includes an `offset`, this is evaluated and subtracted from the response.

If `response` is a matrix a linear model is fitted separately by least-squares to each column of the matrix.

See `model.matrix` for some further details. The terms in the formula will be re-ordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on: to avoid this pass a `terms` object as the formula (see `av` and `demo(glm.vr)` for an example).

A formula has an implied intercept term. To remove this use either `y ~ x - 1` or `y ~ 0 + x`. See `formula` for more details of allowed formulae.

`lm` calls the lower level functions `lm.fit`, etc, see below, for the actual numerical computations. For programming only, you may consider doing likewise.

All of `weights`, `subset` and `offset` are evaluated in the same way as variables in `formula`, that is first in `data` and then in the environment of `formula`.

Value

`lm` returns an object of class `"lm"` or for multiple responses of class `c("mlm", "lm")`.

The functions `summary` and `anova` are used to obtain and print a summary and analysis of variance table of the results. The generic accessor functions `coefficients`, `effects`, `fitted.values` and `residuals` extract various useful features of the value returned by `lm`.

An object of class `"lm"` is a list containing at least the following components:

<code>coefficients</code>	a named vector of coefficients
<code>residuals</code>	the residuals, that is response minus fitted values.
<code>fitted.values</code>	the fitted mean values.
<code>rank</code>	the numeric rank of the fitted linear model.
<code>weights</code>	(only for weighted fits) the specified weights.

<code>df.residual</code>	the residual degrees of freedom.
<code>call</code>	the matched call.
<code>terms</code>	the <code>terms</code> object used.
<code>contrasts</code>	(only where relevant) the contrasts used.
<code>xlevels</code>	(only where relevant) a record of the levels of the factors used in fitting.
<code>offset</code>	the offset used (missing if none were used).
<code>y</code>	if requested, the response used.
<code>x</code>	if requested, the model matrix used.
<code>model</code>	if requested (the default), the model frame used.
<code>na.action</code>	(where relevant) information returned by <code>model.frame</code> on the special handling of NAs.

In addition, non-null fits will have components `assign`, `effects` and (unless not requested) `qr` relating to the linear fit, for use by extractor functions such as `summary` and `effects`.

Using time series

Considerable care is needed when using `lm` with time series.

Unless `na.action = NULL`, the time series attributes are stripped from the variables before the regression is done. (This is necessary as omitting NAs would invalidate the time series attributes, and if NAs are omitted in the middle of the series the result would no longer be a regular time series.)

Even if the time series attributes are retained, they are not used to line up series, so that the time shift of a lagged or differenced regressor would be ignored. It is good practice to prepare a data argument by `ts.intersect(..., dframe = TRUE)`, then apply a suitable `na.action` to that data frame and call `lm` with `na.action = NULL` so that residuals and fitted values are time series.

Note

Offsets specified by `offset` will not be included in predictions by `predict.lm`, whereas those specified by an offset term in the formula will be.

Author(s)

The design was inspired by the `S` function of the same name described in Chambers (1992). The implementation of model formula by Ross Ihaka was based on Wilkinson & Rogers (1973).

lm.fit

Fitter Functions for Linear Models

Description

These are the basic computing engines called by `lm` used to fit linear models. These should usually *not* be used directly unless by experienced users.

Usage

```
lm.fit(x, y,      offset = NULL, method = "qr", tol = 1e-7,
       singular.ok = TRUE, ...)
```

```
lm.wfit(x, y, w, offset = NULL, method = "qr", tol = 1e-7,
       singular.ok = TRUE, ...)
```

Arguments

x	design matrix of dimension $n * p$.
y	vector of observations of length n, or a matrix with n rows.
w	vector of weights (length n) to be used in the fitting process for the <code>wfit</code> functions. Weighted least squares is used with weights w, i.e., $\sum(w * e^2)$ is minimized.
offset	numeric of length n). This can be used to specify an <i>a priori</i> known component to be included in the linear predictor during fitting.
method	currently, only <code>method="qr"</code> is supported.
tol	tolerance for the <code>qr</code> decomposition. Default is 1e-7.
singular.ok	logical. If FALSE, a singular model is an error.
...	currently disregarded.

Value

a list with components

coefficients	p vector
residuals	n vector or matrix
fitted.values	n vector or matrix
effects	(not null fits)n vector of orthogonal single-df effects. The first rank of them correspond to non-aliased coefficients, and are named accordingly.
weights	n vector — <i>only</i> for the <code>*wfit*</code> functions.
rank	integer, giving the rank
df.residual	degrees of freedom of residuals
qr	(not null fits) the QR decomposition, see <code>qr</code> .

See Also

`lm` which you should use for linear least squares regression, unless you know better.

Examples

```
require(utils)
set.seed(129)
n <- 7 ; p <- 2
X <- matrix(rnorm(n * p), n,p) # no intercept!
y <- rnorm(n)
w <- rnorm(n)^2

str(lmw <- lm.wfit(x=X, y=y, w=w))

str(lm. <- lm.fit (x=X, y=y))
```

lm.influence *Regression Diagnostics*

Description

This function provides the basic quantities which are used in forming a wide variety of diagnostics for checking the quality of regression fits.

Usage

```
influence(model, ...)
## S3 method for class 'lm':
influence(model, do.coef = TRUE, ...)
## S3 method for class 'glm':
influence(model, do.coef = TRUE, ...)

lm.influence(model, do.coef = TRUE)
```

Arguments

model	an object as returned by <code>lm</code> or <code>glm</code> .
do.coef	logical indicating if the changed coefficients (see below) are desired. These need $O(n^2p)$ computing time.
...	further arguments passed to or from other methods.

Details

The `influence.measures()` and other functions listed in **See Also** provide a more user oriented way of computing a variety of regression diagnostics. These all build on `lm.influence`. Note that for GLMs (other than the Gaussian family with identity link) these are based on one-step approximations which may be inadequate if a case has high influence.

An attempt is made to ensure that computed hat values that are probably one are treated as one, and the corresponding rows in `sigma` and `coefficients` are NaN. (Dropping such a case would normally result in a variable being dropped, so it is not possible to give simple drop-one diagnostics.)

`naresid` is applied to the results and so will fill in with NAs if the fit had `na.action = na.exclude`.

Value

A list containing the following components of the same length or number of rows n , which is the number of non-zero weights. Cases omitted in the fit are omitted unless a `na.action` method was used (such as `na.exclude`) which restores them.

hat	a vector containing the diagonal of the 'hat' matrix.
coefficients	(unless <code>do.coef</code> is false) a matrix whose i -th row contains the change in the estimated coefficients which results when the i -th case is dropped from the regression. Note that aliased coefficients are not included in the matrix.

<code>sigma</code>	a vector whose <i>i</i> -th element contains the estimate of the residual standard deviation obtained when the <i>i</i> -th case is dropped from the regression. (The approximations needed for GLMs can result in this being NaN.)
<code>wt.res</code>	a vector of <i>weighted</i> (or for class <code>glm</code> rather <i>deviance</i>) residuals.

Note

The coefficients returned by the R version of `lm.influence` differ from those computed by S. Rather than returning the coefficients which result from dropping each case, we return the changes in the coefficients. This is more directly useful in many diagnostic measures. Since these need $O(n^2p)$ computing time, they can be omitted by `do.coef = FALSE`.

Note that cases with `weights == 0` are *dropped* (contrary to the situation in S).

If a model has been fitted with `na.action=na.exclude` (see `na.exclude`), cases excluded in the fit *are* considered here.

`summary.lm` for `summary` and related methods;
[influence.measures](#),
`hat` for the hat matrix diagonals,
[dfbetas](#), [dffits](#), [covratio](#), [cooks.distance](#), `lm`.

Examples

```
## Analysis of the life-cycle savings data
## given in Belsley, Kuh and Welsch.
summary(lm.SR <- lm(sr ~ pop15 + pop75 + dpi + ddpi,
                   data = LifeCycleSavings),
        corr = TRUE)
utils::str(lmI <- lm.influence(lm.SR))

## For more "user level" examples, use example(influence.measures)
```

Description

All these functions are [methods](#) for class "lm" objects.

Usage

```
## S3 method for class 'lm':
family(object, ...)

## S3 method for class 'lm':
formula(x, ...)

## S3 method for class 'lm':
residuals(object,
           type = c("working", "response", "deviance", "pearson",
                   "partial"),
           ...)

## S3 method for class 'lm':
labels(object, ...)

weights(object, ...)
```

Arguments

`object`, `x` an object inheriting from class `lm`, usually the result of a call to `lm` or `aov`.
`...` further arguments passed to or from other methods.
`type` the type of residuals which should be returned.

Details

The generic accessor functions `coef`, `effects`, `fitted` and `residuals` can be used to extract various useful features of the value returned by `lm`.

The `working` and `response` residuals are ‘observed - fitted’. The `deviance` and `pearson` residuals are weighted residuals, scaled by the square root of the weights used in fitting. The `partial` residuals are a matrix with each column formed by omitting a term from the model. In all these, zero weight cases are never omitted (as opposed to the standardized `rstudent` residuals, and the `weighted.residuals`).

How `residuals` treats cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear, with residual value `NA`. See also `naresid`.

The "`lm`" method for generic `labels` returns the term labels for estimable terms, that is the names of the terms with an least one estimable coefficient.

[influence.measures](#) for deletion diagnostics, including standardized ([rstandard](#)) and studentized ([rstudent](#)) residuals.

Examples

```
##-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients

## The 2 basic regression diagnostic plots [plot.lm(.) is preferred]
plot(resid(lm.D90), fitted(lm.D90)) # Tukey-Anscombe's
abline(h=0, lty=2, col = 'gray')

qqnorm(residuals(lm.D90))
```

loadings

Print Loadings in Factor Analysis

Description

Extract or print loadings in factor analysis (or principal components analysis).

Usage

```
loadings(x)

## S3 method for class 'loadings':
print(x, digits = 3, cutoff = 0.1, sort = FALSE, ...)

## S3 method for class 'factanal':
print(x, digits = 3, ...)
```

Arguments

<code>x</code>	an object of class "factanal" or "princomp" or the loadings component of such an object.
<code>digits</code>	number of decimal places to use in printing uniquenesses and loadings.
<code>cutoff</code>	loadings smaller than this (in absolute value) are suppressed.
<code>sort</code>	logical. If true, the variables are sorted by their importance on each factor. Each variable with any loading larger than 0.5 (in modulus) is assigned to the factor with the largest loading, and the variables are printed in the order of the factor they are assigned to, then those unassigned.
<code>...</code>	further arguments for other methods, such as <code>cutoff</code> and <code>sort</code> for <code>print.factanal</code> .

See Also

[factanal](#), [princomp](#)

loess

*Local Polynomial Regression Fitting***Description**

Fit a polynomial surface determined by one or more numerical predictors, using local fitting.

Usage

```
loess(formula, data, weights, subset, na.action, model = FALSE,
      span = 0.75, enp.target, degree = 2,
      parametric = FALSE, drop.square = FALSE, normalize = TRUE,
      family = c("gaussian", "symmetric"),
      method = c("loess", "model.frame"),
      control = loess.control(...), ...)
```

Arguments

formula	a formula specifying the numeric response and one to four numeric predictors (best specified via an interaction, but can also be specified additively). Will be coerced to a formula if necessary.
data	an optional data frame, list or environment (or object coercible by as.data.frame to a data frame) containing the variables in the model. If not found in data, the variables are taken from <code>environment(formula)</code> , typically the environment from which <code>loess</code> is called.
weights	optional weights for each case.
subset	an optional specification of a subset of the data to be used.
na.action	the action to be taken with missing values in the response or predictors. The default is given by <code>getOption("na.action")</code> .
model	should the model frame be returned?
span	the parameter α which controls the degree of smoothing.
enp.target	an alternative way to specify <code>span</code> , as the approximate equivalent number of parameters to be used.
degree	the degree of the polynomials to be used, up to 2.
parametric	should any terms be fitted globally rather than locally? Terms can be specified by name, number or as a logical vector of the same length as the number of predictors.
drop.square	for fits with more than one predictor and <code>degree=2</code> , should the quadratic term (and cross-terms) be dropped for particular predictors? Terms are specified in the same way as for <code>parametric</code> .
normalize	should the predictors be normalized to a common scale if there is more than one? The normalization used is to set the 10% trimmed standard deviation to one. Set to false for spatial coordinate predictors and others know to be a common scale.
family	if "gaussian" fitting is by least-squares, and if "symmetric" a re-descending M estimator is used with Tukey's biweight function.
method	fit the model or just extract the model frame.
control	control parameters: see loess.control .
...	control parameters can also be supplied directly.

Details

Fitting is done locally. That is, for the fit at point x , the fit is made using points in a neighbourhood of x , weighted by their distance from x (with differences in 'parametric' variables being ignored when computing the distance). The size of the neighbourhood is controlled by α (set by `span` or `enp.target`). For $\alpha < 1$, the neighbourhood includes proportion α of the points, and these have tricubic weighting (proportional to $(1 - (\text{dist}/\text{maxdist})^3)^3$). For $\alpha > 1$, all points are used, with the 'maximum distance' assumed to be $\alpha^{1/p}$ times the actual maximum distance for p explanatory variables.

For the default family, fitting is by (weighted) least squares. For `family="symmetric"` a few iterations of an M-estimation procedure with Tukey's biweight are used. Be aware that as the initial value is the least-squares fit, this need not be a very resistant fit.

It can be important to tune the control list to achieve acceptable speed. See `loess.control` for details.

Value

An object of class "loess".

Note

As this is based on the `cloess` package available at `netlib`, it is similar to but not identical to the `loess` function of S. In particular, conditioning is not implemented.

The memory usage of this implementation of `loess` is roughly quadratic in the number of points, with 1000 points taking about 10Mb.

Author(s)

B. D. Ripley, based on the `cloess` package of Cleveland, Grosse and Shyu available at <http://www.netlib.org/a/>.

References

W. S. Cleveland, E. Grosse and W. M. Shyu (1992) Local regression models. Chapter 8 of *Statistical Models in S* eds J.M. Chambers and T.J. Hastie, Wadsworth & Brooks/Cole.

See Also

`loess.control`, `predict.loess`.

`lowess`, the ancestor of `loess` (with different defaults!).

Examples

```
cars.lo <- loess(dist ~ speed, cars)
predict(cars.lo, data.frame(speed = seq(5, 30, 1)), se = TRUE)
# to allow extrapolation
cars.lo2 <- loess(dist ~ speed, cars,
  control = loess.control(surface = "direct"))
predict(cars.lo2, data.frame(speed = seq(5, 30, 1)), se = TRUE)
```

`loess.control`*Set Parameters for Loess*

Description

Set control parameters for loess fits.

Usage

```
loess.control(surface = c("interpolate", "direct"),
              statistics = c("approximate", "exact"),
              trace.hat = c("exact", "approximate"),
              cell = 0.2, iterations = 4, ...)
```

Arguments

<code>surface</code>	should the fitted surface be computed exactly or via interpolation from a kd tree?
<code>statistics</code>	should the statistics be computed exactly or approximately? Exact computation can be very slow.
<code>trace.hat</code>	should the trace of the smoother matrix be computed exactly or approximately? It is recommended to use the approximation for more than about 1000 data points.
<code>cell</code>	if interpolation is used this controls the accuracy of the approximation via the maximum number of points in a cell in the kd tree. Cells with more than $\text{floor}(n \cdot \text{span} \cdot \text{cell})$ points are subdivided.
<code>iterations</code>	the number of iterations used in robust fitting.
<code>...</code>	further arguments which are ignored.

Value

A list with components

`surface``statistics``trace.hat``cell``iterations`

with meanings as explained under ‘Arguments’.

See Also

[loess](#)

Description

Density, distribution function, quantile function and random generation for the logistic distribution with parameters `location` and `scale`.

Usage

```
dlogis(x, location = 0, scale = 1, log = FALSE)
plogis(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qlogis(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rlogis(n, location = 0, scale = 1)
```

Arguments

`x`, `q` vector of quantiles.
`p` vector of probabilities.
`n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
`location`, `scale` location and scale parameters.
`log`, `log.p` logical; if TRUE, probabilities `p` are given as `log(p)`.
`lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If `location` or `scale` are omitted, they assume the default values of 0 and 1 respectively.

The Logistic distribution with `location` = μ and `scale` = σ has distribution function

$$F(x) = \frac{1}{1 + e^{-(x-\mu)/\sigma}}$$

and density

$$f(x) = \frac{1}{\sigma} \frac{e^{(x-\mu)/\sigma}}{(1 + e^{(x-\mu)/\sigma})^2}$$

It is a long-tailed distribution with mean μ and variance $\pi^2/3\sigma^2$.

Value

`dlogis` gives the density, `plogis` gives the distribution function, `qlogis` gives the quantile function, and `rlogis` generates random deviates.

Note

`qlogis(p)` is the same as the well known ‘*logit*’ function, $\text{logit}(p) = \log(p/(1-p))$, and `plogis(x)` has consequently been called the ‘inverse logit’.

The distribution function is a rescaled hyperbolic tangent, `plogis(x) == (1 + tanh(x/2)) / 2`, and it is called a *sigmoid function* in contexts such as neural networks.

Source

[dpr]logis are calculated directly from the definitions.
rlogis uses inversion.

Examples

```
var(rlogis(4000, 0, scale = 5))# approximately (+/- 3)
pi^2/3 * 5^2
```

logLik	<i>Extract Log-Likelihood</i>
--------	-------------------------------

Description

This function is generic; method functions can be written to handle specific classes of objects. Classes which already have methods for this function include: `glm`, `lm`, `nls`, `Arima` and `gls`, `lme` and others in package **nlme**.

Usage

```
logLik(object, ...)
```

```
## S3 method for class 'lm':
logLik(object, REML = FALSE, ...)
```

Arguments

<code>object</code>	any object from which a log-likelihood value, or a contribution to a log-likelihood value, can be extracted.
<code>...</code>	some methods for this generic function require additional arguments.
<code>REML</code>	an optional logical value. If <code>TRUE</code> the restricted log-likelihood is returned, else, if <code>FALSE</code> , the log-likelihood is returned. Defaults to <code>FALSE</code> .

Details

For a "glm" fit the `family` does not have to specify how to calculate the log-likelihood, so this is based on the family's `aic()` function to compute the AIC. For the `gaussian`, `Gamma` and `inverse.gaussian` families it assumed that the dispersion of the GLM is estimated has been counted as a parameter in the AIC value, and for all other families it is assumed that the dispersion is known.

Note that this procedure is not completely accurate for the gamma and inverse gaussian families, as the estimate of dispersion used is not the MLE.

For "lm" fits it is assumed that the scale has been estimated (by maximum likelihood or REML), and all the constants in the log-likelihood are included.

Value

Returns an object, say `r`, of class `logLik` which is a number with attributes, `attr(r, "df")` (**d**egrees of **f**reedom) giving the number of (estimated) parameters in the model. There is a simple `print` method for `logLik` objects.

The details depend on the method function used; see the appropriate documentation.

x <- 1:5
lmx <- lm(x ~ 1)
logLik(lmx) # using print.logLik() method
utils::str(logLik(lmx))

## lm method
(fm1 <- lm(rating ~ ., data = attitude))
logLik(fm1)
logLik(fm1, REML = TRUE)

res <- try(utils::data(Orthodont, package="nlme"))
if(!inherits(res, "try-error")) {
  fm1 <- lm(distance ~ Sex * age, Orthodont)
  print(logLik(fm1))
  print(logLik(fm1, REML = TRUE))
}
```

loglin

Fitting Log-Linear Models

Description

`loglin` is used to fit log-linear models to multidimensional contingency tables by Iterative Proportional Fitting.

Usage

```
loglin(table, margin, start = rep(1, length(table)), fit = FALSE,
       eps = 0.1, iter = 20, param = FALSE, print = TRUE)
```

Arguments

<code>table</code>	a contingency table to be fit, typically the output from <code>table</code> .
<code>margin</code>	a list of vectors with the marginal totals to be fit. (Hierarchical) log-linear models can be specified in terms of these marginal totals which give the 'maximal' factor subsets contained in the model. For example, in a three-factor model, <code>list(c(1, 2), c(1, 3))</code> specifies a model which contains parameters for the grand mean, each factor, and the 1-2 and 1-3 interactions, respectively (but no 2-3 or 1-2-3 interaction), i.e., a model where factors 2 and 3 are independent conditional on factor 1 (sometimes represented as '[12][13]'). The names of factors (i.e., <code>names(dimnames(table))</code>) may be used rather than numeric indices.
<code>start</code>	a starting estimate for the fitted table. This optional argument is important for incomplete tables with structural zeros in <code>table</code> which should be preserved in the fit. In this case, the corresponding entries in <code>start</code> should be zero and the others can be taken as one.
<code>fit</code>	a logical indicating whether the fitted values should be returned.
<code>eps</code>	maximum deviation allowed between observed and fitted margins.
<code>iter</code>	maximum number of iterations.
<code>param</code>	a logical indicating whether the parameter values should be returned.
<code>print</code>	a logical. If <code>TRUE</code> , the number of iterations and the final deviation are printed.

Details

The Iterative Proportional Fitting algorithm as presented in Haberman (1972) is used for fitting the model. At most `iter` iterations are performed, convergence is taken to occur when the maximum deviation between observed and fitted margins is less than `eps`. All internal computations are done in double precision; there is no limit on the number of factors (the dimension of the table) in the model.

Assuming that there are no structural zeros, both the Likelihood Ratio Test and Pearson test statistics have an asymptotic chi-squared distribution with `df` degrees of freedom.

Note that the IPF steps are applied to the factors in the order given in `margin`. Hence if the model is decomposable and the order given in `margin` is a running intersection property ordering then IPF will converge in one iteration.

Package **MASS** contains `loglm`, a front-end to `loglin` which allows the log-linear model to be specified and fitted in a formula-based manner similar to that of other fitting functions such as `lm` or `glm`.

Value

A list with the following components.

<code>lrt</code>	the Likelihood Ratio Test statistic.
<code>pearson</code>	the Pearson test statistic (X-squared).
<code>df</code>	the degrees of freedom for the fitted model. There is no adjustment for structural zeros.
<code>margin</code>	list of the margins that were fit. Basically the same as the input <code>margin</code> , but with numbers replaced by names where possible.

<code>fit</code>	An array like <code>table</code> containing the fitted values. Only returned if <code>fit</code> is <code>TRUE</code> .
<code>param</code>	A list containing the estimated parameters of the model. The ‘standard’ constraints of zero marginal sums (e.g., zero row and column sums for a two factor parameter) are employed. Only returned if <code>param</code> is <code>TRUE</code> .

Lognormal

The Log Normal Distribution

Description

Density, distribution function, quantile function and random generation for the log normal distribution whose logarithm has mean equal to `meanlog` and standard deviation equal to `sdlog`.

Usage

```
dlnorm(x, meanlog = 0, sdlog = 1, log = FALSE)
plnorm(q, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
qlnorm(p, meanlog = 0, sdlog = 1, lower.tail = TRUE, log.p = FALSE)
rlnorm(n, meanlog = 0, sdlog = 1)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>meanlog, sdlog</code>	mean and standard deviation of the distribution on the log scale with default values of 0 and 1 respectively.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The log normal distribution has density

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma x} e^{-(\log(x)-\mu)^2/2\sigma^2}$$

where μ and σ are the mean and standard deviation of the logarithm. The mean is $E(X) = \exp(\mu + 1/2\sigma^2)$, the median is $med(X) = \exp(\mu)$, and the variance $Var(X) = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)$ and hence the coefficient of variation is $\sqrt{\exp(\sigma^2) - 1}$ which is approximately σ when that is small (e.g., $\sigma < 1/2$).

Value

`dlnorm` gives the density, `plnorm` gives the distribution function, `qlnorm` gives the quantile function, and `rlnorm` generates random deviates.

Note

The cumulative hazard $H(t) = -\log(1 - F(t))$ is `-plnorm(t, r, lower = FALSE, log = TRUE)`.

Source

`dlnorm` is calculated from the definition (in ‘Details’). `[pqr]lnorm` are based on the relationship to the normal.

Examples

```
dlnorm(1) == dnorm(0)
```

lowess

*Scatter Plot Smoothing***Description**

This function performs the computations for the *LOWESS* smoother which uses locally-weighted polynomial regression (see the references).

Usage

```
lowess(x, y = NULL, f = 2/3, iter = 3,
       delta = 0.01 * diff(range(xy$x[o])))
```

Arguments

<code>x</code> , <code>y</code>	vectors giving the coordinates of the points in the scatter plot. Alternatively a single plotting structure can be specified – see xy.coords .
<code>f</code>	the smoother span. This gives the proportion of points in the plot which influence the smooth at each value. Larger values give more smoothness.
<code>iter</code>	the number of ‘robustifying’ iterations which should be performed. Using smaller values of <code>iter</code> will make <code>lowess</code> run faster.
<code>delta</code>	See ‘Details’. Defaults to 1/100th of the range of <code>x</code> .

Details

`lowess` is defined by a complex algorithm, the Ratfor original of which (by W. S. Cleveland) can be found in the R sources as file ‘src/appl/lowess.doc’. Normally a local linear polynomial fit is used, but under some circumstances (see the file) a local constant fit can be used. ‘Local’ is defined by the distance to the `floor(f*n)` th nearest neighbour, and tricubic weighting is used for `x` which fall within the neighbourhood.

The initial fit is done using weighted least squares. If `iter > 0`, further weighted fits are done using the product of the weights from the proximity of the `x` values and case weights derived from the residuals at the previous iteration. Specifically, the case weight is Tukey’s biweight, with cutoff 6 times the MAD of the residuals. (The current R implementation differs from the original in stopping iteration if the MAD is effectively zero since the algorithm is highly unstable in that case.)

`delta` is used to speed up computation: instead of computing the local polynomial fit at each data point it is not computed for points within `delta` of the last computed point, and linear interpolation is used to fill in the fitted values for the skipped points.

Value

`lowess` returns a list containing components `x` and `y` which give the coordinates of the smooth. The smooth can be added to a plot of the original points with the function `lines`: see the examples.

plot(cars, main = "lowess(cars)")
lines(lowess(cars), col = 2)
lines(lowess(cars, f=.2), col = 3)
legend(5, 120, c(paste("f = ", c("2/3", ".2"))), lty = 1, col = 2:3)
```

ls.diag

Compute Diagnostics for 'lsfit' Regression Results

Description

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients.

Usage

```
ls.diag(ls.out)
```

Arguments

ls.out Typically the result of `lsfit()`

Value

A list with the following numeric components.

std.dev	The standard deviation of the errors, an estimate of σ .
hat	diagonal entries h_{ii} of the hat matrix H
std.res	standardized residuals
stud.res	studentized residuals
cooks	Cook's distances
dfits	DFITS statistics
correlation	correlation matrix
std.err	standard errors of the regression coefficients
cov.scaled	Scaled covariance matrix of the coefficients
cov.unscaled	Unscaled covariance matrix of the coefficients

References

See Also

[hat](#) for the hat matrix diagonals, [ls.print](#), [lm.influence](#), [summary.lm](#), [anova](#).

Examples

```
##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = as.numeric(gl(2, 10, 20)), y = weight)
dlsD9 <- ls.diag(lsD9)
utils::str(dlsD9, give.attr=FALSE)
abs(1 - sum(dlsD9$hat) / 2) < 10*.Machine$double.eps # sum(h.ii) = p
plot(dlsD9$hat, dlsD9$stud.res, xlim=c(0,0.11))
abline(h = 0, lty = 2, col = "lightgray")
```

ls.print

*Print 'lsfit' Regression Results***Description**

Computes basic statistics, including standard errors, t- and p-values for the regression coefficients and prints them if `print.it` is TRUE.

Usage

```
ls.print(ls.out, digits = 4, print.it = TRUE)
```

Arguments

<code>ls.out</code>	Typically the result of <code>lsfit()</code>
<code>digits</code>	The number of significant digits used for printing
<code>print.it</code>	a logical indicating whether the result should also be printed

Value

A list with the components

<code>summary</code>	The ANOVA table of the regression
<code>coef.table</code>	matrix with regression coefficients, standard errors, t- and p-values

Note

Usually, you'd rather use `summary(lm(...))` and `anova(lm(...))` for obtaining similar output.

See Also

[ls.diag](#), [lsfit](#), also for examples; [lm](#), [lm.influence](#) which usually are preferable.

 lsfit

Find the Least Squares Fit

Description

The least squares estimate of β in the model

$$Y = X\beta + \epsilon$$

is found.

Usage

```
lsfit(x, y, wt = NULL, intercept = TRUE, tolerance = 1e-07,
      yname = NULL)
```

Arguments

<code>x</code>	a matrix whose rows correspond to cases and whose columns correspond to variables.
<code>y</code>	the responses, possibly a matrix if you want to fit multiple left hand sides.
<code>wt</code>	an optional vector of weights for performing weighted least squares.
<code>intercept</code>	whether or not an intercept term should be used.
<code>tolerance</code>	the tolerance to be used in the matrix decomposition.
<code>yname</code>	names to be used for the response variables.

Details

If weights are specified then a weighted least squares is performed with the weight given to the j th case specified by the j th entry in `wt`.

If any observation has a missing value in any field, that observation is removed before the analysis is carried out. This can be quite inefficient if there is a lot of missing data.

The implementation is via a modification of the LINPACK subroutines which allow for multiple left-hand sides.

Value

A list with the following named components:

<code>coef</code>	the least squares estimates of the coefficients in the model (β as stated above).
<code>residuals</code>	residuals from the fit.
<code>intercept</code>	indicates whether an intercept was fitted.
<code>qr</code>	the QR decomposition of the design matrix.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[lm](#) which usually is preferable; [ls.print](#), [ls.diag](#).

Examples

```
##-- Using the same data as the lm(.) example:
lsD9 <- lsfit(x = unclass(gl(2,10)), y = weight)
ls.print(lsD9)
```

mad

Median Absolute Deviation

Description

Compute the median absolute deviation, i.e., the (lo-/hi-) median of the absolute deviations from the median, and (by default) adjust by a factor for asymptotically normal consistency.

Usage

```
mad(x, center = median(x), constant = 1.4826, na.rm = FALSE,
    low = FALSE, high = FALSE)
```

Arguments

<code>x</code>	a numeric vector.
<code>center</code>	Optionally, the centre: defaults to the median.
<code>constant</code>	scale factor.
<code>na.rm</code>	if TRUE then NA values are stripped from <code>x</code> before computation takes place.
<code>low</code>	if TRUE, compute the ‘lo-median’, i.e., for even sample size, do not average the two middle values, but take the smaller one.
<code>high</code>	if TRUE, compute the ‘hi-median’, i.e., take the larger of the two middle values for even sample size.

Details

The actual value calculated is `constant * cMedian(abs(x - center))` with the default value of `center` being `median(x)`, and `cMedian` being the usual, the ‘low’ or ‘high’ median, see the arguments description for `low` and `high` above.

The default `constant = 1.4826` (approximately $1/\Phi^{-1}(\frac{3}{4}) = 1/\text{qnorm}(3/4)$) ensures consistency, i.e.,

$$E[\text{mad}(X_1, \dots, X_n)] = \sigma$$

for X_i distributed as $N(\mu, \sigma^2)$ and large n .

If `na.rm` is TRUE then NA values are stripped from `x` before computation takes place. If this is not done then an NA value in `x` will cause `mad` to return NA.

See Also

[IQR](#) which is simpler but less robust, [median](#), [var](#).

Examples

```

mad(c(1:9))
print(mad(c(1:9), constant=1)) ==
      mad(c(1:8,100), constant=1) # = 2 ; TRUE
x <- c(1,2,3, 5,7,8)
sort(abs(x - median(x)))
c(mad(x, constant=1),
  mad(x, constant=1, low = TRUE),
  mad(x, constant=1, high = TRUE))

```

mahalanobis

*Mahalanobis Distance***Description**

Returns the squared Mahalanobis distance of all rows in `x` and the vector `μ=center` with respect to `Σ=cov`. This is (for vector `x`) defined as

$$D^2 = (x - \mu)' \Sigma^{-1} (x - \mu)$$

Usage

```

mahalanobis(x, center, cov, inverted=FALSE, ...)

```

Arguments

<code>x</code>	vector or matrix of data with, say, p columns.
<code>center</code>	mean vector of the distribution or second data vector of length p .
<code>cov</code>	covariance matrix ($p \times p$) of the distribution.
<code>inverted</code>	logical. If TRUE, <code>cov</code> is supposed to contain the <i>inverse</i> of the covariance matrix.
<code>...</code>	passed to <code>solve</code> for computing the inverse of the covariance matrix (if <code>inverted</code> is false).

See Also

`cov`, `var`

Examples

```

require(graphics)

ma <- cbind(1:6, 1:3)
(S <- var(ma))
mahalanobis(c(0,0), 1:2, S)

x <- matrix(rnorm(100*3), ncol = 3)
stopifnot(mahalanobis(x, 0, diag(ncol(x))) == rowSums(x*x))
          # #- Here, D^2 = usual squared Euclidean distances

Sx <- cov(x)
D2 <- mahalanobis(x, colMeans(x), Sx)

```

```
plot(density(D2, bw=.5),
      main="Squared Mahalanobis distances, n=100, p=3") ; rug(D2)
qqplot(qchisq(ppoints(100), df=3), D2,
        main = expression("Q-Q plot of Mahalanobis" * ~D^2 *
                           " vs. quantiles of" * ~ chi[3]^2))
abline(0, 1, col = 'gray')
```

make.link

*Create a Link for GLM Families***Description**

This function is used with the [family](#) functions in `glm()`. Given the name of a link, it returns a link function, an inverse link function, the derivative $d\mu/d\eta$ and a function for domain checking.

Usage

```
make.link(link)
```

Arguments

`link` character or numeric; one of "logit", "probit", "cauchit", "cloglog", "identity", "log", "sqrt", "1/mu^2", "inverse", or (deprecated) a non-negative number, say λ resulting in [power](#) link = μ^λ . Also (deprecated) a string like "power(0.5)" to indicate a call to [power](#).

Value

A object of class "link-glm", a list with components

linkfun	Link function function(μ)
linkinv	Inverse link function function(η)
mu.eta	Derivative function(η) $d\mu/d\eta$
valideta	function(η) { TRUE if η is in the domain of linkinv }
name	a name to be used for the link

.

See Also

[power](#), [glm](#), [family](#).

Examples

```
utils::str(make.link("logit"))
```

makepredictcall *Utility Function for Safe Prediction*

Description

A utility to help `model.frame.default` create the right matrices when predicting from models with terms like `poly` or `ns`.

Usage

```
makepredictcall(var, call)
```

Arguments

<code>var</code>	A variable.
<code>call</code>	The term in the formula, as a call.

Details

This is a generic function with methods for `poly`, `bs` and `ns`: the default method handles `scale`. If `model.frame.default` encounters such a term when creating a model frame, it modifies the `predvars` attribute of the terms supplied to replace the term with one that will work for predicting new data. For example `makepredictcall.ns` adds arguments for the knots and intercept.

To make use of this, have your model-fitting function return the `terms` attribute of the model frame, or copy the `predvars` attribute of the `terms` attribute of the model frame to your `terms` object.

To extend this, make sure the term creates variables with a class, and write a suitable method for that class.

Value

A replacement for `call` for the `predvars` attribute of the terms.

See Also

`model.frame`, `poly`, `scale`; `bs` and `ns` in package `splines`, `cars`

Examples

```
require(graphics)

## using poly: this did not work in R < 1.5.0
fm <- lm(weight ~ poly(height, 2), data = women)
plot(women, xlab = "Height (in)", ylab = "Weight (lb)")
ht <- seq(57, 73, len = 200)
lines(ht, predict(fm, data.frame(height=ht)))

## see also example(cars)

## see bs and ns for spline examples.
```

`manova`*Multivariate Analysis of Variance*

Description

A class for the multivariate analysis of variance.

Usage

```
manova(...)
```

Arguments

... Arguments to be passed to [aov](#).

Details

Class "manova" differs from class "aov" in selecting a different `summary` method. Function `manova` calls [aov](#) and then add class "manova" to the result object for each stratum.

Value

See [aov](#) and the comments in 'Details' here.

Note

`manova` does not support multistratum analysis of variance, so the formula should not include an `Error` term.

References

Krzanowski, W. J. (1988) *Principles of Multivariate Analysis. A User's Perspective*. Oxford.

mantelhaen.test *Cochran-Mantel-Haenszel Chi-Squared Test for Count Data*

Description

Performs a Cochran-Mantel-Haenszel chi-squared test of the null that two nominal variables are conditionally independent in each stratum, assuming that there is no three-way interaction.

Usage

```
mantelhaen.test(x, y = NULL, z = NULL,
                alternative = c("two.sided", "less", "greater"),
                correct = TRUE, exact = FALSE, conf.level = 0.95)
```

Arguments

<code>x</code>	either a 3-dimensional contingency table in array form where each dimension is at least 2 and the last dimension corresponds to the strata, or a factor object with at least 2 levels.
<code>y</code>	a factor object with at least 2 levels; ignored if <code>x</code> is an array.
<code>z</code>	a factor object with at least 2 levels identifying to which stratum the corresponding elements in <code>x</code> and <code>y</code> belong; ignored if <code>x</code> is an array.
<code>alternative</code>	indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. Only used in the 2 by 2 by K case.
<code>correct</code>	a logical indicating whether to apply continuity correction when computing the test statistic. Only used in the 2 by 2 by K case.
<code>exact</code>	a logical indicating whether the Mantel-Haenszel test or the exact conditional test (given the strata margins) should be computed. Only used in the 2 by 2 by K case.
<code>conf.level</code>	confidence level for the returned confidence interval. Only used in the 2 by 2 by K case.

Details

If `x` is an array, each dimension must be at least 2, and the entries should be nonnegative integers. NA's are not allowed. Otherwise, `x`, `y` and `z` must have the same length. Triples containing NA's are removed. All variables must take at least two different values.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	Only present if no exact test is performed. In the classical case of a 2 by 2 by K table (i.e., of dichotomous underlying variables), the Mantel-Haenszel chi-squared statistic; otherwise, the generalized Cochran-Mantel-Haenszel statistic.
<code>parameter</code>	the degrees of freedom of the approximate chi-squared distribution of the test statistic (1 in the classical case). Only present if no exact test is performed.
<code>p.value</code>	the p-value of the test.

conf.int	a confidence interval for the common odds ratio. Only present in the 2 by 2 by K case.
estimate	an estimate of the common odds ratio. If an exact test is performed, the conditional Maximum Likelihood Estimate is given; otherwise, the Mantel-Haenszel estimate. Only present in the 2 by 2 by K case.
null.value	the common odds ratio under the null of independence, 1. Only present in the 2 by 2 by K case.
alternative	a character string describing the alternative hypothesis. Only present in the 2 by 2 by K case.
method	a character string indicating the method employed, and whether or not continuity correction was used.
data.name	a character string giving the names of the data.

Note

The asymptotic distribution is only valid if there is no three-way interaction. In the classical 2 by 2 by K case, this is equivalent to the conditional odds ratios in each stratum being identical. Currently, no inference on homogeneity of the odds ratios is performed.

See also the example below.

mauchly.test

Mauchly's Test of Sphericity

Description

Tests whether a Wishart-distributed covariance matrix (or transformation thereof) is proportional to a given matrix.

Usage

```
mauchly.test(object, ...)
## S3 method for class 'mlm':
```

```
mauchly.test(object, ...)
## S3 method for class 'SSD':
mauchly.test(object, Sigma = diag(nrow = p),
  T = Thin.row(proj(M) - proj(X)), M = diag(nrow = p), X = ~0,
  idata = data.frame(index = seq_len(p)), ...)
```

Arguments

object	object of class <code>SSD</code> or <code>mlm</code> .
Sigma	matrix to be proportional to.
T	transformation matrix. By default computed from <code>M</code> and <code>X</code> .
M	formula or matrix describing the outer projection (see below).
X	formula or matrix describing the inner projection (see below).
idata	data frame describing intra-block design.
...	arguments to be passed to or from other methods.

Details

Mauchly's test test for whether a covariance matrix can be assumed to be proportional to a given matrix.

This is a generic function with methods for classes `"mlm"` and `"SSD"`.

The basic method is for objects of class `SSD` the method for `mlm` objects just extracts the `SSD` matrix and invokes the corresponding method with the same options and arguments.

The `T` argument is used to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A matrix `T` can be given directly or specified as the difference between two projections onto the spaces spanned by `M` and `X`, which in turn can be given as matrices or as model formulas with respect to `idata` (the tests will be invariant to parametrization of the quotient space M/X).

The common use of this test is in repeated measurements designs, with $X \sim 1$. This is almost, but not quite the same as testing for compound symmetry in the untransformed covariance matrix.

Notice that the defaults involve `p`, which is calculated internally as the dimension of the `SSD` matrix, and a couple of hidden functions in the `stats` name space, namely `proj` which calculates projection matrices from design matrices or model formulas and `Thin.row` which removes linearly dependent rows from a matrix until it has full row rank.

Value

An object of class `"htest"`

Note

The p-value differs slightly from that of SAS because a second order term is included in the asymptotic approximation in `R`.

### tests using intra-subject 3x2 design
idata <- data.frame(deg=gl(3,1,6, labels=c(0,4,8)),
                    noise=gl(2,3,6, labels=c("A","P")))
mauchly.test(mlmfit, X = ~ deg + noise, idata = idata)
mauchly.test(mlmfit, M = ~ deg + noise, X = ~ noise, idata=idata)
```

mcnemar.test

McNemar's Chi-squared Test for Count Data

Description

Performs McNemar's chi-squared test for symmetry of rows and columns in a two-dimensional contingency table.

Usage

```
mcnemar.test(x, y = NULL, correct = TRUE)
```

Arguments

<code>x</code>	either a two-dimensional contingency table in matrix form, or a factor object.
<code>y</code>	a factor object; ignored if <code>x</code> is a matrix.
<code>correct</code>	a logical indicating whether to apply continuity correction when computing the test statistic.

Details

The null is that the probabilities of being classified into cells $[i, j]$ and $[j, i]$ are the same.

If `x` is a matrix, it is taken as a two-dimensional contingency table, and hence its entries should be nonnegative integers. Otherwise, both `x` and `y` must be vectors of the same length. Incomplete cases are removed, the vectors are coerced into factor objects, and the contingency table is computed from these.

Continuity correction is only used in the 2-by-2 case if `correct` is TRUE.

Value

A list with class "htest" containing the following components:

statistic	the value of McNemar's statistic.
parameter	the degrees of freedom of the approximate chi-squared distribution of the test statistic.
p.value	the p-value of the test.
method	a character string indicating the type of test performed, and whether continuity correction was used.
data.name	a character string giving the name(s) of the data.

## => significant change (in fact, drop) in approval ratings
```

median

Median Value

Description

Compute the sample median.

Usage

```
median(x, na.rm = FALSE)
```

Arguments

x	an object for which a method has been defined, or a numeric vector containing the values whose median is to be computed.
na.rm	a logical value indicating whether NA values should be stripped before the computation proceeds.

Details

This is a generic function for which methods can be written. However, the default method makes use of `sort` and `mean`, both of which are generic, and so the default method will work for most classes (e.g. "`Date`") for which a median is a reasonable concept.

Value

The default method returns a length-one object of the same type as `x`, except when `x` is integer of even length, when the result will be double.

If there are no values or if `na.rm = FALSE` and there are `NA` values the result is `NA` of the same type as `x` (or more generally the result of `x[FALSE][NA]`).

median(c(1:3,100,1000))# = 3 [odd, robust]
```

 medpolish

Median Polish of a Matrix

Description

Fits an additive model using Tukey's *median polish* procedure.

Usage

```
medpolish(x, eps = 0.01, maxiter = 10, trace.iter = TRUE,
          na.rm = FALSE)
```

Arguments

<code>x</code>	a numeric matrix.
<code>eps</code>	real number greater than 0. A tolerance for convergence: see 'Details'.
<code>maxiter</code>	the maximum number of iterations
<code>trace.iter</code>	logical. Should progress in convergence be reported?
<code>na.rm</code>	logical. Should missing values be removed?

Details

The model fitted is additive (constant + rows + columns). The algorithm works by alternately removing the row and column medians, and continues until the proportional reduction in the sum of absolute residuals is less than `eps` or until there have been `maxiter` iterations. The sum of absolute residuals is printed at each iteration of the fitting process, if `trace.iter` is TRUE. If `na.rm` is FALSE the presence of any NA value in `x` will cause an error, otherwise NA values are ignored.

`medpolish` returns an object of class `medpolish` (see below). There are printing and plotting methods for this class, which are invoked via by the generics `print` and `plot`.

Value

An object of class `medpolish` with the following named components:

<code>overall</code>	the fitted constant term.
<code>row</code>	the fitted row effects.
<code>col</code>	the fitted column effects.
<code>residuals</code>	the residuals.
<code>name</code>	the name of the dataset.

```

model.extract *Extract Components from a Model Frame*

Description

Returns the response, offset, subset, weights or other special components of a model frame passed as optional arguments to `model.frame`.

Usage

```
model.extract(frame, component)
model.offset(x)
model.response(data, type = "any")
model.weights(x)
```

Arguments

frame, x, data	A model frame.
component	literal character string or name. The name of a component to extract, such as "weights", "subset".
type	One of "any", "numeric", "double". Using either of latter two coerces the result to have storage mode "double".

Details

`model.extract` is provided for compatibility with S, which does not have the more specific functions. It is also useful to extract e.g. the `etastart` and `mustart` components of a `glm` fit.

`model.offset` and `model.response` are equivalent to `model.extract(, "offset")` and `model.extract(, "response")` respectively. `model.offset` sums any terms specified by `offset` terms in the formula or by `offset` arguments in the call producing the model frame: it does check that the offset is numeric.

`model.weights` is slightly different from `model.frame(, "weights")` in not naming the vector it returns.

Value

The specified component of the model frame, usually a vector.

See Also

`model.frame`, `offset`

Examples

```
a <- model.frame(cbind(ncases,ncontrols) ~ agegp+tobgp+alcgp, data=esoph)
model.extract(a, "response")
stopifnot(model.extract(a, "response") == model.response(a))

a <- model.frame(ncases/(ncases+ncontrols) ~ agegp+tobgp+alcgp,
                 data = esoph, weights = ncases+ncontrols)
```

```

model.response(a)
model.extract(a, "weights")

a <- model.frame(cbind(ncases, ncontrols) ~ agegp,
                 something = tobgp, data = esoph)
names(a)
stopifnot(model.extract(a, "something") == esoph$tobgp)

```

model.frame	<i>Extracting the “Environment” of a Model Formula</i>
-------------	--

Description

`model.frame` (a generic function) and its methods return a `data.frame` with the variables needed to use `formula` and any `...` arguments.

Usage

```

model.frame(formula, ...)

## Default S3 method:
model.frame(formula, data = NULL,
            subset = NULL, na.action = na.fail,
            drop.unused.levels = FALSE, xlev = NULL, ...)

## S3 method for class 'aovlist':
model.frame(formula, data = NULL, ...)

## S3 method for class 'glm':
model.frame(formula, ...)

## S3 method for class 'lm':
model.frame(formula, ...)

get_all_vars(formula, data, ...)

```

Arguments

<code>formula</code>	a model <code>formula</code> or <code>terms</code> object or an R object.
<code>data</code>	a <code>data.frame</code> , list or environment (or object coercible by <code>as.data.frame</code> to a <code>data.frame</code>), containing the variables in <code>formula</code> . Neither a matrix nor an array will be accepted.
<code>subset</code>	a specification of the rows to be used: defaults to all rows. This can be any valid indexing vector (see <code>[.data.frame]</code>) for the rows of <code>data</code> or if that is not supplied, a data frame made up of the variables used in <code>formula</code> .
<code>na.action</code>	how NAs are treated. The default is first, any <code>na.action</code> attribute of <code>data</code> , second a <code>na.action</code> setting of <code>options</code> , and third <code>na.fail</code> if that is unset. The ‘factory-fresh’ default is <code>na.omit</code> . Another possible value is <code>NULL</code> .
<code>drop.unused.levels</code>	should factors have unused levels dropped? Defaults to <code>FALSE</code> .

xlev	a named list of character vectors giving the full set of levels to be assumed for each factor.
...	further arguments such as <code>data</code> , <code>na.action</code> , <code>subset</code> . Any additional arguments such as <code>offset</code> and <code>weights</code> which reach the default method are used to create further columns in the model frame, with parenthesised names such as <code>"(offset)"</code> .

Details

Exactly what happens depends on the class and attributes of the object `formula`. If this is an object of fitted-model class such as `"lm"`, the method will either return the saved model frame used when fitting the model (if any, often selected by argument `model = TRUE`) or pass the call used when fitting on to the default method. The default method itself can cope with rather standard model objects such as those of class `"lqs"` from package **MASS** if no other arguments are supplied.

The rest of this section applies only to the default method.

If either `formula` or `data` is already a model frame (a data frame with a `"terms"` attribute) and the other is missing, the model frame is returned. Unless `formula` is a terms object, `as.formula` and then `terms` is called on it. (If you wish to use the `keep.order` argument of `terms.formula`, pass a terms object rather than a formula.)

Row names for the model frame are taken from the `data` argument if present, then from the names of the response in the formula (or `rownames` if it is a matrix), if there is one.

All the variables in `formula`, `subset` and in `...` are looked for first in `data` and then in the environment of `formula` (see the help for `formula()` for further details) and collected into a data frame. Then the `subset` expression is evaluated, and it is used as a row index to the data frame. Then the `na.action` function is applied to the data frame (and may well add attributes). The levels of any factors in the data frame are adjusted according to the `drop.unused.levels` and `xlev` arguments.

Unless `na.action = NULL`, time-series attributes will be removed from the variables found (since they will be wrong if NAs are removed).

Note that *all* the variables in the formula are included in the data frame, even those preceded by `-`.

Only variables whose type is raw, logical, integer, real, complex or character can be included in a model frame: this includes classed variables such as factors (whose underlying type is integer), but excludes lists.

`get_all_vars` returns a `data.frame` containing the variables used in `formula` plus those specified `...`. Unlike `model.frame.default`, it returns the input variables and not those resulting from function calls in `formula`.

Value

A `data.frame` containing the variables used in `formula` plus those specified in `...`. It will have additional attributes, including `"terms"` for an object of class `"terms"` derived from `formula`, and possibly `"na.action"` giving information on the handling of NAs (which will not be present if no special handling was done, e.g. by `na.pass`).

Examples

```
data.class(model.frame(dist ~ speed, data = cars))
```

model.matrix	<i>Construct Design Matrices</i>
--------------	----------------------------------

Description

`model.matrix` creates a design matrix.

Usage

```
model.matrix(object, ...)

## Default S3 method:
model.matrix(object, data = environment(object),
             contrasts.arg = NULL, xlev = NULL, ...)
```

Arguments

object	an object of an appropriate class. For the default method, a model formula or terms object.
data	a data frame created with <code>model.frame</code> . If another sort of object, <code>model.frame</code> is called first.
contrasts.arg	A list, whose entries are contrasts suitable for input to the <code>contrasts</code> replacement function and whose names are the names of columns of <code>data</code> containing <code>factors</code> .
xlev	to be used as argument of <code>model.frame</code> if <code>data</code> has no "terms" attribute.
...	further arguments passed to or from other methods.

Details

`model.matrix` creates a design matrix from the description given in `terms(object)`, using the data in `data` which must contain variables with the same names as would be created by a call to `model.frame(object)` or, more precisely, by evaluating `attr(terms(object), "variables")`. If it is a data frame, there may be other columns and the order of columns is not important. Any character variables are coerced to factors, with a warning. After coercion, all the variables used in RHD of the formula must be logical, integer, numeric or factor.

If `contrasts.arg` is specified for a factor it overrides the default factor coding for that variable and any "contrasts" attribute set by `C` or `contrasts`.

In an interaction term, the variable whose levels vary fastest is the first one to appear in the formula (and not in the term), so in `~ a + b + b:a` the interaction will have `a` varying fastest.

By convention, if the response variable also appears on the right-hand side of the formula it is dropped (with a warning), although interactions involving the term are retained.

Value

The design matrix for a regression model with the specified formula and data.

There is an attribute "assign", an integer vector with an entry for each column in the matrix giving the term in the formula which gave rise to the column. Value 0 corresponds to the intercept (if any), and positive values to terms in the order given by the `terms.labels` attribute of the `terms` structure corresponding to `object`.

If there are any factors in terms in the model, there is an attribute "contrasts", a named list with an entry for each factor. This specifies the contrasts that would be used in terms in which the factor is coded by contrasts (in some terms dummy coding may be used), either as a character vector naming a function or as a numeric matrix.

crossprod(m.orth) # m.orth is ALMOST orthogonal
```

model.tables

Compute Tables of Results from an Aov Model Fit

Description

Computes summary tables for model fits, especially complex aov fits.

Usage

```
model.tables(x, ...)

## S3 method for class 'aov':
model.tables(x, type = "effects", se = FALSE, cterms, ...)

## S3 method for class 'aovlist':
model.tables(x, type = "effects", se = FALSE, ...)
```

Arguments

x	a model object, usually produced by <code>aov</code>
type	type of table: currently only "effects" and "means" are implemented.
se	should standard errors be computed?
cterm	A character vector giving the names of the terms for which tables should be computed. The default is all tables.
...	further arguments passed to or from other methods.

Details

For `type = "effects"` give tables of the coefficients for each term, optionally with standard errors.

For `type = "means"` give tables of the mean response for each combinations of levels of the factors in a term.

The "aov" method cannot be applied to components of a "aovlist" fit.

Value

An object of class "tables.aov", as list which may contain components

tables	A list of tables for each requested term.
n	The replication information for each term.
se	Standard error information.

Warning

The implementation is incomplete, and only the simpler cases have been tested thoroughly. Weighted `aov` fits are not supported.

```

 monthplot

Plot a Seasonal or other Subseries from a Time Series

Description

These functions plot seasonal (or other) subseries of a time series. For each season (or other category), a time series is plotted.

Usage

```
monthplot(x, ...)

## S3 method for class 'stl':
monthplot(x, labels = NULL, ylab = choice, choice = "seasonal",
          ...)

## S3 method for class 'StructTS':
monthplot(x, labels = NULL, ylab = choice, choice = "sea", ...)

## S3 method for class 'ts':
monthplot(x, labels = NULL, times = time(x), phase = cycle(x),
          ylab = deparse(substitute(x)), ...)

## Default S3 method:
monthplot(x, labels = 1:12,
          ylab = deparse(substitute(x)),
          times = 1:length(x),
          phase = (times - 1)%length(labels) + 1, base = mean,
          axes = TRUE, type = c("l", "h"), box = TRUE,
          add = FALSE, ...)
```

Arguments

x	Time series or related object.
labels	Labels to use for each 'season'.
ylab	y label.
times	Time of each observation.
phase	Indicator for each 'season'.
base	Function to use for reference line for subseries.
choice	Which series of an stl or StructTS object?
...	Arguments to be passed to the default method or graphical parameters.
axes	Should axes be drawn (ignored if add=TRUE)?
type	Type of plot. The default is to join the points with lines, and "h" is for histogram-like vertical lines.
box	Should a box be drawn (ignored if add=TRUE)?
add	Should thus just add on an existing plot.

Details

These functions extract subseries from a time series and plot them all in one frame. The `ts`, `stl`, and `StructTS` methods use the internally recorded frequency and start and finish times to set the scale and the seasons. The default method assumes observations come in groups of 12 (though this can be changed).

If the `labels` are not given but the `phase` is given, then the `labels` default to the unique values of the `phase`. If both are given, then the `phase` values are assumed to be indices into the `labels` array, i.e., they should be in the range from 1 to `length(labels)`.

Value

These functions are executed for their side effect of drawing a seasonal subseries plot on the current graphical window.

mood.test

Mood Two-Sample Test of Scale

Description

Performs Mood's two-sample test for a difference in scale parameters.

Usage

```
mood.test(x, ...)

## Default S3 method:
mood.test(x, y,
          alternative = c("two.sided", "less", "greater"), ...)

## S3 method for class 'formula':
mood.test(formula, data, subset, na.action, ...)
```

Arguments

<code>x, y</code>	numeric vectors of data values.
<code>alternative</code>	indicates the alternative hypothesis and must be one of "two.sided" (default), "greater" or "less" all of which can be abbreviated.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

The underlying model is that the two samples are drawn from $f(x-l)$ and $f((x-l)/s)/s$, respectively, where l is a common location parameter and s is a scale parameter.

The null hypothesis is $s = 1$.

There are more useful tests for this problem.

In the case of ties, the formulation of Mielke (1967) is employed.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>alternative</code>	a character string describing the alternative hypothesis.
<code>method</code>	the character string "Mood two-sample test of scale".
<code>data.name</code>	a character string giving the names of the data.

References

See Also

`fligner.test` for a rank-based (nonparametric) k-sample test for homogeneity of variances; `ansari.test` for another rank-based two-sample test for a difference in scale parameters; `var.test` and `bartlett.test` for parametric tests for the homogeneity in variance.

Examples

```
## Same data as for the Ansari-Bradley test:
## Serum iron determination using Hyland control sera
ramsay <- c(111, 107, 100, 99, 102, 106, 109, 108, 104, 99,
           101, 96, 97, 102, 107, 113, 116, 113, 110, 98)
jung.parekh <- c(107, 108, 106, 98, 105, 103, 110, 105, 104,
                100, 96, 108, 103, 104, 114, 114, 113, 108, 106, 99)
mood.test(ramsay, jung.parekh)
## Compare this to ansari.test(ramsay, jung.parekh)
```

Multinomial

The Multinomial Distribution

Description

Generate multinomially distributed random number vectors and compute multinomial probabilities.

Usage

```
rmultinom(n, size, prob)
dmultinom(x, size = NULL, prob, log = FALSE)
```

Arguments

<code>x</code>	vector of length K of integers in $0 : \text{size}$.
<code>n</code>	number of random vectors to draw.
<code>size</code>	integer, say N , specifying the total number of objects that are put into K boxes in the typical multinomial experiment. For <code>dmultinom</code> , it defaults to $\text{sum}(x)$.
<code>prob</code>	numeric non-negative vector of length K , specifying the probability for the K classes; is internally normalized to sum 1.
<code>log</code>	logical; if TRUE, log probabilities are computed.

Details

If \mathbf{x} is a K -component vector, `dmultinom(x, prob)` is the probability

$$P(X_1 = x_1, \dots, X_K = x_k) = C \times \prod_{j=1}^K \pi_j^{x_j}$$

where C is the ‘multinomial coefficient’ $C = N!/(x_1! \cdots x_K!)$ and $N = \sum_{j=1}^K x_j$.

By definition, each component X_j is binomially distributed as `Bin(size, prob[j])` for $j = 1, \dots, K$.

The `rmultinom()` algorithm draws binomials from $Bin(n_j, P_j)$ sequentially, where $n_1 = N$ ($N := \text{size}$), $P_1 = \pi_1$ (π is `prob` scaled to sum 1), and for $j \geq 2$, recursively $n_j = N - \sum_{k=1}^{j-1} n_k$ and $P_j = \pi_j / (1 - \sum_{k=1}^{j-1} \pi_k)$.

Value

For `rmultinom()`, an integer $K \times n$ matrix where each column is a random vector generated according to the desired multinomial law, and hence summing to `size`. Whereas the *transposed* result would seem more natural at first, the returned matrix is more efficient because of columnwise storage.

Note

`dmultinom` is currently *not vectorized* at all and has no C interface (API); this may be amended in the future.

See Also

[rbinom](#) which is a special case conceptually.

Examples

```
rmultinom(10, size = 12, prob=c(0.1,0.2,0.8))

pr <- c(1,3,6,10) # normalization not necessary for generation
rmultinom(10, 20, prob = pr)

## all possible outcomes of Multinom(N = 3, K = 3)
X <- t(as.matrix(expand.grid(0:3, 0:3))); X <- X[, colSums(X) <= 3]
X <- rbind(X, 3:3 - colSums(X)); dimnames(X) <- list(letters[1:3], NULL)
X
round(apply(X, 2, function(x) dmultinom(x, prob = c(1,2,5))), 3)
```

na.action

NA Action

Description

Extract information on the NA action used to create an object.

Usage

```
na.action(object, ...)
```

Arguments

`object` any object whose `NA` action is given.
`...` further arguments special methods could require.

Details

`na.action` is a generic function, and `na.action.default` its default method. The latter extracts the "`na.action`" component of a list if present, otherwise the "`na.action`" attribute.

When `model.frame` is called, it records any information on NA handling in a "`na.action`" attribute. Most model-fitting functions return this as a component of their result.

Value

Information from the action which was applied to `object` if NAs were handled specially, or `NULL`.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

`options("na.action")`, `na.omit`, `na.fail`, also for `na.exclude`, `na.pass`.

Examples

```
na.action(na.omit(c(1, NA)))
```

`na.contiguous` *Find Longest Contiguous Stretch of non-NAs*

Description

Find the longest consecutive stretch of non-missing values in a time series object. (In the event of a tie, the first such stretch.)

Usage

```
na.contiguous(object, ...)
```

Arguments

`object` a univariate or multivariate time series.
`...` further arguments passed to or from other methods.

Value

A time series without missing values. The class of `object` will be preserved.

See Also

`na.omit` and `na.omit.ts`; `na.fail`

Examples

```
na.contiguous(presidents)
```

na.fail

Handle Missing Values in Objects

Description

These generic functions are useful for dealing with [NAs](#) in e.g., data frames. `na.fail` returns the object if it does not contain any missing values, and signals an error otherwise. `na.omit` returns the object with incomplete cases removed. `na.pass` returns the object unchanged.

Usage

```
na.fail(object, ...)  
na.omit(object, ...)  
na.exclude(object, ...)  
na.pass(object, ...)
```

Arguments

<code>object</code>	an R object, typically a data frame
<code>...</code>	further arguments special methods could require.

Details

At present these will handle vectors, matrices and data frames comprising vectors and matrices (only).

If `na.omit` removes cases, the row numbers of the cases form the "`na.action`" attribute of the result, of class "omit".

`na.exclude` differs from `na.omit` only in the class of the "`na.action`" attribute of the result, which is "exclude". This gives different behaviour in functions making use of `naresid` and `napredict`: when `na.exclude` is used the residuals and predictions are padded to the correct length by inserting NAs for cases omitted by `na.exclude`.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

`na.action`; `options` with argument `na.action` for setting NA actions; and `lm` and `glm` for functions using these. `na.contiguous` as alternative for time series.

Examples

```
DF <- data.frame(x = c(1, 2, 3), y = c(0, 10, NA))
na.omit(DF)
m <- as.matrix(DF)
na.omit(m)
stopifnot(all(na.omit(1:3) == 1:3)) # does not affect objects with no NA's
try(na.fail(DF))#> Error: missing values in ...

options("na.action")
```

 nprint

Adjust for Missing Values

Description

Use missing value information to report the effects of an `na.action`.

Usage

```
nprint(x, ...)
```

Arguments

`x` An object produced by an `na.action` function.
`...` further arguments passed to or from other methods.

Details

This is a generic function, and the exact information differs by method. `nprint.omit` reports the number of rows omitted: `nprint.default` reports an empty string.

Value

A character string providing information on missing values, for example the number.

 naresid

Adjust for Missing Values

Description

Use missing value information to adjust residuals and predictions.

Usage

```
naresid(omit, x, ...)
napredict(omit, x, ...)
```

Arguments

<code>omit</code>	an object produced by an <code>na.action</code> function, typically the <code>"na.action"</code> attribute of the result of <code>na.omit</code> or <code>na.exclude</code> .
<code>x</code>	a vector, data frame, or matrix to be adjusted based upon the missing value information.
<code>...</code>	further arguments passed to or from other methods.

Details

These are utility functions used to allow `predict`, `fitted` and `residuals` methods for modelling functions to compensate for the removal of NAs in the fitting process. They are used by the default, `"lm"`, `"glm"` and `"nls"` methods, and by further methods in packages **MASS**, **rpart** and **survival**. Also used for the scores returned by `factanal`, `prcomp` and `princomp`.

The default methods do nothing. The default method for the `na.exclude` action is to pad the object with NAs in the correct positions to have the same number of rows as the original data frame.

Currently `naresid` and `napredict` are identical, but future methods need not be. `naresid` is used for residuals, and `napredict` for fitted values and predictions.

Value

These return a similar object to `x`.

Note

Packages `rpart` and `survival5` used to contain versions of these functions that had an `na.omit` action equivalent to that now used for `na.exclude`.

NegBinomial

The Negative Binomial Distribution

Description

Density, distribution function, quantile function and random generation for the negative binomial distribution with parameters `size` and `prob`.

Usage

```
dnbinom(x, size, prob, mu, log = FALSE)
pnbinom(q, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
qnbinom(p, size, prob, mu, lower.tail = TRUE, log.p = FALSE)
rnbinom(n, size, prob, mu)
```

Arguments

<code>x</code>	vector of (non-negative integer) quantiles.
<code>q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.

<code>size</code>	target for number of successful trials, or dispersion parameter (the shape parameter of the gamma mixing distribution). Must be strictly positive.
<code>prob</code>	probability of success in each trial. $0 < \text{prob} \leq 1$.
<code>mu</code>	alternative parametrization via mean: see ‘Details’.
<code>log, log.p</code>	logical; if TRUE, probabilities p are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The negative binomial distribution with `size` = n and `prob` = p has density

$$p(x) = \frac{\Gamma(x+n)}{\Gamma(n)x!} p^n (1-p)^x$$

for $x = 0, 1, 2, \dots, n > 0$ and $0 < p \leq 1$.

This represents the number of failures which occur in a sequence of Bernoulli trials before a target number of successes is reached.

A negative binomial distribution can arise as a mixture of Poisson distributions with mean distributed as a Γ (`pgamma`) distribution with scale parameter $(1 - \text{prob})/\text{prob}$ and shape parameter `size`. (This definition allows non-integer values of `size`.) In this model `prob` = $\text{scale}/(1+\text{scale})$, and the mean is $\text{size} * (1 - \text{prob})/\text{prob}$.

The alternative parametrization (often used in ecology) is by the *mean* `mu`, and `size`, the *dispersion parameter*, where `prob` = $\text{size}/(\text{size}+\text{mu})$. The variance is $\text{mu} + \text{mu}^2/\text{size}$ in this parametrization or $n(1-p)/p^2$ in the first one.

If an element of `x` is not integer, the result of `dnbinom` is zero, with a warning.

The quantile is defined as the smallest value x such that $F(x) \geq p$, where F is the distribution function.

Value

`dnbinom` gives the density, `pnbinom` gives the distribution function, `qnbinom` gives the quantile function, and `rnbinom` generates random deviates.

Invalid `size` or `prob` will result in return value NaN, with a warning.

Source

`dnbinom` computes via binomial probabilities, using code contributed by Catherine Loader (see [dbinom](#)).

`pnbinom` uses [pbeta](#).

`qnbinom` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

`rnbinom` uses the derivation as a gamma mixture of Poissons, see

Devroye, L. (1986) *Non-Uniform Random Variate Generation*. Springer-Verlag, New York. Page 480.

See Also

Examples

```

require(graphics)
x <- 0:11
dnbinom(x, size = 1, prob = 1/2) * 2^(1 + x) # == 1
126 / dnbinom(0:8, size = 2, prob = 1/2) #- theoretically integer

## Cumulative ('p') = Sum of discrete prob.s ('d'); Relative error :
summary(1 - cumsum(dnbinom(x, size = 2, prob = 1/2)) /
        pnbinom(x, size = 2, prob = 1/2))

x <- 0:15
size <- (1:20)/4
persp(x,size, dnb <- outer(x, size, function(x,s) dnbinom(x,s, prob= 0.4)),
      xlab = "x", ylab = "s", zlab="density", theta = 150)
title(tit <- "negative binomial density(x,s, pr = 0.4) vs. x & s")

image (x,size, log10(dnb), main= paste("log [",tit,"]")
contour(x,size, log10(dnb),add=TRUE)

## Alternative parametrization
x1 <- rnbinom(500, mu = 4, size = 1)
x2 <- rnbinom(500, mu = 4, size = 10)
x3 <- rnbinom(500, mu = 4, size = 100)
h1 <- hist(x1, breaks = 20, plot = FALSE)
h2 <- hist(x2, breaks = h1$breaks, plot = FALSE)
h3 <- hist(x3, breaks = h1$breaks, plot = FALSE)
barplot(rbind(h1$counts, h2$counts, h3$counts),
        beside = TRUE, col = c("red", "blue", "cyan"),
        names.arg = round(h1$breaks[-length(h1$breaks)]))

```

nextn

Highly Composite Numbers

Description

nextn returns the smallest integer, greater than or equal to n, which can be obtained as a product of powers of the values contained in factors. nextn is intended to be used to find a suitable length to zero-pad the argument of fft to so that the transform is computed quickly. The default value for factors ensures this.

Usage

```
nextn(n, factors = c(2, 3, 5))
```

Arguments

n an integer.
factors a vector of positive integer factors.

See Also

[convolve](#), [fft](#).

Examples

```
nextn(1001) # 1024
table(sapply(599:630, nextn))
```

nlm

*Non-Linear Minimization***Description**

This function carries out a minimization of the function f using a Newton-type algorithm. See the references for details.

Usage

```
nlm(f, p, ..., hessian = FALSE, typsize = rep(1, length(p)),
     fscale = 1, print.level = 0, ndigit = 12, gradtol = 1e-6,
     stepmax = max(1000 * sqrt(sum((p/typsize)^2)), 1000),
     steptol = 1e-6, iterlim = 100, check.analyticals = TRUE)
```

Arguments

<code>f</code>	the function to be minimized. If the function value has an attribute called <code>gradient</code> or both <code>gradient</code> and <code>hessian</code> attributes, these will be used in the calculation of updated parameter values. Otherwise, numerical derivatives are used. <code>deriv</code> returns a function with suitable <code>gradient</code> attribute. This should be a function of a vector of the length of <code>p</code> followed by any other arguments specified by the <code>...</code> argument.
<code>p</code>	starting parameter values for the minimization.
<code>...</code>	additional arguments to <code>f</code> .
<code>hessian</code>	if TRUE, the hessian of f at the minimum is returned.
<code>typsize</code>	an estimate of the size of each parameter at the minimum.
<code>fscale</code>	an estimate of the size of f at the minimum.
<code>print.level</code>	this argument determines the level of printing which is done during the minimization process. The default value of 0 means that no printing occurs, a value of 1 means that initial and final details are printed and a value of 2 means that full tracing information is printed.
<code>ndigit</code>	the number of significant digits in the function f .
<code>gradtol</code>	a positive scalar giving the tolerance at which the scaled gradient is considered close enough to zero to terminate the algorithm. The scaled gradient is a measure of the relative change in f in each direction $p[i]$ divided by the relative change in $p[i]$.
<code>stepmax</code>	a positive scalar which gives the maximum allowable scaled step length. <code>stepmax</code> is used to prevent steps which would cause the optimization function to overflow, to prevent the algorithm from leaving the area of interest in parameter space, or to detect divergence in the algorithm. <code>stepmax</code> would be chosen small enough to prevent the first two of these occurrences, but should be larger than any anticipated reasonable step.
<code>steptol</code>	A positive scalar providing the minimum allowable relative step length.

<code>iterlim</code>	a positive integer specifying the maximum number of iterations to be performed before the program is terminated.
<code>check.analyticals</code>	a logical scalar specifying whether the analytic gradients and Hessians, if they are supplied, should be checked against numerical derivatives at the initial parameter values. This can help detect incorrectly formulated gradients or Hessians.

Details

Note that arguments after `. . .` must be matched exactly.

If a gradient or hessian is supplied but evaluates to the wrong mode or length, it will be ignored if `check.analyticals = TRUE` (the default) with a warning. The hessian is not even checked unless the gradient is present and passes the sanity checks.

From the three methods available in the original source, we always use method “1” which is line search.

The functions supplied must always return finite (including not NA and not NaN) values.

Value

A list containing the following components:

<code>minimum</code>	the value of the estimated minimum of f .
<code>estimate</code>	the point at which the minimum value of f is obtained.
<code>gradient</code>	the gradient at the estimated minimum of f .
<code>hessian</code>	the hessian at the estimated minimum of f (if requested).
<code>code</code>	an integer indicating why the optimization process terminated. <ol style="list-style-type: none"> 1: relative gradient is close to zero, current iterate is probably solution. 2: successive iterates within tolerance, current iterate is probably solution. 3: last global step failed to locate a point lower than <code>estimate</code>. Either <code>estimate</code> is an approximate local minimum of the function or <code>steptol</code> is too small. 4: iteration limit exceeded. 5: maximum step size <code>stepmax</code> exceeded five consecutive times. Either the function is unbounded below, becomes asymptotic to a finite value from above in some direction or <code>stepmax</code> is too small.
<code>iterations</code>	the number of iterations performed.

nlminb

*Optimization using PORT routines***Description**

Unconstrained and constrained optimization using PORT routines.

Usage

```
nlminb(start, objective, gradient = NULL, hessian = NULL, ...,
       scale = 1, control = list(), lower = -Inf, upper = Inf)
```

Arguments

start	numeric vector, initial values for the parameters to be optimized.
objective	Function to be minimized. Must return a scalar value (possibly NA/Inf). The first argument to <code>objective</code> is the vector of parameters to be optimized, whose initial values are supplied through <code>start</code> . Further arguments (fixed during the course of the optimization) to <code>objective</code> may be specified as well (see ...).
gradient	Optional function that takes the same arguments as <code>objective</code> and evaluates the gradient of <code>objective</code> at its first argument. Must return a vector as long as <code>start</code> .
hessian	Optional function that takes the same arguments as <code>objective</code> and evaluates the hessian of <code>objective</code> at its first argument. Must return a square matrix of order <code>length(start)</code> . Only the lower triangle is used.
...	Further arguments to be supplied to <code>objective</code> .
scale	See PORT documentation (or leave alone).
control	A list of control parameters. See below for details.
lower, upper	vectors of lower and upper bounds, replicated to be as long as <code>start</code> . If unspecified, all parameters are assumed to be unconstrained.

Details

Any names of `start` are (as from R 2.8.1) passed on to `objective` and where applicable, `gradient` and `hessian`. The parameter vector will be coerced to double.

The PORT documentation is at <http://netlib.bell-labs.com/cm/cs/cstr/153.pdf>.

Value

A list with components:

<code>par</code>	The best set of parameters found.
<code>objective</code>	The value of <code>objective</code> corresponding to <code>par</code> .
<code>convergence</code>	An integer code. 0 indicates successful convergence.
<code>message</code>	A character string giving any additional information returned by the optimizer, or NULL. For details, see PORT documentation.
<code>iterations</code>	Number of iterations performed.
<code>evaluations</code>	Number of objective function and gradient function evaluations

Control parameters

Possible names in the `control` list and their default values are:

<code>eval.max</code>	Maximum number of evaluations of the objective function allowed. Defaults to 200.
<code>iter.max</code>	Maximum number of iterations allowed. Defaults to 150.
<code>trace</code>	The value of the objective function and the parameters is printed every <code>trace</code> 'th iteration. Defaults to 0 which indicates no trace information is to be printed.
<code>abs.tol</code>	Absolute tolerance. Defaults to $1e-20$.
<code>rel.tol</code>	Relative tolerance. Defaults to $1e-10$.
<code>x.tol</code>	X tolerance. Defaults to $1.5e-8$.
<code>step.min</code>	Minimum step size. Defaults to $2.2e-14$.

Author(s)

(of R port) Douglas Bates and Deepayan Sarkar.

```

Description

Determine the nonlinear (weighted) least-squares estimates of the parameters of a nonlinear model.

Usage

```
nls(formula, data, start, control, algorithm,
    trace, subset, weights, na.action, model,
    lower, upper, ...)
```

Arguments

<code>formula</code>	a nonlinear model <code>formula</code> including variables and parameters. Will be coerced to a formula if necessary.
<code>data</code>	an optional data frame in which to evaluate the variables in <code>formula</code> and <code>weights</code> . Can also be a list or an environment, but not a matrix.
<code>start</code>	a named list or named numeric vector of starting estimates. When <code>start</code> is missing, a very cheap guess for <code>start</code> is tried (if <code>algorithm</code> != "plinear").
<code>control</code>	an optional list of control settings. See <code>nls.control</code> for the names of the settable control values and their effect.
<code>algorithm</code>	character string specifying the algorithm to use. The default algorithm is a Gauss-Newton algorithm. Other possible values are "plinear" for the Golub-Pereyra algorithm for partially linear least-squares models and "port" for the 'nl2sol' algorithm from the Port library – see the references.
<code>trace</code>	logical value indicating if a trace of the iteration progress should be printed. Default is FALSE. If TRUE the residual (weighted) sum-of-squares and the parameter values are printed at the conclusion of each iteration. When the "plinear" algorithm is used, the conditional estimates of the linear parameters are printed after the nonlinear parameters. When the "port" algorithm is used the objective function value printed is half the residual (weighted) sum-of-squares.
<code>subset</code>	an optional vector specifying a subset of observations to be used in the fitting process.
<code>weights</code>	an optional numeric vector of (fixed) weights. When present, the objective function is weighted least squares.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The 'factory-fresh' default is <code>na.omit</code> . Value <code>na.exclude</code> can be useful.
<code>model</code>	logical. If true, the model frame is returned as part of the object. Default is FALSE.
<code>lower, upper</code>	vectors of lower and upper bounds, replicated to be as long as <code>start</code> . If unspecified, all parameters are assumed to be unconstrained. Bounds can only be used with the "port" algorithm. They are ignored, with a warning, if given for other algorithms.
<code>...</code>	Additional optional arguments. None are used at present.

Details

An `nls` object is a type of fitted model object. It has methods for the generic functions `anova`, `coef`, `confint`, `deviance`, `df.residual`, `fitted`, `formula`, `logLik`, `predict`, `print`, `profile`, `residuals`, `summary`, `vcov` and `weights`.

Variables in `formula` (and `weights` if not missing) are looked for first in `data`, then the environment of `formula` and finally along the search path. Functions in `formula` are searched for first in the environment of `formula` and then along the search path.

Arguments `subset` and `na.action` are supported only when all the variables in the formula taken from `data` are of the same length: other cases give a warning.

Note that the `anova` method does not check that the models are nested: this cannot easily be done automatically, so use with care.

Value

A list of

<code>m</code>	an <code>nlsModel</code> object incorporating the model.
<code>data</code>	the expression that was passed to <code>nls</code> as the <code>data</code> argument. The actual data values are present in the environment of the <code>m</code> component.
<code>call</code>	the matched call with several components, notably <code>algorithm</code> .
<code>na.action</code>	the <code>"na.action"</code> attribute (if any) of the model frame.
<code>dataClasses</code>	the <code>"dataClasses"</code> attribute (if any) of the <code>"terms"</code> attribute of the model frame.
<code>model</code>	if <code>model = TRUE</code> , the model frame.
<code>weights</code>	if <code>weights</code> is supplied, the weights.
<code>convInfo</code>	when <code>algorithm</code> is not <code>"port"</code> , a list with convergence information.
<code>control</code>	the control list used, see the <code>control</code> argument.
<code>convergence,</code> <code>message,</code>	for an <code>algorithm = "port"</code> fit only, a convergence code (0 for convergence) and message.

Note that setting `warnOnly = TRUE` in the `control` argument (see `nls.control`) returns a non-converged object (since R version 2.5.0) which might be useful for further convergence analysis, *but not for inference*.

Warning

Do not use `nls` on artificial "zero-residual" data.

The `nls` function uses a relative-offset convergence criterion that compares the numerical imprecision at the current parameter estimates to the residual sum-of-squares. This performs well on data of the form

$$y = f(x, \theta) + \epsilon$$

(with `var(eps) > 0`). It fails to indicate convergence on data of the form

$$y = f(x, \theta)$$

because the criterion amounts to comparing two components of the round-off error. If you wish to test `nls` on artificial data please add a noise component, as shown in the example below.

The `algorithm = "port"` code appears unfinished, and does not even check that the starting value is within the bounds. Use with caution, especially where bounds are supplied.

summary(musc.2)

```

Description

Allow the user to set some characteristics of the `nls` nonlinear least squares algorithm.

Usage

```
nls.control(maxiter = 50, tol = 1e-05, minFactor = 1/1024,  
           printEval = FALSE, warnOnly = FALSE)
```

Arguments

<code>maxiter</code>	A positive integer specifying the maximum number of iterations allowed.
<code>tol</code>	A positive numeric value specifying the tolerance level for the relative offset convergence criterion.
<code>minFactor</code>	A positive numeric value specifying the minimum step-size factor allowed on any step in the iteration. The increment is calculated with a Gauss-Newton algorithm and successively halved until the residual sum of squares has been decreased or until the step-size factor has been reduced below this limit.
<code>printEval</code>	a logical specifying whether the number of evaluations (steps in the gradient direction taken each iteration) is printed.
<code>warnOnly</code>	a logical specifying whether <code>nls()</code> should return instead of signalling an error in the case of termination before convergence. Termination before convergence happens upon completion of <code>maxiter</code> iterations, in the case of a singular gradient, and in the case that the step-size factor is reduced below <code>minFactor</code> .

Value

A list with exactly five components:

```
maxiter  
tol  
minFactor  
printEval  
warnOnly
```

with meanings as explained under ‘Arguments’.

NLSstAsymptotic *Fit the Asymptotic Regression Model*

Description

Fits the asymptotic regression model, in the form $b_0 + b_1 * (1 - \exp(-\exp(lrc) * x))$ to the `xy` data. This can be used as a building block in determining starting estimates for more complicated models.

Usage

```
NLSstAsymptotic(xy)
```

Arguments

`xy` a sortedXyData object

Value

A numeric value of length 3 with components labelled `b0`, `b1`, and `lrc`. `b0` is the estimated intercept on the `y`-axis, `b1` is the estimated difference between the asymptote and the `y`-intercept, and `lrc` is the estimated logarithm of the rate constant.

```

NLSstClosestX *Inverse Interpolation*

Description

Use inverse linear interpolation to approximate the `x` value at which the function represented by `xy` is equal to `yval`.

Usage

```
NLSstClosestX(xy, yval)
```

Arguments

`xy` a `sortedXyData` object
`yval` a numeric value on the `y` scale

Value

A single numeric value on the `x` scale.

```

NLSstLfAsymptote *Horizontal Asymptote on the Left Side*

Description

Provide an initial guess at the horizontal asymptote on the left side (i.e., small values of `x`) of the graph of `y` versus `x` from the `xy` object. Primarily used within `initial` functions for self-starting nonlinear regression models.

Usage

```
NLSstLfAsymptote(xy)
```

Arguments

`xy` a `sortedXyData` object

Value

A single numeric value estimating the horizontal asymptote for small `x`.

```

NLSstRtAsymptote *Horizontal Asymptote on the Right Side*

Description

Provide an initial guess at the horizontal asymptote on the right side (i.e., large values of x) of the graph of y versus x from the `xy` object. Primarily used within `initial` functions for self-starting nonlinear regression models.

Usage

```
NLSstRtAsymptote(xy)
```

Arguments

`xy` a `sortedXyData` object

Value

A single numeric value estimating the horizontal asymptote for large x .

Normal

*The Normal Distribution***Description**

Density, distribution function, quantile function and random generation for the normal distribution with mean equal to `mean` and standard deviation equal to `sd`.

Usage

```
dnorm(x, mean = 0, sd = 1, log = FALSE)
pnorm(q, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
qnorm(p, mean = 0, sd = 1, lower.tail = TRUE, log.p = FALSE)
rnorm(n, mean = 0, sd = 1)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>mean</code>	vector of means.
<code>sd</code>	vector of standard deviations.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If `mean` or `sd` are not specified they assume the default values of 0 and 1, respectively.

The normal distribution has density

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{-(x-\mu)^2/2\sigma^2}$$

where μ is the mean of the distribution and σ the standard deviation.

`qnorm` is based on Wichura's algorithm AS 241 which provides precise results up to about 16 digits.

Value

`dnorm` gives the density, `pnorm` gives the distribution function, `qnorm` gives the quantile function, and `rnorm` generates random deviates.

Source

For `pnorm`, based on

Cody, W. D. (1993) Algorithm 715: SPECFUN – A portable FORTRAN package of special function routines and test drivers. *ACM Transactions on Mathematical Software* **19**, 22–32.

For `qnorm`, the code is a C translation of

Wichura, M. J. (1988) Algorithm AS 241: The Percentage Points of the Normal Distribution. *Applied Statistics*, **37**, 477–484.

For `rnorm`, see [RNG](#) for how to select the algorithm and for references to the supplied methods.

## and the so-called 'complementary error function'
erfc <- function(x) 2 * pnorm(x * sqrt(2), lower = FALSE)
## and the inverses
erfinv <- function(x) qnorm((1 + x)/2)/sqrt(2)
erfcinv <- function(x) qnorm(x/2, lower = FALSE)/sqrt(2)
```

numericDeriv	<i>Evaluate derivatives numerically</i>
--------------	---

Description

`numericDeriv` numerically evaluates the gradient of an expression.

Usage

```
numericDeriv(expr, theta, rho = parent.frame(), dir = 1.0)
```

Arguments

<code>expr</code>	The expression to be differentiated. The value of this expression should be a numeric vector.
<code>theta</code>	A character vector of names of numeric variables used in <code>expr</code> .
<code>rho</code>	An environment containing all the variables needed to evaluate <code>expr</code> .
<code>dir</code>	A numeric vector of directions to use for the finite differences.

Details

This is a front end to the C function `numeric_deriv`, which is described in *Writing R Extensions*. The numeric variables must be of type `real` and not `integer`.

Value

The value of `eval(expr, envir = rho)` plus a matrix attribute called `gradient`. The columns of this matrix are the derivatives of the value with respect to the variables listed in `theta`.

Author(s)

Saikat DebRoy <saikat@stat.wisc.edu>

Examples

```
myenv <- new.env()
assign("mean", 0., envir = myenv)
assign("sd", 1., envir = myenv)
assign("x", seq(-3., 3., len = 31), envir = myenv)
numericDeriv(quote(pnorm(x, mean, sd)), c("mean", "sd"), myenv)
```

`offset`*Include an Offset in a Model Formula*

Description

An offset is a term to be added to a linear predictor, such as in a generalised linear model, with known coefficient 1 rather than an estimated coefficient.

Usage

```
offset(object)
```

Arguments

`object` An offset to be included in a model frame

Details

There can be more than one offset in a model formula, but `-` is not supported for `offset` terms (and is equivalent to `+`).

Value

The input value.

See Also

[model.offset](#), [model.frame](#).

For examples see [glm](#) and [Insurance](#) in package **MASS**.

`oneway.test`*Test for Equal Means in a One-Way Layout*

Description

Test whether two or more samples from normal distributions have the same means. The variances are not necessarily assumed to be equal.

Usage

```
oneway.test(formula, data, subset, na.action, var.equal = FALSE)
```

Arguments

<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the sample values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>var.equal</code>	a logical variable indicating whether to treat the variances in the samples as equal. If <code>TRUE</code> , then a simple F test for the equality of means in a one-way analysis of variance is performed. If <code>FALSE</code> , an approximate method of Welch (1951) is used, which generalizes the commonly known 2-sample Welch test to the case of arbitrarily many samples.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value of the test statistic.
<code>parameter</code>	the degrees of freedom of the exact or approximate F distribution of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>method</code>	a character string indicating the test performed.
<code>data.name</code>	a character string giving the names of the data.

References

B. L. Welch (1951), On the comparison of several mean values: an alternative approach. *Biometrika*, **38**, 330–336.

See Also

The standard t test (`t.test`) as the special case for two samples; the Kruskal-Wallis test `kruskal.test` for a nonparametric test for equal location parameters in a one-way layout.

Examples

```
## Not assuming equal variances
oneway.test(extra ~ group, data = sleep)
## Assuming equal variances
oneway.test(extra ~ group, data = sleep, var.equal = TRUE)
## which gives the same result as
anova(lm(extra ~ group, data = sleep))
```

optim

*General-purpose Optimization***Description**

General-purpose optimization based on Nelder–Mead, quasi-Newton and conjugate-gradient algorithms. It includes an option for box-constrained optimization and simulated annealing.

Usage

```
optim(par, fn, gr = NULL, ...,
      method = c("Nelder-Mead", "BFGS", "CG", "L-BFGS-B", "SANN"),
      lower = -Inf, upper = Inf,
      control = list(), hessian = FALSE)
```

Arguments

par	Initial values for the parameters to be optimized over.
fn	A function to be minimized (or maximized), with first argument the vector of parameters over which minimization is to take place. It should return a scalar result.
gr	A function to return the gradient for the "BFGS", "CG" and "L-BFGS-B" methods. If it is NULL, a finite-difference approximation will be used. For the "SANN" method it specifies a function to generate a new candidate point. If it is NULL a default Gaussian Markov kernel is used.
...	Further arguments to be passed to fn and gr.
method	The method to be used. See 'Details'.
lower, upper	Bounds on the variables for the "L-BFGS-B" method.
control	A list of control parameters. See 'Details'.
hessian	Logical. Should a numerically differentiated Hessian matrix be returned?

Details

Note that arguments after . . . must be matched exactly.

By default this function performs minimization, but it will maximize if `control$fnscale` is negative.

The default method is an implementation of that of Nelder and Mead (1965), that uses only function values and is robust but relatively slow. It will work reasonably well for non-differentiable functions.

Method "BFGS" is a quasi-Newton method (also known as a variable metric algorithm), specifically that published simultaneously in 1970 by Broyden, Fletcher, Goldfarb and Shanno. This uses function values and gradients to build up a picture of the surface to be optimized.

Method "CG" is a conjugate gradients method based on that by Fletcher and Reeves (1964) (but with the option of Polak–Ribiere or Beale–Sorenson updates). Conjugate gradient methods will generally be more fragile than the BFGS method, but as they do not store a matrix they may be successful in much larger optimization problems.

Method "L-BFGS-B" is that of Byrd *et al.* (1995) which allows *box constraints*, that is each variable can be given a lower and/or upper bound. The initial value must satisfy the constraints.

This uses a limited-memory modification of the BFGS quasi-Newton method. If non-trivial bounds are supplied, this method will be selected, with a warning.

Nocedal and Wright (1999) is a comprehensive reference for the previous three methods.

Method "SANN" is by default a variant of simulated annealing given in Belisle (1992). Simulated-annealing belongs to the class of stochastic global optimization methods. It uses only function values but is relatively slow. It will also work for non-differentiable functions. This implementation uses the Metropolis function for the acceptance probability. By default the next candidate point is generated from a Gaussian Markov kernel with scale proportional to the actual temperature. If a function to generate a new candidate point is given, method "SANN" can also be used to solve combinatorial optimization problems. Temperatures are decreased according to the logarithmic cooling schedule as given in Belisle (1992, p. 890); specifically, the temperature is set to $\text{temp} / \log(((t-1) \% \% \text{tmax}) * \text{tmax} + \exp(1))$, where t is the current iteration step and temp and tmax are specifiable via `control`, see below. Note that the "SANN" method depends critically on the settings of the control parameters. It is not a general-purpose method but can be very useful in getting to a good value on a very rough surface.

Function `fn` can return `NA` or `Inf` if the function cannot be evaluated at the supplied value, but the initial value must have a computable finite value of `fn`. (Except for method "L-BFGS-B" where the values should always be finite.)

`optim` can be used recursively, and for a single parameter as well as many. It also accepts a zero-length `par`, and just evaluates the function with that argument.

The `control` argument is a list that can supply any of the following components:

trace Non-negative integer. If positive, tracing information on the progress of the optimization is produced. Higher values may produce more tracing information: for method "L-BFGS-B" there are six levels of tracing. (To understand exactly what these do see the source code: higher levels give more detail.)

fnscale An overall scaling to be applied to the value of `fn` and `gr` during optimization. If negative, turns the problem into a maximization problem. Optimization is performed on $\text{fn}(\text{par}) / \text{fnscale}$.

parscale A vector of scaling values for the parameters. Optimization is performed on $\text{par} / \text{parscale}$ and these should be comparable in the sense that a unit change in any element produces about a unit change in the scaled value.

ndeps A vector of step sizes for the finite-difference approximation to the gradient, on $\text{par} / \text{parscale}$ scale. Defaults to $1e-3$.

maxit The maximum number of iterations. Defaults to 100 for the derivative-based methods, and 500 for "Nelder-Mead". For "SANN" `maxit` gives the total number of function evaluations. There is no other stopping criterion. Defaults to 10000.

abstol The absolute convergence tolerance. Only useful for non-negative functions, as a tolerance for reaching zero.

reltol Relative convergence tolerance. The algorithm stops if it is unable to reduce the value by a factor of $\text{reltol} * (\text{abs}(\text{val}) + \text{reltol})$ at a step. Defaults to $\sqrt{.Machine\$double.eps}$, typically about $1e-8$.

alpha, beta, gamma Scaling parameters for the "Nelder-Mead" method. `alpha` is the reflection factor (default 1.0), `beta` the contraction factor (0.5) and `gamma` the expansion factor (2.0).

REPORT The frequency of reports for the "BFGS", "L-BFGS-B" and "SANN" methods if `control$trace` is positive. Defaults to every 10 iterations for "BFGS" and "L-BFGS-B", or every 100 temperatures for "SANN".

type for the conjugate-gradients method. Takes value 1 for the Fletcher–Reeves update, 2 for Polak–Ribiere and 3 for Beale–Sorenson.

lmm is an integer giving the number of BFGS updates retained in the "L-BFGS-B" method, It defaults to 5.

factr controls the convergence of the "L-BFGS-B" method. Convergence occurs when the reduction in the objective is within this factor of the machine tolerance. Default is $1e7$, that is a tolerance of about $1e-8$.

pgtol helps control the convergence of the "L-BFGS-B" method. It is a tolerance on the projected gradient in the current search direction. This defaults to zero, when the check is suppressed.

temp controls the "SANN" method. It is the starting temperature for the cooling schedule. Defaults to 10.

tmax is the number of function evaluations at each temperature for the "SANN" method. Defaults to 10.

Any names given to `par` will be copied to the vectors passed to `fn` and `gr`. Note that no other attributes of `par` are copied over.

Value

A list with components:

<code>par</code>	The best set of parameters found.
<code>value</code>	The value of <code>fn</code> corresponding to <code>par</code> .
<code>counts</code>	A two-element integer vector giving the number of calls to <code>fn</code> and <code>gr</code> respectively. This excludes those calls needed to compute the Hessian, if requested, and any calls to <code>fn</code> to compute a finite-difference approximation to the gradient.
<code>convergence</code>	An integer code. 0 indicates successful convergence. Error codes are <ul style="list-style-type: none"> 1 indicates that the iteration limit <code>maxit</code> had been reached. 10 indicates degeneracy of the Nelder–Mead simplex. 51 indicates a warning from the "L-BFGS-B" method; see component <code>message</code> for further details. 52 indicates an error from the "L-BFGS-B" method; see component <code>message</code> for further details.
<code>message</code>	A character string giving any additional information returned by the optimizer, or NULL.
<code>hessian</code>	Only if argument <code>hessian</code> is true. A symmetric matrix giving an estimate of the Hessian at the solution found. Note that this is the Hessian of the unconstrained problem even if the box constraints are active.

Note

`optim` will work with one-dimensional `pars`, but the default method does not work well (and will warn). Use `optimize` instead.

Source

The code for methods "Nelder-Mead", "BFGS" and "CG" was based originally on Pascal code in Nash (1990) that was translated by p2c and then hand-optimized. Dr Nash has agreed that the code can be made freely available.

The code for method "L-BFGS-B" is based on Fortran code by Zhu, Byrd, Lu-Chen and Nocedal obtained from Netlib (file 'opt/lbfgs_bcm.shar': another version is in 'toms/778').

The code for method "SANN" was contributed by A. Trapletti.

```

optimize

*One Dimensional Optimization***Description**

The function `optimize` searches the interval from `lower` to `upper` for a minimum or maximum of the function `f` with respect to its first argument.

`optimise` is an alias for `optimize`.

Usage

```
optimize(f = , interval = , ..., lower = min(interval),
        upper = max(interval), maximum = FALSE,
        tol = .Machine$double.eps^0.25)
optimise(f = , interval = , ..., lower = min(interval),
        upper = max(interval), maximum = FALSE,
        tol = .Machine$double.eps^0.25)
```

Arguments

<code>f</code>	the function to be optimized. The function is either minimized or maximized over its first argument depending on the value of <code>maximum</code> .
<code>interval</code>	a vector containing the end-points of the interval to be searched for the minimum.
<code>...</code>	additional named or unnamed arguments to be passed to <code>f</code> .
<code>lower</code>	the lower end point of the interval to be searched.
<code>upper</code>	the upper end point of the interval to be searched.
<code>maximum</code>	logical. Should we maximize or minimize (the default)?
<code>tol</code>	the desired accuracy.

Details

Note that arguments after `...` must be matched exactly.

The method used is a combination of golden section search and successive parabolic interpolation, and was designed for use with continuous functions. Convergence is never much slower than that for a Fibonacci search. If `f` has a continuous second derivative which is positive at the minimum (which is not at `lower` or `upper`), then convergence is superlinear, and usually of the order of about 1.324.

The function `f` is never evaluated at two points closer together than $\epsilon|x_0| + (tol/3)$, where ϵ is approximately $\sqrt{.Machine$double.eps}$ and x_0 is the final abscissa `optimize()$minimum`.

If `f` is a unimodal function and the computed values of `f` are always unimodal when separated by at least $\epsilon|x| + (tol/3)$, then x_0 approximates the abscissa of the global minimum of `f` on the interval `lower, upper` with an error less than $\epsilon|x_0| + tol$.

If f is not unimodal, then `optimize()` may approximate a local, but perhaps non-global, minimum to the same accuracy.

The first evaluation of f is always at $x_1 = a + (1 - \phi)(b - a)$ where $(a, b) = (\text{lower}, \text{upper})$ and $\phi = (\sqrt{5} - 1)/2 = 0.61803\dots$ is the golden section ratio. Almost always, the second evaluation is at $x_2 = a + \phi(b - a)$. Note that a local minimum inside $[x_1, x_2]$ will be found as solution, even when f is constant in there, see the last example.

f will be called as $f(x, \dots)$ for a numeric value of x .

Value

A list with components `minimum` (or `maximum`) and `objective` which give the location of the minimum (or maximum) and the value of the function at that point.

Source

A C translation of Fortran code <http://www.netlib.org/fmm/fmin.f> based on the Algol 60 procedure `localmin` given in the reference.

Examples

```
require(graphics)

f <- function(x,a) (x-a)^2
xmin <- optimize(f, c(0, 1), tol = 0.0001, a = 1/3)
xmin

## See where the function is evaluated:
optimize(function(x) x^2*(print(x)-1), lower=0, upper=10)

## "wrong" solution with unlucky interval and piecewise constant f():
f <- function(x) ifelse(x > -1, ifelse(x < 4, exp(-1/abs(x - 1)), 10), 10)
fp <- function(x) { print(x); f(x) }

plot(f, -2,5, ylim = 0:1, col = 2)
optimize(fp, c(-4, 20))# doesn't see the minimum
optimize(fp, c(-7, 20))# ok
```

order.dendrogram *Ordering or Labels of the Leaves in a Dendrogram*

Description

These functions return the order (index) or the "label" attribute for the leaves in a dendrogram. These indices can then be used to access the appropriate components of any additional data.

Usage

```
order.dendrogram(x)

## S3 method for class 'dendrogram':
labels(object, ...)
```

Arguments

`x`, `object` a dendrogram (see [as.dendrogram](#)).
`...` additional arguments

Details

The indices or labels for the leaves in left to right order are retrieved.

Value

A vector with length equal to the number of leaves in the dendrogram is returned. From `r <- order.dendrogram()`, each element is the index into the original data (from which the dendrogram was computed).

Author(s)

R. Gentleman (`order.dendrogram`) and Martin Maechler (`labels.dendrogram`).

See Also

[reorder.dendrogram](#).

Examples

```
set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
hc$order
dd <- as.dendrogram(hc)
order.dendrogram(dd) ## the same :
stopifnot(hc$order == order.dendrogram(dd))

d2 <- as.dendrogram(hclust(dist(USArrests)))
labels(d2) ## in this case the same as
stopifnot(labels(d2) == rownames(USArrests)[order.dendrogram(d2)])
```

p.adjust

Adjust P-values for Multiple Comparisons

Description

Given a set of p-values, returns p-values adjusted using one of several methods.

Usage

```
p.adjust(p, method = p.adjust.methods, n = length(p))
```

```
p.adjust.methods
# c("holm", "hochberg", "hommel", "bonferroni", "BH", "BY",
#   "fdr", "none")
```

Arguments

p	vector of p-values (possibly with NAs).
method	correction method
n	number of comparisons, must be at least <code>length(p)</code> ; only set this (to non-default) when you know what you are doing!

Details

The adjustment methods include the Bonferroni correction ("bonferroni") in which the p-values are multiplied by the number of comparisons. Less conservative corrections are also included by Holm (1979) ("holm"), Hochberg (1988) ("hochberg"), Hommel (1988) ("hommel"), Benjamini & Hochberg (1995) ("BH"), and Benjamini & Yekutieli (2001) ("BY"), respectively. A pass-through option ("none") is also included. The set of methods are contained in the `p.adjust.methods` vector for the benefit of methods that need to have the method as an option and pass it on to `p.adjust`.

The first four methods are designed to give strong control of the family wise error rate. There seems no reason to use the unmodified Bonferroni correction because it is dominated by Holm's method, which is also valid under arbitrary assumptions.

Hochberg's and Hommel's methods are valid when the hypothesis tests are independent or when they are non-negatively associated (Sarkar, 1998; Sarkar and Chang, 1997). Hommel's method is more powerful than Hochberg's, but the difference is usually small and the Hochberg p-values are faster to compute.

The "BH" and "BY" method of Benjamini, Hochberg, and Yekutieli control the false discovery rate, the expected proportion of false discoveries amongst the rejected hypotheses. The false discovery rate is a less stringent condition than the family wise error rate, so these methods are more powerful than the others.

Note that you can set `n` larger than `length(p)` which means the unobserved p-values are assumed to be greater than all the observed p for "bonferroni" and "holm" methods and equal to 1 for the other methods.

Value

A vector of corrected p-values (same length as `p`).

        main = "P-value adjustments")
legend(.7,.6, p.adjust.M, col=1:6, lty=1:6)

## Can work with NA's:
pN <- p; iN <- c(46,47); pN[iN] <- NA
pN.a <- sapply(p.adjust.M, function(meth) p.adjust(pN, meth))
## The smallest 20 P-values all affected by the NA's :
```

```
round((pN.a / p.adj)[1:20, ] , 4)
```

```
pairwise.prop.test Pairwise comparisons for proportions
```

Description

Calculate pairwise comparisons between pairs of proportions with correction for multiple testing

Usage

```
pairwise.prop.test(x, n, p.adjust.method = p.adjust.methods, ...)
```

Arguments

`x` Vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.

`n` Vector of counts of trials; ignored if `x` is a matrix.

`p.adjust.method` Method for adjusting p values (see [p.adjust](#))

`...` Additional arguments to pass to `prop.test`

Value

Object of class "pairwise.htest"

See Also

[prop.test](#), [p.adjust](#)

Examples

```
smokers <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
pairwise.prop.test(smokers, patients)
```

```
pairwise.t.test Pairwise t tests
```

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing

Usage

```
pairwise.t.test(x, g, p.adjust.method = p.adjust.methods,
               pool.sd = !paired, paired = FALSE,
               alternative = c("two.sided", "less", "greater"), ...)
```

Arguments

<code>x</code>	response vector.
<code>g</code>	grouping vector or factor.
<code>p.adjust.method</code>	Method for adjusting p values (see p.adjust).
<code>pool.sd</code>	switch to allow/disallow the use of a pooled SD
<code>paired</code>	a logical indicating whether you want paired t-tests.
<code>alternative</code>	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less".
<code>...</code>	additional arguments to pass to <code>t.test</code> .

Details

The `pool.sd` switch calculates a common SD for all groups and used that for all comparisons (this can be useful if some groups are small). This method does not actually call `t.test`, so extra arguments are ignored. Pooling does not generalize to paired tests so `pool.sd` and `paired` cannot both be `TRUE`.

Only the lower triangle of the matrix of possible comparisons is being calculated, so setting `alternative` to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

[t.test](#), [p.adjust](#)

Examples

```
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
pairwise.t.test(Ozone, Month)
pairwise.t.test(Ozone, Month, p.adj = "bonf")
pairwise.t.test(Ozone, Month, pool.sd = FALSE)
detach()
```

<code>pairwise.table</code>	<i>Tabulate p values for pairwise comparisons</i>
-----------------------------	---

Description

Creates table of p values for pairwise comparisons with corrections for multiple testing.

Usage

```
pairwise.table(compare.levels, level.names, p.adjust.method)
```

Arguments

`compare.levels`
 Function to compute (raw) p value given indices *i* and *j*

`level.names` Names of the group levels

`p.adjust.method`
 Method for multiple testing adjustment

Details

Functions that do multiple group comparisons create separate `compare.levels` functions (assumed to be symmetrical in *i* and *j*) and passes them to this function.

Value

Table of p values in lower triangular form.

See Also

[pairwise.t.test](#), et al.

`pairwise.wilcox.test`

Pairwise Wilcoxon rank sum tests

Description

Calculate pairwise comparisons between group levels with corrections for multiple testing.

Usage

```
pairwise.wilcox.test(x, g, p.adjust.method = p.adjust.methods,
                    paired=FALSE, ...)
```

Arguments

`x` response vector.

`g` grouping vector or factor.

`p.adjust.method`
 method for adjusting p values (see [p.adjust](#)).

`paired` a logical indicating whether you want a paired test.

`...` additional arguments to pass to [wilcox.test](#).

Details

Extra arguments that are passed on to `wilcox.test` may or may not be sensible in this context. In particular, only the lower triangle of the matrix of possible comparisons is being calculated, so setting `alternative` to anything other than "two.sided" requires that the levels of `g` are ordered sensibly.

Value

Object of class "pairwise.htest"

See Also

[wilcox.test](#), [p.adjust](#)

Examples

```
attach(airquality)
Month <- factor(Month, labels = month.abb[5:9])
## These give warnings because of ties :
pairwise.wilcox.test(Ozone, Month)
pairwise.wilcox.test(Ozone, Month, p.adj = "bonf")
detach()
```

plot.acf

Plot Autocovariance and Autocorrelation Functions

Description

Plot method for objects of class "acf".

Usage

```
## S3 method for class 'acf':
plot(x, ci = 0.95, type = "h", xlab = "Lag", ylab = NULL,
      ylim = NULL, main = NULL,
      ci.col = "blue", ci.type = c("white", "ma"),
      max.mfrow = 6, ask = Npgs > 1 && dev.interactive(),
      mar = if(nser > 2) c(3,2,2,0.8) else par("mar"),
      oma = if(nser > 2) c(1,1.2,1,1) else par("oma"),
      mgp = if(nser > 2) c(1.5,0.6,0) else par("mgp"),
      xpd = par("xpd"),
      cex.main = if(nser > 2) 1 else par("cex.main"),
      verbose = getOption("verbose"),
      ...)
```

Arguments

x	an object of class "acf".
ci	coverage probability for confidence interval. Plotting of the confidence interval is suppressed if ci is zero or negative.
type	the type of plot to be drawn, default to histogram like vertical lines.
xlab	the x label of the plot.
ylab	the y label of the plot.
ylim	numeric of length 2 giving the y limits for the plot.
main	overall title for the plot.
ci.col	colour to plot the confidence interval lines.

<code>ci.type</code>	should the confidence limits assume a white noise input or for lag k an $MA(k-1)$ input?
<code>max.mfrow</code>	positive integer; for multivariate x indicating how many rows and columns of plots should be put on one page, using <code>par(mfrow = c(m,m))</code> .
<code>ask</code>	logical; if TRUE, the user is asked before a new page is started.
<code>mar, oma, mgp, xpd, cex.main</code>	graphics parameters as in <code>par(*)</code> , by default adjusted to use smaller than default margins for multivariate x only.
<code>verbose</code>	logical. Should R report extra information on progress?
<code>...</code>	graphics parameters to be passed to the plotting routines.

Note

The confidence interval plotted in `plot.acf` is based on an *uncorrelated* series and should be treated with appropriate caution. Using `ci.type = "ma"` may be less potentially misleading.

See Also

`acf` which calls `plot.acf` by default.

Examples

```
require(graphics)

z4 <- ts(matrix(rnorm(400), 100, 4), start=c(1961, 1), frequency=12)
z7 <- ts(matrix(rnorm(700), 100, 7), start=c(1961, 1), frequency=12)
acf(z4)
acf(z7, max.mfrow = 7) # squeeze on 1 page
acf(z7) # multi-page
```

`plot.density`

Plot Method for Kernel Density Estimation

Description

The plot method for density objects.

Usage

```
## S3 method for class 'density':
plot(x, main = NULL, xlab = NULL, ylab = "Density", type = "l",
      zero.line = TRUE, ...)
```

Arguments

<code>x</code>	a "density" object.
<code>main, xlab, ylab, type</code>	plotting parameters with useful defaults.
<code>...</code>	further plotting parameters.
<code>zero.line</code>	logical; if TRUE, add a base line at $y = 0$

Value

None.

See Also[density](#).

plot.HoltWinters *Plot function for HoltWinters objects*

Description

Produces a chart of the original time series along with the fitted values. Optionally, predicted values (and their confidence bounds) can also be plotted.

Usage

```
## S3 method for class 'HoltWinters':
plot(x, predicted.values = NA, intervals = TRUE,
      separator = TRUE, col = 1, col.predicted = 2,
      col.intervals = 4, col.separator = 1, lty = 1,
      lty.predicted = 1, lty.intervals = 1, lty.separator = 3,
      ylab = "Observed / Fitted",
      main = "Holt-Winters filtering",
      ylim = NULL, ...)
```

Arguments

x	Object of class "HoltWinters"
predicted.values	Predicted values as returned by predict.HoltWinters
intervals	If TRUE, the prediction intervals are plotted (default).
separator	If TRUE, a separating line between fitted and predicted values is plotted (default).
col, lty	Color/line type of original data (default: black solid).
col.predicted, lty.predicted	Color/line type of fitted and predicted values (default: red solid).
col.intervals, lty.intervals	Color/line type of prediction intervals (default: blue solid).
col.separator, lty.separator	Color/line type of observed/predicted values separator (default: black dashed).
ylab	Label of the y-axis.
main	Main title.
ylim	Limits of the y-axis. If NULL, the range is chosen such that the plot contains the original series, the fitted values, and the predicted values if any.
...	Other graphics parameters.

plot.isoreg

Plot Method for isoreg Objects

Description

The [plot](#) and [lines](#) method for R objects of class [isoreg](#).

Usage

```
## S3 method for class 'isoreg':
plot(x, plot.type = c("single", "row.wise", "col.wise"),
     main = paste("Isotonic regression", deparse(x$call)),
     main2 = "Cumulative Data and Convex Minorant",
     xlab = "x0", ylab = "x$y",
     par.fit = list(col = "red", cex = 1.5, pch = 13, lwd = 1.5),
     mar = if (both) 0.1 + c(3.5, 2.5, 1, 1) else par("mar"),
     mgp = if (both) c(1.6, 0.7, 0) else par("mgp"),
     grid = length(x$x) < 12, ...)
## S3 method for class 'isoreg':
lines(x, col = "red", lwd = 1.5,
      do.points = FALSE, cex = 1.5, pch = 13, ...)
```

Arguments

<code>x</code>	an isoreg object.
<code>plot.type</code>	character indicating which type of plot is desired. The first (default) only draws the data and the fit, where the others add a plot of the cumulative data and fit.
<code>main</code>	main title of plot, see title .
<code>main2</code>	title for second (cumulative) plot.
<code>xlab, ylab</code>	x- and y- axis annotation.
<code>par.fit</code>	a list of arguments (for points and lines) for drawing the fit.
<code>mar, mgp</code>	graphical parameters, see par , mainly for the case of two plots.

`grid` logical indicating if grid lines should be drawn. If true, `grid()` is used for the first plot, where as vertical lines are drawn at 'touching' points for the cumulative plot.
`do.points` for `lines()`: logical indicating if the step points should be drawn as well (and as they are drawn in `plot()`).
`col, lwd, cex, pch` graphical arguments for `lines()`, where `cex` and `pch` are only used when `do.points` is TRUE.
`...` further arguments passed to and from methods.

See Also

[isoreg](#) for computation of `isoreg` objects.

Examples

```

require(graphics)

utils::example(isoreg) # for the examples there

plot(y3, main = "simple plot(.) + lines(<isoreg>)")
lines(ir3)

## 'same' plot as above, "proving" that only ranks of 'x' are important
plot(isoreg(2^(1:9), c(1,0,4,3,3,5,4,2,0)), plot.type = "row", log = "x")

plot(ir3, plot.type = "row", ylab = "y3")
plot(isoreg(y3 - 4), plot.t="r", ylab = "y3 - 4")
plot(ir4, plot.type = "ro", ylab = "y4", xlab = "x = 1:n")

## experiment a bit with these (C-c C-j):
plot(isoreg(sample(9), y3), plot.type="row")
plot(isoreg(sample(9), y3), plot.type="col.wise")

plot(ir <- isoreg(sample(10), sample(10, replace = TRUE)),
      plot.type = "r")

```

plot.lm

Plot Diagnostics for an lm Object

Description

Six plots (selectable by `which`) are currently available: a plot of residuals against fitted values, a Scale-Location plot of $\sqrt{|residuals|}$ against fitted values, a Normal Q-Q plot, a plot of Cook's distances versus row labels, a plot of residuals against leverages, and a plot of Cook's distances against leverage/(1-leverage). By default, the first three and 5 are provided.

Usage

```

## S3 method for class 'lm':
plot(x, which = c(1:3,5),
      caption = list("Residuals vs Fitted", "Normal Q-Q",

```

```

      "Scale-Location", "Cook's distance",
      "Residuals vs Leverage",
      expression("Cook's dist vs Leverage " * h[ii] / (1 - h[ii]))),
panel = if(add.smooth) panel.smooth else points,
sub.caption = NULL, main = "",
ask = prod(par("mfcol")) < length(which) && dev.interactive(),
...,
id.n = 3, labels.id = names(residuals(x)), cex.id = 0.75,
qqline = TRUE, cook.levels = c(0.5, 1.0),
add.smooth = getOption("add.smooth"), label.pos = c(4,2),
cex.caption = 1)

```

Arguments

<code>x</code>	lm object, typically result of <code>lm</code> or <code>glm</code> .
<code>which</code>	if a subset of the plots is required, specify a subset of the numbers 1:6.
<code>caption</code>	captions to appear above the plots; <code>character</code> vector or <code>list</code> of valid graphics annotations, see <code>as.graphicsAnnot</code> . Can be set to "" or NA to suppress all captions.
<code>panel</code>	panel function. The useful alternative to <code>points</code> , <code>panel.smooth</code> can be chosen by <code>add.smooth = TRUE</code> .
<code>sub.caption</code>	common title—above figures if there are multiple; used as sub (<code>s.title</code>) otherwise. If NULL, as by default, a possible shortened version of <code>deparse(x\$call)</code> is used.
<code>main</code>	title to each plot—in addition to the above <code>caption</code> .
<code>ask</code>	logical; if TRUE, the user is <i>asked</i> before each plot, see <code>par(ask=.)</code> .
<code>...</code>	other parameters to be passed through to plotting functions.
<code>id.n</code>	number of points to be labelled in each plot, starting with the most extreme.
<code>labels.id</code>	vector of labels, from which the labels for extreme points will be chosen. NULL uses observation numbers.
<code>cex.id</code>	magnification of point labels.
<code>qqline</code>	logical indicating if a <code>qqline()</code> should be added to the normal Q-Q plot.
<code>cook.levels</code>	levels of Cook's distance at which to draw contours.
<code>add.smooth</code>	logical indicating if a smoother should be added to most plots; see also <code>panel</code> above.
<code>label.pos</code>	positioning of labels, for the left half and right half of the graph respectively, for plots 1-3.
<code>cex.caption</code>	controls the size of <code>caption</code> .

Details

`sub.caption`—by default the function call—is shown as a subtitle (under the x-axis title) on each plot when plots are on separate pages, or as a subtitle in the outer margin (if any) when there are multiple plots per page.

The ‘Scale-Location’ plot, also called ‘Spread-Location’ or ‘S-L’ plot, takes the square root of the absolute residuals in order to diminish skewness ($\sqrt{|E|}$ is much less skewed than $|E|$ for Gaussian zero-mean E).

The 'S-L', the Q-Q, and the Residual-Leverage plot, use *standardized* residuals which have identical variance (under the hypothesis). They are given as $R_i/(s \times \sqrt{1 - h_{ii}})$ where h_{ii} are the diagonal entries of the hat matrix, `influence()` `$hat`, see also `hat`, and where the Residual-Leverage uses standardized Pearson residuals (`residuals.glm(type = "pearson")`) for $R[i]$.

The Residual-Leverage plot shows contours of equal Cook's distance, for values of `cook.levels` (by default 0.5 and 1) and omits cases with leverage one with a warning. If the leverages are constant (as is typically the case in a balanced `avov` situation) the plot uses factor level combinations instead of the leverages for the x-axis. (The factor levels are ordered by mean fitted value.)

In the Cook's distance vs leverage/(1-leverage) plot, contours of standardized residuals that are equal in magnitude are lines through the origin. The contour lines are labelled with the magnitudes.

## Gives a smoother curve
plot(lm.SR, panel = function(x,y) panel.smooth(x, y, span = 1))
```

```
par(mfrow=c(2,1))# same oma as above
plot(lm.SR, which = 1:2, sub.caption = "Saving Rates, n=50, p=5")
```

plot.ppr

Plot Ridge Functions for Projection Pursuit Regression Fit

Description

Plot ridge functions for projection pursuit regression fit.

Usage

```
## S3 method for class 'ppr':
plot(x, ask, type = "o", ...)
```

Arguments

x	A fit of class "ppr" as produced by a call to ppr.
ask	the graphics parameter ask: see par for details. If set to TRUE will ask between the plot of each cross-section.
type	the type of line to draw
...	further graphical parameters

Value

None

Side Effects

A series of plots are drawn on the current graphical device, one for each term in the fit.

})
```

plot.profile.nls *Plot a profile.nls Object*

Description

Displays a series of plots of the profile t function and interpolated confidence intervals for the parameters in a nonlinear regression model that has been fit with `nls` and profiled with `profile.nls`.

Usage

```
## S3 method for class 'profile.nls':
plot(x, levels, conf= c(99, 95, 90, 80, 50)/100,
     absVal =TRUE, ...)
```

Arguments

<code>x</code>	an object of class "profile.nls"
<code>levels</code>	levels, on the scale of the absolute value of a t statistic, at which to interpolate intervals. Usually <code>conf</code> is used instead of giving <code>levels</code> explicitly.
<code>conf</code>	a numeric vector of confidence levels for profile-based confidence intervals on the parameters. Defaults to <code>c(0.99, 0.95, 0.90, 0.80, 0.50)</code> .
<code>absVal</code>	a logical value indicating whether or not the plots should be on the scale of the absolute value of the profile t . Defaults to <code>TRUE</code> .
<code>...</code>	other arguments to the <code>plot</code> function can be passed here.

plot.spec *Plotting Spectral Densities*

Description

Plotting method for objects of class "spec". For multivariate time series it plots the marginal spectra of the series or pairs plots of the coherency and phase of the cross-spectra.

Usage

```
## S3 method for class 'spec':
plot(x, add = FALSE, ci = 0.95, log = c("yes", "dB", "no"),
     xlab = "frequency", ylab = NULL, type = "l",
     ci.col = "blue", ci.lty = 3,
     main = NULL, sub = NULL,
     plot.type = c("marginal", "coherency", "phase"),
     ...)

plot.spec.phase(x, ci = 0.95,
               xlab = "frequency", ylab = "phase",
               ylim = c(-pi, pi), type = "l",
               main = NULL, ci.col = "blue", ci.lty = 3, ...)

plot.spec.coherency(x, ci = 0.95,
                   xlab = "frequency",
                   ylab = "squared coherency",
                   ylim = c(0, 1), type = "l",
                   main = NULL, ci.col = "blue", ci.lty = 3, ...)
```

Arguments

x	an object of class "spec".
add	logical. If TRUE, add to already existing plot. Only valid for plot.type = "marginal".
ci	coverage probability for confidence interval. Plotting of the confidence bar/limits is omitted unless ci is strictly positive.
log	If "dB", plot on log10 (decibel) scale (as S-PLUS), otherwise use conventional log scale or linear scale. Logical values are also accepted. The default is "yes" unless options(ts.S.compat = TRUE) has been set, when it is "dB". Only valid for plot.type = "marginal".
xlab	the x label of the plot.
ylab	the y label of the plot. If missing a suitable label will be constructed.
type	the type of plot to be drawn, defaults to lines.
ci.col	colour for plotting confidence bar or confidence intervals for coherency and phase.

ci.lty	line type for confidence intervals for coherency and phase.
main	overall title for the plot. If missing, a suitable title is constructed.
sub	a sub title for the plot. Only used for <code>plot.type = "marginal"</code> . If missing, a description of the smoothing is used.
plot.type	For multivariate time series, the type of plot required. Only the first character is needed.
ylim, ...	Graphical parameters.

See Also

[spectrum](#)

plot.stepfun *Plot Step Functions*

Description

Method of the generic `plot` for `stepfun` objects and utility for plotting piecewise constant functions.

Usage

```
## S3 method for class 'stepfun':
plot(x, xval, xlim, ylim,
     xlab = "x", ylab = "f(x)", main = NULL,
     add = FALSE, verticals = TRUE, do.points = TRUE,
     pch = par("pch"),
     col.points = par("col"), cex.points = par("cex"),
     col.hor = par("col"), col.vert = par("col"),
     lty = par("lty"), lwd = par("lwd"), ...)

## S3 method for class 'stepfun':
lines(x, ...)
```

Arguments

x	an R object inheriting from "stepfun".
xval	numeric vector of abscissa values at which to evaluate x. Defaults to <code>knots(x)</code> restricted to <code>xlim</code> .
xlim, ylim	numeric(2) each; range of x or y values to use. Both have sensible defaults.
xlab, ylab	labels of x and y axis.
main	main title.
add	logical; if TRUE only <i>add</i> to an existing plot.
verticals	logical; if TRUE, draw vertical lines at steps.
do.points	logical; if true, also draw points at the (<code>xlim</code> restricted) knot locations.
pch	character; point character if <code>do.points</code> .
col.points	character or integer code; color of points if <code>do.points</code> .

`cex.points` numeric; character expansion factor if `do.points`.
`col.hor` color of horizontal lines.
`col.vert` color of vertical lines.
`lty, lwd` line type and thickness for all lines.
`...` further arguments of `plot(.)`, or if (add) `segments(.)`.

Value

A list with two components

`t` abscissa (x) values, including the two outermost ones.
`y` y values 'in between' the `t[]`.

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch>, 1990, 1993; ported to R, 1997.

See Also

`ecdf` for empirical distribution functions as special step functions, `approxfun` and `splinefun`.

Examples

```

require(graphics)

y0 <- c(1,2,4,3)
sfun0 <- stepfun(1:3, y0, f = 0)
sfun.2 <- stepfun(1:3, y0, f = .2)
sfun1 <- stepfun(1:3, y0, right = TRUE)

tt <- seq(0,3, by=0.1)
op <- par(mfrow=c(2,2))
plot(sfun0); plot(sfun0, xval=tt, add=TRUE, col.hor="bisque")
plot(sfun.2); plot(sfun.2, xval=tt, add=TRUE, col.hor="orange")
plot(sfun1); lines(sfun1, xval=tt, col.hor="coral")
##-- This is revealing :
plot(sfun0, verticals= FALSE,
      main = "stepfun(x, y0, f=f) for f = 0, .2, 1")
for(i in 1:3)
  lines(list(sfun0, sfun.2, stepfun(1:3, y0, f = 1))[[i]],
        col.hor=i, col.vert=i)
legend(2.5, 1.9, paste("f =", c(0,0.2,1)), col=1:3, lty=1, y.intersp=1)
par(op)

# Extend and/or restrict 'viewport':
plot(sfun0, xlim = c(0,5), ylim = c(0, 3.5),
      main = "plot(stepfun(*), xlim= . , ylim = .)")

##-- this works too (automatic call to ecdf(.)):
plot.stepfun(rt(50, df=3), col.vert = "gray20")

```

plot.ts

*Plotting Time-Series Objects***Description**

Plotting method for objects inheriting from class "ts".

Usage

```
## S3 method for class 'ts':
plot(x, y = NULL, plot.type = c("multiple", "single"),
      xy.labels, xy.lines, panel = lines, nc, yax.flip = FALSE,
      mar.multi = c(0, 5.1, 0, if(yax.flip) 5.1 else 2.1),
      oma.multi = c(6, 0, 5, 0), axes = TRUE, ...)

## S3 method for class 'ts':
lines(x, ...)
```

Arguments

<code>x, y</code>	time series objects, usually inheriting from class "ts".
<code>plot.type</code>	for multivariate time series, should the series be plotted separately (with a common time axis) or on a single plot?
<code>xy.labels</code>	logical, indicating if <code>text()</code> labels should be used for an x-y plot, or character, supplying a vector of labels to be used. The default is to label for up to 150 points, and not for more.
<code>xy.lines</code>	logical, indicating if <code>lines</code> should be drawn for an x-y plot. Defaults to the value of <code>xy.labels</code> if that is logical, otherwise to TRUE.
<code>panel</code>	a function(<code>x, col, bg, pch, type, ...</code>) which gives the action to be carried out in each panel of the display for <code>plot.type="multiple"</code> . The default is <code>lines</code> .
<code>nc</code>	the number of columns to use when <code>type="multiple"</code> . Defaults to 1 for up to 4 series, otherwise to 2.
<code>yax.flip</code>	logical indicating if the y-axis (ticks and numbering) should flip from side 2 (left) to 4 (right) from series to series when <code>type="multiple"</code> .
<code>mar.multi, oma.multi</code>	the (default) <code>par</code> settings for <code>plot.type="multiple"</code> . Modify with care!
<code>axes</code>	logical indicating if x- and y- axes should be drawn.
<code>...</code>	additional graphical arguments, see <code>plot</code> , <code>plot.default</code> and <code>par</code> .

Details

If `y` is missing, this function creates a time series plot, for multivariate series of one of two kinds depending on `plot.type`.

If `y` is present, both `x` and `y` must be univariate, and a scatter plot $y \sim x$ will be drawn, enhanced by using `text` if `xy.labels` is TRUE or character, and `lines` if `xy.lines` is TRUE.

See Also

[ts](#) for basic time series construction and access functionality.

Examples

```
require(graphics)

## Multivariate
z <- ts(matrix(rt(200 * 8, df = 3), 200, 8),
         start = c(1961, 1), frequency = 12)
plot(z, yax.flip = TRUE)
plot(z, axes = FALSE, ann = FALSE, frame.plot = TRUE,
     mar.multi = c(0,0,0,0), oma.multi = c(1,1,5,1))
title("plot(ts(..), axes=FALSE, ann=FALSE, frame.plot=TRUE, mar..., oma...)")

z <- window(z[,1:3], end = c(1969,12))
plot(z, type = "b")      # multiple
plot(z, plot.type="single", lty=1:3, col=4:2)

## A phase plot:
plot(nhtemp, c(nhtemp[-1], NA), cex = .8, col="blue",
     main = "Lag plot of New Haven temperatures")
## a clearer way to do this would be
## Not run:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col="blue",
     main = "Lag plot of New Haven temperatures")
## End(Not run)

## xy.lines and xy.labels are FALSE for large series:
plot(lag(sunspots, 1), sunspots, pch = ".")

SMI <- EuStockMarkets[, "SMI"]
plot(lag(SMI, 1), SMI, pch = ".")
plot(lag(SMI, 20), SMI, pch = ".", log = "xy",
     main = "4 weeks lagged SMI stocks -- log scale", xy.lines= TRUE)
```

Description

Density, distribution function, quantile function and random generation for the Poisson distribution with parameter λ .

Usage

```
dpois(x, lambda, log = FALSE)
ppois(q, lambda, lower.tail = TRUE, log.p = FALSE)
qpois(p, lambda, lower.tail = TRUE, log.p = FALSE)
rpois(n, lambda)
```

Arguments

<code>x</code>	vector of (non-negative integer) quantiles.
<code>q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of random values to return.
<code>lambda</code>	vector of (non-negative) means.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The Poisson distribution has density

$$p(x) = \frac{\lambda^x e^{-\lambda}}{x!}$$

for $x = 0, 1, 2, \dots$. The mean and variance are $E(X) = Var(X) = \lambda$.

If an element of `x` is not integer, the result of `dpois` is zero, with a warning. $p(x)$ is computed using Loader's algorithm, see the reference in [dbinom](#).

The quantile is left continuous: `qgeom(q, prob)` is the largest integer x such that $P(X \leq x) < q$.

Setting `lower.tail = FALSE` allows to get much more precise results when the default, `lower.tail = TRUE` would return 1, see the example below.

Value

`dpois` gives the (log) density, `ppois` gives the (log) distribution function, `qpois` gives the quantile function, and `rpois` generates random deviates.

Invalid `lambda` will result in return value `NaN`, with a warning.

Source

`dpois` uses C code contributed by Catherine Loader (see [dbinom](#)).

`ppois` uses `pgamma`.

`qpois` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

`rpois` uses

Ahrens, J. H. and Dieter, U. (1982). Computer generation of Poisson deviates from modified normal distributions. *ACM Transactions on Mathematical Software*, **8**, 163–179.

See Also

[dbinom](#) for the binomial and [dnbinom](#) for the negative binomial distribution.

Examples

```
require(graphics)

-log(dpois(0:7, lambda=1) * gamma(1+ 0:7)) # == 1
Ni <- rpois(50, lambda = 4); table(factor(Ni, 0:max(Ni)))

1 - ppois(10*(15:25), lambda=100) # becomes 0 (cancellation)
  ppois(10*(15:25), lambda=100, lower.tail=FALSE) # no cancellation

par(mfrow = c(2, 1))
x <- seq(-0.01, 5, 0.01)
plot(x, ppois(x, 1), type="s", ylab="F(x)", main="Poisson(1) CDF")
plot(x, pbinom(x, 100, 0.01), type="s", ylab="F(x)",
      main="Binomial(100, 0.01) CDF")
```

poly

*Compute Orthogonal Polynomials***Description**

Returns or evaluates orthogonal polynomials of degree 1 to degree over the specified set of points x . These are all orthogonal to the constant polynomial of degree 0. Alternatively, evaluate raw polynomials.

Usage

```
poly(x, ..., degree = 1, coefs = NULL, raw = FALSE)
polym(..., degree = 1, raw = FALSE)

## S3 method for class 'poly':
predict(object, newdata, ...)
```

Arguments

<code>x</code> , <code>newdata</code>	a numeric vector at which to evaluate the polynomial. <code>x</code> can also be a matrix. Missing values are not allowed in <code>x</code> .
<code>degree</code>	the degree of the polynomial. Must be less than the number of unique points.
<code>coefs</code>	for prediction, coefficients from a previous fit.
<code>raw</code>	if true, use raw and not orthogonal polynomials.
<code>object</code>	an object inheriting from class "poly", normally the result of a call to <code>poly</code> with a single vector argument.
<code>...</code>	<code>poly</code> , <code>polym</code> : further vectors. <code>predict.poly</code> : arguments to be passed to or from other methods.

Details

Although formally `degree` should be named (as it follows `...`), an unnamed second argument of length 1 will be interpreted as the degree.

The orthogonal polynomial is summarized by the coefficients, which can be used to evaluate it via the three-term recursion given in Kennedy & Gentle (1980, pp. 343–4), and used in the `predict` part of the code.

Value

For `poly` with a single vector argument:

A matrix with rows corresponding to points in `x` and columns corresponding to the degree, with attributes `"degree"` specifying the degrees of the columns and (unless `raw = TRUE`) `"coefs"` which contains the centering and normalization constants used in constructing the orthogonal polynomials. The matrix has given class `c("poly", "matrix")`.

Other cases of `poly` and `polym`, and `predict.poly`: a matrix.

Note

This routine is intended for statistical purposes such as `contr.poly`: it does not attempt to orthogonalize to machine accuracy.

See Also

[contr.poly](#).

[cars](#) for an example of polynomial regression.

Examples

```
(z <- poly(1:10, 3))
predict(z, seq(2, 4, 0.5))
poly(seq(4, 6, 0.5), 3, coefs = attr(z, "coefs"))

polym(1:4, c(1, 4:6), degree=3) # or just poly()
poly(cbind(1:4, c(1, 4:6)), degree=3)
```

power

Create a Power Link Object

Description

Creates a link object based on the link function $\eta = \mu^\lambda$.

Usage

```
power(lambda = 1)
```

Arguments

`lambda` a real number.

Details

If `lambda` is non-positive, it is taken as zero, and the log link is obtained. The default `lambda = 1` gives the identity link.

Value

A list with components `linkfun`, `linkinv`, `mu.eta`, and `valideta`. See [make.link](#) for information on their meaning.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

[make.link](#), [family](#)

To raise a number to a power, see [Arithmetic](#).

To calculate the power of a test, see various functions in the **stats** package, e.g., [power.t.test](#).

Examples

```
power()
quasi(link=power(1/3)) [c("linkfun", "linkinv")]
```

power.anova.test *Power calculations for balanced one-way analysis of variance tests*

Description

Compute power of test or determine parameters to obtain target power.

Usage

```
power.anova.test(groups = NULL, n = NULL,
                 between.var = NULL, within.var = NULL,
                 sig.level = 0.05, power = NULL)
```

Arguments

<code>groups</code>	Number of groups
<code>n</code>	Number of observations (per group)
<code>between.var</code>	Between group variance
<code>within.var</code>	Within group variance
<code>sig.level</code>	Significance level (Type I error probability)
<code>power</code>	Power of test (1 minus Type II error probability)

Details

Exactly one of the parameters `groups`, `n`, `between.var`, `power`, `within.var`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has non-`NULL` default so `NULL` must be explicitly passed if you want it computed.

Value

Object of class "power.htest", a list of the arguments (including the computed one) augmented with method and note elements.

Note

uniroot is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

Author(s)

Claus Ekstrøm

See Also

[anova](#), [lm](#), [uniroot](#)

Examples

```
power.anova.test(groups=4, n=5, between.var=1, within.var=3)
# Power = 0.3535594

power.anova.test(groups=4, between.var=1, within.var=3,
                 power=.80)
# n = 11.92613

## Assume we have prior knowledge of the group means:
groupmeans <- c(120, 130, 140, 150)
power.anova.test(groups = length(groupmeans),
                 between.var=var(groupmeans),
                 within.var=500, power=.90) # n = 15.18834
```

power.prop.test *Power calculations two sample test for proportions*

Description

Compute power of test, or determine parameters to obtain target power.

Usage

```
power.prop.test(n = NULL, p1 = NULL, p2 = NULL, sig.level = 0.05,
               power = NULL,
               alternative = c("two.sided", "one.sided"),
               strict = FALSE)
```

Arguments

<code>n</code>	Number of observations (per group)
<code>p1</code>	probability in one group
<code>p2</code>	probability in other group
<code>sig.level</code>	Significance level (Type I error probability)
<code>power</code>	Power of test (1 minus Type II error probability)
<code>alternative</code>	One- or two-sided test
<code>strict</code>	Use strict interpretation in two-sided case

Details

Exactly one of the parameters `n`, `p1`, `p2`, `power`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that `sig.level` has a non-`NULL` default so `NULL` must be explicitly passed if you want it computed.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Value

Object of class `"power.htest"`, a list of the arguments (including the computed one) augmented with `method` and `note` elements.

Note

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given. If one of them is computed $p1 < p2$ will hold, although this is not enforced when both are specified.

Author(s)

Peter Dalgaard. Based on previous work by Claus Ekstrøm

power.prop.test(p1 = .50, p2 = .75, power = .90)
power.prop.test(n = 50, p1 = .5, power = .90)
```

power.t.test *Power calculations for one and two sample t tests*

Description

Compute power of test, or determine parameters to obtain target power.

Usage

```
power.t.test(n = NULL, delta = NULL, sd = 1, sig.level = 0.05,
             power = NULL,
             type = c("two.sample", "one.sample", "paired"),
             alternative = c("two.sided", "one.sided"),
             strict = FALSE)
```

Arguments

n	Number of observations (per group)
delta	True difference in means
sd	Standard deviation
sig.level	Significance level (Type I error probability)
power	Power of test (1 minus Type II error probability)
type	Type of t test
alternative	One- or two-sided test
strict	Use strict interpretation in two-sided case

Details

Exactly one of the parameters `n`, `delta`, `power`, `sd`, and `sig.level` must be passed as `NULL`, and that parameter is determined from the others. Notice that the last two have non-`NULL` defaults so `NULL` must be explicitly passed if you want to compute them.

If `strict = TRUE` is used, the power will include the probability of rejection in the opposite direction of the true effect, in the two-sided case. Without this the power will be half the significance level if the true difference is zero.

Value

Object of class `"power.htest"`, a list of the arguments (including the computed one) augmented with `method` and `note` elements.

Note

`uniroot` is used to solve power equation for unknowns, so you may see errors from it, notably about inability to bracket the root when invalid arguments are given.

```

 PP.test

Phillips-Perron Test for Unit Roots

Description

Computes the Phillips-Perron test for the null hypothesis that x has a unit root against a stationary alternative.

Usage

```
PP.test(x, lshort = TRUE)
```

Arguments

<code>x</code>	a numeric vector or univariate time series.
<code>lshort</code>	a logical indicating whether the short or long version of the truncation lag parameter is used.

Details

The general regression equation which incorporates a constant and a linear trend is used and the corrected t-statistic for a first order autoregressive coefficient equals one is computed. To estimate σ^2 the Newey-West estimator is used. If `lshort` is TRUE, then the truncation lag parameter is set to `trunc(4*(n/100)^0.25)`, otherwise `trunc(12*(n/100)^0.25)` is used. The p-values are interpolated from Table 4.2, page 103 of Banerjee *et al.* (1993).

Missing values are not handled.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value of the test statistic.
<code>parameter</code>	the truncation lag parameter.
<code>p.value</code>	the p-value of the test.
<code>method</code>	a character string indicating what type of test was performed.
<code>data.name</code>	a character string giving the name of the data.

ppoints

Ordinates for Probability Plotting

Description

Generates the sequence of probability points $(1:m - a) / (m + (1-a) - a)$ where m is either n , if $\text{length}(n) == 1$, or $\text{length}(n)$.

Usage

```
ppoints(n, a = ifelse(n <= 10, 3/8, 1/2))
```

Arguments

n either the number of points generated or a vector of observations.
 a the offset fraction to be used; typically in $(0, 1)$.

Details

If $0 < a < 1$, the resulting values are within $(0, 1)$ (excluding boundaries). In any case, the resulting sequence is symmetric in $[0, 1]$, i.e., $p + \text{rev}(p) == 1$.

`ppoints()` is used in `qqplot` and `qqnorm` to generate the set of probabilities at which to evaluate the inverse distribution.

The choice of a follows the documentation of the function of the same name in Becker *et al* (1988), and appears to have been motivated by results from Blom (1958) on approximations to expected normal order statistics (see also [quantile](#)).

ppr

*Projection Pursuit Regression***Description**

Fit a projection pursuit regression model.

Usage

```
ppr(x, ...)

## S3 method for class 'formula':
ppr(formula, data, weights, subset, na.action,
     contrasts = NULL, ..., model = FALSE)

## Default S3 method:
ppr(x, y, weights = rep(1,n),
     ww = rep(1,q), nterms, max.terms = nterms, optlevel = 2,
     sm.method = c("supsmu", "spline", "gcv spline"),
     bass = 0, span = 0, df = 5, gcvpen = 1, ...)
```

Arguments

formula	a formula specifying one or more numeric response variables and the explanatory variables.
x	numeric matrix of explanatory variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
y	numeric matrix of response variables. Rows represent observations, and columns represent variables. Missing values are not accepted.
nterms	number of terms to include in the final model.
data	a data frame (or similar: see model.frame) from which variables specified in formula are preferentially to be taken.
weights	a vector of weights w_i for each <i>case</i> .
ww	a vector of weights for each <i>response</i> , so the fit criterion is the sum over case i and responses j of $w_i w_j (y_{ij} - \text{fit}_{ij})^2$ divided by the sum of w_i .
subset	an index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
na.action	a function to specify the action to be taken if NAs are found. The default action is given by <code>getOption("na.action")</code> . (NOTE: If given, this argument must be named.)
contrasts	the contrasts to be used when any factor explanatory variables are coded.
max.terms	maximum number of terms to choose from when building the model.

<code>optlevel</code>	integer from 0 to 3 which determines the thoroughness of an optimization routine in the SMART program. See the 'Details' section.
<code>sm.method</code>	the method used for smoothing the ridge functions. The default is to use Friedman's super smoother <code>supsmu</code> . The alternatives are to use the smoothing spline code underlying <code>smooth.spline</code> , either with a specified (equivalent) degrees of freedom for each ridge functions, or to allow the smoothness to be chosen by GCV.
<code>bass</code>	super smoother bass tone control used with automatic span selection (see <code>supsmu</code>); the range of values is 0 to 10, with larger values resulting in increased smoothing.
<code>span</code>	super smoother span control (see <code>supsmu</code>). The default, 0, results in automatic span selection by local cross validation. <code>span</code> can also take a value in $(0, 1]$.
<code>df</code>	if <code>sm.method</code> is "spline" specifies the smoothness of each ridge term via the requested equivalent degrees of freedom.
<code>gcvpen</code>	if <code>sm.method</code> is "gcv spline" this is the penalty used in the GCV selection for each degree of freedom used.
<code>...</code>	arguments to be passed to or from other methods.
<code>model</code>	logical. If true, the model frame is returned.

Details

The basic method is given by Friedman (1984), and is essentially the same code used by S-PLUS's `ppreg`. This code is extremely sensitive to the compiler used.

The algorithm first adds up to `max.terms` ridge terms one at a time; it will use less if it is unable to find a term to add that makes sufficient difference. It then removes the least important term at each step until `nterms` terms are left.

The levels of optimization (argument `optlevel`) differ in how thoroughly the models are refitted during this process. At level 0 the existing ridge terms are not refitted. At level 1 the projection directions are not refitted, but the ridge functions and the regression coefficients are. Levels 2 and 3 refit all the terms and are equivalent for one response; level 3 is more careful to re-balance the contributions from each regressor at each step and so is a little less likely to converge to a saddle point of the sum of squares criterion.

Value

A list with the following components, many of which are for use by the method functions.

<code>call</code>	the matched call
<code>p</code>	the number of explanatory variables (after any coding)
<code>q</code>	the number of response variables
<code>mu</code>	the argument <code>nterms</code>
<code>ml</code>	the argument <code>max.terms</code>
<code>gof</code>	the overall residual (weighted) sum of squares for the selected model
<code>gofn</code>	the overall residual (weighted) sum of squares against the number of terms, up to <code>max.terms</code> . Will be invalid (and zero) for less than <code>nterms</code> .
<code>df</code>	the argument <code>df</code>
<code>edf</code>	if <code>sm.method</code> is "spline" or "gcv spline" the equivalent number of degrees of freedom for each ridge term used.

xnames	the names of the explanatory variables
yname	the names of the response variables
alpha	a matrix of the projection directions, with a column for each ridge term
beta	a matrix of the coefficients applied for each response to the ridge terms: the rows are the responses and the columns the ridge terms
yb	the weighted means of each response
ys	the overall scale factor used: internally the responses are divided by ys to have unit total weighted sum of squares.
fitted.values	the fitted values, as a matrix if $q > 1$.
residuals	the residuals, as a matrix if $q > 1$.
smod	internal work array, which includes the ridge functions evaluated at the training set points.
model	(only if model=TRUE) the model frame.

prcomp

*Principal Components Analysis***Description**

Performs a principal components analysis on the given data matrix and returns the results as an object of class `prcomp`.

Usage

```
prcomp(x, ...)

## S3 method for class 'formula':
prcomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
prcomp(x, retx = TRUE, center = TRUE, scale. = FALSE,
       tol = NULL, ...)

## S3 method for class 'prcomp':
predict(object, newdata, ...)
```

Arguments

<code>formula</code>	a formula with no response variable, referring only to numeric variables.
<code>data</code>	an optional data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector used to select rows (observations) of the data matrix <code>x</code> .
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The 'factory-fresh' default is <code>na.omit</code> .
<code>...</code>	arguments passed to or from other methods. If <code>x</code> is a formula one might specify <code>scale.</code> or <code>tol</code> .
<code>x</code>	a numeric or complex matrix (or data frame) which provides the data for the principal components analysis.

<code>retx</code>	a logical value indicating whether the rotated variables should be returned.
<code>center</code>	a logical value indicating whether the variables should be shifted to be zero centered. Alternately, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .
<code>scale.</code>	a logical value indicating whether the variables should be scaled to have unit variance before the analysis takes place. The default is <code>FALSE</code> for consistency with <code>S</code> , but in general scaling is advisable. Alternatively, a vector of length equal the number of columns of <code>x</code> can be supplied. The value is passed to <code>scale</code> .
<code>tol</code>	a value indicating the magnitude below which components should be omitted. (Components are omitted if their standard deviations are less than or equal to <code>tol</code> times the standard deviation of the first component.) With the default null setting, no components are omitted. Other settings for <code>tol</code> could be <code>tol = 0</code> or <code>tol = sqrt(.Machine\$double.eps)</code> , which would omit essentially constant components.
<code>object</code>	Object of class inheriting from <code>"prcomp"</code>
<code>newdata</code>	An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, <code>newdata</code> must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

The calculation is done by a singular value decomposition of the (centered and possibly scaled) data matrix, not by using `eigen` on the covariance matrix. This is generally the preferred method for numerical accuracy. The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot.

Note that `scale = TRUE` cannot be used if there are zero or constant (for `center = TRUE`) variables.

Value

`prcomp` returns a list with class `"prcomp"` containing the following components:

<code>sdev</code>	the standard deviations of the principal components (i.e., the square roots of the eigenvalues of the covariance/correlation matrix, though the calculation is actually done with the singular values of the data matrix).
<code>rotation</code>	the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). The function <code>princomp</code> returns this in the element <code>loadings</code> .
<code>x</code>	if <code>retx</code> is true the value of the rotated data (the centred (and scaled if requested) data multiplied by the <code>rotation</code> matrix) is returned. Hence, <code>cov(x)</code> is the diagonal matrix <code>diag(sdev^2)</code> . For the formula method, <code>na.predict</code> is applied to handle the treatment of values omitted by the <code>na.action</code> .
<code>center, scale</code>	the centering and scaling used, or <code>FALSE</code> .

Note

The signs of the columns of the rotation matrix are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

predict

Model Predictions

Description

`predict` is a generic function for predictions from the results of various model fitting functions. The function invokes particular *methods* which depend on the `class` of the first argument.

Usage

```
predict(object, ...)
```

Arguments

`object` a model object for which prediction is desired.

`...` additional arguments affecting the predictions produced.

Details

Most prediction methods which similar to fitting linear models have an argument `newdata` specifying the first place to look for explanatory variables to be used for prediction. Some considerable attempts are made to match up the columns in `newdata` to those used for fitting, for example that they are of comparable types and that any factors have the same level set in the same order (or can be transformed to be so).

Time series prediction methods in package `stats` have an argument `n.ahead` specifying how many time steps ahead to predict.

Many methods have a logical argument `se.fit` saying if standard errors are to returned.

Value

The form of the value returned by `predict` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

`predict.princomp`, `predict.smooth.spline`.

For time-series prediction, `predict.ar`, `predict.Arima`, `predict.arima0`,
`predict.HoltWinters`, `predict.StructTS`.

Examples

```
require(utils)

## All the "predict" methods found
## NB most of the methods in the standard packages are hidden.
for(fn in methods("predict"))
  try({
    f <- eval(substitute(getAnywhere(fn)$objs[[1]], list(fn = fn)))
    cat(fn, "\n\t", deparse(args(f)), "\n")
  }, silent = TRUE)
```

predict.Arima	<i>Forecast from ARIMA fits</i>
---------------	---------------------------------

Description

Forecast from models fitted by `arima`.

Usage

```
## S3 method for class 'Arima':
predict(object, n.ahead = 1, newxreg = NULL,
        se.fit = TRUE, ...)
```

Arguments

<code>object</code>	The result of an <code>arima</code> fit.
<code>n.ahead</code>	The number of steps ahead for which prediction is required.
<code>newxreg</code>	New values of <code>xreg</code> to be used for prediction. Must have at least <code>n.ahead</code> rows.
<code>se.fit</code>	Logical: should standard errors of prediction be returned?
<code>...</code>	arguments passed to or from other methods.

Details

Finite-history prediction is used, via `KalmanForecast`. This is only statistically efficient if the MA part of the fit is invertible, so `predict.Arima` will give a warning for non-invertible MA models.

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients. According to Harvey (1993, pp. 58–9) the effect is small.

Value

A time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

predict(fit, n.ahead = 6)
```

predict.glm

Predict Method for GLM Fits

Description

Obtains predictions and optionally estimates standard errors of those predictions from a fitted generalized linear model object.

Usage

```
## S3 method for class 'glm':
predict(object, newdata = NULL,
        type = c("link", "response", "terms"),
        se.fit = FALSE, dispersion = NULL, terms = NULL,
        na.action = na.pass, ...)
```

Arguments

<code>object</code>	a fitted object of class inheriting from "glm".
<code>newdata</code>	optionally, a data frame in which to look for variables with which to predict. If omitted, the fitted linear predictors are used.
<code>type</code>	the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and <code>type = "response"</code> gives the predicted probabilities. The "terms" option returns a matrix giving the fitted values of each term in the model formula on the linear predictor scale. The value of this argument can be abbreviated.
<code>se.fit</code>	logical switch indicating if standard errors are required.
<code>dispersion</code>	the dispersion of the GLM fit to be assumed in computing the standard errors. If omitted, that returned by <code>summary</code> applied to the object is used.
<code>terms</code>	with <code>type="terms"</code> by default all terms are returned. A character vector specifies which terms are to be returned
<code>na.action</code>	function determining what should be done with missing values in <code>newdata</code> . The default is to predict NA.
<code>...</code>	further arguments passed to or from other methods.

Details

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear (in predictions and standard errors), with residual value NA. See also [napredict](#).

Value

If `se = FALSE`, a vector or matrix of predictions. If `se = TRUE`, a list with components

<code>fit</code>	Predictions
<code>se.fit</code>	Estimated standard errors
<code>residual.scale</code>	A scalar giving the square root of the dispersion used in computing the standard errors.

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

```

```
predict.HoltWinters
```

prediction function for fitted Holt-Winters models

Description

Computes predictions and prediction intervals for models fitted by the Holt-Winters method.

Usage

```
## S3 method for class 'HoltWinters':
predict(object, n.ahead=1, prediction.interval = FALSE,
        level = 0.95, ...)
```

Arguments

<code>object</code>	An object of class <code>HoltWinters</code> .
<code>n.ahead</code>	Number of future periods to predict.
<code>prediction.interval</code>	logical. If <code>TRUE</code> , the lower and upper bounds of the corresponding prediction intervals are computed.
<code>level</code>	Confidence level for the prediction interval.
<code>...</code>	arguments passed to or from other methods.

Value

A time series of the predicted values. If prediction intervals are requested, a multiple time series is returned with columns `fit`, `lwr` and `upr` for the predicted values and the lower and upper bounds respectively.

predict.lm

Predict method for Linear Model Fits

Description

Predicted values based on linear model object.

Usage

```
## S3 method for class 'lm':
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
        interval = c("none", "confidence", "prediction"),
        level = 0.95, type = c("response", "terms"),
        terms = NULL, na.action = na.pass,
        pred.var = res.var/weights, weights = 1, ...)
```

Arguments

object	Object of class inheriting from "lm"
newdata	An optional data frame in which to look for variables with which to predict. If omitted, the fitted values are used.
se.fit	A switch indicating if standard errors are required.
scale	Scale parameter for std.err. calculation
df	Degrees of freedom for scale
interval	Type of interval calculation.
level	Tolerance/confidence level
type	Type of prediction (response or model term).

terms	If <code>type="terms"</code> , which terms (default is all terms)
na.action	function determining what should be done with missing values in <code>newdata</code> . The default is to predict NA.
pred.var	the variance(s) for future observations to be assumed for prediction intervals. See 'Details'.
weights	variance weights for prediction. This can be a numeric vector or a one-sided model formula. In the latter case, it is interpreted as an expression evaluated in <code>newdata</code>
...	further arguments passed to or from other methods.

Details

`predict.lm` produces predicted values, obtained by evaluating the regression function in the frame `newdata` (which defaults to `model.frame(object)`). If the logical `se.fit` is TRUE, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `intervals` specifies computation of confidence or prediction (tolerance) intervals at the specified `level`, sometimes referred to as narrow vs. wide intervals.

If the fit is rank-deficient, some of the columns of the design matrix will have been dropped. Prediction from such a fit only makes sense if `newdata` is contained in the same subspace as the original data. That cannot be checked accurately, so a warning is issued.

If `newdata` is omitted the predictions are based on the data used for the fit. In that case how cases with missing values in the original fit is determined by the `na.action` argument of that fit. If `na.action = na.omit` omitted cases will not appear in the residuals, whereas if `na.action = na.exclude` they will appear (in predictions, standard errors or interval limits), with residual value NA. See also `napredict`.

The prediction intervals are for a single observation at each case in `newdata` (or by default, the data used for the fit) with error variance(s) `pred.var`. This can be a multiple of `res.var`, the estimated value of σ^2 : the default is to assume that future observations have the same error variance as those used for fitting. If `weights` is supplied, the inverse of this is used as a scale factor. For a weighted fit, if the prediction is for the original data frame, `weights` defaults to the weights used for the model fit, with a warning since it might not be the intended result. If the fit was weighted and `newdata` is given, the default is to assume constant prediction variance, with a warning.

Value

`predict.lm` produces a vector of predictions or a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr` if `interval` is set. If `se.fit` is TRUE, a list with the following components is returned:

fit	vector or matrix as above
se.fit	standard error of predicted means
residual.scale	residual standard deviations
df	degrees of freedom for residual

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Offsets specified by `offset` in the fit by `lm` will not be included in predictions, whereas those specified by an offset term in the formula will be.

Notice that prediction variances and prediction intervals always refer to *future* observations, possibly corresponding to the same predictors as used for the fit. The variance of the *residuals* will be smaller.

Strictly speaking, the formula used for prediction limits assumes that the degrees of freedom for the fit are the same as those for the residual variance. This may not be the case if `res.var` is not obtained from the fit.

The model fitting function `lm`, `predict`, `SafePrediction`

Examples

```
require(graphics)

## Predictions
x <- rnorm(15)
y <- x + rnorm(15)
predict(lm(y ~ x))
new <- data.frame(x = seq(-3, 3, 0.5))
predict(lm(y ~ x), new, se.fit = TRUE)
pred.w.plim <- predict(lm(y ~ x), new, interval="prediction")
pred.w.clim <- predict(lm(y ~ x), new, interval="confidence")
matplot(new$x, cbind(pred.w.clim, pred.w.plim[, -1]),
        lty=c(1,2,2,3,3), type="l", ylab="predicted y")

## Prediction intervals, special cases
## The first three of these throw warnings
w <- 1 + x^2
fit <- lm(y ~ x)
wfit <- lm(y ~ x, weights = w)
predict(fit, interval = "prediction")
predict(wfit, interval = "prediction")
predict(wfit, new, interval = "prediction")
predict(wfit, new, interval = "prediction", weights = (new$x)^2)
predict(wfit, new, interval = "prediction", weights = ~x^2)
```

predict.loess

Predict Loess Curve or Surface

Description

Predictions from a `loess` fit, optionally with standard errors.

Usage

```
## S3 method for class 'loess':  
predict(object, newdata = NULL, se = FALSE, ...)
```

Arguments

<code>object</code>	an object fitted by <code>loess</code> .
<code>newdata</code>	an optional data frame in which to look for variables with which to predict, or a matrix or vector containing exactly the variables needed for prediction. If missing, the original data points are used.
<code>se</code>	should standard errors be computed?
<code>...</code>	arguments passed to or from other methods.

Details

The standard errors calculation is slower than prediction.

When the fit was made using `surface="interpolate"` (the default), `predict.loess` will not extrapolate – so points outside an axis-aligned hypercube enclosing the original data will have missing (NA) predictions and standard errors.

Value

If `se = FALSE`, a vector giving the prediction for each row of `newdata` (or the original data). If `se = TRUE`, a list containing components

<code>fit</code>	the predicted values.
<code>se</code>	an estimated standard error for each predicted value.
<code>residual.scale</code>	the estimated scale of the residuals used in computing the standard errors.
<code>df</code>	an estimate of the effective degrees of freedom used in estimating the residual scale, intended for use with t-based confidence intervals.

If `newdata` was the result of a call to `expand.grid`, the predictions (and s.e.'s if requested) will be an array of the appropriate dimensions.

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

Author(s)

B. D. Ripley, based on the `cloess` package of Cleveland, Grosse and Shyu.

  control=loess.control(surface="direct"))
predict(cars.lo2, data.frame(speed=seq(5, 30, 1)), se=TRUE)
```

 predict.nls

Predicting from Nonlinear Least Squares Fits

Description

`predict.nls` produces predicted values, obtained by evaluating the regression function in the frame `newdata`. If the logical `se.fit` is `TRUE`, standard errors of the predictions are calculated. If the numeric argument `scale` is set (with optional `df`), it is used as the residual standard deviation in the computation of the standard errors, otherwise this is extracted from the model fit. Setting `interval` specifies computation of confidence or prediction (tolerance) intervals at the specified level.

At present `se.fit` and `interval` are ignored.

Usage

```
## S3 method for class 'nls':
predict(object, newdata, se.fit = FALSE, scale = NULL, df = Inf,
  interval = c("none", "confidence", "prediction"),
  level = 0.95, ...)
```

Arguments

<code>object</code>	An object that inherits from class <code>nls</code> .
<code>newdata</code>	A named list or data frame in which to look for variables with which to predict. If <code>newdata</code> is missing the fitted values at the original data points are returned.
<code>se.fit</code>	A logical value indicating if the standard errors of the predictions should be calculated. Defaults to <code>FALSE</code> . At present this argument is ignored.
<code>scale</code>	A numeric scalar. If it is set (with optional <code>df</code>), it is used as the residual standard deviation in the computation of the standard errors, otherwise this information is extracted from the model fit. At present this argument is ignored.
<code>df</code>	A positive numeric scalar giving the number of degrees of freedom for the <code>scale</code> estimate. At present this argument is ignored.
<code>interval</code>	A character string indicating if prediction intervals or a confidence interval on the mean responses are to be calculated. At present this argument is ignored.
<code>level</code>	A numeric scalar between 0 and 1 giving the confidence level for the intervals (if any) to be calculated. At present this argument is ignored.
<code>...</code>	Additional optional arguments. At present no optional arguments are used.

Value

`predict.nls` produces a vector of predictions. When implemented, `interval` will produce a matrix of predictions and bounds with column names `fit`, `lwr`, and `upr`. When implemented, if `se.fit` is TRUE, a list with the following components will be returned:

<code>fit</code>	vector or matrix as above
<code>se.fit</code>	standard error of predictions
<code>residual.scale</code>	residual standard deviations
<code>df</code>	degrees of freedom for residual

Note

Variables are first looked for in `newdata` and then searched for in the usual way (which will include the environment of the formula used in the fit). A warning will be given if the variables found are not of the same length as those in `newdata` if it was supplied.

par(opar)
```

```
predict.smooth.spline
Predict from Smoothing Spline Fit
```

Description

Predict a smoothing spline fit at new points, return the derivative if desired. The predicted fit is linear beyond the original data.

Usage

```
## S3 method for class 'smooth.spline':
predict(object, x, deriv = 0, ...)
```

Arguments

object	a fit from smooth.spline.
x	the new values of x.
deriv	integer; the order of the derivative required.
...	further arguments passed to or from other methods.

Value

A list with components

x	The input x.
y	The fitted values or derivatives at x.

  abline(h=0, lty = 3, col = "gray")
}
detach(); par(op)
```

`preplot`*Pre-computations for a Plotting Object*

Description

Compute an object to be used for plots relating to the given model object.

Usage

```
preplot(object, ...)
```

Arguments

`object` a fitted model object.
`...` additional arguments for specific methods.

Details

Only the generic function is currently provided in base R, but some add-on packages have methods. Principally here for S compatibility.

Value

An object set up to make a plot that describes `object`.

`princomp`*Principal Components Analysis*

Description

`princomp` performs a principal components analysis on the given numeric data matrix and returns the results as an object of class `princomp`.

Usage

```
princomp(x, ...)

## S3 method for class 'formula':
princomp(formula, data = NULL, subset, na.action, ...)

## Default S3 method:
princomp(x, cor = FALSE, scores = TRUE, covmat = NULL,
         subset = rep(TRUE, nrow(as.matrix(x))), ...)

## S3 method for class 'princomp':
predict(object, newdata, ...)
```

Arguments

<code>formula</code>	a formula with no response variable, referring only to numeric variables.
<code>data</code>	an optional data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector used to select rows (observations) of the data matrix <code>x</code> .
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. The default is set by the <code>na.action</code> setting of <code>options</code> , and is <code>na.fail</code> if that is unset. The 'factory-fresh' default is <code>na.omit</code> .
<code>x</code>	a numeric matrix or data frame which provides the data for the principal components analysis.
<code>cor</code>	a logical value indicating whether the calculation should use the correlation matrix or the covariance matrix. (The correlation matrix can only be used if there are no constant variables.)
<code>scores</code>	a logical value indicating whether the score on each principal component should be calculated.
<code>covmat</code>	a covariance matrix, or a covariance list as returned by <code>cov.wt</code> (and <code>cov.mve</code> or <code>cov.mcd</code> from package MASS). If supplied, this is used rather than the covariance matrix of <code>x</code> .
<code>...</code>	arguments passed to or from other methods. If <code>x</code> is a formula one might specify <code>cor</code> or <code>scores</code> .
<code>object</code>	Object of class inheriting from <code>"princomp"</code>
<code>newdata</code>	An optional data frame or matrix in which to look for variables with which to predict. If omitted, the scores are used. If the original fit used a formula or a data frame or a matrix with column names, <code>newdata</code> must contain columns with the same names. Otherwise it must contain the same number of columns, to be used in the same order.

Details

`princomp` is a generic function with `"formula"` and `"default"` methods.

The calculation is done using `eigen` on the correlation or covariance matrix, as determined by `cor`. This is done for compatibility with the S-PLUS result. A preferred method of calculation is to use `svd` on `x`, as is done in `prcomp`.

Note that the default calculation uses divisor `N` for the covariance matrix.

The `print` method for these objects prints the results in a nice format and the `plot` method produces a scree plot (`screepplot`). There is also a `biplot` method.

If `x` is a formula then the standard NA-handling is applied to the scores (if requested): see `napredict`.

`princomp` only handles so-called R-mode PCA, that is feature extraction of variables. If a data matrix is supplied (possibly via a formula) it is required that there are at least as many units as variables. For Q-mode PCA use `prcomp`.

Value

`princomp` returns a list with class `"princomp"` containing the following components:

`sdev` the standard deviations of the principal components.

loadings	the matrix of variable loadings (i.e., a matrix whose columns contain the eigenvectors). This is of class "loadings": see loadings for its print method.
center	the means that were subtracted.
scale	the scalings applied to each variable.
n.obs	the number of observations.
scores	if <code>scores = TRUE</code> , the scores of the supplied data on the principal components. These are non-null only if <code>x</code> was supplied, and if <code>covmat</code> was also supplied if it was a covariance list. For the formula method, <code>napredict</code> is applied to handle the treatment of values omitted by the <code>na.action</code> .
call	the matched call.
na.action	If relevant.

Note

The signs of the columns of the loadings and scores are arbitrary, and so may differ between different programs for PCA, and even between different builds of R.

```

`print.power.htest` *Print method for power calculation object*

Description

Print object of class "power.htest" in nice layout.

Usage

```
## S3 method for class 'power.htest':  
print(x, ...)
```

Arguments

`x` Object of class "power.htest".
`...` further arguments to be passed to or from methods.

Details

A `power.htest` object is just a named list of numbers and character strings, supplemented with `method` and `note` elements. The `method` is displayed as a title, the `note` as a footnote, and the remaining elements are given in an aligned 'name = value' format.

Value

none

```

printCoefmat

Print Coefficient Matrices

Description

Utility function to be used in higher-level [print](#) methods, such as [print.summary.lm](#), [print.summary.glm](#) and [print.anova](#). The goal is to provide a flexible interface with smart defaults such that often, only x needs to be specified.

Usage

```
printCoefmat(x, digits=max(3, getOption("digits") - 2),
             signif.stars = getOption("show.signif.stars"),
             signif.legend = signif.stars,
             dig.tst = max(1, min(5, digits - 1)),
             cs.ind = 1:k, tst.ind = k + 1, zap.ind = integer(0),
             P.values = NULL,
             has.Pvalue = nc >= 4 &&
               substr(colnames(x)[nc], 1, 3) == "Pr(",
             eps.Pvalue = .Machine$double.eps,
             na.print = "NA", ...)
```

Arguments

x	a numeric matrix like object, to be printed.
digits	minimum number of significant digits to be used for most numbers.
signif.stars	logical; if TRUE, P-values are additionally encoded visually as ‘significance stars’ in order to help scanning of long coefficient tables. It defaults to the show.signif.stars slot of options .

<code>signif.legend</code>	logical; if TRUE, a legend for the ‘significance stars’ is printed provided <code>signif.stars=TRUE</code> .
<code>dig.tst</code>	minimum number of significant digits for the test statistics, see <code>tst.ind</code> .
<code>cs.ind</code>	indices (integer) of column numbers which are (like) coefficients and standard errors to be formatted together.
<code>tst.ind</code>	indices (integer) of column numbers for test statistics.
<code>zap.ind</code>	indices (integer) of column numbers which should be formatted by <code>zapsmall</code> , i.e., by ‘zapping’ values close to 0.
<code>P.values</code>	logical or NULL; if TRUE, the last column of <code>x</code> is formatted by <code>format.pval</code> as P values. If <code>P.values = NULL</code> , the default, it is set to TRUE only if <code>options("show.coef.Pvalue")</code> is TRUE <i>and</i> <code>x</code> has at least 4 columns <i>and</i> the last column name of <code>x</code> starts with "Pr (".
<code>has.Pvalue</code>	logical; if TRUE, the last column of <code>x</code> contains P values; in that case, it is printed if and only if <code>P.values</code> (above) is true.
<code>eps.Pvalue</code>	number, ..
<code>na.print</code>	a character string to code NA values in printed output.
<code>...</code>	further arguments for <code>print</code> .

Value

Invisibly returns its argument, `x`.

profile	<i>Generic Function for Profiling Models</i>
---------	--

Description

Investigates behavior of objective function near the solution represented by `fitted`.
See documentation on method functions for further details.

Usage

```
profile(fitted, ...)
```

Arguments

<code>fitted</code>	the original fitted model object.
<code>...</code>	additional parameters. See documentation on individual methods.

Value

A list with an element for each parameter being profiled. See the individual methods for further details.

See Also

[profile.nls](#), [profile.glm](#) in package **MASS**, ...

For profiling R code, see [Rprof](#).

profile.nls	<i>Method for Profiling nls Objects</i>
-------------	---

Description

Investigates the profile log-likelihood function for a fitted model of class "nls".

Usage

```
## S3 method for class 'nls':
profile(fitted, which = 1:npar, maxpts = 100, alphamax = 0.01,
        delta.t = cutoff/5, ...)
```

Arguments

<code>fitted</code>	the original fitted model object.
<code>which</code>	the original model parameters which should be profiled. This can be a numeric or character vector. By default, all non-linear parameters are profiled.
<code>maxpts</code>	maximum number of points to be used for profiling each parameter.
<code>alphamax</code>	highest significance level allowed for the profile t-statistics.
<code>delta.t</code>	suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
<code>...</code>	further arguments passed to or from other methods.

Details

The profile t-statistics is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list with an element for each parameter being profiled. The elements are data-frames with two variables

`par.vals` a matrix of parameter values for each fitted model.
`tau` the profile t-statistics.

```

proj

Projections of Models

Description

`proj` returns a matrix or list of matrices giving the projections of the data onto the terms of a linear model. It is most frequently used for [aov](#) models.

Usage

```
proj(object, ...)
```

S3 method for class 'aov':

```
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

S3 method for class 'aovlist':

```
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)

## Default S3 method:
proj(object, onedf = TRUE, ...)

## S3 method for class 'lm':
proj(object, onedf = FALSE, unweighted.scale = FALSE, ...)
```

Arguments

<code>object</code>	An object of class "lm" or a class inheriting from it, or an object with a similar structure including in particular components <code>qr</code> and <code>effects</code> .
<code>onedf</code>	A logical flag. If <code>TRUE</code> , a projection is returned for all the columns of the model matrix. If <code>FALSE</code> , the single-column projections are collapsed by terms of the model (as represented in the analysis of variance table).
<code>unweighted.scale</code>	If the fit producing <code>object</code> used weights, this determines if the projections correspond to weighted or unweighted observations.
<code>...</code>	Swallow and ignore any other arguments.

Details

A projection is given for each stratum of the object, so for `aov` models with an `Error` term the result is a list of projections.

Value

A projection matrix or (for multi-stratum objects) a list of projection matrices.

Each projection is a matrix with a row for each observations and either a column for each term (`onedf = FALSE`) or for each coefficient (`onedf = TRUE`). Projection matrices from the default method have orthogonal columns representing the projection of the response onto the column space of the `Q` matrix from the QR decomposition. The fitted values are the sum of the projections, and the sum of squares for each column is the reduction in sum of squares from fitting that column (after those to the left of it).

The methods for `lm` and `aov` models add a column to the projection matrix giving the residuals (the projection of the data onto the orthogonal complement of the model space).

Strictly, when `onedf = FALSE` the result is not a projection, but the columns represent sums of projections onto the columns of the model matrix corresponding to that term. In this case the matrix does not depend on the coding used.

Author(s)

The design was inspired by the `S` function of the same name described in Chambers *et al.* (1992).

```

prop.test

Test of Equal or Given Proportions

Description

prop.test can be used for testing the null that the proportions (probabilities of success) in several groups are the same, or that they equal certain given values.

Usage

```

prop.test(x, n, p = NULL,
          alternative = c("two.sided", "less", "greater"),
          conf.level = 0.95, correct = TRUE)

```

Arguments

x	a vector of counts of successes or a matrix with 2 columns giving the counts of successes and failures, respectively.
n	a vector of counts of trials; ignored if x is a matrix.
p	a vector of probabilities of success. The length of p must be the same as the number of groups specified by x, and its elements must be greater than 0 and less than 1.
alternative	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter. Only used for testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.
conf.level	confidence level of the returned confidence interval. Must be a single number between 0 and 1. Only used when testing the null that a single proportion equals a given value, or that two proportions are equal; ignored otherwise.
correct	a logical indicating whether Yates' continuity correction should be applied.

Details

Only groups with finite numbers of successes and failures are used. Counts of successes and failures must be nonnegative and hence not greater than the corresponding numbers of trials which must be positive. All finite counts should be integers.

If `p` is `NULL` and there is more than one group, the null tested is that the proportions in each group are the same. If there are two groups, the alternatives are that the probability of success in the first group is less than, not equal to, or greater than the probability of success in the second group, as specified by `alternative`. A confidence interval for the difference of proportions with confidence level as specified by `conf.level` and clipped to $[-1, 1]$ is returned. Continuity correction is used only if it does not exceed the difference of the sample proportions in absolute value. Otherwise, if there are more than 2 groups, the alternative is always `"two.sided"`, the returned confidence interval is `NULL`, and continuity correction is never used.

If there is only one group, then the null tested is that the underlying probability of success is `p`, or `.5` if `p` is not given. The alternative is that the probability of success is less than, not equal to, or greater than `p` or `0.5`, respectively, as specified by `alternative`. A confidence interval for the underlying proportion with confidence level as specified by `conf.level` and clipped to $[0, 1]$ is returned. Continuity correction is used only if it does not exceed the difference between sample and null proportions in absolute value. The confidence interval is computed by inverting the score test.

Finally, if `p` is given and there are more than 2 groups, the null tested is that the underlying probabilities of success are those given by `p`. The alternative is always `"two.sided"`, the returned confidence interval is `NULL`, and continuity correction is never used.

Value

A list with class `"htest"` containing the following components:

<code>statistic</code>	the value of Pearson's chi-squared test statistic.
<code>parameter</code>	the degrees of freedom of the approximate chi-squared distribution of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>estimate</code>	a vector with the sample proportions x/n .
<code>conf.int</code>	a confidence interval for the true proportion if there is one group, or for the difference in proportions if there are 2 groups and <code>p</code> is not given, or <code>NULL</code> otherwise. In the cases where it is not <code>NULL</code> , the returned confidence interval has an asymptotic confidence level as specified by <code>conf.level</code> , and is appropriate to the specified alternative hypothesis.
<code>null.value</code>	the value of <code>p</code> if specified by the null, or <code>NULL</code> otherwise.
<code>alternative</code>	a character string describing the alternative.
<code>method</code>	a character string indicating the method used, and whether Yates' continuity correction was applied.
<code>data.name</code>	a character string giving the names of the data.

Examples

```
heads <- rbinom(1, size=100, prob = .5)
prop.test(heads, 100)          # continuity correction TRUE by default
prop.test(heads, 100, correct = FALSE)

## Data from Fleiss (1981), p. 139.
## H0: The null hypothesis is that the four populations from which
##     the patients were drawn have the same true proportion of smokers.
## A:  The alternative is that this proportion is different in at
##     least one of the populations.

smokers <- c( 83, 90, 129, 70 )
patients <- c( 86, 93, 136, 82 )
prop.test(smokers, patients)
```

prop.trend.test *Test for trend in proportions*

Description

Performs chi-squared test for trend in proportions, i.e., a test asymptotically optimal for local alternatives where the log odds vary in proportion with score. By default, score is chosen as the group numbers.

Usage

```
prop.trend.test(x, n, score = 1:length(x))
```

Arguments

x	Number of events
n	Number of trials
score	Group score

Value

An object of class "htest" with title, test statistic, p-value, etc.

Note

This really should get integrated with `prop.test`

qqnorm

*Quantile-Quantile Plots***Description**

qqnorm is a generic function the default method of which produces a normal QQ plot of the values in *y*. qqline adds a line to a normal quantile-quantile plot which passes through the first and third quartiles.

qqplot produces a QQ plot of two datasets.

Graphical parameters may be given as arguments to qqnorm, qqplot and qqline.

Usage

```
qqnorm(y, ...)
## Default S3 method:
qqnorm(y, ylim, main = "Normal Q-Q Plot",
       xlab = "Theoretical Quantiles", ylab = "Sample Quantiles",
       plot.it = TRUE, datax = FALSE, ...)

qqline(y, datax = FALSE, ...)

qqplot(x, y, plot.it = TRUE, xlab = deparse(substitute(x)),
       ylab = deparse(substitute(y)), ...)
```

Arguments

<i>x</i>	The first sample for qqplot.
<i>y</i>	The second or only data sample.
<i>xlab</i> , <i>ylab</i> , <i>main</i>	plot labels. The <i>xlab</i> and <i>ylab</i> refer to the y and x axes respectively if <i>datax</i> = TRUE.
<i>plot.it</i>	logical. Should the result be plotted?
<i>datax</i>	logical. Should data values be on the x-axis?
<i>ylim</i> , ...	graphical parameters.

Value

For qqnorm and qqplot, a list with components

<i>x</i>	The x coordinates of the points that were/would be plotted
<i>y</i>	The original <i>y</i> vector, i.e., the corresponding y coordinates <i>including NAs</i> .

[ppoints](#), used by `qqnorm` to generate approximations to expected order statistics for a normal distribution.

Examples

```
require(graphics)

y <- rt(200, df = 5)
qqnorm(y); qqline(y, col = 2)
qqplot(y, rt(300, df = 5))

qqnorm(precip, ylab = "Precipitation [in/yr] for 70 US cities")
```

quade.test

Quade Test

Description

Performs a Quade test with unreplicated blocked data.

Usage

```
quade.test(y, ...)

## Default S3 method:
quade.test(y, groups, blocks, ...)

## S3 method for class 'formula':
quade.test(formula, data, subset, na.action, ...)
```

Arguments

<code>y</code>	either a numeric vector of data values, or a data matrix.
<code>groups</code>	a vector giving the group for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.
<code>blocks</code>	a vector giving the block for the corresponding elements of <code>y</code> if this is a vector; ignored if <code>y</code> is a matrix. If not a factor object, it is coerced to one.
<code>formula</code>	a formula of the form $a \sim b \mid c$, where <code>a</code> , <code>b</code> and <code>c</code> give the data values and corresponding groups and blocks, respectively.
<code>data</code>	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

`quade.test` can be used for analyzing unreplicated complete block designs (i.e., there is exactly one observation in `y` for each combination of levels of `groups` and `blocks`) where the normality assumption may be violated.

The null hypothesis is that apart from an effect of `blocks`, the location parameter of `y` is the same in each of the `groups`.

If `y` is a matrix, `groups` and `blocks` are obtained from the column and row indices, respectively. NA's are not allowed in `groups` or `blocks`; if `y` contains NA's, corresponding blocks are removed.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value of Quade's F statistic.
<code>parameter</code>	a vector with the numerator and denominator degrees of freedom of the approximate F distribution of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>method</code>	the character string "Quade test".
<code>data.name</code>	a character string giving the names of the data.

              list(Store = as.character(1:7),
                  Brand = LETTERS[1:5]))
y
quade.test(y)
```

quantile

*Sample Quantiles***Description**

The generic function `quantile` produces sample quantiles corresponding to the given probabilities. The smallest observation corresponds to a probability of 0 and the largest to a probability of 1.

Usage

```
quantile(x, ...)

## Default S3 method:
quantile(x, probs = seq(0, 1, 0.25), na.rm = FALSE,
         names = TRUE, type = 7, ...)
```

Arguments

<code>x</code>	numeric vectors whose sample quantiles are wanted. Missing values are ignored.
<code>probs</code>	numeric vector of probabilities with values in $[0, 1]$. (As from R 2.8.0 values up to $2e-14$ outside that range are accepted and moved to the nearby endpoint.)
<code>na.rm</code>	logical; if true, any NA and NaN's are removed from <code>x</code> before the quantiles are computed.
<code>names</code>	logical; if true, the result has a <code>names</code> attribute. Set to FALSE for speedup with many <code>probs</code> .
<code>type</code>	an integer between 1 and 9 selecting one of the nine quantile algorithms detailed below to be used.
<code>...</code>	further arguments passed to or from other methods.

Details

A vector of length `length(probs)` is returned; if `names = TRUE`, it has a `names` attribute. NA and NaN values in `probs` are propagated to the result.

Types

`quantile` returns estimates of underlying distribution quantiles based on one or two order statistics from the supplied elements in `x` at probabilities in `probs`. One of the nine quantile algorithms discussed in Hyndman and Fan (1996), selected by `type`, is employed.

Sample quantiles of type i are defined by

$$Q_i(p) = (1 - \gamma)x_j + \gamma x_{j+1}$$

where $1 \leq i \leq 9$, $\frac{j-m}{n} \leq p < \frac{j-m+1}{n}$, x_j is the j th order statistic, n is the sample size, and m is a constant determined by the sample quantile type. Here γ depends on the fractional part of $g = np + m - j$.

For the continuous sample quantile types (4 through 9), the sample quantiles can be obtained by linear interpolation between the k th order statistic and $p(k)$:

$$p(k) = \frac{k - \alpha}{n - \alpha - \beta + 1}$$

where α and β are constants determined by the type. Further, $m = \alpha + p(1 - \alpha - \beta)$, and $\gamma = g$.

Discontinuous sample quantile types 1, 2, and 3

Type 1 Inverse of empirical distribution function.

Type 2 Similar to type 1 but with averaging at discontinuities.

Type 3 SAS definition: nearest even order statistic.

Continuous sample quantile types 4 through 9

Type 4 $p(k) = \frac{k}{n}$. That is, linear interpolation of the empirical cdf.

Type 5 $p(k) = \frac{k-0.5}{n}$. That is a piecewise linear function where the knots are the values midway through the steps of the empirical cdf. This is popular amongst hydrologists.

Type 6 $p(k) = \frac{k}{n+1}$. Thus $p(k) = E[F(x_k)]$. This is used by Minitab and by SPSS.

Type 7 $p(k) = \frac{k-1}{n-1}$. In this case, $p(k) = \text{mode}[F(x_k)]$. This is used by S.

Type 8 $p(k) = \frac{k-\frac{1}{3}}{n+\frac{1}{3}}$. Then $p(k) \approx \text{median}[F(x_k)]$. The resulting quantile estimates are approximately median-unbiased regardless of the distribution of x .

Type 9 $p(k) = \frac{k-\frac{3}{4}}{n+\frac{1}{4}}$. The resulting quantile estimates are approximately unbiased for the expected order statistics if x is normally distributed.

Hyndman and Fan (1996) recommend type 8. The default method is type 7, as used by S and by R < 2.0.0.

r2dtable

*Random 2-way Tables with Given Marginals***Description**

Generate random 2-way tables with given marginals using Patefield's algorithm.

Usage

```
r2dtable(n, r, c)
```

Arguments

n a non-negative numeric giving the number of tables to be drawn.

r a non-negative vector of length at least 2 giving the row totals, to be coerced to integer. Must sum to the same as **c**.

c a non-negative vector of length at least 2 giving the column totals, to be coerced to integer.

Value

A list of length **n** containing the generated tables as its components.

References

Patefield, W. M. (1981) Algorithm AS159. An efficient method of generating $r \times c$ tables with given row and column totals. *Applied Statistics* **30**, 91–97.

Examples

```

## Fisher's Tea Drinker data.
TeaTasting <-
matrix(c(3, 1, 1, 3),
       nrow = 2,
       dimnames = list(Guess = c("Milk", "Tea"),
                       Truth = c("Milk", "Tea")))
## Simulate permutation test for independence based on the maximum
## Pearson residuals (rather than their sum).
rowTotals <- rowSums(TeaTasting)
colTotals <- colSums(TeaTasting)
nOfCases <- sum(rowTotals)

```

```

expected <- outer(rowTotals, colTotals, "*") / nOfCases
maxSqResid <- function(x) max((x - expected) ^ 2 / expected)
simMaxSqResid <-
  sapply(r2dtable(1000, rowTotals, colTotals), maxSqResid)
sum(simMaxSqResid >= maxSqResid(TeaTasting)) / 1000
## Fisher's exact test gives p = 0.4857 ...

```

read.ftable *Manipulate Flat Contingency Tables*

Description

Read, write and coerce ‘flat’ contingency tables.

Usage

```

read.ftable(file, sep = "", quote = "\"",
            row.var.names, col.vars, skip = 0)

write.ftable(x, file = "", quote = TRUE, append = FALSE,
            digits = getOption("digits"))

## S3 method for class 'ftable':
format(x, quote = TRUE, digits = getOption("digits"), ...)

```

Arguments

file	either a character string naming a file or a connection which the data are to be read from or written to. "" indicates input from the console for reading and output to the console for writing.
sep	the field separator string. Values on each line of the file are separated by this string.
quote	a character string giving the set of quoting characters for read.ftable; to disable quoting altogether, use quote="". For write.table, a logical indicating whether strings in the data will be surrounded by double quotes.
row.var.names	a character vector with the names of the row variables, in case these cannot be determined automatically.
col.vars	a list giving the names and levels of the column variables, in case these cannot be determined automatically.
skip	the number of lines of the data file to skip before beginning to read data.
x	an object of class "ftable".
append	logical. If TRUE and file is the name of a file (and not a connection or " cmd"), the output from write.ftable is appended to the file. If FALSE, the contents of file will be overwritten.
digits	an integer giving the number of significant digits to use for (the cell entries of) x.
...	further arguments to be passed to or from methods.

Details

`read.ftable` reads in a flat-like contingency table from a file. If the file contains the written representation of a flat table (more precisely, a header with all information on names and levels of column variables, followed by a line with the names of the row variables), no further arguments are needed. Similarly, flat tables with only one column variable the name of which is the only entry in the first line are handled automatically. Other variants can be dealt with by skipping all header information using `skip`, and providing the names of the row variables and the names and levels of the column variable using `row.var.names` and `col.vars`, respectively. See the examples below.

Note that flat tables are characterized by their ‘ragged’ display of row (and maybe also column) labels. If the full grid of levels of the row variables is given, one should instead use `read.table` to read in the data, and create the contingency table from this using `xtabs`.

`write.ftable` writes a flat table to a file, which is useful for generating ‘pretty’ ASCII representations of contingency tables.

rect.hclust

Draw Rectangles Around Hierarchical Clusters

Description

Draws rectangles around the branches of a dendrogram highlighting the corresponding clusters. First the dendrogram is cut at a certain level, then a rectangle is drawn around selected branches.

Usage

```

rect.hclust(tree, k = NULL, which = NULL, x = NULL, h = NULL,
            border = 2, cluster = NULL)

```

Arguments

<code>tree</code>	an object of the type produced by <code>hclust</code> .
<code>k, h</code>	Scalar. Cut the dendrogram such that either exactly <code>k</code> clusters are produced or by cutting at height <code>h</code> .
<code>which, x</code>	A vector selecting the clusters around which a rectangle should be drawn. <code>which</code> selects clusters by number (from left to right in the tree), <code>x</code> selects clusters containing the respective horizontal coordinates. Default is <code>which = 1:k</code> .
<code>border</code>	Vector with border colors for the rectangles.
<code>cluster</code>	Optional vector with cluster memberships as returned by <code>cutree(hclust.obj, k = k)</code> , can be specified for efficiency if already computed.

Value

(Invisibly) returns a list where each element contains a vector of data points contained in the respective cluster.

See Also

[hclust](#), [identify.hclust](#).

Examples

```

require(graphics)

hca <- hclust(dist(USArrests))
plot(hca)
rect.hclust(hca, k=3, border="red")
x <- rect.hclust(hca, h=50, which=c(2,7), border=3:4)
x

```

relevel

Reorder Levels of Factor

Description

The levels of a factor are re-ordered so that the level specified by `ref` is first and the others are moved down. This is useful for `contr.treatment` contrasts which take the first level as the reference.

Usage

```
relevel(x, ref, ...)
```

Arguments

<code>x</code>	An unordered factor.
<code>ref</code>	The reference level.
<code>...</code>	Additional arguments for future methods.

Value

A factor of the same length as `x`.

See Also

[factor](#), [contr.treatment](#), [levels](#), [reorder](#).

Examples

```
warpbreaks$tension <- relevel(warpbreaks$tension, ref="M")
summary(lm(breaks ~ wool + tension, data=warpbreaks))
```

reorder.dendrogram *Reorder a Dendrogram*

Description

A method for the generic function [reorder](#).

There are many different orderings of a dendrogram that are consistent with the structure imposed. This function takes a dendrogram and a vector of values and reorders the dendrogram in the order of the supplied vector, maintaining the constraints on the dendrogram.

Usage

```
## S3 method for class 'dendrogram':
reorder(x, wts, agglo.FUN = sum, ...)
```

Arguments

<code>x</code>	the (dendrogram) object to be reordered
<code>wts</code>	numeric weights (arbitrary values) for reordering.
<code>agglo.FUN</code>	a function for weights agglomeration, see below.
<code>...</code>	additional arguments

Details

Using the weights `wts`, the leaves of the dendrogram are reordered so as to be in an order as consistent as possible with the weights. At each node, the branches are ordered in increasing weights where the weight of a branch is defined as $f(w_j)$ where f is `agglo.FUN` and w_j is the weight of the j -th sub branch).

Value

A dendrogram where each node has a further attribute `value` with its corresponding weight.

Author(s)

R. Gentleman and M. Maechler

See Also

[reorder](#).

[rev.dendrogram](#) which simply reverses the nodes' order; [heatmap](#), [cophenetic](#).

Examples

```
require(graphics)

set.seed(123)
x <- rnorm(10)
hc <- hclust(dist(x))
dd <- as.dendrogram(hc)
dd.reorder <- reorder(dd, 10:1)
plot(dd, main = "random dendrogram 'dd'")

op <- par(mfcol = 1:2)
plot(dd.reorder, main = "reorder(dd, 10:1)")
plot(reorder(dd, 10:1, agglo.FUN= mean),
     main = "reorder(dd, 10:1, mean)")
par(op)
```

`reorder.factor`

Reorder Levels of a Factor

Description

`reorder` is a generic function. Its `"factor"` method reorders the levels of a factor depending on values of a second variable, usually numeric. The `"character"` method is a convenient alias.

Usage

```
reorder(x, ...)

## S3 method for class 'factor':
reorder(x, X, FUN = mean, ...,
        order = is.ordered(x))

## S3 method for class 'character':
reorder(x, X, FUN = mean, ...,
        order = is.ordered(x))
```

Arguments

<code>x</code>	a character vector or factor (possibly ordered) or whose levels will be reordered.
<code>X</code>	a vector of the same length as <code>x</code> , whose subset of values for each unique level of <code>x</code> determines the eventual order of that level.
<code>FUN</code>	a function whose first argument is a vector and returns a scalar, to be applied to each subset of <code>X</code> determined by the levels of <code>x</code> .
<code>...</code>	optional: extra arguments supplied to <code>FUN</code>
<code>order</code>	logical, whether return value will be an ordered factor rather than a factor.

Value

A factor or an ordered factor (depending on the value of `order`), with the order of the levels determined by `FUN` applied to `X` grouped by `x`. The levels are ordered such that the values returned by `FUN` are in increasing order.

Additionally, the values of `FUN` applied to the subsets of `X` (in the original order of the levels of `x`) is returned as the "scores" attribute.

[reorder.dendrogram](#), [levels](#), [relevel](#).

Examples

```
require(graphics)

bymedian <- with(InsectSprays, reorder(spray, count, median))
boxplot(count ~ bymedian, data = InsectSprays,
        xlab = "Type of spray", ylab = "Insect count",
        main = "InsectSprays data", varwidth = TRUE,
        col = "lightgray")
```

replications	<i>Number of Replications of Terms</i>
--------------	--

Description

Returns a vector or a list of the number of replicates for each term in the formula.

Usage

```
replications(formula, data=NULL, na.action)
```

Arguments

<code>formula</code>	a formula or a terms object or a data frame.
<code>data</code>	a data frame used to find the objects in <code>formula</code> .
<code>na.action</code>	function for handling missing values. Defaults to a <code>na.action</code> attribute of <code>data</code> , then a setting of the option <code>na.action</code> , or <code>na.fail</code> if that is not set.

Details

If `formula` is a data frame and `data` is missing, `formula` is used for data with the formula ~ ..

Value

A vector or list with one entry for each term in the formula giving the number(s) of replications for each level. If all levels are balanced (have the same number of replications) the result is a vector, otherwise it is a list with a component for each terms, as a vector, matrix or array as required.

A test for balance is `!is.list(replications(formula, data))`.

Author(s)

The design was inspired by the S function of the same name described in Chambers *et al.* (1992).

```

reshape

*Reshape Grouped Data***Description**

This function reshapes a data frame between ‘wide’ format with repeated measurements in separate columns of the same record and ‘long’ format with the repeated measurements in separate records.

Usage

```
reshape(data, varying = NULL, v.names = NULL, timevar = "time",
        idvar = "id", ids = 1:NROW(data),
        times = seq_along(varying[[1]]),
        drop = NULL, direction, new.row.names = NULL,
        sep = ".",
        split = if (sep=="") {
          list(regex="[A-Za-z][0-9]", include=TRUE)
        } else {
          list(regex=sep, include=FALSE, fixed=TRUE)
        }
        )
```

Arguments

data	a data frame
varying	names of sets of variables in the wide format that correspond to single variables in long format (‘time-varying’). This is canonically a list of vectors of variable names, but it can optionally be a matrix of names, or a single vector of names. In each case, the names can be replaced by indexes which are interpreted as referring to names (data). See below for more details and options.
v.names	names of variables in the long format that correspond to multiple variables in the wide format. See below for details.
timevar	the variable in long format that differentiates multiple records from the same group or individual.
idvar	Names of one or more variables in long format that identify multiple records from the same group/individual. These variables may also be present in wide format
ids	the values to use for a newly created idvar variable in long format.

<code>times</code>	the values to use for a newly created <code>timevar</code> variable in long format. See below for details.
<code>drop</code>	a vector of names of variables to drop before reshaping
<code>direction</code>	character string, either "wide" to reshape to wide format, or "long" to reshape to long format.
<code>new.row.names</code>	logical; if TRUE and <code>direction="wide"</code> , create new row names in long format from the values of the <code>id</code> and <code>time</code> variables.
<code>sep</code>	A character vector of length 1, indicating a separating character in the variable names in the wide format. This is used for guessing <code>v.names</code> and <code>times</code> arguments based on the names in <code>varying</code> . If <code>sep=""</code> , the split is just before the first numeral that follows an alphabetic character.
<code>split</code>	A list with three components, <code>regexp</code> , <code>include</code> , and (optionally) <code>fixed</code> . This allows an extended interface to variable name splitting. See below for details.

Details

The arguments to this function are described in terms of longitudinal data, as that is the application motivating the functions. A 'wide' longitudinal dataset will have one record for each individual with some time-constant variables that occupy single columns and some time-varying variables that occupy a column for each time point. In 'long' format there will be multiple records for each individual, with some variables being constant across these records and others varying across the records. A 'long' format dataset also needs a 'time' variable identifying which time point each record comes from and an 'id' variable showing which records refer to the same person.

If the data frame resulted from a previous `reshape` then the operation can be reversed simply by `reshape(a)`. The `direction` argument is optional and the other arguments are stored as attributes on the data frame.

If `direction="wide"` and no `varying` or `v.names` arguments are supplied it is assumed that all variables except `idvar` and `timevar` are time-varying. They are all expanded into multiple variables in wide format.

If `direction="long"` the `varying` argument can be a vector of column names (or a corresponding index). The function will attempt to guess the `v.names` and `times` from these names. The default is variable names like `x.1`, `x.2`, where `sep="."` specifies to split at the dot and drop it from the name. To have alphabetic followed by numeric times use `sep=""`.

Variable name splitting as described above is only attempted in the case where `varying` is an atomic vector, if it is a list or a matrix, `v.names` and `times` will generally need to be specified, although they will default to, respectively, the first variable name in each set, and sequential times.

Also, guessing is not attempted if `v.names` is given explicitly. Notice that the order of variables in `varying` is like `x.1,y.1,x.2,y.2`.

The `split` argument should not usually be necessary. The `split$regexp` component is passed to either `strsplit()` or `regexp()`, where the latter is used if `split$include` is TRUE, in which case the splitting occurs after the first character of the matched string. In the `strsplit()` case, the separator is not included in the result, and it is possible to specify fixed-string matching using `split$fixed`.

Value

The reshaped data frame with added attributes to simplify reshaping back to the original form.

Examples

```
summary(Indometh)
wide <- reshape(Indometh, v.names="conc", idvar="Subject",
               timevar="time", direction="wide")
wide

reshape(wide, direction="long")
reshape(wide, idvar="Subject", varying=list(2:12),
       v.names="conc", direction="long")

## times need not be numeric
df <- data.frame(id=rep(1:4,rep(2,4)),
                visit=I(rep(c("Before","After"),4)),
                x=rnorm(4), y=runif(4))
df
reshape(df, timevar="visit", idvar="id", direction="wide")
## warns that y is really varying
reshape(df, timevar="visit", idvar="id", direction="wide", v.names="x")

## unbalanced 'long' data leads to NA fill in 'wide' form
df2 <- df[1:7,]
df2
reshape(df2, timevar="visit", idvar="id", direction="wide")

## Alternative regular expressions for guessing names
df3 <- data.frame(id=1:4, age=c(40,50,60,50), dose1=c(1,2,1,2),
                 dose2=c(2,1,2,1), dose4=c(3,3,3,3))
reshape(df3, direction="long", varying=3:5, sep="")

## an example that isn't longitudinal data
state.x77 <- as.data.frame(state.x77)
long <- reshape(state.x77, idvar="state", ids=row.names(state.x77),
               times=names(state.x77), timevar="Characteristic",
               varying=list(names(state.x77)), direction="long")

reshape(long, direction="wide")

reshape(long, direction="wide", new.row.names=unique(long$state))

## multiple id variables
df3 <- data.frame(school=rep(1:3,each=4), class=rep(9:10,6),
                 time=rep(c(1,1,2,2),3),
                 score=rnorm(12))
wide <- reshape(df3, idvar=c("school","class"), direction="wide")
wide
## transform back
reshape(wide)
```

`residuals`*Extract Model Residuals*

Description

`residuals` is a generic function which extracts model residuals from objects returned by modeling functions.

The abbreviated form `resid` is an alias for `residuals`. It is intended to encourage users to access object components through an accessor function rather than by directly referencing an object slot.

All object classes which are returned by model fitting functions should provide a `residuals` method. (Note that the method is for 'residuals' and not 'resid'.)

Methods can make use of `naresid` methods to compensate for the omission of missing values. The default, `nls` and `smooth.spline` methods do.

Usage

```
residuals(object, ...)  
resid(object, ...)
```

Arguments

<code>object</code>	an object for which the extraction of model residuals is meaningful.
<code>...</code>	other arguments.

Value

Residuals extracted from the object `object`.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

`coefficients`, `fitted.values`, `glm`, `lm`.

`influence.measures` for standardized (`rstandard`) and studentized (`rstudent`) residuals.

`runmed`*Running Medians – Robust Scatter Plot Smoothing*

Description

Compute running medians of odd span. This is the 'most robust' scatter plot smoothing possible. For efficiency (and historical reason), you can use one of two different algorithms giving identical results.

Usage

```
runmed(x, k, endrule = c("median", "keep", "constant"),
       algorithm = NULL, print.level = 0)
```

Arguments

x numeric vector, the ‘dependent’ variable to be smoothed.

k integer width of median window; must be odd. Turlach had a default of $k \leftarrow 1 + 2 * \min((n-1) \% \% 2, \text{ceiling}(0.1*n))$. Use $k = 3$ for ‘minimal’ robust smoothing eliminating isolated outliers.

endrule character string indicating how the values at the beginning and the end (of the data) should be treated.

"keep" keeps the first and last k_2 values at both ends, where k_2 is the half-bandwidth $k_2 = k \% \% 2$, i.e., $y[j] = x[j]$ for $j \in \{1, \dots, k_2; n - k_2 + 1, \dots, n\}$;

"constant" copies `median(y[1:k2])` to the first values and analogously for the last ones making the smoothed ends *constant*;

"median" the default, smooths the ends by using symmetrical medians of subsequently smaller bandwidth, but for the very first and last value where Tukey’s robust end-point rule is applied, see [smoothEnds](#).

algorithm character string (partially matching "Turlach" or "Stuetzle") or the default NULL, specifying which algorithm should be applied. The default choice depends on $n = \text{length}(x)$ and k where "Turlach" will be used for larger problems.

print.level integer, indicating verbosity of algorithm; should rarely be changed by average users.

Details

Apart from the end values, the result $y = \text{runmed}(x, k)$ simply has $y[j] = \text{median}(x[(j-k_2) : (j+k_2)])$ ($k = 2*k_2+1$), computed very efficiently.

The two algorithms are internally entirely different:

"Turlach" is the Härdle-Steiger algorithm (see Ref.) as implemented by Berwin Turlach. A tree algorithm is used, ensuring performance $O(n \log k)$ where $n \leftarrow \text{length}(x)$ which is asymptotically optimal.

"Stuetzle" is the (older) Stuetzle-Friedman implementation which makes use of median *updating* when one observation enters and one leaves the smoothing window. While this performs as $O(n \times k)$ which is slower asymptotically, it is considerably faster for small k or n .

Value

vector of smoothed values of the same length as x with an `attribute` k containing (the ‘oddified’) k .

Author(s)

Martin Maechler (maechler@stat.math.ethz.ch), based on Fortran code from Werner Stuetzle and S-plus and C code from Berwin Turlach.

See Also

`smoothEnds` which implements Tukey's end point rule and is called by default from `runmed(*, endrule = "median")`. `smooth` uses running medians of 3 for its compound smoothers.

Examples

```
require(graphics)

utils::example(nhtemp)
myNHT <- as.vector(nhtemp)
myNHT[20] <- 2 * nhtemp[20]
plot(myNHT, type="b", ylim = c(48,60), main = "Running Medians Example")
lines(runmed(myNHT, 7), col = "red")

## special: multiple y values for one x
plot(cars, main = "'cars' data and runmed(dist, 3)")
lines(cars, col = "light gray", type = "c")
with(cars, lines(speed, runmed(dist, k = 3), col = 2))

## nice quadratic with a few outliers
y <- ys <- (-20:20)^2
y[c(1,10,21,41)] <- c(150, 30, 400, 450)
all(y == runmed(y, 1)) # 1-neighbourhood <==> interpolation
plot(y) ## lines(y, lwd=.1, col="light gray")
lines(lowess(seq(y),y, f = .3), col = "brown")
lines(runmed(y, 7), lwd=2, col = "blue")
lines(runmed(y,11), lwd=2, col = "red")

## Lowess is not robust
y <- ys ; y[21] <- 6666 ; x <- seq(y)
col <- c("black", "brown", "blue")
plot(y, col=col[1])
lines(lowess(x,y, f = .3), col = col[2])
lines(runmed(y, 7), lwd=2, col = col[3])
legend(length(y),max(y), c("data", "lowess(y, f = 0.3)", "runmed(y, 7)"),
       xjust = 1, col = col, lty = c(0, 1,1), pch = c(1,NA,NA))
```

scatter.smooth

Scatter Plot with Smooth Curve Fitted by Loess

Description

Plot and add a smooth curve computed by `loess` to a scatter plot.

Usage

```
scatter.smooth(x, y = NULL, span = 2/3, degree = 1,
              family = c("symmetric", "gaussian"),
              xlab = NULL, ylab = NULL,
              ylim = range(y, prediction$y, na.rm = TRUE),
              evaluation = 50, ...)

loess.smooth(x, y, span = 2/3, degree = 1,
            family = c("symmetric", "gaussian"), evaluation = 50, ...)
```

Arguments

<code>x, y</code>	the <code>x</code> and <code>y</code> arguments provide the <code>x</code> and <code>y</code> coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function xy.coords for details.
<code>span</code>	smoothness parameter for <code>loess</code> .
<code>degree</code>	degree of local polynomial used.
<code>family</code>	if "gaussian" fitting is by least-squares, and if <code>family="symmetric"</code> a re-descending M estimator is used.
<code>xlab</code>	label for <code>x</code> axis.
<code>ylab</code>	label for <code>y</code> axis.
<code>ylim</code>	the <code>y</code> limits of the plot.
<code>evaluation</code>	number of points at which to evaluate the smooth curve.
<code>...</code>	graphical parameters.

Details

`loess.smooth` is an auxiliary function which evaluates the `loess` smooth at `evaluation` equally spaced points covering the range of `x`.

Value

For `scatter.smooth`, none.

For `loess.smooth`, a list with two components, `x` (the grid of evaluation points) and `y` (the smoothed values at the grid points).

See Also

[loess](#)

Examples

```
require(graphics)

with(cars, scatter.smooth(speed, dist))
```

`screeplot`*Screeplots*

Description

`screeplot.default` plots the variances against the number of the principal component. This is also the plot method for classes `"princomp"` and `"prcomp"`.

Usage

```
## Default S3 method:
screeplot(x, npc = min(10, length(x$sdev)),
          type = c("barplot", "lines"),
          main = deparse(substitute(x)), ...)
```

Arguments

`x` an object containing a `sdev` component, such as that returned by `princomp()` and `prcomp()`.

`npc` the number of components to be plotted.

`type` the type of plot.

`main, ...` graphics parameters.

screeplot(fit)
screeplot(fit, npc=24, type="lines")
```

sd *Standard Deviation*

Description

This function computes the standard deviation of the values in `x`. If `na.rm` is `TRUE` then missing values are removed before computation proceeds. If `x` is a matrix or a data frame, a vector of the standard deviation of the columns is returned.

Usage

```
sd(x, na.rm = FALSE)
```

Arguments

`x` a numeric vector, matrix or data frame. An object which is not a vector, matrix or data frame is coerced (if possible) by `as.vector`.

`na.rm` logical. Should missing values be removed?

Details

Like `var` this uses denominator $n - 1$.

The standard deviation of a zero-length vector (after removal of NAs if `na.rm = TRUE`) is not defined and gives an error. The standard deviation of a length-one vector is NA.

See Also

`var` for its square, and `mad`, the most robust alternative.

Examples

```
sd(1:2) ^ 2
```

se.contrast *Standard Errors for Contrasts in Model Terms*

Description

Returns the standard errors for one or more contrasts in an `aov` object.

Usage

```
se.contrast(object, ...)
## S3 method for class 'aov':
se.contrast(object, contrast.obj,
             coef = contr.helmert(ncol(contrast))[, 1],
             data = NULL, ...)
```

Arguments

<code>object</code>	A suitable fit, usually from <code>aov</code> .
<code>contrast.obj</code>	The contrasts for which standard errors are requested. This can be specified via a list or via a matrix. A single contrast can be specified by a list of logical vectors giving the cells to be contrasted. Multiple contrasts should be specified by a matrix, each column of which is a numerical contrast vector (summing to zero).
<code>coef</code>	used when <code>contrast.obj</code> is a list; it should be a vector of the same length as the list with zero sum. The default value is the first Helmert contrast, which contrasts the first and second cell means specified by the list.
<code>data</code>	The data frame used to evaluate <code>contrast.obj</code> .
<code>...</code>	further arguments passed to or from other methods.

Details

Contrasts are usually used to test if certain means are significantly different; it can be easier to use `se.contrast` than compute them directly from the coefficients.

In multistratum models, the contrasts can appear in more than one stratum, in which case the standard errors are computed in the lowest stratum and adjusted for efficiencies and comparisons between strata. (See the comments in the note in the help for `aov` about using orthogonal contrasts.) Such standard errors are often conservative.

Suitable matrices for use with `coef` can be found by calling `contrasts` and indexing the columns by a factor.

Value

A vector giving the standard errors for each contrast.

```

selfStart

Construct Self-starting Nonlinear Models

Description

Construct self-starting nonlinear models.

Usage

```
selfStart(model, initial, parameters, template)
```

Arguments

model a function object defining a nonlinear model or a nonlinear formula object of the form `~expression`.

initial	a function object, taking three arguments: <code>mCall</code> , <code>data</code> , and <code>LHS</code> , representing, respectively, a matched call to the function <code>model</code> , a data frame in which to interpret the variables in <code>mCall</code> , and the expression from the left-hand side of the model formula in the call to <code>nls</code> . This function should return initial values for the parameters in <code>model</code> .
parameters	a character vector specifying the terms on the right hand side of <code>model</code> for which initial estimates should be calculated. Passed as the <code>namevec</code> argument to the <code>deriv</code> function.
template	an optional prototype for the calling sequence of the returned object, passed as the <code>function.arg</code> argument to the <code>deriv</code> function. By default, a template is generated with the covariates in <code>model</code> coming first and the parameters in <code>model</code> coming last in the calling sequence.

Details

This function is generic; methods functions can be written to handle specific classes of objects.

Value

a function object of class "selfStart", for the formula method obtained by applying `deriv` to the right hand side of the model formula. An `initial` attribute (defined by the `initial` argument) is added to the function to calculate starting estimates for the parameters in the model automatically.

## End(Not run)
```

setNames

Set the Names in an Object

Description

This is a convenience function that sets the names on an object and returns the object. It is most useful at the end of a function definition where one is creating the object to be returned and would prefer not to store it under a name just so the names can be assigned.

Usage

```
setNames(object, nm)
```

Arguments

object	an object for which a names attribute will be meaningful
nm	a character vector of names to assign to the object

Value

An object of the same sort as `object` with the new names assigned.

Author(s)

Douglas M. Bates and Saikat DebRoy

```
setNames( 1:3, c("foo", "bar", "baz") )
# this is just a short form of
tmp <- 1:3
names(tmp) <- c("foo", "bar", "baz")
tmp
```

shapiro.test	<i>Shapiro-Wilk Normality Test</i>
--------------	------------------------------------

Description

Performs the Shapiro-Wilk test of normality.

Usage

```
shapiro.test(x)
```

Arguments

`x` a numeric vector of data values. Missing values are allowed, but the number of non-missing values must be between 3 and 5000.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value of the Shapiro-Wilk statistic.
<code>p.value</code>	an approximate p-value for the test. This is said in Royston (1995) to be adequate for <code>p.value < 0.1</code> .
<code>method</code>	the character string "Shapiro-Wilk normality test".
<code>data.name</code>	a character string giving the name(s) of the data.

Source

The algorithm used is a C translation of the Fortran code described in Royston (1995) and found at <http://lib.stat.cmu.edu/apstat/R94>. The calculation of the p value is exact for $n = 3$, otherwise approximations are used, separately for $4 \leq n \leq 11$ and $n \geq 12$.

See Also

[qqnorm](#) for producing a normal quantile-quantile plot.

Examples

```
shapiro.test(rnorm(100, mean = 5, sd = 3))
shapiro.test(runif(100, min = 2, max = 4))
```

Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon Signed Rank statistic obtained from a sample with size n .

Usage

```
dsignrank(x, n, log = FALSE)
psignrank(q, n, lower.tail = TRUE, log.p = FALSE)
qsignrank(p, n, lower.tail = TRUE, log.p = FALSE)
rsignrank(nn, n)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>nn</code>	number of observations. If <code>length(nn) > 1</code> , the length is taken to be the number required.
<code>n</code>	number(s) of observations in the sample(s). A positive integer, or a vector of such integers.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

This distribution is obtained as follows. Let x be a sample of size n from a continuous distribution symmetric about the origin. Then the Wilcoxon signed rank statistic is the sum of the ranks of the absolute values $x[i]$ for which $x[i]$ is positive. This statistic takes values between 0 and $n(n+1)/2$, and its mean and variance are $n(n+1)/4$ and $n(n+1)(2n+1)/24$, respectively.

If either of the first two arguments is a vector, the recycling rule is used to do the calculations for all combinations of the two up to the length of the longer vector.

Value

`dsignrank` gives the density, `psignrank` gives the distribution function, `qsignrank` gives the quantile function, and `rsignrank` generates random deviates.

Author(s)

Kurt Hornik; efficiency improvement by Ivo Ugrina.

See Also

`wilcox.test` to calculate the statistic from data, find p values and so on.

`dwilcox` etc, for the distribution of *two-sample* Wilcoxon rank sum statistic.

Examples

```
require(graphics)

par(mfrow=c(2,2))
for(n in c(4:5,10,40)) {
  x <- seq(0, n*(n+1)/2, length=501)
  plot(x, dsignrank(x,n=n), type='l', main=paste("dsignrank(x,n=",n,""))
}
```

simulate

*Simulate Responses***Description**

Simulate one or more response vectors from the theoretical distribution corresponding to a fitted model object.

Usage

```
simulate(object, nsim, seed, ...)
```

Arguments

object	an object representing a fitted model.
nsim	number of response vectors to simulate. Defaults to 1.
seed	an object specifying if and how the random number generator should be initialized ('seeded'). For the "lm" method, either NULL or an integer that will be used in a call to <code>set.seed</code> before simulating the response vectors. If set, the value is saved as the "seed" attribute of the returned value. The default, NULL will not change the random generator state, and return <code>.Random.seed</code> as "seed" attribute, see below.
...	additional optional arguments.

Details

This is a generic function with a method for `lm` objects. Consult the individual modeling functions for details on how to use this function.

Value

Typically, a list of length `nsim` of simulated response vectors. When appropriate the result can be a data frame (which is a special type of list).

For the "lm" method, the result is a data frame with an attribute "seed" containing the `seed` argument and `as.list(RNGkind())` if `seed` was not NULL, or the value of `.Random.seed` before the simulation was started when `seed` was NULL as by default.

See Also

`fitted.values` and `residuals` for related methods; `glm`, `lm` for model fitting.

Examples

```
x <- 1:5
mod1 <- lm(c(1:3,7,6) ~ x)
S1 <- simulate(mod1, nsim = 4)
## repeat the simulation:
.Random.seed <- attr(S1, "seed")
identical(S1, simulate(mod1, nsim = 4))

S2 <- simulate(mod1, nsim = 200, seed = 101)
rowMeans(S2) # should be about
fitted(mod1)

## repeat identically:
(sseed <- attr(S2, "seed")) # seed; RNGkind as attribute
stopifnot(identical(S2, simulate(mod1, nsim = 200, seed = sseed)))

## To be sure about the proper RNGkind, e.g., after
RNGversion("2.7.0")
## first set the RNG kind, then simulate
do.call(RNGkind, attr(sseed, "kind"))
identical(S2, simulate(mod1, nsim = 200, seed = sseed))
```

smooth

*Tukey's (Running Median) Smoothing***Description**

Tukey's smoothers, *3RS3R*, *3RSS*, *3R*, etc.

Usage

```
smooth(x, kind = c("3RS3R", "3RSS", "3RSR", "3R", "3", "S"),
       twiceit = FALSE, endrule = "Tukey", do.ends = FALSE)
```

Arguments

x	a vector or time series
kind	a character string indicating the kind of smoother required; defaults to "3RS3R".
twiceit	logical, indicating if the result should be 'twiced'. Twicing a smoother $S(y)$ means $S(y) + S(y - S(y))$, i.e., adding smoothed residuals to the smoothed values. This decreases bias (increasing variance).
endrule	a character string indicating the rule for smoothing at the boundary. Either "Tukey" (default) or "copy".
do.ends	logical, indicating if the 3-splitting of ties should also happen at the boundaries (ends). This is only used for kind = "S".

Details

3 is Tukey's short notation for running [medians](#) of length 3,
 3R stands for **R**epeated 3 until convergence, and
 S for **S**plitting of horizontal stretches of length 2 or 3.

Hence, 3RS3R is a concatenation of 3R, S and 3R, 3RSS similarly, whereas 3RSR means first 3R and then (S and 3) **R**epeated until convergence – which can be bad.

Value

An object of class "tukeysmooth" (which has `print` and `summary` methods) and is a vector or time series containing the smoothed values with additional attributes.

Note

S and S-PLUS use a different (somewhat better) Tukey smoother in `smooth(*)`. Note that there are other smoothing methods which provide rather better results. These were designed for hand calculations and may be used mainly for didactical purposes.

Since R version 1.2, `smooth` *does* really implement Tukey's end-point rule correctly (see argument `endrule`).

`kind = "3RSR"` has been the default till R-1.1, but it can have very bad properties, see the examples.

Note that repeated application of `smooth(*)` *does* smooth more, for the "3RS*" kinds.

smooth.spline *Fit a Smoothing Spline*

Description

Fits a cubic smoothing spline to the supplied data.

Usage

```

smooth.spline(x, y = NULL, w = NULL, df, spar = NULL,
              cv = FALSE, all.knots = FALSE, nknots = NULL,
              keep.data = TRUE, df.offset = 0, penalty = 1,
              control.spar = list())

```

Arguments

<code>x</code>	a vector giving the values of the predictor variable, or a list or a two-column matrix specifying <code>x</code> and <code>y</code> .
<code>y</code>	responses. If <code>y</code> is missing, the responses are assumed to be specified by <code>x</code> .
<code>w</code>	optional vector of weights of the same length as <code>x</code> ; defaults to all 1.
<code>df</code>	the desired equivalent number of degrees of freedom (trace of the smoother matrix).
<code>spar</code>	smoothing parameter, typically (but not necessarily) in $(0, 1]$. The coefficient λ of the integral of the squared second derivative in the fit (penalized log likelihood) criterion is a monotone function of <code>spar</code> , see the details below.
<code>cv</code>	ordinary (TRUE) or ‘generalized’ cross-validation (GCV) when FALSE.
<code>all.knots</code>	if TRUE, all distinct points in <code>x</code> are used as knots. If FALSE (default), a subset of <code>x[]</code> is used, specifically <code>x[j]</code> where the <code>nknots</code> indices are evenly spaced in $1:n$, see also the next argument <code>nknots</code> .
<code>nknots</code>	integer giving the number of knots to use when <code>all.knots=FALSE</code> . Per default, this is less than n , the number of unique <code>x</code> values for $n > 49$.
<code>keep.data</code>	logical specifying if the input data should be kept in the result. If TRUE (as per default), fitted values and residuals are available from the result.
<code>df.offset</code>	allows the degrees of freedom to be increased by <code>df.offset</code> in the GCV criterion.
<code>penalty</code>	the coefficient of the penalty for degrees of freedom in the GCV criterion.

`control.spar` optional list with named components controlling the root finding when the smoothing parameter `spar` is computed, i.e., missing or NULL, see below.

Note that this is partly *experimental* and may change with general `spar` computation improvements!

low: lower bound for `spar`; defaults to -1.5 (used to implicitly default to 0 in R versions earlier than 1.4).

high: upper bound for `spar`; defaults to +1.5.

tol: the absolute precision (**tolerance**) used; defaults to 1e-4 (formerly 1e-3).

eps: the relative precision used; defaults to 2e-8 (formerly 0.00244).

trace: logical indicating if iterations should be traced.

maxit: integer giving the maximal number of iterations; defaults to 500.

Note that `spar` is only searched for in the interval $[low, high]$.

Details

The `x` vector should contain at least four distinct values. *Distinct* here means ‘distinct after rounding to 6 significant digits’, i.e., `x` will be transformed to `unique(sort(signif(x, 6)))`, and `y` and `w` are pooled accordingly.

The computational λ used (as a function of $s = spar$) is $\lambda = r * 256^{3s-1}$ where $r = tr(X'WX)/tr(\Sigma)$, Σ is the matrix given by $\Sigma_{ij} = \int B_i''(t)B_j''(t)dt$, X is given by $X_{ij} = B_j(x_i)$, W is the diagonal matrix of weights (scaled such that its trace is n , the original number of observations) and $B_k(\cdot)$ is the k -th B-spline.

Note that with these definitions, $f_i = f(x_i)$, and the B-spline basis representation $f = Xc$ (i.e., c is the vector of spline coefficients), the penalized log likelihood is $L = (y - f)'W(y - f) + \lambda c' \Sigma c$, and hence c is the solution of the (ridge regression) $(X'WX + \lambda \Sigma)c = X'Wy$.

If `spar` is missing or NULL, the value of `df` is used to determine the degree of smoothing. If both are missing, leave-one-out cross-validation (ordinary or ‘generalized’ as determined by `cv`) is used to determine λ . Note that from the above relation, `spar` is $s = s0 + 0.0601 * \log \lambda$, which is intentionally *different* from the S-plus implementation of `smooth.spline` (where `spar` is proportional to λ). In R’s $(\log \lambda)$ scale, it makes more sense to vary `spar` linearly.

Note however that currently the results may become very unreliable for `spar` values smaller than about -1 or -2. The same may happen for values larger than 2 or so. Don’t think of setting `spar` or the controls `low` and `high` outside such a safe range, unless you know what you are doing!

The ‘generalized’ cross-validation method will work correctly when there are duplicated points in `x`. However, it is ambiguous what leave-one-out cross-validation means with duplicated points, and the internal code uses an approximation that involves leaving out groups of duplicated points. `cv=TRUE` is best avoided in that case.

Value

An object of class "smooth.spline" with components

<code>x</code>	the <i>distinct</i> <code>x</code> values in increasing order, see the ‘Details’ above.
<code>y</code>	the fitted values corresponding to <code>x</code> .
<code>w</code>	the weights used at the unique values of <code>x</code> .
<code>yin</code>	the <code>y</code> values used at the unique <code>y</code> values.
<code>data</code>	only if <code>keep.data = TRUE</code> : itself a <code>list</code> with components <code>x</code> , <code>y</code> and <code>w</code> of the same length. These are the original $(x_i, y_i, w_i), i = 1, \dots, n$, values where <code>data\$x</code> may have repeated values and hence be longer than the above <code>x</code> component; see details.

lev	leverages, the diagonal values of the smoother matrix.
cv.crit	cross-validation score, ‘generalized’ or true, depending on cv.
pen.crit	penalized criterion
crit	the criterion value minimized in the underlying <code>.Fortran</code> routine ‘ <code>sslvrg</code> ’.
df	equivalent degrees of freedom used. Note that (currently) this value may become quite imprecise when the true df is between and 1 and 2.
spar	the value of <code>spar</code> computed or given.
lambda	the value of λ corresponding to <code>spar</code> , see the details above.
iparms	named integer(3) vector where <code>..\$ipars["iter"]</code> gives number of <code>spar</code> computing iterations used.
fit	list for use by <code>predict.smooth.spline</code> , with components knot: the knot sequence (including the repeated boundary knots). nk: number of coefficients or number of ‘proper’ knots plus 2. coef: coefficients for the spline basis used. min, range: numbers giving the corresponding quantities of <code>x</code> .
call	the matched call.

Note

The default `all.knots = FALSE` and `nknots = NULL` entails using only $O(n^{0.2})$ knots instead of n for $n > 49$. This cuts speed and memory requirements, but not drastically anymore since R version 1.5.1 where it is only $O(n_k) + O(n)$ where n_k is the number of knots. In this case where not all unique `x` values are used as knots, the result is not a smoothing spline in the strict sense, but very close unless a small smoothing parameter (or large `df`) is used.

Author(s)

R implementation by B. D. Ripley and Martin Maechler (`spar/lambda`, etc).

This function is based on code in the `GAMFIT` Fortran program by T. Hastie and R. Tibshirani (<http://lib.stat.cmu.edu/general/>), which makes use of spline code by Finbarr O’Sullivan. Its design parallels the `smooth.spline` function of Chambers & Hastie (1992).

Examples

```

require(graphics)

attach(cars)
plot(speed, dist, main = "data(cars) & smoothing splines")
cars.spl <- smooth.spline(speed, dist)
(cars.spl)
## This example has duplicate points, so avoid cv=TRUE

lines(cars.spl, col = "blue")
lines(smooth.spline(speed, dist, df=10), lty=2, col = "red")
legend(5,120,c(paste("default [C.V.] => df =",round(cars.spl$df,1)),
               "s( * , df = 10)"), col = c("blue","red"), lty = 1:2,
       bg='bisque')
detach()

## Residual (Tukey Anscombe) plot:
plot(residuals(cars.spl) ~ fitted(cars.spl))
abline(h = 0, col="gray")

## consistency check:
stopifnot(all.equal(cars$dist,
                    fitted(cars.spl) + residuals(cars.spl)))

##-- artificial example
y18 <- c(1:3,5,4,7:3,2*(2:5),rep(10,4))
xx <- seq(1,length(y18), len=201)
(s2 <- smooth.spline(y18)) # GCV
(s02 <- smooth.spline(y18, spar = 0.2))
plot(y18, main=deparse(s2$call), col.main=2)
lines(s2, col = "gray"); lines(predict(s2, xx), col = 2)
lines(predict(s02, xx), col = 3); mtext(deparse(s02$call), col = 3)

## The following shows the problematic behavior of 'spar' searching:
(s2 <- smooth.spline(y18, control = list(trace=TRUE,tol=1e-6, low= -1.5)))
(s2m <- smooth.spline(y18, cv = TRUE,
                      control = list(trace=TRUE,tol=1e-6, low= -1.5)))
## both above do quite similarly (Df = 8.5 +- 0.2)

```

smoothEnds

End Points Smoothing (for Running Medians)

Description

Smooth end points of a vector y using subsequently smaller medians and Tukey's end point rule at the very end. (of odd span),

Usage

```
smoothEnds(y, k = 3)
```

Arguments

`y` dependent variable to be smoothed (vector).
`k` width of largest median window; must be odd.

Details

`smoothEnds` is used to only do the ‘end point smoothing’, i.e., change at most the observations closer to the beginning/end than half the window `k`. The first and last value are computed using *Tukey’s end point rule*, i.e., $sm[1] = \text{median}(y[1], sm[2], 3*sm[2] - 2*sm[3])$.

Value

vector of smoothed values, the same length as `y`.

Author(s)

Martin Maechler

Examples

```
require(graphics)

y <- ys <- (-20:20)^2
y [c(1,10,21,41)] <- c(100, 30, 400, 470)
s7k <- runmed(y, 7, endrule = "keep")
s7. <- runmed(y, 7, endrule = "const")
s7m <- runmed(y, 7)
col3 <- c("midnightblue", "blue", "steelblue")
plot(y, main = "Running Medians -- runmed(*, k=7, end.rule = X)")
lines(ys, col = "light gray")
matlines(cbind(s7k, s7., s7m), lwd= 1.5, lty = 1, col = col3)
legend(1, 470, paste("endrule", c("keep", "constant", "median")), sep=" = "),
      col = col3, lwd = 1.5, lty = 1)

stopifnot(identical(s7m, smoothEnds(s7k, 7)))
```

sortedXyData *Create a sortedXyData object*

Description

This is a constructor function for the class of sortedXyData objects. These objects are mostly used in the `initial` function for a self-starting nonlinear regression model, which will be of the `selfStart` class.

Usage

```
sortedXyData(x, y, data)
```

Arguments

<code>x</code>	a numeric vector or an expression that will evaluate in <code>data</code> to a numeric vector
<code>y</code>	a numeric vector or an expression that will evaluate in <code>data</code> to a numeric vector
<code>data</code>	an optional data frame in which to evaluate expressions for <code>x</code> and <code>y</code> , if they are given as expressions

Value

A sortedXyData object. This is a data frame with exactly two numeric columns, named `x` and `y`. The rows are sorted so the `x` column is in increasing order. Duplicate `x` values are eliminated by averaging the corresponding `y` values.

Author(s)

Jose Pinheiro and Douglas Bates

sortedXyData( expression(log(conc)), expression(density), DNase.2 )
```

spec.ar *Estimate Spectral Density of a Time Series from AR Fit*

Description

Fits an AR model to `x` (or uses the existing fit) and computes (and by default plots) the spectral density of the fitted model.

Usage

```
spec.ar(x, n.freq, order = NULL, plot = TRUE, na.action = na.fail,
        method = "yule-walker", ...)
```

Arguments

<code>x</code>	A univariate (not yet:or multivariate) time series or the result of a fit by <code>ar</code> .
<code>n.freq</code>	The number of points at which to plot.
<code>order</code>	The order of the AR model to be fitted. If omitted, the order is chosen by AIC.
<code>plot</code>	Plot the periodogram?
<code>na.action</code>	NA action function.
<code>method</code>	method for ar fit.
<code>...</code>	Graphical arguments passed to <code>plot.spec</code> .

Value

An object of class "spec". The result is returned invisibly if `plot` is true.

Warning

Some authors, for example Thomson (1990), warn strongly that AR spectra can be misleading.

Note

The multivariate case is not yet implemented.

```

spec.pgram	<i>Estimate Spectral Density of a Time Series by a Smoothed Periodogram</i>
------------	---

Description

spec.pgram calculates the periodogram using a fast Fourier transform, and optionally smooths the result with a series of modified Daniell smoothers (moving averages giving half weight to the end values).

Usage

```
spec.pgram(x, spans = NULL, kernel, taper = 0.1,
           pad = 0, fast = TRUE, demean = FALSE, detrend = TRUE,
           plot = TRUE, na.action = na.fail, ...)
```

Arguments

x	univariate or multivariate time series.
spans	vector of odd integers giving the widths of modified Daniell smoothers to be used to smooth the periodogram.
kernel	alternatively, a kernel smoother of class "tskernel".
taper	specifies the proportion of data to taper. A split cosine bell taper is applied to this proportion of the data at the beginning and end of the series.
pad	proportion of data to pad. Zeros are added to the end of the series to increase its length by the proportion pad.
fast	logical; if TRUE, pad the series to a highly composite length.
demean	logical. If TRUE, subtract the mean of the series.
detrend	logical. If TRUE, remove a linear trend from the series. This will also remove the mean.
plot	plot the periodogram?
na.action	NA action function.
...	graphical arguments passed to plot.spec.

Details

The raw periodogram is not a consistent estimator of the spectral density, but adjacent values are asymptotically independent. Hence a consistent estimator can be derived by smoothing the raw periodogram, assuming that the spectral density is smooth.

The series will be automatically padded with zeros until the series length is a highly composite number in order to help the Fast Fourier Transform. This is controlled by the *fast* and not the *pad* argument.

The periodogram at zero is in theory zero as the mean of the series is removed (but this may be affected by tapering): it is replaced by an interpolation of adjacent values during smoothing, and no value is returned for that frequency.

Value

A list object of class "spec" (see [spectrum](#)) with the following additional components:

kernel	The kernel argument, or the kernel constructed from spans.
df	The distribution of the spectral density estimate can be approximated by a (scaled) chi square distribution with df degrees of freedom.
bandwidth	The equivalent bandwidth of the kernel smoother as defined by Bloomfield (1976, page 201).
taper	The value of the taper argument.
pad	The value of the pad argument.
detrend	The value of the detrend argument.
demean	The value of the demean argument.

The result is returned invisibly if plot is true.

```

spec.taper

Taper a Time Series by a Cosine Bell

Description

Apply a cosine-bell taper to a time series.

Usage

```
spec.taper(x, p = 0.1)
```

Arguments

x	A univariate or multivariate time series
p	The proportion to be tapered at each end of the series, either a scalar (giving the proportion for all series) or a vector of the length of the number of series (giving the proportion for each series..

Details

The cosine-bell taper is applied to the first and last $p[i]$ observations of time series $x[, i]$.

Value

A new time series object.

See Also

[spec.pgram](#), [cpgram](#)

spectrum

*Spectral Density Estimation***Description**

The `spectrum` function estimates the spectral density of a time series.

Usage

```
spectrum(x, ..., method = c("pgram", "ar"))
```

Arguments

<code>x</code>	A univariate or multivariate time series.
<code>method</code>	String specifying the method used to estimate the spectral density. Allowed methods are "pgram" (the default) and "ar".
<code>...</code>	Further arguments to specific spec methods or <code>plot.spec</code> .

Details

`spectrum` is a wrapper function which calls the methods `spec.pgram` and `spec.ar`.

The spectrum here is defined with scaling $1/\text{frequency}(x)$, following S-PLUS. This makes the spectral density a density over the range $(-\text{frequency}(x)/2, +\text{frequency}(x)/2]$, whereas a more common scaling is 2π and range $(-0.5, 0.5]$ (e.g., Bloomfield) or 1 and range $(-\pi, \pi]$.

If available, a confidence interval will be plotted by `plot.spec`: this is asymmetric, and the width of the centre mark indicates the equivalent bandwidth.

Value

An object of class "spec", which is a list containing at least the following components:

<code>freq</code>	vector of frequencies at which the spectral density is estimated. (Possibly approximate Fourier frequencies.) The units are the reciprocal of cycles per unit time (and not per observation spacing): see 'Details' below.
<code>spec</code>	Vector (for univariate series) or matrix (for multivariate series) of estimates of the spectral density at frequencies corresponding to <code>freq</code> .
<code>coh</code>	NULL for univariate series. For multivariate time series, a matrix containing the <i>squared</i> coherency between different series. Column $i + (j - 1) * (j - 2)/2$ of <code>coh</code> contains the squared coherency between columns i and j of <code>x</code> , where $i < j$.
<code>phase</code>	NULL for univariate series. For multivariate time series a matrix containing the cross-spectrum phase between different series. The format is the same as <code>coh</code> .
<code>series</code>	The name of the time series.
<code>snames</code>	For multivariate input, the names of the component series.
<code>method</code>	The method used to calculate the spectrum.

The result is returned invisibly if `plot` is true.

Note

The default plot for objects of class "spec" is quite complex, including an error bar and default title, subtitle and axis labels. The defaults can all be overridden by supplying the appropriate graphical parameters.

## spec.ar
spectrum(lh, method="ar")
spectrum(ldeaths, method="ar")
```

Description

Perform cubic (or Hermite) spline interpolation of given data points, returning either a list of points obtained by the interpolation or a *function* performing the interpolation.

Usage

```
splinefun(x, y = NULL, method = c("fmm", "periodic", "natural", "monoH.FC"),
          ties = mean)

spline(x, y = NULL, n = 3*length(x), method = "fmm",
        xmin = min(x), xmax = max(x), xout, ties = mean)

splinefunH(x, y, m)
```

Arguments

<code>x, y</code>	vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see xy.coords .
<code>m</code>	(for <code>splinefunH()</code>): vector of <i>slopes</i> m_i at the points (x_i, y_i) ; these together determine the Hermite “spline” which is piecewise cubic, (only) <i>once</i> differentiable continuously.
<code>method</code>	specifies the type of spline to be used. Possible values are "fmm", "natural", "periodic" and "monoH.FC".
<code>n</code>	if <code>xout</code> is left unspecified, interpolation takes place at <code>n</code> equally spaced points spanning the interval <code>[xmin, xmax]</code> .
<code>xmin, xmax</code>	left-hand and right-hand endpoint of the interpolation interval (when <code>xout</code> is unspecified).
<code>xout</code>	an optional set of values specifying where interpolation is to take place.
<code>ties</code>	Handling of tied <code>x</code> values. Either a function with a single vector argument returning a single number result or the string "ordered".

Details

The inputs can contain missing values which are deleted, so at least one complete (x, y) pair is required. If `method = "fmm"`, the spline used is that of Forsythe, Malcolm and Moler (an exact cubic is fitted through the four points at each end of the data, and this is used to determine the end conditions). Natural splines are used when `method = "natural"`, and periodic splines when `method = "periodic"`.

The new (R 2.8.0) method "monoH.FC" computes a *monotone* Hermite spline according to the method of Fritsch and Carlson. It does so by determining slopes such that the Hermite spline, determined by (x_i, y_i, m_i) , is monotone (increasing or decreasing) **iff** the data are.

These interpolation splines can also be used for extrapolation, that is prediction at points outside the range of `x`. Extrapolation makes little sense for `method = "fmm"`; for natural splines it is linear using the slope of the interpolating curve at the nearest data point.

Value

`spline` returns a list containing components `x` and `y` which give the ordinates where interpolation took place and the interpolated values.

`splinefun` returns a function with formal arguments `x` and `deriv`, the latter defaulting to zero. This function can be used to evaluate the interpolating cubic spline (`deriv=0`), or its derivatives (`deriv=1,2,3`) at the points `x`, where the spline function interpolates the data points originally specified. This is often more useful than `spline`.

SSasymp

Asymptotic Regression Model

Description

This `selfStart` model evaluates the asymptotic regression function and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Asym`, `R0`, and `lrc` for a given set of data.

Usage

```
SSasymp(input, Asym, R0, lrc)
```

Arguments

<code>input</code>	a numeric vector of values at which to evaluate the model.
<code>Asym</code>	a numeric parameter representing the horizontal asymptote on the right side (very large values of <code>input</code>).
<code>R0</code>	a numeric parameter representing the response when <code>input</code> is zero.
<code>lrc</code>	a numeric parameter representing the natural logarithm of the rate constant.

Value

a numeric vector of the same length as `input`. It is the value of the expression $Asym + (R0 - Asym) * \exp(-\exp(lrc) * input)$. If all of the arguments `Asym`, `R0`, and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

summary(fm1)
```

SSasympOff

Asymptotic Regression Model with an Offset

Description

This `selfStart` model evaluates an alternative parametrization of the asymptotic regression function and the gradient with respect to those parameters. It has an `initial` attribute that creates initial estimates of the parameters `Asym`, `lrc`, and `c0`.

Usage

```
SSasympOff(input, Asym, lrc, c0)
```

Arguments

<code>input</code>	a numeric vector of values at which to evaluate the model.
<code>Asym</code>	a numeric parameter representing the horizontal asymptote on the right side (very large values of <code>input</code>).
<code>lrc</code>	a numeric parameter representing the natural logarithm of the rate constant.
<code>c0</code>	a numeric parameter representing the <code>input</code> for which the response is zero.

Value

a numeric vector of the same length as `input`. It is the value of the expression $Asym * (1 - \exp(-\exp(lrc) * (input - c0)))$. If all of the arguments `Asym`, `lrc`, and `c0` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSasympOrig

Asymptotic Regression Model through the Origin

Description

This `selfStart` model evaluates the asymptotic regression function through the origin and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Asym` and `lrc` for a given set of data.

Usage

```
SSasympOrig(input, Asym, lrc)
```

Arguments

<code>input</code>	a numeric vector of values at which to evaluate the model.
<code>Asym</code>	a numeric parameter representing the horizontal asymptote.
<code>lrc</code>	a numeric parameter representing the natural logarithm of the rate constant.

Value

a numeric vector of the same length as `input`. It is the value of the expression `Asym*(1 - exp(-exp(lrc)*input))`. If all of the arguments `Asym` and `lrc` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSbiexp

Biexponential model

Description

This `selfStart` model evaluates the biexponential model function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters `A1`, `lrc1`, `A2`, and `lrc2`.

Usage

```
SSbiexp(input, A1, lrc1, A2, lrc2)
```

Arguments

<code>input</code>	a numeric vector of values at which to evaluate the model.
<code>A1</code>	a numeric parameter representing the multiplier of the first exponential.
<code>lrc1</code>	a numeric parameter representing the natural logarithm of the rate constant of the first exponential.
<code>A2</code>	a numeric parameter representing the multiplier of the second exponential.
<code>lrc2</code>	a numeric parameter representing the natural logarithm of the rate constant of the second exponential.

Value

a numeric vector of the same length as `input`. It is the value of the expression $A1 \cdot \exp(-\exp(lrc1) \cdot \text{input}) + A2 \cdot \exp(-\exp(lrc2) \cdot \text{input})$. If all of the arguments `A1`, `lrc1`, `A2`, and `lrc2` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSD

SSD Matrix and Estimated Variance Matrix in Multivariate Models

Description

Functions to compute matrix of residual sums of squares and products, or the estimated variance matrix for multivariate linear models.

Usage

```

# S3 method for class 'mlm'
SSD(object, ...)

# S3 methods for class 'SSD' and 'mlm'
estVar(object, ...)

```

Arguments

object	object of class "mlm", or "SSD" in the case of estVar.
...	Unused

Value

SSD() returns a list of class "SSD" containing the following components

SSD	The residual sums of squares and products matrix
df	Degrees of freedom
call	Copied from object

estVar returns a matrix with the estimated variances and covariances.

*First-order Compartment Model***Description**

This `selfStart` model evaluates the first-order compartment function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters `lKe`, `lKa`, and `lCl`.

Usage

```
SSfol(Dose, input, lKe, lKa, lCl)
```

Arguments

<code>Dose</code>	a numeric value representing the initial dose.
<code>input</code>	a numeric vector at which to evaluate the model.
<code>lKe</code>	a numeric parameter representing the natural logarithm of the elimination rate constant.
<code>lKa</code>	a numeric parameter representing the natural logarithm of the absorption rate constant.
<code>lCl</code>	a numeric parameter representing the natural logarithm of the clearance.

Value

a numeric vector of the same length as `input`, which is the value of the expression $Dose * \exp(lKe + lKa - lCl) * (\exp(-\exp(lKe) * input) - \exp(-\exp(lKa) * input)) / (\exp(lKa) - \exp(lKe))$.

If all of the arguments `lKe`, `lKa`, and `lCl` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSfpl

Four-parameter Logistic Model

Description

This `selfStart` model evaluates the four-parameter logistic function and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `A`, `B`, `xmid`, and `scal` for a given set of data.

Usage

```
SSfpl(input, A, B, xmid, scal)
```

Arguments

<code>input</code>	a numeric vector of values at which to evaluate the model.
<code>A</code>	a numeric parameter representing the horizontal asymptote on the left side (very small values of <code>input</code>).
<code>B</code>	a numeric parameter representing the horizontal asymptote on the right side (very large values of <code>input</code>).
<code>xmid</code>	a numeric parameter representing the <code>input</code> value at the inflection point of the curve. The value of <code>SSfpl</code> will be midway between <code>A</code> and <code>B</code> at <code>xmid</code> .
<code>scal</code>	a numeric scale parameter on the <code>input</code> axis.

Value

a numeric vector of the same length as `input`. It is the value of the expression $A + (B - A) / (1 + \exp((xmid - input) / scal))$. If all of the arguments `A`, `B`, `xmid`, and `scal` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSgompertz

Gompertz Growth Model

Description

This `selfStart` model evaluates the Gompertz growth model and its gradient. It has an initial attribute that creates initial estimates of the parameters `Asym`, `b2`, and `b3`.

Usage

```
SSgompertz(x, Asym, b2, b3)
```

Arguments

<code>x</code>	a numeric vector of values at which to evaluate the model.
<code>Asym</code>	a numeric parameter representing the asymptote.
<code>b2</code>	a numeric parameter related to the value of the function at $x = 0$
<code>b3</code>	a numeric parameter related to the scale the x axis.

Value

a numeric vector of the same length as `input`. It is the value of the expression $Asym * \exp(-b2 * b3^x)$. If all of the arguments `Asym`, `b2`, and `b3` are names of objects the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSlogis

Logistic Model

Description

This `selfStart` model evaluates the logistic function and its gradient. It has an `initial` attribute that creates initial estimates of the parameters `Asym`, `xmid`, and `scal`.

Usage

```
SSlogis(input, Asym, xmid, scal)
```

Arguments

<code>input</code>	a numeric vector of values at which to evaluate the model.
<code>Asym</code>	a numeric parameter representing the asymptote.
<code>xmid</code>	a numeric parameter representing the x value at the inflection point of the curve. The value of <code>SSlogis</code> will be <code>Asym/2</code> at <code>xmid</code> .
<code>scal</code>	a numeric scale parameter on the <code>input</code> axis.

Value

a numeric vector of the same length as `input`. It is the value of the expression $\text{Asym}/(1+\exp((\text{xmid}-\text{input})/\text{scal}))$. If all of the arguments `Asym`, `xmid`, and `scal` are names of objects the gradient matrix with respect to these names is attached as an attribute named `gradient`.

SSmicmen

Michaelis-Menten Model

Description

This `selfStart` model evaluates the Michaelis-Menten model and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters V_m and K .

Usage

```
SSmicmen(input, Vm, K)
```

Arguments

<code>input</code>	a numeric vector of values at which to evaluate the model.
<code>Vm</code>	a numeric parameter representing the maximum value of the response.
<code>K</code>	a numeric parameter representing the <code>input</code> value at which half the maximum response is attained. In the field of enzyme kinetics this is called the Michaelis parameter.

Value

a numeric vector of the same length as `input`. It is the value of the expression $V_m \cdot \text{input} / (K + \text{input})$. If both the arguments `Vm` and `K` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

summary( fm2)

```

SSweibull

*Weibull growth curve model***Description**

This `selfStart` model evaluates the Weibull model for growth curve data and its gradient. It has an `initial` attribute that will evaluate initial estimates of the parameters `Asym`, `Drop`, `lrc`, and `pwr` for a given set of data.

Usage

```
SSweibull(x, Asym, Drop, lrc, pwr)
```

Arguments

<code>x</code>	a numeric vector of values at which to evaluate the model.
<code>Asym</code>	a numeric parameter representing the horizontal asymptote on the right side (very small values of <code>x</code>).
<code>Drop</code>	a numeric parameter representing the change from <code>Asym</code> to the <code>y</code> intercept.
<code>lrc</code>	a numeric parameter representing the natural logarithm of the rate constant.
<code>pwr</code>	a numeric parameter representing the power to which <code>x</code> is raised.

Details

This model is a generalization of the `SSasymp` model in that it reduces to `SSasymp` when `pwr` is unity.

Value

a numeric vector of the same length as `x`. It is the value of the expression `Asym-Drop*exp(-exp(lrc)*x^pwr)`. If all of the arguments `Asym`, `Drop`, `lrc`, and `pwr` are names of objects, the gradient matrix with respect to these names is attached as an attribute named `gradient`.

start

Encode the Terminal Times of Time Series

Description

Extract and encode the times the first and last observations were taken. Provided only for compatibility with S version 2.

Usage

```
start(x, ...)
end(x, ...)
```

Arguments

`x` a univariate or multivariate time-series, or a vector or matrix.
`...` extra arguments for future methods.

Details

These are generic functions, which will use the `tsp` attribute of `x` if it exists. Their default methods decode the start time from the original time units, so that for a monthly series 1995.5 is represented as `c(1995, 7)`. For a series of frequency `f`, time `n+i/f` is presented as `c(n, i+1)` (even for `i = 0` and `f = 1`).

Warning

The representation used by `start` and `end` has no meaning unless the frequency is supplied.

`stat.anova`*GLM Anova Statistics*

Description

This is a utility function, used in `lm` and `glm` methods for `anova(..., test != NULL)` and should not be used by the average user.

Usage

```
stat.anova(table, test = c("Chisq", "F", "Cp"), scale, df.scale, n)
```

Arguments

<code>table</code>	numeric matrix as results from <code>anova.glm(..., test=NULL)</code> .
<code>test</code>	a character string, matching one of "Chisq", "F" or "Cp".
<code>scale</code>	a residual mean square or other scale estimate to be used as the denominator in an F test.
<code>df.scale</code>	degrees of freedom corresponding to <code>scale</code> .
<code>n</code>	number of observations.

Value

A matrix which is the original `table`, augmented by a column of test statistics, depending on the `test` argument.

References

step *Choose a model by AIC in a Stepwise Algorithm*

Description

Select a formula-based model by AIC.

Usage

```
step(object, scope, scale = 0,
      direction = c("both", "backward", "forward"),
      trace = 1, keep = NULL, steps = 1000, k = 2, ...)
```

Arguments

object	an object representing a model of an appropriate class (mainly "lm" and "glm"). This is used as the initial model in the stepwise search.
scope	defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components <code>upper</code> and <code>lower</code> , both formulae. See the details for how to specify the formulae and how they are used.
scale	used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>ov</code> and <code>glm</code> models. The default value, 0, indicates the scale should be estimated: see <code>extractAIC</code> .
direction	the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the <code>scope</code> argument is missing the default for <code>direction</code> is "backward".
trace	if positive, information is printed during the running of <code>step</code> . Larger values may give more detailed information.
keep	a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically <code>keep</code> will select a subset of the components of the object and return them. The default is not to keep anything.

steps	the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.
k	the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.
...	any additional arguments to <code>extractAIC</code> .

Details

`step` uses `add1` and `drop1` repeatedly; it will work for any method for which they work, and that is determined by having a valid method for `extractAIC`. When the additive constant can be chosen so that AIC is equal to Mallows' C_p , this is done and the tables are labelled appropriately.

The set of models searched is determined by the `scope` argument. The right-hand-side of its `lower` component is always included in the model, and right-hand-side of the model is included in the `upper` component. If `scope` is a single formula, it specifies the `upper` component, and the `lower` model is empty. If `scope` is missing, the initial model is used as the `upper` model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`. So using `.` in a `scope` formula means 'what is already there', with `.^2` indicating all interactions of existing terms.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The "glm" method for function `extractAIC` makes the appropriate adjustment for a `gaussian` family, but may need to be amended for other cases. (The `binomial` and `poisson` families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

Warning

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used. We suggest you remove the missing values first.

Note

This function differs considerably from the function in S, which uses a number of approximations and does not in general compute the correct AIC.

This is a minimal implementation. Use `stepAIC` in package **MASS** for a wider range of object classes.

Author(s)

B. D. Ripley: `step` is a slightly simplified version of `stepAIC` in package **MASS** (Venables & Ripley, 2002 and earlier editions).

The idea of a step function follows that described in Hastie & Pregibon (1992); but the implementation in R is more general.

stepfun

Step Function Class

Description

Given the vectors (x_1, \dots, x_n) and (y_0, y_1, \dots, y_n) (one value more!), `stepfun(x, y, ...)` returns an interpolating ‘step’ function, say `fn`. I.e., $fn(t) = c_i$ (constant) for $t \in (x_i, x_{i+1})$ and at the abscissa values, if (by default) `right = FALSE`, $fn(x_i) = y_i$ and for `right = TRUE`, $fn(x_i) = y_{i-1}$, for $i = 1, \dots, n$.

The value of the constant c_i above depends on the ‘continuity’ parameter `f`. For the default, `right = FALSE`, `f = 0`, `fn` is a *cadlag* function, i.e., continuous at right, limit (‘the point’) at left. In general, c_i is interpolated in between the neighbouring y values, $c_i = (1-f)y_i + f \cdot y_{i+1}$. Therefore, for non-0 values of `f`, `fn` may no longer be a proper step function, since it can be discontinuous from both sides, unless `right = TRUE`, `f = 1` which is right-continuous.

Usage

```
stepfun(x, y, f = as.numeric(right), ties = "ordered",
        right = FALSE)

is.stepfun(x)
knots(Fn, ...)
as.stepfun(x, ...)

## S3 method for class 'stepfun':
print(x, digits = getOption("digits") - 2, ...)

## S3 method for class 'stepfun':
summary(object, ...)
```

Arguments

<code>x</code>	numeric vector giving the knots or jump locations of the step function for <code>stepfun()</code> . For the other functions, <code>x</code> is as object below.
<code>y</code>	numeric vector one longer than <code>x</code> , giving the heights of the function values <i>between</i> the <code>x</code> values.
<code>f</code>	a number between 0 and 1, indicating how interpolation outside the given <code>x</code> values should happen. See approxfun .
<code>ties</code>	Handling of tied <code>x</code> values. Either a function or the string "ordered". See approxfun .
<code>right</code>	logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
<code>Fn, object</code>	an R object inheriting from "stepfun".
<code>digits</code>	number of significant digits to use, see print .
<code>...</code>	potentially further arguments (required by the generic).

Value

A function of class "stepfun", say `fn`. There are methods available for summarizing ("`summary(.)`"), representing ("`print(.)`") and plotting ("`plot(.)`", see [plot.stepfun](#)) "stepfun" objects.

The [environment](#) of `fn` contains all the information needed;

"x", "y"	the original arguments
"n"	number of knots (x values)
"f"	continuity parameter
"yleft", "yright"	the function values <i>outside</i> the knots
"method"	(always == "constant", from approxfun(.)).

The knots are also available via `knots(fn)`.

stl

Seasonal Decomposition of Time Series by Loess

Description

Decompose a time series into seasonal, trend and irregular components using loess, acronym STL.

Usage

```
stl(x, s.window, s.degree = 0,
    t.window = NULL, t.degree = 1,
    l.window = nextodd(period), l.degree = t.degree,
    s.jump = ceiling(s.window/10),
    t.jump = ceiling(t.window/10),
    l.jump = ceiling(l.window/10),
    robust = FALSE,
    inner = if(robust) 1 else 2,
    outer = if(robust) 15 else 0,
    na.action = na.fail)
```

Arguments

x	univariate time series to be decomposed. This should be an object of class "ts" with a frequency greater than one.
s.window	either the character string "periodic" or the span (in lags) of the loess window for seasonal extraction, which should be odd. This has no default.
s.degree	degree of locally-fitted polynomial in seasonal extraction. Should be zero or one.
t.window	the span (in lags) of the loess window for trend extraction, which should be odd. If NULL, the default, $\text{nextodd}(\text{ceiling}((1.5 \cdot \text{period}) / (1 - (1.5/s.window))))$, is taken.
t.degree	degree of locally-fitted polynomial in trend extraction. Should be zero or one.
l.window	the span (in lags) of the loess window of the low-pass filter used for each subseries. Defaults to the smallest odd integer greater than or equal to frequency(x) which is recommended since it prevents competition between the trend and seasonal components. If not an odd integer its given value is increased to the next odd one.

<code>l.degree</code>	degree of locally-fitted polynomial for the subseries low-pass filter. Must be 0 or 1.
<code>s.jump</code> , <code>t.jump</code> , <code>l.jump</code>	integers at least one to increase speed of the respective smoother. Linear interpolation happens between every <code>*.jumpth</code> value.
<code>robust</code>	logical indicating if robust fitting be used in the <code>loess</code> procedure.
<code>inner</code>	integer; the number of ‘inner’ (backfitting) iterations; usually very few (2) iterations suffice.
<code>outer</code>	integer; the number of ‘outer’ robustness iterations.
<code>na.action</code>	action on missing values.

Details

The seasonal component is found by *loess* smoothing the seasonal sub-series (the series of all January values, ...); if `s.window = "periodic"` smoothing is effectively replaced by taking the mean. The seasonal values are removed, and the remainder smoothed to find the trend. The overall level is removed from the seasonal component and added to the trend component. This process is iterated a few times. The `remainder` component is the residuals from the seasonal plus trend fit.

Several methods for the resulting class "stl" objects, see, `plot.stl`.

Value

`stl` returns an object of class "stl" with components

<code>time.series</code>	a multiple time series with columns <code>seasonal</code> , <code>trend</code> and <code>remainder</code> .
<code>weights</code>	the final robust weights (all one if fitting is not done robustly).
<code>call</code>	the matched call.
<code>win</code>	integer (length 3 vector) with the spans used for the "s", "t", and "l" smoothers.
<code>deg</code>	integer (length 3) vector with the polynomial degrees for these smoothers.
<code>jump</code>	integer (length 3) vector with the ‘jumps’ (skips) used for these smoothers.
<code>ni</code>	number of inner iterations
<code>no</code>	number of outer robustness iterations

Note

This is similar to but not identical to the `stl` function in S-PLUS. The `remainder` component given by S-PLUS is the sum of the `trend` and `remainder` series from this function.

Examples

```
require(graphics)

plot(stl(nottem, "per"))
plot(stl(nottem, s.window = 4, t.window = 50, t.jump = 1))

plot(stllc <- stl(log(co2), s.window=21))
summary(stllc)
## linear trend, strict period.
plot(stl(log(co2), s.window="per", t.window=1000))

## Two STL plotted side by side :
      stmd <- stl(mdeaths, s.window = "per") # non-robust
summary(stmR <- stl(mdeaths, s.window = "per", robust = TRUE))
op <- par(mar = c(0, 4, 0, 3), oma = c(5, 0, 4, 0), mfcol = c(4, 2))
plot(stmd, set.pars=NULL, labels = NULL,
      main = "stl(mdeaths, s.w = \"per\", robust = FALSE / TRUE)")
plot(stmR, set.pars=NULL)
# mark the 'outliers' :
(iO <- which(stmR $ weights < 1e-8)) # 10 were considered outliers
sts <- stmR$time.series
points(time(sts)[iO], 0.8* sts[,"remainder"][iO], pch = 4, col = "red")
par(op)# reset
```

stlmethods

*Methods for STL Objects***Description**

Methods for objects of class `stl`, typically the result of `stl`. The `plot` method does a multiple figure plot with some flexibility.

There are also (non-visible) `print` and `summary` methods.

Usage

```
## S3 method for class 'stl':
plot(x, labels = colnames(X),
      set.pars = list(mar = c(0, 6, 0, 6), oma = c(6, 0, 4, 0),
                     tck = -0.01, mfrow = c(nplot, 1)),
      main = NULL, range.bars = TRUE, ..., col.range = "light gray")
```

Arguments

`x` `stl` object.
`labels` character of length 4 giving the names of the component time-series.
`set.pars` settings for `par(.)` when setting up the plot.

<code>main</code>	plot main title.
<code>range.bars</code>	logical indicating if each plot should have a bar at its right side which are of equal heights in user coordinates.
<code>...</code>	further arguments passed to or from other methods.
<code>col.range</code>	colour to be used for the range bars, if plotted. Note this appears after <code>...</code> and so cannot be abbreviated.

`plot.ts` and `stl`, particularly for examples.

StructTS

Fit Structural Time Series

Description

Fit a structural model for a time series by maximum likelihood.

Usage

```
StructTS(x, type = c("level", "trend", "BSM"), init = NULL,
         fixed = NULL, optim.control = NULL)
```

Arguments

<code>x</code>	a univariate numeric time series. Missing values are allowed.
<code>type</code>	the class of structural model. If omitted, a BSM is used for a time series with $\text{frequency}(x) > 1$, and a local trend model otherwise.
<code>init</code>	initial values of the variance parameters.
<code>fixed</code>	optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in <code>fixed</code> will be varied. Probably most useful for setting variances to zero.
<code>optim.control</code>	List of control parameters for <code>optim</code> . Method "L-BFGS-B" is used.

Details

Structural time series models are (linear Gaussian) state-space models for (univariate) time series based on a decomposition of the series into a number of components. They are specified by a set of error variances, some of which may be zero.

The simplest model is the *local level* model specified by `type = "level"`. This has an underlying level μ_t which evolves by

$$\mu_{t+1} = \mu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

The observations are

$$x_t = \mu_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

There are two parameters, σ_ξ^2 and σ_ϵ^2 . It is an ARIMA(0,1,1) model, but with restrictions on the parameter set.

The *local linear trend model*, `type = "trend"`, has the same measurement equation, but with a time-varying slope in the dynamics for μ_t , given by

$$\mu_{t+1} = \mu_t + \nu_t + \xi_t, \quad \xi_t \sim N(0, \sigma_\xi^2)$$

$$\nu_{t+1} = \nu_t + \zeta_t, \quad \zeta_t \sim N(0, \sigma_\zeta^2)$$

with three variance parameters. It is not uncommon to find $\sigma_\xi^2 = 0$ (which reduces to the local level model) or $\sigma_\zeta^2 = 0$, which ensures a smooth trend. This is a restricted ARIMA(0,2,2) model.

The *basic structural model*, `type = "BSM"`, is a local trend model with an additional seasonal component. Thus the measurement equation is

$$x_t = \mu_t + \gamma_t + \epsilon_t, \quad \epsilon_t \sim N(0, \sigma_\epsilon^2)$$

where γ_t is a seasonal component with dynamics

$$\gamma_{t+1} = -\gamma_t + \dots + \gamma_{t-s+2} + \omega_t, \quad \omega_t \sim N(0, \sigma_\omega^2)$$

The boundary case $\sigma_\omega^2 = 0$ corresponds to a deterministic (but arbitrary) seasonal pattern. (This is sometimes known as the ‘dummy variable’ version of the BSM.)

Value

A list of class "StructTS" with components:

<code>coef</code>	the estimated variances of the components.
<code>loglik</code>	the maximized log-likelihood. Note that as all these models are non-stationary this includes a diffuse prior for some observations and hence is not comparable with arima nor different types of structural models.
<code>data</code>	the time series <code>x</code> .
<code>residuals</code>	the standardized residuals.
<code>fitted</code>	a multiple time series with one component for the level, slope and seasonal components, estimated contemporaneously (that is at time t and not at the end of the series).
<code>call</code>	the matched call.
<code>series</code>	the name of the series <code>x</code> .
<code>code</code>	the convergence code returned by optim .
<code>model, model0</code>	Lists representing the Kalman Filter used in the fitting. See KalmanLike . <code>model0</code> is the initial state of the filter, <code>model</code> its final state.
<code>xtsp</code>	the <code>tsp</code> attributes of <code>x</code> .

Note

Optimization of structural models is a lot harder than many of the references admit. For example, the [AirPassengers](#) data are considered in Brockwell & Davis (1996): their solution appears to be a local maximum, but nowhere near as good a fit as that produced by `StructTS`. It is quite common to find fits with one or more variances zero, and this can include σ_ϵ^2 .

         optim.control = list(trace=TRUE))
```

summary.aov

Summarize an Analysis of Variance Model

Description

Summarize an analysis of variance model.

Usage

```
## S3 method for class 'aov':
summary(object, intercept = FALSE, split,
        expand.split = TRUE, keep.zero.df = TRUE, ...)

## S3 method for class 'aovlist':
summary(object, ...)
```

Arguments

object	An object of class "aov" or "aovlist".
intercept	logical: should intercept terms be included?
split	an optional named list, with names corresponding to terms in the model. Each component is itself a list with integer components giving contrasts whose contributions are to be summed.
expand.split	logical: should the split apply also to interactions involving the factor?
keep.zero.df	logical: should terms with no degrees of freedom be included?
...	Arguments to be passed to or from other methods, for summary.aovlist including those for summary.aov.

Value

An object of class `c("summary.aov", "listof")` or `"summary.aovlist"` respectively. For a fits with a single stratum the result will be a list of ANOVA tables, one for each response (even if there is only one response): the tables are of class `"anova"` inheriting from class `"data.frame"`. They have columns `"Df"`, `"Sum Sq"`, `"Mean Sq"`, as well as `"F value"` and `"Pr(>F)"` if there are non-zero residual degrees of freedom. There is a row for each term in the model, plus one for `"Residuals"` if there are any.

For multistratum fits the return value is a list of such summaries, one for each stratum.

Note

The use of `expand.split = TRUE` is little tested: it is always possible to set it to `FALSE` and specify exactly all the splits required.

```

summary.glm

Summarizing Generalized Linear Model Fits

Description

These functions are all [methods](#) for class `glm` or `summary.glm` objects.

Usage

```
## S3 method for class 'glm':
summary(object, dispersion = NULL, correlation = FALSE,
        symbolic.cor = FALSE, ...)

## S3 method for class 'summary.glm':
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

<code>object</code>	an object of class "glm", usually, a result of a call to glm .
<code>x</code>	an object of class "summary.glm", usually, a result of a call to <code>summary.glm</code> .
<code>dispersion</code>	the dispersion parameter for the family used. Either a single numerical value or NULL (the default), when it is inferred from <code>object</code> (see 'Details').
<code>correlation</code>	logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
<code>digits</code>	the number of significant digits to use when printing.
<code>symbolic.cor</code>	logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.
<code>signif.stars</code>	logical. If TRUE, 'significance stars' are printed for each coefficient.
<code>...</code>	further arguments passed to or from other methods.

Details

`print.summary.glm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is `TRUE`. The `coefficients` component of the result gives the estimated coefficients and their estimated standard errors, together with their ratio. This third column is labelled `t_ratio` if the dispersion is estimated, and `z_ratio` if the dispersion is known (or fixed by the family). A fourth column gives the two-tailed p-value corresponding to the t or z ratio based on a Student t or Normal reference distribution. (It is possible that the dispersion is not known and there are no residual degrees of freedom from which to estimate it. In that case the estimate is `NaN`.)

Aliased coefficients are omitted in the returned object but restored by the `print` method.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

The dispersion of a GLM is not used in the fitting process, but it is needed to find standard errors. If `dispersion` is not supplied or `NULL`, the dispersion is taken as 1 for the `binomial` and `Poisson` families, and otherwise estimated by the residual Chisquared statistic (calculated from cases with non-zero weights) divided by the residual degrees of freedom.

`summary` can be used with Gaussian `glm` fits to handle the case of a linear regression with known error variance, something not handled by `summary.lm`.

Value

`summary.glm` returns an object of class "`summary.glm`", a list with components

<code>call</code>	the component from <code>object</code> .
<code>family</code>	the component from <code>object</code> .
<code>deviance</code>	the component from <code>object</code> .
<code>contrasts</code>	the component from <code>object</code> .
<code>df.residual</code>	the component from <code>object</code> .
<code>null.deviance</code>	the component from <code>object</code> .
<code>df.null</code>	the component from <code>object</code> .
<code>deviance.resid</code>	the deviance residuals: see <code>residuals.glm</code> .
<code>coefficients</code>	the matrix of coefficients, standard errors, z-values and p-values. Aliased coefficients are omitted.
<code>aliased</code>	named logical vector showing if the original coefficients are aliased.
<code>dispersion</code>	either the supplied argument or the inferred/estimated dispersion if the latter is <code>NULL</code> .
<code>df</code>	a 3-vector of the rank of the model and the number of residual degrees of freedom, plus number of non-aliased coefficients.
<code>cov.unscaled</code>	the unscaled (<code>dispersion = 1</code>) estimated covariance matrix of the estimated coefficients.
<code>cov.scaled</code>	ditto, scaled by <code>dispersion</code> .
<code>correlation</code>	(only if <code>correlation</code> is true.) The estimated correlations of the estimated coefficients.
<code>symbolic.cor</code>	(only if <code>correlation</code> is true.) The value of the argument <code>symbolic.cor</code> .

summary(glm.D93)
```

summary.lm

Summarizing Linear Model Fits

Description

summary method for class "lm".

Usage

```
## S3 method for class 'lm':
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.lm':
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

object	an object of class "lm", usually, a result of a call to lm .
x	an object of class "summary.lm", usually, a result of a call to <code>summary.lm</code> .
correlation	logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
digits	the number of significant digits to use when printing.
symbolic.cor	logical. If TRUE, print the correlations in a symbolic form (see symnum) rather than as numbers.
signif.stars	logical. If TRUE, 'significance stars' are printed for each coefficient.
...	further arguments passed to or from other methods.

Details

`print.summary.lm` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

Value

The function `summary.lm` computes and returns a list of summary statistics of the fitted linear model given in `object`, using the components (list elements) `"call"` and `"terms"` from its argument, plus

`residuals` the *weighted* residuals, the usual residuals rescaled by the square root of the weights specified in the call to `lm`.

`coefficients` a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value. Aliased coefficients are omitted.

`aliased` named logical vector showing if the original coefficients are aliased.

`sigma` the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i w_i R_i^2,$$

where R_i is the i -th residual, `residuals[i]`.

`df` degrees of freedom, a 3-vector $(p, n-p, p^*)$, the last being the number of non-aliased coefficients.

`fstatistic` (for models including non-intercept terms) a 3-vector with the value of the F-statistic with its numerator and denominator degrees of freedom.

`r.squared` R^2 , the ‘fraction of variance explained by the model’,

$$R^2 = 1 - \frac{\sum_i R_i^2}{\sum_i (y_i - y^*)^2},$$

where y^* is the mean of y_i if there is an intercept and zero otherwise.

`adj.r.squared`

the above R^2 statistic ‘adjusted’, penalizing for higher p .

`cov.unscaled` a $p \times p$ matrix of (unscaled) covariances of the $\hat{\beta}_j, j = 1, \dots, p$.

`correlation` the correlation matrix corresponding to the above `cov.unscaled`, if `correlation = TRUE` is specified.

`symbolic.cor` (only if `correlation` is true.) The value of the argument `symbolic.cor`.

`na.action` from `object`, if present there.

See Also

The model fitting function `lm`, `summary`.

Function `coef` will extract the matrix of coefficients with standard errors, t-statistics and p-values.

Examples

```
##-- Continuing the lm(.) example:
coef(lm.D90) # the bare coefficients
sld90 <- summary(lm.D90 <- lm(weight ~ group -1)) # omitting intercept
sld90
coef(sld90) # much more
```

summary.manova

*Summary Method for Multivariate Analysis of Variance***Description**

A summary method for class "manova".

Usage

```
## S3 method for class 'manova':
summary(object,
        test = c("Pillai", "Wilks", "Hotelling-Lawley", "Roy"),
        intercept = FALSE, tol = 1e-7, ...)
```

Arguments

object	An object of class "manova" or an aov object with multiple responses.
test	The name of the test statistic to be used. Partial matching is used so the name can be abbreviated.
intercept	logical. If TRUE, the intercept term is included in the table.
tol	tolerance to be used in deciding if the residuals are rank-deficient: see qr .
...	further arguments passed to or from other methods.

Details

The `summary.manova` method uses a multivariate test statistic for the summary table. Wilks' statistic is most popular in the literature, but the default Pillai-Bartlett statistic is recommended by Hand and Taylor (1987).

The table gives a transformation of the test statistic which has approximately an F distribution. The approximations used follow S-PLUS and SAS (the latter apart from some cases of the Hotelling-Lawley statistic), but many other distributional approximations exist: see Anderson (1984) and Krzanowski and Marriott (1994) for further references. All four approximate F statistics are the same when the term being tested has one degree of freedom, but in other cases that for the Roy statistic is an upper bound.

The tolerance `tol` is applied to the QR decomposition of the residual correlation matrix (unless some response has essentially zero residuals, when it is unscaled). Thus the default value guards against very highly correlated responses: it can be reduced but doing so will allow rather inaccurate results and it will normally be better to transform the responses to remove the high correlation.

Value

An object of class "summary.manova". If there is a positive residual degrees of freedom, this is a list with components

row.names	The names of the terms, the row names of the <code>stats</code> table if present.
SS	A named list of sums of squares and product matrices.
Eigenvalues	A matrix of eigenvalues.
stats	A matrix of the statistics, approximate F value, degrees of freedom and P value.

otherwise components `row.names`, `SS` and `Df` (degrees of freedom) for the terms (and not the residuals).

```

summary.nls

Summarizing Non-Linear Least-Squares Model Fits

Description

summary method for class "nls".

Usage

```
## S3 method for class 'nls':
summary(object, correlation = FALSE, symbolic.cor = FALSE, ...)

## S3 method for class 'summary.nls':
print(x, digits = max(3, getOption("digits") - 3),
      symbolic.cor = x$symbolic.cor,
      signif.stars = getOption("show.signif.stars"), ...)
```

Arguments

<code>object</code>	an object of class "nls".
<code>x</code>	an object of class "summary.nls", usually the result of a call to <code>summary.nls</code> .
<code>correlation</code>	logical; if TRUE, the correlation matrix of the estimated parameters is returned and printed.
<code>digits</code>	the number of significant digits to use when printing.
<code>symbolic.cor</code>	logical. If TRUE, print the correlations in a symbolic form (see <code>symnum</code>) rather than as numbers.
<code>signif.stars</code>	logical. If TRUE, 'significance stars' are printed for each coefficient.
<code>...</code>	further arguments passed to or from other methods.

Details

The distribution theory used to find the distribution of the standard errors and of the residual standard error (for t ratios) is based on linearization and is approximate, maybe very approximate.

`print.summary.nls` tries to be smart about formatting the coefficients, standard errors, etc. and additionally gives 'significance stars' if `signif.stars` is TRUE.

Correlations are printed to two decimal places (or symbolically): to see the actual correlations print `summary(object)$correlation` directly.

Value

The function `summary.nls` computes and returns a list of summary statistics of the fitted model given in `object`, using the component "formula" from its argument, plus

<code>residuals</code>	the <i>weighted</i> residuals, the usual residuals rescaled by the square root of the weights specified in the call to <code>nls</code> .
<code>coefficients</code>	a $p \times 4$ matrix with columns for the estimated coefficient, its standard error, t-statistic and corresponding (two-sided) p-value.
<code>sigma</code>	the square root of the estimated variance of the random error

$$\hat{\sigma}^2 = \frac{1}{n-p} \sum_i R_i^2,$$

where R_i is the i -th weighted residual.

<code>df</code>	degrees of freedom, a 2-vector $(p, n-p)$. (Here and elsewhere n omits observations with zero weights.)
<code>cov.unscaled</code>	a $p \times p$ matrix of (unscaled) covariances of the parameter estimates.
<code>correlation</code>	the correlation matrix corresponding to the above <code>cov.unscaled</code> , if <code>correlation = TRUE</code> is specified and there are a non-zero number of residual degrees of freedom.
<code>symbolic.cor</code>	(only if <code>correlation</code> is true.) The value of the argument <code>symbolic.cor</code> .

See Also

The model fitting function `nls`, `summary`.

Function `coef` will extract the matrix of coefficients with standard errors, t-statistics and p-values.

summary.princomp *Summary method for Principal Components Analysis*

Description

The `summary` method for class "princomp".

Usage

```
## S3 method for class 'princomp':
summary(object, loadings = FALSE, cutoff = 0.1, ...)

## S3 method for class 'summary.princomp':
print(x, digits = 3, loadings = x$print.loadings,
      cutoff = x$cutoff, ...)
```

Arguments

<code>object</code>	an object of class "princomp", as from <code>princomp()</code> .
<code>loadings</code>	logical. Should loadings be included?
<code>cutoff</code>	numeric. Loadings below this cutoff in absolute value are shown as blank in the output.
<code>x</code>	an object of class "summary.princomp".
<code>digits</code>	the number of significant digits to be used in listing loadings.
<code>...</code>	arguments to be passed to or from other methods.

Value

object with additional components `cutoff` and `print.loadings`.

See Also

[princomp](#)

Examples

```
summary(pc.cr <- princomp(USArrests, cor=TRUE))
print(summary(princomp(USArrests, cor=TRUE),
               loadings = TRUE, cutoff = 0.2), digits = 2)
```

supsmu

*Friedman's SuperSmoother***Description**

Smooth the (x, y) values by Friedman's 'super smoother'.

Usage

```
supsmu(x, y, wt, span = "cv", periodic = FALSE, bass = 0)
```

Arguments

x	x values for smoothing
y	y values for smoothing
wt	case weights, by default all equal
span	the fraction of the observations in the span of the running lines smoother, or "cv" to choose this by leave-one-out cross-validation.
periodic	if TRUE, the x values are assumed to be in [0, 1] and of period 1.
bass	controls the smoothness of the fitted curve. Values of up to 10 indicate increasing smoothness.

Details

supsmu is a running lines smoother which chooses between three spans for the lines. The running lines smoothers are symmetric, with $k/2$ data points each side of the predicted point, and values of k as $0.5 * n$, $0.2 * n$ and $0.05 * n$, where n is the number of data points. If `span` is specified, a single smoother with span `span * n` is used.

The best of the three smoothers is chosen by cross-validation for each prediction. The best spans are then smoothed by a running lines smoother and the final prediction chosen by linear interpolation.

The FORTRAN code says: "For small samples ($n < 40$) or if there are substantial serial correlations between observations close in x-value, then a pre-specified fixed span smoother (`span > 0`) should be used. Reasonable span values are 0.2 to 0.4."

Cases with non-finite values of `x`, `y` or `wt` are dropped, with a warning.

Value

A list with components

x	the input values in increasing order with duplicates removed.
y	the corresponding y values on the fitted curve.

See Also[ppr](#)**Examples**

```
require(graphics)

with(cars, {
  plot(speed, dist)
  lines(supsmu(speed, dist))
  lines(supsmu(speed, dist, bass = 7), lty = 2)
})
```

symnum

*Symbolic Number Coding***Description**

Symbolically encode a given numeric or logical vector or array. Particularly useful for visualization of structured matrices, e.g., correlation, sparse, or logical ones.

Usage

```
symnum(x, cutpoints = c(0.3, 0.6, 0.8, 0.9, 0.95),
       symbols = if(numeric.x) c(" ", ".", ",", "+", "*", "B")
         else c(".", "|"),
       legend = length(symbols) >= 3,
       na = "?", eps = 1e-5, numeric.x = is.numeric(x),
       corr = missing(cutpoints) && numeric.x,
       show.max = if(corr) "1", show.min = NULL,
       abbr.colnames = has.colnames,
       lower.triangular = corr && is.numeric(x) && is.matrix(x),
       diag.lower.tri = corr && !is.null(show.max))
```

Arguments

<code>x</code>	numeric or logical vector or array.
<code>cutpoints</code>	numeric vector whose values <code>cutpoints[j] = c_j</code> (<i>after</i> augmentation, see <code>corr</code> below) are used for intervals.
<code>symbols</code>	character vector, one shorter than (the <i>augmented</i> , see <code>corr</code> below) <code>cutpoints</code> . <code>symbols[j] = s_j</code> are used as ‘code’ for the (half open) interval $(c_j, c_{j+1}]$. When <code>numeric.x</code> is FALSE, i.e., by default when argument <code>x</code> is logical, the default is <code>c(" ", " ")</code> (graphical 0/1 s).
<code>legend</code>	logical indicating if a "legend" attribute is desired.
<code>na</code>	character or logical. How NAs are coded. If <code>na == FALSE</code> , NAs are coded invisibly, <i>including</i> the "legend" attribute below, which otherwise mentions NA coding.
<code>eps</code>	absolute precision to be used at left and right boundary.

`numeric.x` logical indicating if `x` should be treated as numbers, otherwise as logical.
`corr` logical. If TRUE, `x` contains correlations. The cutpoints are augmented by 0 and 1 and `abs(x)` is coded.
`show.max` if TRUE, or of mode `character`, the maximal cutpoint is coded especially.
`show.min` if TRUE, or of mode `character`, the minimal cutpoint is coded especially.
`abbr.colnames` logical, integer or NULL indicating how column names should be abbreviated (if they are); if NULL (or FALSE and `x` has no column names), the column names will all be empty, i.e., ""; otherwise if `abbr.colnames` is false, they are left unchanged. If TRUE or integer, existing column names will be abbreviated to `abbreviate(*, minlength = abbr.colnames)`.
`lower.triangular` logical. If TRUE and `x` is a matrix, only the *lower triangular* part of the matrix is coded as non-blank.
`diag.lower.tri` logical. If `lower.triangular` and this are TRUE, the *diagonal* part of the matrix is shown.

Value

An atomic character object of class `noquote` and the same dimensions as `x`.

If `legend` is TRUE (as by default when there are more than two classes), the result has an attribute "legend" containing a legend of the returned character codes, in the form

$$c_1 s_1 c_2 s_2 \dots s_n c_{n+1}$$

where $c_j = \text{cutpoints}[j]$ and $s_j = \text{symbols}[j]$.

Note

The optional (mostly logical) arguments all try to use smart defaults. Specifying them explicitly may lead to considerably improved output in many cases.

noquote(cbind(P.val = format(pval), Signif= symp))

```

t.test

Student's t-Test

Description

Performs one and two sample t-tests on vectors of data.

Usage

```

t.test(x, ...)

## Default S3 method:
t.test(x, y = NULL,
       alternative = c("two.sided", "less", "greater"),
       mu = 0, paired = FALSE, var.equal = FALSE,
       conf.level = 0.95, ...)

## S3 method for class 'formula':
t.test(formula, data, subset, na.action, ...)

```

Arguments

x a (non-empty) numeric vector of data values.

y an optional (non-empty) numeric vector of data values.

alternative a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.

<code>mu</code>	a number indicating the true value of the mean (or difference in means if you are performing a two sample test).
<code>paired</code>	a logical indicating whether you want a paired t-test.
<code>var.equal</code>	a logical variable indicating whether to treat the two variances as being equal. If <code>TRUE</code> then the pooled variance is used to estimate the variance otherwise the Welch (or Satterthwaite) approximation to the degrees of freedom is used.
<code>conf.level</code>	confidence level of the interval.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

`alternative = "greater"` is the alternative that `x` has a larger mean than `y`.

If `paired` is `TRUE` then both `x` and `y` must be specified and they must be the same length. Missing values are removed (in pairs if `paired` is `TRUE`). If `var.equal` is `TRUE` then the pooled estimate of the variance is used. By default, if `var.equal` is `FALSE` then the variance is estimated separately for both groups and the Welch modification to the degrees of freedom is used.

If the input data are effectively constant (compared to the larger of the two means) an error is generated.

Value

A list with class `"htest"` containing the following components:

<code>statistic</code>	the value of the t-statistic.
<code>parameter</code>	the degrees of freedom for the t-statistic.
<code>p.value</code>	the p-value for the test.
<code>conf.int</code>	a confidence interval for the mean appropriate to the specified alternative hypothesis.
<code>estimate</code>	the estimated mean or difference in means depending on whether it was a one-sample test or a two-sample test.
<code>null.value</code>	the specified hypothesized value of the mean or mean difference depending on whether it was a one-sample test or a two-sample test.
<code>alternative</code>	a character string describing the alternative hypothesis.
<code>method</code>	a character string indicating what type of t-test was performed.
<code>data.name</code>	a character string giving the name(s) of the data.

[prop.test](#)

Examples

```
require(graphics)

t.test(1:10,y=c(7:20))      # P = .00001855
t.test(1:10,y=c(7:20, 200)) # P = .1245    -- NOT significant anymore

## Classical example: Student's sleep data
plot(extra ~ group, data = sleep)
## Traditional interface
with(sleep, t.test(extra[group == 1], extra[group == 2]))
## Formula interface
t.test(extra ~ group, data = sleep)
```

TDist

*The Student t Distribution***Description**

Density, distribution function, quantile function and random generation for the t distribution with `df` degrees of freedom (and optional non-centrality parameter `ncp`).

Usage

```
dt(x, df, ncp, log = FALSE)
pt(q, df, ncp, lower.tail = TRUE, log.p = FALSE)
qt(p, df, ncp, lower.tail = TRUE, log.p = FALSE)
rt(n, df, ncp)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>df</code>	degrees of freedom (> 0 , maybe non-integer). <code>df = Inf</code> is allowed.
<code>ncp</code>	non-centrality parameter δ ; currently except for <code>rt()</code> , only for <code>abs(ncp) <= 37.62</code> . If omitted, use the central t distribution.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The *t* distribution with `df = ν` degrees of freedom has density

$$f(x) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)}(1 + x^2/\nu)^{-(\nu+1)/2}$$

for all real x . It has mean 0 (for $\nu > 1$) and variance $\frac{\nu}{\nu-2}$ (for $\nu > 2$).

The general *non-central t* with parameters $(\nu, \delta) = (\text{df}, \text{ncp})$ is defined as the distribution of $T_\nu(\delta) := (U + \delta)/\sqrt{V/\nu}$ where U and V are independent random variables, $U \sim \mathcal{N}(0, 1)$ and $V \sim \chi_\nu^2$ (see [Chisquare](#)).

The most used applications are power calculations for t -tests:

Let $T = \frac{\bar{X} - \mu_0}{S/\sqrt{n}}$ where \bar{X} is the [mean](#) and S the sample standard deviation ([sd](#)) of X_1, X_2, \dots, X_n which are i.i.d. $\mathcal{N}(\mu, \sigma^2)$. Then T is distributed as non-central t with $\text{df} = n - 1$ degrees of freedom and non-centrality parameter $\text{ncp} = (\mu - \mu_0)\sqrt{n}/\sigma$.

Value

`dt` gives the density, `pt` gives the distribution function, `qt` gives the quantile function, and `rt` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

Note

Setting `ncp = 0` is *not* equivalent to omitting `ncp`. **R** uses the non-centrality functionality whenever `ncp` is specified which provides continuous behavior at $\text{ncp} = 0$.

Source

The central `dt` is computed via an accurate formula provided by Catherine Loader (see the reference in [dbinom](#)).

For the non-central case of `dt`, contributed by Claus Ekstrøm based on the relationship (for $x \neq 0$) to the cumulative distribution.

For the central case of `pt`, a normal approximation in the tails, otherwise via [pbeta](#).

For the non-central case of `pt` based on a C translation of

Lenth, R. V. (1989). *Algorithm AS 243* — Cumulative distribution function of the non-central t distribution, *Applied Statistics* **38**, 185–189.

For central `qt`, a C translation of

Hill, G. W. (1970) Algorithm 396: Student's t -quantiles. *Communications of the ACM*, **13**(10), 619–620.

altered to take account of

Hill, G. W. (1981) Remark on Algorithm 396, *ACM Transactions on Mathematical Software*, **7**, 250–1.

The non-central case is done by inversion.

[df](#) for the F distribution.

Examples

```
require(graphics)

1 - pt(1:5, df = 1)
qt(.975, df = c(1:10,20,50,100,1000))

tt <- seq(0,10, len=21)
ncp <- seq(0,6, len=31)
ptn <- outer(tt,ncp, function(t,d) pt(t, df = 3, ncp=d))
t.tit <- "Non-central t - Probabilities"
image(tt,ncp,ptn, zlim=c(0,1), main = t.tit)
persp(tt,ncp,ptn, zlim=0:1, r=2, phi=20, theta=200, main=t.tit,
      xlab = "t", ylab = "non-centrality parameter",
      zlab = "Pr(T <= t)")

plot(function(x) dt(x, df = 3, ncp = 2), -3, 11, ylim = c(0, 0.32),
      main="Non-central t - Density", yaxs="i")
```

termplot

*Plot regression terms***Description**

Plots regression terms against their predictors, optionally with standard errors and partial residuals added.

Usage

```
termplot(model, data = NULL, envir = environment(formula(model)),
  partial.resid = FALSE, rug = FALSE,
  terms = NULL, se = FALSE,
  xlabs = NULL, ylabs = NULL, main = NULL,
  col.term = 2, lwd.term = 1.5,
  col.se = "orange", lty.se = 2, lwd.se = 1,
  col.res = "gray", cex = 1, pch = par("pch"),
  col.smth = "darkred", lty.smth = 2, span.smth = 2/3,
  ask = dev.interactive() && nb.fig < n.tms,
  use.factor.levels = TRUE, smooth = NULL, ylim = "common",
  ...)
```

Arguments

model	fitted model object
data	data frame in which variables in model can be found
envir	environment in which variables in model can be found
partial.resid	logical; should partial residuals be plotted?
rug	add rugplots (jittered 1-d histograms) to the axes?
terms	which terms to plot (default NULL means all terms)
se	plot pointwise standard errors?

`xlabs` vector of labels for the x axes
`ylabs` vector of labels for the y axes
`main` logical, or vector of main titles; if TRUE, the model's call is taken as main title, NULL or FALSE mean no titles.
`col.term, lwd.term` color and line width for the 'term curve', see [lines](#).
`col.se, lty.se, lwd.se` color, line type and line width for the 'twice-standard-error curve' when `se = TRUE`.
`col.res, cex, pch` color, plotting character expansion and type for partial residuals, when `partial.resid = TRUE`, see [points](#).
`ask` logical; if TRUE, the user is *asked* before each plot, see [par](#) (`ask=.`).
`use.factor.levels` Should x-axis ticks use factor levels or numbers for factor terms?
`smooth` NULL or a function with the same arguments as [panel.smooth](#) to draw a smooth through the partial residuals for non-factor terms
`lty.smth, col.smth, span.smth` Passed to `smooth`
`ylim` an optional range for the y axis, or "common" when a range sufficient for all the plot will be computed, or "free" when limits are computed for each plot.
`...` other graphical parameters.

Details

The model object must have a `predict` method that accepts `type=terms`, eg [glm](#) in the **base** package, [coxph](#) and [survreg](#) in the **survival** package.

For the `partial.resid=TRUE` option it must have a `residuals` method that accepts `type="partial"`, which [lm](#) and [glm](#) do.

The `data` argument should rarely be needed, but in some cases `termplot` may be unable to reconstruct the original data frame. Using `na.action=na.exclude` makes these problems less likely.

Nothing sensible happens for interaction terms.

See Also

For (generalized) linear models, [plot.lm](#) and [predict.glm](#).

Examples

```

require(graphics)

had.splines <- "package:splines" %in% search()
if(!had.splines) rs <- require(splines)
x <- 1:100
z <- factor(rep(LETTERS[1:4],25))
y <- rnorm(100, sin(x/10)+as.numeric(z))
model <- glm(y ~ ns(x,6) + z)

par(mfrow=c(2,2)) ## 2 x 2 plots for same model :
termplot(model, main = paste("termplot( ", deparse(model$call), " ..."))

```

```
termpplot(model, rug=TRUE)
termpplot(model, partial.resid=TRUE, se = TRUE, main = TRUE)
termpplot(model, partial.resid=TRUE, smooth=panel.smooth, span.smth=1/4)
if(!had.splines && rs) detach("package:splines")
```

terms

Model Terms

Description

The function `terms` is a generic function which can be used to extract *terms* objects from various kinds of R data objects.

Usage

```
terms(x, ...)
```

Arguments

`x` object used to select a method to dispatch.
`...` further arguments passed to or from other methods.

Details

There are methods for classes "aovlist", and "terms" "formula" (see [terms.formula](#)): the default method just extracts the `terms` component of the object (if any).

There are [print](#) and [labels](#) methods for class "terms": the latter prints the term labels (see [terms.object](#)).

Value

An object of class `c("terms", "formula")` which contains the *terms* representation of a symbolic model. See [terms.object](#) for its structure.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical models*. Chapter 2 of *Statistical Models in S* eds J. M. Chambers and T. J. Hastie, Wadsworth & Brooks/Cole.

See Also

[terms.object](#), [terms.formula](#), [lm](#), [glm](#), [formula](#).

terms.formula	<i>Construct a terms Object from a Formula</i>
---------------	--

Description

This function takes a formula and some optional arguments and constructs a terms object. The terms object can then be used to construct a `model.matrix`.

Usage

```
## S3 method for class 'formula':
terms(x, specials = NULL, abb = NULL, data = NULL, neg.out = TRUE,
      keep.order = FALSE, simplify = FALSE, ...,
      allowDotAsName = FALSE)
```

Arguments

x	a formula.
specials	which functions in the formula should be marked as special in the <code>terms</code> object.
abb	Not implemented in R.
data	a data frame from which the meaning of the special symbol <code>.</code> can be inferred. It is unused if there is no <code>.</code> in the formula.
neg.out	Not implemented in R.
keep.order	a logical value indicating whether the terms should keep their positions. If <code>FALSE</code> the terms are reordered so that main effects come first, followed by the interactions, all second-order, all third-order and so on. Effects of a given order are kept in the order specified.
simplify	should the formula be expanded and simplified, the pre-1.7.0 behaviour?
...	further arguments passed to or from other methods.
allowDotAsName	normally <code>.</code> in a formula refers to the remaining variables contained in <code>data</code> . Exceptionally, <code>.</code> can be treated as a name for non-standard uses of formulae.

Details

Not all of the options work in the same way that they do in S and not all are implemented.

Value

A `terms.object` object is returned. The object itself is the re-ordered (unless `keep.order = TRUE`) formula. In all cases variables within an interaction term in the formula are re-ordered by the ordering of the `"variables"` attribute, which is the order in which the variables occur in the formula.

See Also

[terms](#), [terms.object](#)

terms.object	<i>Description of Terms Objects</i>
--------------	-------------------------------------

Description

An object of class `terms` holds information about a model. Usually the model was specified in terms of a `formula` and that formula was used to determine the terms object.

Value

The object itself is simply the formula supplied to the call of `terms.formula`. The object has a number of attributes and they are used to construct the model frame:

factors	A matrix of variables by terms showing which variables appear in which terms. The entries are 0 if the variable does not occur in the term, 1 if it does occur and should be coded by contrasts, and 2 if it occurs and should be coded via dummy variables for all levels (as when an intercept or lower-order term is missing). If there are no terms other than an intercept and offsets, this is <code>numeric(0)</code> .
term.labels	A character vector containing the labels for each of the terms in the model, except for offsets. Non-syntactic names will be quoted by backticks. Note that these are after possible re-ordering (unless argument <code>keep.order</code> was false).
variables	A call to <code>list</code> of the variables in the model.
intercept	Either 0, indicating no intercept is to be fit, or 1 indicating that an intercept is to be fit.
order	A vector of the same length as <code>term.labels</code> indicating the order of interaction for each term.
response	The index of the variable (in <code>variables</code>) of the response (the left hand side of the formula). Zero, if there is no response.
offset	If the model contains <code>offset</code> terms there is an <code>offset</code> attribute indicating which variable(s) are offsets
specials	If a <code>specials</code> argument was given to <code>terms.formula</code> there is a <code>specials</code> attribute, a list of vectors (one for each specified special function) giving numeric indices of the arguments of the list returned as the <code>variables</code> attribute which contain these special functions.
dataClasses	optional. A named character vector giving the classes (as given by <code>.MFclass</code>) of the variables used in a fit.

The object has class `c("terms", "formula")`.

Note

These objects are different from those found in S. In particular there is no `formula` attribute, instead the object is itself a formula. Thus, the mode of a terms object is different as well.

Examples of the `specials` argument can be seen in the `av` and `coxph` functions.

See Also

`terms`, `formula`.

Examples

```
## use of specials (as used for gam() in packages mgcv and gam)
(tf <- terms(y ~ x + x:z + s(x), specials = "s"))
## Note that the "factors" attribute has variables as row names
## and term labels as column names, both as character vectors.
attr(tf, "specials")      # index 's' variable(s)
rownames(attr(tf, "factors"))[attr(tf, "specials")]$s

## we can keep the order by
terms(y ~ x + x:z + s(x), specials = "s", keep.order = TRUE)
```

time

*Sampling Times of Time Series***Description**

`time` creates the vector of times at which a time series was sampled.

`cycle` gives the positions in the cycle of each observation.

`frequency` returns the number of samples per unit time and `deltat` the time interval between observations (see [ts](#)).

Usage

```
time(x, ...)
## Default S3 method:
time(x, offset=0, ...)

cycle(x, ...)
frequency(x, ...)
deltat(x, ...)
```

Arguments

`x` a univariate or multivariate time-series, or a vector or matrix.

`offset` can be used to indicate when sampling took place in the time unit. 0 (the default) indicates the start of the unit, 0.5 the middle and 1 the end of the interval.

`...` extra arguments for future methods.

Details

These are all generic functions, which will use the `ts` attribute of `x` if it exists. `time` and `cycle` have methods for class `ts` that coerce the result to that class.

# a simple series plot
plot(as.vector(time(presidents)), as.vector(presidents), type="l")
```

toeplitz

Form Symmetric Toeplitz Matrix

Description

Forms a symmetric Toeplitz matrix given its first row.

Usage

```
toeplitz(x)
```

Arguments

`x` the first row to form the Toeplitz matrix.

Value

The Toeplitz matrix.

Author(s)

A. Trapletti

Examples

```
x <- 1:5
toeplitz(x)
```

 ts *Time-Series Objects*

Description

The function `ts` is used to create time-series objects.

`as.ts` and `is.ts` coerce an object to a time-series and test whether an object is a time series.

Usage

```
ts(data = NA, start = 1, end = numeric(0), frequency = 1,
   deltat = 1, ts.eps = getOption("ts.eps"), class = , names = )
as.ts(x, ...)
is.ts(x)
```

Arguments

<code>data</code>	a numeric vector or matrix of the observed time-series values. A data frame will be coerced to a numeric matrix via <code>data.matrix</code> .
<code>start</code>	the time of the first observation. Either a single number or a vector of two integers, which specify a natural time unit and a (1-based) number of samples into the time unit. See the examples for the use of the second form.
<code>end</code>	the time of the last observation, specified in the same way as <code>start</code> .
<code>frequency</code>	the number of observations per unit of time.
<code>deltat</code>	the fraction of the sampling period between successive observations; e.g., 1/12 for monthly data. Only one of <code>frequency</code> or <code>deltat</code> should be provided.
<code>ts.eps</code>	time series comparison tolerance. Frequencies are considered equal if their absolute difference is less than <code>ts.eps</code> .
<code>class</code>	class to be given to the result, or <code>NULL</code> or <code>"none"</code> . The default is <code>"ts"</code> for a single series, <code>c("mts", "ts")</code> for multiple series.
<code>names</code>	a character vector of names for the series in a multiple series: defaults to the <code>colnames</code> of <code>data</code> , or <code>Series 1, Series 2, ...</code> .
<code>x</code>	an arbitrary R object.
<code>...</code>	arguments passed to methods (unused for the default method).

Details

The function `ts` is used to create time-series objects. These are vector or matrices with class of `"ts"` (and additional attributes) which represent data which has been sampled at equispaced points in time. In the matrix case, each column of the matrix `data` is assumed to contain a single (univariate) time series. Time series must have at least one observation, and although they need not be numeric there is very limited support for non-numeric series.

Class `"ts"` has a number of methods. In particular arithmetic will attempt to align time axes, and subsetting to extract subsets of series can be used (e.g., `EuStockMarkets[, "DAX"]`). However, subsetting the first (or only) dimension will return a matrix or vector, as will matrix subsetting. Subassignment can be used to replace values but not to extend a series (see [window](#)). There is a method for `t` that transposes the series as a matrix (a one-column matrix if a vector) and hence returns a result that does not inherit from class `"ts"`.

The value of argument `frequency` is used when the series is sampled an integral number of times in each unit time interval. For example, one could use a value of 7 for `frequency` when the data are sampled daily, and the natural time period is a week, or 12 when the data are sampled monthly and the natural time period is a year. Values of 4 and 12 are assumed in (e.g.) `print` methods to imply a quarterly and monthly series respectively.

`as.ts` is generic. Its default method will use the `tsp` attribute of the object if it has one to set the start and end times and frequency.

`is.ts` tests if an object is a time series. It is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`tsp`, `frequency`, `start`, `end`, `time`, `window`; `print.ts`, the print method for time series objects; `plot.ts`, the plot method for time series objects.

Examples

```
require(graphics)

ts(1:10, frequency = 4, start = c(1959, 2)) # 2nd Quarter of 1959
print( ts(1:10, frequency = 7, start = c(12, 2)), calendar = TRUE)
# print.ts(.)
## Using July 1954 as start date:
gnp <- ts(cumsum(1 + round(rnorm(100), 2)),
          start = c(1954, 7), frequency = 12)
plot(gnp) # using 'plot.ts' for time-series plot

## Multivariate
z <- ts(matrix(rnorm(300), 100, 3), start=c(1961, 1), frequency=12)
class(z)
plot(z)
plot(z, plot.type="single", lty=1:3)

## A phase plot:
plot(nhtemp, c(nhtemp[-1], NA), cex = .8, col="blue",
     main = "Lag plot of New Haven temperatures")
## a clearer way to do this would be
## Not run:
plot(nhtemp, lag(nhtemp, 1), cex = .8, col="blue",
     main = "Lag plot of New Haven temperatures")
## End(Not run)
```

Description

Methods for objects of class `"ts"`, typically the result of `ts`.

Usage

```
## S3 method for class 'ts':
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'ts':
na.omit(object, ...)
```

Arguments

`x` an object of class "ts" containing the values to be differenced.

`lag` an integer indicating which lag to use.

`differences` an integer indicating the order of the difference.

`object` a univariate or multivariate time series.

`...` further arguments to be passed to or from methods.

Details

The `na.omit` method omits initial and final segments with missing values in one or more of the series. 'Internal' missing values will lead to failure.

Value

For the `na.omit` method, a time series without missing values. The class of `object` will be preserved.

See Also

`diff`; `na.omit`, `na.fail`, `na.contiguous`.

ts.plot

Plot Multiple Time Series

Description

Plot several time series on a common plot. Unlike `plot.ts` the series can have a different time bases, but they should have the same frequency.

Usage

```
ts.plot(..., gpars = list())
```

Arguments

`...` one or more univariate or multivariate time series.

`gpars` list of named graphics parameters to be passed to the plotting functions. Those commonly used can be supplied directly in `...`

Value

None.

Note

Although this can be used for a single time series, `plot` is easier to use and is preferred.

See Also

[plot.ts](#)

Examples

```
require(graphics)

ts.plot(ldeaths, mdeaths, fdeaths,
        gpars=list(xlab="year", ylab="deaths", lty=c(1:3)))
```

ts.union

Bind Two or More Time Series

Description

Bind time series which have a common frequency. `ts.union` pads with NAs to the total time coverage, `ts.intersect` restricts to the time covered by all the series.

Usage

```
ts.intersect(..., dframe = FALSE)
ts.union(..., dframe = FALSE)
```

Arguments

<code>...</code>	two or more univariate or multivariate time series, or objects which can coerced to time series.
<code>dframe</code>	logical; if TRUE return the result as a data frame.

Details

As a special case, `...` can contain vectors or matrices of the same length as the combined time series of the time series present, as well as those of a single row.

Value

A time series object if `dframe` is FALSE, otherwise a data frame.

See Also

[cbind](#).

Examples

```
ts.union(mdeaths, fdeaths)
cbind(mdeaths, fdeaths) # same as the previous line
ts.intersect(window(mdeaths, 1976), window(fdeaths, 1974, 1978))

sales1 <- ts.union(BJsales, lead = BJsales.lead)
ts.intersect(sales1, lead3 = lag(BJsales.lead, -3))
```

`tsdiag`*Diagnostic Plots for Time-Series Fits*

Description

A generic function to plot time-series diagnostics.

Usage

```
tsdiag(object, gof.lag, ...)
```

Arguments

<code>object</code>	a fitted time-series model
<code>gof.lag</code>	the maximum number of lags for a Portmanteau goodness-of-fit test
<code>...</code>	further arguments to be passed to particular methods

Details

This is a generic function. It will generally plot the residuals, often standardized, the autocorrelation function of the residuals, and the p-values of a Portmanteau test for all lags up to `gof.lag`.

The methods for `arima` and `StructTS` objects plots residuals scaled by the estimate of their (individual) variance, and use the Ljung–Box version of the portmanteau test.

Value

None. Diagnostics are plotted.

See Also

`arima`, `StructTS`, `Box.test`

Examples

```
## Not run: require(graphics)

fit <- arima(lh, c(1,0,0))
tsdiag(fit)

## see also examples(arima)

(fit <- StructTS(log10(JohnsonJohnson), type="BSM"))
tsdiag(fit)
## End(Not run)
```

`tsp`*Tsp Attribute of Time-Series-like Objects*

Description

`tsp` returns the `tsp` attribute (or `NULL`). It is included for compatibility with S version 2. `tsp<-` sets the `tsp` attribute. `hasTsp` ensures `x` has a `tsp` attribute, by adding one if needed.

Usage

```
tsp(x)
tsp(x) <- value
hasTsp(x)
```

Arguments

`x` a vector or matrix or univariate or multivariate time-series.
`value` a numeric vector of length 3 or `NULL`.

Details

The `tsp` attribute was previously described here as `c(start(x), end(x), frequency(x))`, but this is incorrect. It gives the start time *in time units*, the end time and the frequency.

Assignments are checked for consistency.

Assigning `NULL` which removes the `tsp` attribute *and* any "ts" (or "mts") class of `x`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[ts](#), [time](#), [start](#).

`tsSmooth`*Use Fixed-Interval Smoothing on Time Series*

Description

Performs fixed-interval smoothing on a univariate time series via a state-space model. Fixed-interval smoothing gives the best estimate of the state at each time point based on the whole observed series.

Usage

```
tsSmooth(object, ...)
```

Arguments

object a time-series fit. Currently only class "[StructTS](#)" is supported
 . . . possible arguments for future methods.

Value

A time series, with as many dimensions as the state space and results at each time point of the original series. (For seasonal models, only the current seasonal component is returned.)

Author(s)

B. D. Ripley

References

Durbin, J. and Koopman, S. J. (2001) *Time Series Analysis by State Space Methods*. Oxford University Press.

Tukey

The Studentized Range Distribution

Description

Functions of the distribution of the studentized range, R/s , where R is the range of a standard normal sample and $df \times s^2$ is independently distributed as chi-squared with df degrees of freedom, see [pchisq](#).

Usage

```
ptukey(q, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
qtukey(p, nmeans, df, nranges = 1, lower.tail = TRUE, log.p = FALSE)
```

Arguments

q vector of quantiles.
 p vector of probabilities.
 nmeans sample size for range (same for each group).
 df degrees of freedom for s (see below).
 nranges number of *groups* whose **maximum** range is considered.
 log.p logical; if TRUE, probabilities p are given as $\log(p)$.
 lower.tail logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If $n_g = \text{nranges}$ is greater than one, R is the *maximum* of n_g groups of n_{means} observations each.

Value

`ptukey` gives the distribution function and `qtukey` its inverse, the quantile function.

Note

A Legendre 16-point formula is used for the integral of `ptukey`. The computations are relatively expensive, especially for `qtukey` which uses a simple secant method for finding the inverse of `ptukey`. `qtukey` will be accurate to the 4th decimal place.

References

Copenhaver, Margaret Diponzio and Holland, Burt S. (1988) Multiple comparisons of simple effects in the two-way analysis of variance with fixed effects. *Journal of Statistical Computation and Simulation*, **30**, 1–15.

See Also

Examples

```
if(interactive())
  curve(ptukey(x, nm=6, df=5), from=-1, to=8, n=101)
(ptt <- ptukey(0:10, 2, df= 5))
(qtt <- qtukey(.95, 2, df= 2:11))
## The precision may be not much more than about 8 digits:
summary(abs(.95 - ptukey(qtt,2, df = 2:11)))
```

 TukeyHSD

Compute Tukey Honest Significant Differences

Description

Create a set of confidence intervals on the differences between the means of the levels of a factor with the specified family-wise probability of coverage. The intervals are based on the Studentized range statistic, Tukey's 'Honest Significant Difference' method. There is a `plot` method.

Usage

```
TukeyHSD(x, which, ordered = FALSE, conf.level = 0.95, ...)
```

Arguments

<code>x</code>	A fitted model object, usually an <code>av</code> fit.
<code>which</code>	A character vector listing terms in the fitted model for which the intervals should be calculated. Defaults to all the terms.
<code>ordered</code>	A logical value indicating if the levels of the factor should be ordered according to increasing average in the sample before taking differences. If <code>ordered</code> is true then the calculated differences in the means will all be positive. The significant differences will be those for which the <code>lwr</code> end point is positive.
<code>conf.level</code>	A numeric value between zero and one giving the family-wise confidence level to use.
<code>...</code>	Optional additional arguments. None are used at present.

Details

When comparing the means for the levels of a factor in an analysis of variance, a simple comparison using t-tests will inflate the probability of declaring a significant difference when it is not in fact present. This because the intervals are calculated with a given coverage probability for each interval but the interpretation of the coverage is usually with respect to the entire family of intervals.

John Tukey introduced intervals based on the range of the sample means rather than the individual differences. The intervals returned by this function are based on this Studentized range statistics.

Technically the intervals constructed in this way would only apply to balanced designs where there are the same number of observations made at each level of the factor. This function incorporates an adjustment for sample size that produces sensible intervals for mildly unbalanced designs.

If `which` specifies non-factor terms these will be dropped with a warning: if no terms are left this is an error.

Value

A list with one component for each term requested in `which`. Each component is a matrix with columns `diff` giving the difference in the observed means, `lwr` giving the lower end point of the interval, `upr` giving the upper end point and `p.adj` giving the p-value after adjustment for the multiple comparisons.

Examples

```
require(graphics)

summary(fm1 <- aov(breaks ~ wool + tension, data = warpbreaks))
TukeyHSD(fm1, "tension", ordered = TRUE)
plot(TukeyHSD(fm1, "tension"))
```

Uniform

*The Uniform Distribution***Description**

These functions provide information about the uniform distribution on the interval from `min` to `max`. `dunif` gives the density, `pnif` gives the distribution function `qunif` gives the quantile function and `runif` generates random deviates.

Usage

```
dunif(x, min=0, max=1, log = FALSE)
pnif(q, min=0, max=1, lower.tail = TRUE, log.p = FALSE)
qunif(p, min=0, max=1, lower.tail = TRUE, log.p = FALSE)
runif(n, min=0, max=1)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>min, max</code>	lower and upper limits of the distribution. Must be finite.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If `min` or `max` are not specified they assume the default values of 0 and 1 respectively.

The uniform distribution has density

$$f(x) = \frac{1}{max - min}$$

for $min \leq x \leq max$.

For the case of $u := min == max$, the limit case of $X \equiv u$ is assumed, although there is no density in that case and `dunif` will return NaN (the error condition).

`runif` will not generate either of the extreme values unless `max = min` or `max-min` is small compared to `min`, and in particular not for the default arguments.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[.Random.seed](#) about random number generation, [rnorm](#), etc for other distributions.

Examples

```
u <- runif(20)

## The following relations always hold :
punif(u) == u
dunif(u) == 1

var(runif(10000))#- ~ = 1/12 = .08333
```

uniroot

One Dimensional Root (Zero) Finding

Description

The function `uniroot` searches the interval from `lower` to `upper` for a root (i.e., zero) of the function `f` with respect to its first argument.

Usage

```
uniroot(f, interval, ...,
        lower = min(interval), upper = max(interval),
        f.lower = f(lower, ...), f.upper = f(upper, ...),
        tol = .Machine$double.eps^0.25, maxiter = 1000)
```

Arguments

<code>f</code>	the function for which the root is sought.
<code>interval</code>	a vector containing the end-points of the interval to be searched for the root.
<code>...</code>	additional named or unnamed arguments to be passed to <code>f</code>
<code>lower, upper</code>	the lower and upper end points of the interval to be searched.
<code>f.lower, f.upper</code>	the same as <code>f(upper)</code> and <code>f(lower)</code> , respectively. Passing these values from the caller where they are often known is more economical as soon as <code>f()</code> contains non-trivial computations.
<code>tol</code>	the desired accuracy (convergence tolerance).
<code>maxiter</code>	the maximum number of iterations.

Details

Note that arguments after `...` must be matched exactly.

Either `interval` or both `lower` and `upper` must be specified: the upper endpoint must be strictly larger than the lower endpoint. The function values at the endpoints must be of opposite signs (or zero).

The function uses Fortran subroutine “`zeroin`” (from Netlib) based on algorithms given in the reference below. They assume a continuous function (which then is known to have at least one root in the interval).

Convergence is declared either if $f(x) == 0$ or the change in x for one step of the algorithm is less than `tol` (plus an allowance for representation error in x).

If the algorithm does not converge in `maxiter` steps, a warning is printed and the current approximation is returned.

`f` will be called as `f(x, ...)` for a numeric value of x .

Value

A list with four components: `root` and `f.root` give the location of the root and the value of the function evaluated at that point. `iter` and `estim.prec` give the number of iterations used and an approximate estimated precision for `root`. (If the root occurs at one of the endpoints, the estimated precision is NA.)

Source

Based on 'zeroin.c' in <http://www.netlib.org/c/brent.shar>.

exp(minexp)      # typically denormalized
```

update

Update and Re-fit a Model Call

Description

`update` will update and (by default) re-fit a model. It does this by extracting the call stored in the object, updating the call and (by default) evaluating that call. Sometimes it is useful to call `update` with only one argument, for example if the data frame has been corrected.

Usage

```
update(object, ...)

## Default S3 method:
update(object, formula., ..., evaluate = TRUE)
```

Arguments

object	An existing fit from a model function such as <code>lm</code> , <code>glm</code> and many others.
formula.	Changes to the formula – see <code>update.formula</code> for details.
...	Additional arguments to the call, or arguments with changed values. Use <code>name=NULL</code> to remove the argument <code>name</code> .
evaluate	If true evaluate the new call else return the call.

Value

If `evaluate = TRUE` the fitted object, otherwise the updated call.

```

update.formula *Model Updating*

Description

`update.formula` is used to update model formulae. This typically involves adding or dropping terms, but updates can be more general.

Usage

```
## S3 method for class 'formula':
update(old, new, ...)
```

Arguments

```
old          a model formula to be updated.
new          a formula giving a template which specifies how to update.
...          further arguments passed to or from other methods.
```

Details

Either or both of `old` and `new` can be objects such as length-one character vectors which can be coerced to a formula via `as.formula`.

The function works by first identifying the *left-hand side* and *right-hand side* of the `old` formula. It then examines the `new` formula and substitutes the *lhs* of the `old` formula for any occurrence of `'.'` on the left of `new`, and substitutes the *rhs* of the `old` formula for any occurrence of `'.'` on the right of `new`. The result is then simplified via `terms.formula(simplify = TRUE)`.

Value

The updated formula is returned. The environment of the result will that of `old`.

See Also

`terms`, `model.matrix`.

Examples

```
update(y ~ x,      ~ . + x2) #> y ~ x + x2
update(y ~ x, log(.) ~ . ) #> log(y) ~ x
```

var.test

F Test to Compare Two Variances

Description

Performs an F test to compare the variances of two samples from normal populations.

Usage

```
var.test(x, ...)
```

```
## Default S3 method:
var.test(x, y, ratio = 1,
         alternative = c("two.sided", "less", "greater"),
         conf.level = 0.95, ...)
```

```
## S3 method for class 'formula':
var.test(formula, data, subset, na.action, ...)
```

Arguments

<code>x, y</code>	numeric vectors of data values, or fitted linear model objects (inheriting from class "lm").
<code>ratio</code>	the hypothesized ratio of the population variances of <code>x</code> and <code>y</code> .
<code>alternative</code>	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
<code>conf.level</code>	confidence level for the returned confidence interval.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

The null hypothesis is that the ratio of the variances of the populations from which `x` and `y` were drawn, or in the data to which the linear models `x` and `y` were fitted, is equal to `ratio`.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value of the F test statistic.
<code>parameter</code>	the degrees of the freedom of the F distribution of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>conf.int</code>	a confidence interval for the ratio of the population variances.
<code>estimate</code>	the ratio of the sample variances of <code>x</code> and <code>y</code> .
<code>null.value</code>	the ratio of population variances under the null.
<code>alternative</code>	a character string describing the alternative hypothesis.
<code>method</code>	the character string "F test to compare two variances".
<code>data.name</code>	a character string giving the names of the data.

See Also

[bartlett.test](#) for testing homogeneity of variances in more than two samples from normal distributions; [ansari.test](#) and [mood.test](#) for two rank based (nonparametric) two-sample tests for difference in scale.

Examples

```
x <- rnorm(50, mean = 0, sd = 2)
y <- rnorm(30, mean = 1, sd = 1)
var.test(x, y) # Do x and y have the same variance?
var.test(lm(x ~ 1), lm(y ~ 1)) # The same.
```

Description

These functions ‘rotate’ loading matrices in factor analysis.

Usage

```
varimax(x, normalize = TRUE, eps = 1e-5)
promax(x, m = 4)
```

Arguments

<code>x</code>	A loadings matrix, with p rows and $k < p$ columns
<code>m</code>	The power used the target for <code>promax</code> . Values of 2 to 4 are recommended.
<code>normalize</code>	logical. Should Kaiser normalization be performed? If so the rows of <code>x</code> are re-scaled to unit length before rotation, and scaled back afterwards.
<code>eps</code>	The tolerance for stopping: the relative change in the sum of singular values.

Details

These seek a ‘rotation’ of the factors $x \%*\% T$ that aims to clarify the structure of the loadings matrix. The matrix T is a rotation (possibly with reflection) for `varimax`, but a general linear transformation for `promax`, with the variance of the factors being preserved.

Value

A list with components

<code>loadings</code>	The ‘rotated’ loadings matrix, $x \%*\% rotmat$, of class "loadings".
<code>rotmat</code>	The ‘rotation’ matrix.

varimax(loadings(fa), normalize = FALSE)
promax(loadings(fa))
```

vcov

Calculate Variance-Covariance Matrix for a Fitted Model Object

Description

Returns the variance-covariance matrix of the main parameters of a fitted model object.

Usage

```
vcov(object, ...)
```

Arguments

`object` a fitted model object.

`...` additional arguments for method functions. For the `glm` method this can be used to pass a `dispersion` parameter.

Details

This is a generic function. Functions with names beginning in `vcov.` will be methods for this function. Classes with methods for this function include: `lm`, `mlm`, `glm`, `nls`, `negbin`, `polr`, `rlm` (in package **MASS**), `multinom` (in package `nnet`) `gls`, `lme` (in package **nlme**, `coxph` and `survreg` (in package **survival**)).

Value

A matrix of the estimated covariances between the parameter estimates in the linear or non-linear predictor of the model.

Weibull

The Weibull Distribution

Description

Density, distribution function, quantile function and random generation for the Weibull distribution with parameters `shape` and `scale`.

Usage

```
dweibull(x, shape, scale = 1, log = FALSE)
pweibull(q, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
qweibull(p, shape, scale = 1, lower.tail = TRUE, log.p = FALSE)
rweibull(n, shape, scale = 1)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>shape, scale</code>	shape and scale parameters, the latter defaulting to 1.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The Weibull distribution with shape parameter a and scale parameter σ has density given by

$$f(x) = (a/\sigma)(x/\sigma)^{a-1} \exp(-(x/\sigma)^a)$$

for $x \geq 0$. The cumulative distribution function is $F(x) = 1 - \exp(-(x/\sigma)^a)$ on $x \geq 0$, the mean is $E(X) = \sigma\Gamma(1 + 1/a)$, and the $Var(X) = \sigma^2(\Gamma(1 + 2/a) - (\Gamma(1 + 1/a))^2)$.

Value

`dweibull` gives the density, `pweibull` gives the distribution function, `qweibull` gives the quantile function, and `rweibull` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

Note

The cumulative hazard $H(t) = -\log(1 - F(t))$ is `-pweibull(t, a, b, lower = FALSE, log = TRUE)` which is just $H(t) = (t/b)^a$.

Source

`[dpq]weibull` are calculated directly from the definitions. `rweibull` uses inversion.

References

Johnson, N. L., Kotz, S. and Balakrishnan, N. (1995) *Continuous Univariate Distributions*, volume 1, chapter 21. Wiley, New York.

See Also

The [Exponential](#) is a special case of the Weibull distribution.

Examples

```
x <- c(0, rlnorm(50))
all.equal(dweibull(x, shape = 1), dexp(x))
all.equal(pweibull(x, shape = 1, scale = pi), pexp(x, rate = 1/pi))
## Cumulative hazard H():
all.equal(pweibull(x, 2.5, pi, lower.tail=FALSE, log.p=TRUE), -(x/pi)^2.5,
          tol = 1e-15)
all.equal(qweibull(x/11, shape = 1, scale = pi), qexp(x/11, rate = 1/pi))
```

weighted.mean *Weighted Arithmetic Mean*

Description

Compute a weighted mean of a numeric vector.

Usage

```
weighted.mean(x, w, na.rm = FALSE)
```

Arguments

`x` a numeric vector containing the values whose mean is to be computed.

`w` a vector of weights the same length as `x` giving the weights to use for each element of `x`.

`na.rm` a logical value indicating whether NA values in `x` should be stripped before the computation proceeds.

Details

If `w` is missing then all elements of `x` are given the same weight.

Missing values in `w` are not handled.

See Also

[mean](#)

Examples

```
## GPA from Siegel 1994
wt <- c(5, 5, 4, 1)/15
x <- c(3.7, 3.3, 3.5, 2.8)
xm <- weighted.mean(x, wt)
```

weighted.residuals *Compute Weighted Residuals*

Description

Computed weighted residuals from a linear model fit.

Usage

```
weighted.residuals(obj, drop0 = TRUE)
```

Arguments

`obj` R object, typically of class `lm` or `glm`.

`drop0` logical. If TRUE, drop all cases with `weights == 0`.

Details

Weighted residuals are based on the deviance residuals, which for a `lm` fit are the raw residuals R_i multiplied by $\sqrt{w_i}$, where w_i are the weights as specified in `lm`'s call.

Dropping cases with weights zero is compatible with `influence` and related functions.

Value

Numeric vector of length n' , where n' is the number of non-0 weights (`drop0 = TRUE`) or the number of observations, otherwise.

See Also

[residuals](#), [lm.influence](#), etc.

Examples

```
utils::example("lm")
all.equal(weighted.residuals(lm.D9),
          residuals(lm.D9))
x <- 1:10
w <- 0:9
y <- rnorm(x)
weighted.residuals(lmxy <- lm(y ~ x, weights = w))
weighted.residuals(lmxy, drop0 = FALSE)
```

wilcox.test

Wilcoxon Rank Sum and Signed Rank Tests

Description

Performs one and two sample Wilcoxon tests on vectors of data; the latter is also known as ‘Mann-Whitney’ test.

Usage

```
wilcox.test(x, ...)

## Default S3 method:
wilcox.test(x, y = NULL,
            alternative = c("two.sided", "less", "greater"),
            mu = 0, paired = FALSE, exact = NULL, correct = TRUE,
            conf.int = FALSE, conf.level = 0.95, ...)

## S3 method for class 'formula':
wilcox.test(formula, data, subset, na.action, ...)
```

Arguments

<code>x</code>	numeric vector of data values. Non-finite (e.g. infinite or missing) values will be omitted.
<code>y</code>	an optional numeric vector of data values.
<code>alternative</code>	a character string specifying the alternative hypothesis, must be one of "two.sided" (default), "greater" or "less". You can specify just the initial letter.
<code>mu</code>	a number specifying an optional parameter used to form the null hypothesis. See 'Details'.
<code>paired</code>	a logical indicating whether you want a paired test.
<code>exact</code>	a logical indicating whether an exact p-value should be computed.
<code>correct</code>	a logical indicating whether to apply continuity correction in the normal approximation for the p-value.
<code>conf.int</code>	a logical indicating whether a confidence interval should be computed.
<code>conf.level</code>	confidence level of the interval.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

The formula interface is only applicable for the 2-sample tests.

If only `x` is given, or if both `x` and `y` are given and `paired` is `TRUE`, a Wilcoxon signed rank test of the null that the distribution of `x` (in the one sample case) or of `x - y` (in the paired two sample case) is symmetric about `mu` is performed.

Otherwise, if both `x` and `y` are given and `paired` is `FALSE`, a Wilcoxon rank sum test (equivalent to the Mann-Whitney test: see the Note) is carried out. In this case, the null hypothesis is that the distributions of `x` and `y` differ by a location shift of `mu` and the alternative is that they differ by some other location shift (and the one-sided alternative "greater" is that `x` is shifted to the right of `y`).

By default (if `exact` is not specified), an exact p-value is computed if the samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally (if argument `conf.int` is true), a nonparametric confidence interval and an estimator for the pseudomedian (one-sample case) or for the difference of the location parameters `x-y` is computed. (The pseudomedian of a distribution F is the median of the distribution of $(u + v)/2$, where u and v are independent, each with distribution F . If F is symmetric, then the pseudomedian and median coincide. See Hollander & Wolfe (1973), page 34.) If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

With small samples it may not be possible to achieve very high confidence interval coverages. If this happens a warning will be given and an interval with lower coverage will be substituted.

Value

A list with class "htest" containing the following components:

statistic	the value of the test statistic with a name describing it.
parameter	the parameter(s) for the exact distribution of the test statistic.
p.value	the p-value for the test.
null.value	the location parameter μ .
alternative	a character string describing the alternative hypothesis.
method	the type of test applied.
data.name	a character string giving the names of the data.
conf.int	a confidence interval for the location parameter. (Only present if argument <code>conf.int = TRUE</code> .)
estimate	an estimate of the location parameter. (Only present if argument <code>conf.int = TRUE</code> .)

Warning

This function can use large amounts of memory and stack (and even crash R if the stack limit is exceeded) if `exact = TRUE` and one sample is large (several thousands or more).

Note

The literature is not unanimous about the definitions of the Wilcoxon rank sum and Mann-Whitney tests. The two most common definitions correspond to the sum of the ranks of the first sample with the minimum value subtracted or not: R subtracts and S-PLUS does not, giving a value which is larger by $m(m + 1)/2$ for a first sample of size m . (It seems Wilcoxon's original paper used the unadjusted sum of the ranks but subsequent tables subtracted the minimum.)

R's value can also be computed as the number of all pairs $(x[i], y[j])$ for which $y[j]$ is not greater than $x[i]$, the most common definition of the Mann-Whitney test.

Wilcoxon

Distribution of the Wilcoxon Rank Sum Statistic

Description

Density, distribution function, quantile function and random generation for the distribution of the Wilcoxon rank sum statistic obtained from samples with size m and n , respectively.

Usage

```

dwilcox(x, m, n, log = FALSE)
pwilcox(q, m, n, lower.tail = TRUE, log.p = FALSE)
qwilcox(p, m, n, lower.tail = TRUE, log.p = FALSE)
rwilcox(nn, m, n)

```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>nn</code>	number of observations. If <code>length(nn) > 1</code> , the length is taken to be the number required.
<code>m, n</code>	numbers of observations in the first and second sample, respectively. Can be vectors of positive integers.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

This distribution is obtained as follows. Let x and y be two random, independent samples of size m and n . Then the Wilcoxon rank sum statistic is the number of all pairs $(x[i], y[j])$ for which $y[j]$ is not greater than $x[i]$. This statistic takes values between 0 and $m * n$, and its mean and variance are $m * n / 2$ and $m * n * (m + n + 1) / 12$, respectively.

If any of the first three arguments are vectors, the recycling rule is used to do the calculations for all combinations of the three up to the length of the longest vector.

Value

`dwilcox` gives the density, `pwilcox` gives the distribution function, `qwilcox` gives the quantile function, and `rwilcox` generates random deviates.

Warning

These functions can use large amounts of memory and stack (and even crash R if the stack limit is exceeded and stack-checking is not in place) if one sample is large (several thousands or more).

Note

S-PLUS uses a different (but equivalent) definition of the Wilcoxon statistic: see [wilcox.test](#) for details.

Author(s)

Kurt Hornik

Source

These are calculated via recursion, based on `cwilcox(k, m, n)`, the number of choices with statistic k from samples of size m and n , which is itself calculated recursively and the results cached. Then `dwilcox` and `pwilcox` sum appropriate values of `cwilcox`, and `qwilcox` is based on inversion.

`rwilcox` generates a random permutation of ranks and evaluates the statistic.

See Also

[wilcox.test](#) to calculate the statistic from data, find p values and so on.

[dsignrank](#) etc, for the distribution of the *one-sample* Wilcoxon signed rank statistic.

Examples

```

require(graphics)

x <- -1:(4*6 + 1)
fx <- dwilcox(x, 4, 6)
Fx <- pwilcox(x, 4, 6)

layout(rbind(1,2), widths=1, heights=c(3,2))
plot(x, fx,type='h', col="violet",
      main= "Probabilities (density) of Wilcoxon-Statist.(n=6,m=4)")
plot(x, Fx,type="s", col="blue",
      main= "Distribution of Wilcoxon-Statist.(n=6,m=4)")
abline(h=0:1, col="gray20",lty=2)
layout(1)# set back

N <- 200
hist(U <- rwilcox(N, m=4,n=6), breaks=0:25 - 1/2,
      border="red", col="pink", sub = paste("N =",N))
mtext("N * f(x), f() = true \"density\"", side=3, col="blue")
lines(x, N*fx, type='h', col='blue', lwd=2)
points(x, N*fx, cex=2)

## Better is a Quantile-Quantile Plot
qqplot(U, qw <- qwilcox((1:N - 1/2)/N, m=4,n=6),
        main = paste("Q-Q-Plot of empirical and theoretical quantiles",
                     "Wilcoxon Statistic, (m=4, n=6)", sep="\n"))
n <- as.numeric(names(print(tU <- table(U))))
text(n+.2, n+.5, labels=tU, col="red")

```

window

*Time Windows***Description**

window is a generic function which extracts the subset of the object `x` observed between the times `start` and `end`. If a frequency is specified, the series is then re-sampled at the new frequency.

Usage

```

window(x, ...)
## S3 method for class 'ts':
window(x, ...)
## Default S3 method:
window(x, start = NULL, end = NULL,
       frequency = NULL, deltat = NULL, extend = FALSE, ...)

window(x, ...) <- value
## S3 replacement method for class 'ts':
window(x, start, end, frequency, deltat, ...) <- value

```

Arguments

<code>x</code>	a time-series (or other object if not replacing values).
<code>start</code>	the start time of the period of interest.
<code>end</code>	the end time of the period of interest.
<code>frequency, deltat</code>	the new frequency can be specified by either (or both if they are consistent).
<code>extend</code>	logical. If true, the <code>start</code> and <code>end</code> values are allowed to extend the series. If false, attempts to extend the series give a warning and are ignored.
<code>...</code>	further arguments passed to or from other methods.
<code>value</code>	replacement values.

Details

The start and end times can be specified as for `ts`. If there is no observation at the new `start` or `end`, the immediately following (`start`) or preceding (`end`) observation time is used.

The replacement function has a method for `ts` objects, and is allowed to extend the series (with a warning). There is no default method.

Value

The value depends on the method. `window.default` will return a vector or matrix with an appropriate `tsp` attribute.

`window.ts` differs from `window.default` only in ensuring the result is a `ts` object.

If `extend = TRUE` the series will be padded with NAs if needed.

window(presidents, start=c(1945,3), deltat=1) # All Qtr3s
window(presidents, 1944, c(1979,2), extend=TRUE)

pres <- window(presidents, 1945, c(1949,4)) # values in the 1940's
window(pres, 1945.25, 1945.50) <- c(60, 70)
window(pres, 1944, 1944.75) <- 0 # will generate a warning
window(pres, c(1945,4), c(1949,4), frequency=1) <- 85:89
pres

```

xtabs

*Cross Tabulation***Description**

Create a contingency table from cross-classifying factors, usually contained in a data frame, using a formula interface.

Usage

```
xtabs(formula = ~., data = parent.frame(), subset, na.action,
      exclude = c(NA, NaN), drop.unused.levels = FALSE)
```

Arguments

<code>formula</code>	a formula object with the cross-classifying variables (separated by +) on the right hand side (or an object which can be coerced to a formula). Interactions are not allowed. On the left hand side, one may optionally give a vector or a matrix of counts; in the latter case, the columns are interpreted as corresponding to the levels of a variable. This is useful if the data have already been tabulated, see the examples below.
<code>data</code>	an optional matrix or data frame (or similar: see model.frame) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs.
<code>exclude</code>	a vector of values to be excluded when forming the set of levels of the classifying factors.
<code>drop.unused.levels</code>	a logical indicating whether to drop unused levels in the classifying factors. If this is <code>FALSE</code> and there are unused levels, the table will contain zero marginals, and a subsequent chi-squared test for independence of the factors will not work.

Details

There is a `summary` method for contingency table objects created by `table` or `xtabs`, which gives basic information and performs a chi-squared test for independence of factors (note that the function `chisq.test` currently only handles 2-d tables).

If a left hand side is given in `formula`, its entries are simply summed over the cells corresponding to the right hand side; this also works if the lhs does not give counts.

Value

A contingency table in array representation of class `c("xtabs", "table")`, with a `"call"` attribute storing the matched call.

See Also

[table](#) for traditional cross-tabulation, and [as.data.frame.table](#) which is the inverse operation of `xtabs` (see the DF example below).

Examples

```
## 'esoph' has the frequencies of cases and controls for all levels of
## the variables 'agegp', 'alcgp', and 'tobgp'.
xtabs(cbind(ncases, ncontrols) ~ ., data = esoph)
## Output is not really helpful ... flat tables are better:
ftable(xtabs(cbind(ncases, ncontrols) ~ ., data = esoph))
## In particular if we have fewer factors ...
ftable(xtabs(cbind(ncases, ncontrols) ~ agegp, data = esoph))

## This is already a contingency table in array form.
DF <- as.data.frame(UCBAdmissions)
## Now 'DF' is a data frame with a grid of the factors and the counts
## in variable 'Freq'.
DF
## Nice for taking margins ...
xtabs(Freq ~ Gender + Admit, DF)
## And for testing independence ...
summary(xtabs(Freq ~ ., DF))

## Create a nice display for the warp break data.
warpbreaks$replicate <- rep(1:9, len = 54)
ftable(xtabs(breaks ~ wool + tension + replicate, data = warpbreaks))
```

Chapter 8

The `tools` package

`tools-package` *Tools for Package Development*

Description

Tools for package development, administration and documentation.

Details

This package contains tools for manipulating R packages and their documentation.

For a complete list of functions, use `library(help="tools")`.

`buildVignettes` *List and Build Package Vignettes*

Description

Run [Sweave](#) and [texi2dvi](#) on all vignettes of a package.

Usage

```
buildVignettes(package, dir, lib.loc = NULL, quiet = TRUE, clean = TRUE)
pkgVignettes(package, dir, lib.loc = NULL)
```

Arguments

<code>package</code>	a character string naming an installed package. If given, Sweave files are searched in subdirectory <code>'doc'</code> .
<code>dir</code>	a character string specifying the path to a package's root source directory. This subdirectory <code>'inst/doc'</code> is searched for Sweave files.
<code>lib.loc</code>	a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .
<code>quiet</code>	logical. Run <code>Sweave</code> and <code>texi2dvi</code> in quiet mode.
<code>clean</code>	Remove all files generated by the build, even if there were copies there before.

Value

`buildVignettes` is called for its side effect of creating the PDF versions of all vignettes.
`pkgVignettes` returns an object of class `"pkgVignettes"`.

charsets

Conversion Tables between Character Sets

Description

`charset_to_Unicode` is a matrix of Unicode points with columns for the common 8-bit encodings.

`Adobe_glyphs` is a dataframe which gives Adobe glyph names for Unicode points. It has two character columns, `"adobe"` and `"unicode"` (a 4-digit hex representation).

Usage

```
charset_to_Unicode
```

```
Adobe_glyphs
```

Details

`charset_to_Unicode` is an integer matrix of class `c("noquote", "noquote")` so prints in hexadecimal. The mappings are those used by `libiconv`: there are differences in the way quotes and minus/hyphen are mapped between sources (and the postscript encoding files use a different mapping).

`Adobe_glyphs` include all the Adobe glyph names which correspond to single Unicode characters. It is sorted by Unicode point and within a point alphabetically on the glyph (there can be more than one name for a Unicode point). The data are in the file `'R_HOME/share/encodings/Adobe_glyphlist'`.

Source

<http://partners.adobe.com/public/developer/en/opentype/glyphlist.txt>

Examples

```
## find Adobe names for ISOLatin2 chars.
latin2 <- charset_to_Unicode[, "ISOLatin2"]
aUnicode <- as.numeric(paste("0x", Adobe_glyphs$unicode, sep=""))
keep <- aUnicode %in% latin2
aUnicode <- aUnicode[keep]
aAdobe <- Adobe_glyphs[keep, 1]
## first match
aLatin2 <- aAdobe[match(latin2, aUnicode)]
## all matches
bLatin2 <- lapply(1:256, function(x) aAdobe[aUnicode == latin2[x]])
format(bLatin2, justify="none")
```

checkFF

*Check Foreign Function Calls***Description**

Performs checks on calls to compiled code from R code. Currently only checks whether the interface functions such as `.C` and `.Fortran` are called with a `"NativeSymbolInfo"` first argument or with argument `PACKAGE` specified, which is highly recommended to avoid name clashes in foreign function calls.

Usage

```
checkFF(package, dir, file, lib.loc = NULL,
        verbose = getOption("verbose"))
```

Arguments

<code>package</code>	a character string naming an installed package. If given, the installed R code of the package is checked.
<code>dir</code>	a character string specifying the path to a package's root source directory. This should contain the subdirectory 'R' (for R code). Only used if <code>package</code> is not given.
<code>file</code>	the name of a file containing R code to be checked. Used if neither <code>package</code> nor <code>dir</code> are given.
<code>lib.loc</code>	a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .
<code>verbose</code>	a logical. If <code>TRUE</code> , additional diagnostics are printed (and the result is returned invisibly).

Details

Note that we can only check if the `name` argument is a symbol or a character string, not what class of object the symbol resolves to at run-time.

If the package has a name space and if that contains a `useDynLib` directive, calls in top-level functions in the package are not reported as their symbols will be preferentially looked up in the DLL named in the first `useDynLib` directive.

Value

An object of class "checkFF", which currently is a list of the (parsed) foreign function calls with a character first argument and no PACKAGE argument.

There is a `print` method to display the information contained in such objects.

Warning

This function is still experimental. Both name and interface might change in future versions.

See Also

`.C`, `.Fortran`; `Foreign`.

Examples

```
checkFF(package = "stats", verbose = TRUE)
```

checkMD5sums

Check and Create MD5 Checksum Files

Description

`checkMD5sums` checks the files against a file 'MD5'.

Usage

```
checkMD5sums(package, dir)
```

Arguments

<code>package</code>	the name of an installed package
<code>dir</code>	the path to the top-level directory of an installed package.

Details

The file 'MD5' which is created is in a format which can be checked by `md5sum -c MD5` if a suitable command-line version of `md5sum` is available. (One is supplied in the bundle at <http://www.murdoch-sutherland.com/Rtools/tools.zip>.)

If `dir` is missing, an installed package of name `package` is searched for.

The private function `tools:::installMD5sums` is used to create MD5 files in the Windows build.

Value

`checkMD5sums` returns a logical, NA if there is no 'MD5' file to be checked.

See Also

`md5sum`

`checkTnF`*Check R Packages or Code for T/F*

Description

Checks the specified R package or code file for occurrences of T or F, and gathers the expression containing these. This is useful as in R T and F are just variables which are set to the logicals TRUE and FALSE by default, but are not reserved words and hence can be overwritten by the user. Hence, one should always use TRUE and FALSE for the logicals.

Usage

```
checkTnF(package, dir, file, lib.loc = NULL)
```

Arguments

<code>package</code>	a character string naming an installed package. If given, the installed R code and the examples in the documentation files of the package are checked. R code installed as an image file cannot be checked.
<code>dir</code>	a character string specifying the path to a package's root source directory. This must contain the subdirectory 'R' (for R code), and should also contain 'man' (for documentation). Only used if <code>package</code> is not given. If used, the R code files and the examples in the documentation files are checked.
<code>file</code>	the name of a file containing R code to be checked. Used if neither <code>package</code> nor <code>dir</code> are given.
<code>lib.loc</code>	a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .

Value

An object of class "checkTnF" which is a list containing, for each file where occurrences of T or F were found, a list with the expressions containing these occurrences. The names of the list are the corresponding file names.

There is a `print` method for nicely displaying the information contained in such objects.

Warning

This function is still experimental. Both name and interface might change in future versions.

checkVignettes *Check Package Vignettes*

Description

Check all [Sweave](#) files of a package by running [Sweave](#) and/or [Stangle](#) on them. All R source code files found after the tangling step are [sourced](#) to check whether all code can be executed without errors.

Usage

```
checkVignettes(package, dir, lib.loc = NULL,
               tangle = TRUE, weave = TRUE, latex = FALSE,
               workdir = c("tmp", "src", "cur"),
               keepfiles = FALSE)
```

Arguments

package	a character string naming an installed package. If given, Sweave files are searched in subdirectory 'doc'.
dir	a character string specifying the path to a package's root source directory. This subdirectory 'inst/doc' is searched for Sweave files.
lib.loc	a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for package.
tangle	Perform a tangle and source the extracted code?
weave	Perform a weave?
latex	logical: if tangle, weave and latex are TRUE and there is no 'Makefile' in the vignettes directory, run the tangled files through <code>pdflatex</code> .
workdir	Directory used as working directory while checking the vignettes. If "tmp" then a temporary directory is created, this is the default. If "src" then the directory containing the vignettes itself is used, if "cur" then the current working directory of R is used.
keepfiles	Delete file in temporary directory? This option is ignored when workdir != "tmp".

Value

An object of class "checkVignettes" which is a list with the error messages found during the tangle and weave steps. There is a `print` method for nicely displaying the information contained in such objects.

Description

Find inconsistencies between actual and documented ‘structure’ of R objects in a package. `codoc` compares names and optionally also corresponding positions and default values of the arguments of functions. `codocClasses` and `codocData` compare slot names of S4 classes and variable names of data sets, respectively.

Usage

```
codoc(package, dir, lib.loc = NULL,
       use.values = NULL, verbose = getOption("verbose"))
codocClasses(package, lib.loc = NULL)
codocData(package, lib.loc = NULL)
```

Arguments

<code>package</code>	a character string naming an installed package.
<code>dir</code>	a character string specifying the path to a package’s root source directory. This must contain the subdirectories ‘man’ with R documentation sources (in Rd format) and ‘R’ with R code. Only used if <code>package</code> is not given.
<code>lib.loc</code>	a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .
<code>use.values</code>	if <code>FALSE</code> , do not use function default values when comparing code and docs. Otherwise, compare <i>all</i> default values if <code>TRUE</code> , and only the ones documented in the usage otherwise (default).
<code>verbose</code>	a logical. If <code>TRUE</code> , additional diagnostics are printed.

Details

The purpose of `codoc` is to check whether the documented usage of function objects agrees with their formal arguments as defined in the R code. This is not always straightforward, in particular as the usage information for methods to generic functions often employs the name of the generic rather than the method.

The following algorithm is used. If an installed package is used, it is loaded (unless it is the **base** package), after possibly detaching an already loaded version of the package. Otherwise, if the sources are used, the R code files of the package are collected and sourced in a new environment. Then, the usage sections of the Rd files are extracted and parsed ‘as much as possible’ to give the formals documented. For interpreted functions in the code environment, the formals are compared between code and documentation according to the values of the argument `use.values`. Synopsis sections are used if present; their occurrence is reported if `verbose` is true.

If a package has a name space both exported and unexported objects are checked, as well as registered S3 methods. (In the unlikely event of differences the order is exported objects in the package, registered S3 methods and finally objects in the name space and only the first found is checked.)

Currently, the R documentation format has no high-level markup for the basic ‘structure’ of classes and data sets (similar to the usage sections for function synopses). Variable names for data frames in

documentation objects obtained by suitably editing ‘templates’ created by `prompt` are recognized by `codocData` and used provided that the documentation object is for a single data frame (i.e., only has one alias). `codocClasses` analogously handles slot names for classes in documentation objects obtained by editing shells created by `promptClass`.

Help files named ‘*pkgname-defunct.Rd*’ for the appropriate *pkgname* are checked more loosely, as they may have undocumented arguments.

Value

`codoc` returns an object of class "codoc". Currently, this is a list which, for each Rd object in the package where an inconsistency was found, contains an element with a list of the mismatches (which in turn are lists with elements `code` and `docs`, giving the corresponding arguments obtained from the function’s code and documented usage).

`codocClasses` and `codocData` return objects of class "codocClasses" and "codocData", respectively, with a structure similar to class "codoc".

There are `print` methods for nicely displaying the information contained in such objects.

Warning

Both `codocClasses` and `codocData` are still experimental. Names, interfaces and values might change in future versions.

Note

The default for `use.values` has been changed from `FALSE` to `NULL`, for R versions 1.9.0 and later.

See Also

[undoc](#), [QC](#)

delimMatch

Delimited Pattern Matching

Description

Match delimited substrings in a character vector, with proper nesting.

Usage

```
delimMatch(x, delim = c("{", "}"), syntax = "Rd")
```

Arguments

<code>x</code>	a character vector.
<code>delim</code>	a character vector of length 2 giving the start and end delimiters. Future versions might allow for arbitrary regular expressions.
<code>syntax</code>	currently, always the string "Rd" indicating Rd syntax (i.e., ‘%’ starts a comment extending till the end of the line, and ‘\’ escapes). Future versions might know about other syntax, perhaps via ‘syntax tables’ allowing to flexibly specify comment, escape, and quote characters.

Value

An integer vector of the same length as `x` giving the starting position (in characters) of the first match, or `-1` if there is none, with attribute `"match.length"` giving the length (in characters) of the matched text (or `-1` for no match).

See Also

[regexr](#) for ‘simple’ pattern matching.

Examples

```
x <- c("\\value{foo}", "function(bar)")
delimMatch(x)
delimMatch(x, c(" ", " "))
```

encoded_text_to_latex

Translate non-ASCII Text to LaTeX Escapes

Description

Translate non-ASCII characters in text to LaTeX escape sequences.

Usage

```
encoded_text_to_latex(x,
                      encoding = c("latin1", "latin2", "latin9",
                                    "UTF-8", "utf8"))
```

Arguments

<code>x</code>	a character vector.
<code>encoding</code>	the encoding to be assumed. "latin9" is officially ISO-8859-15 or Latin-9, but known as latin9 to LaTeX's <code>inputenc</code> package.

Details

Non-ASCII characters in `x` are replaced by an appropriate LaTeX escape sequence, or ‘?’ if there is no appropriate sequence.

Even if there is an appropriate sequence, it may not be supported by the font in use. Hyphen is mapped to ‘\-’.

Value

A character vector of the same length as `x`.

See Also

[iconv](#)

Examples

```

x <- "fa\xE7ile"
encoded_text_to_latex(x, "latin1")
## Not run:
## create a tex file to show the upper half of 8-bit charsets

writeLines(paste(xx, "\\ ", sep=""), con)
writeLines(trailer, con)
close(con)
## End(Not run)

```

fileutils

File Utilities

Description

Utilities for listing files, and manipulating file paths.

Usage

```
file_path_as_absolute(x)
```

```
file_path_sans_ext(x)
```

```
list_files_with_exts(dir, exts, all.files = FALSE,
```

```

                                full.names = TRUE)
list_files_with_type(dir, type, all.files = FALSE,
                    full.names = TRUE, OS_subdirs = .OSType())

```

Arguments

<code>x</code>	character vector giving file paths.
<code>dir</code>	a character string with the path name to a directory.
<code>exts</code>	a character vector of possible file extensions.
<code>all.files</code>	a logical. If <code>FALSE</code> (default), only visible files are considered; if <code>TRUE</code> , all files are used.
<code>full.names</code>	a logical indicating whether the full paths of the files found are returned (default), or just the file names.
<code>type</code>	a character string giving the ‘type’ of the files to be listed, as characterized by their extensions. Currently, possible values are "code" (R code), "data" (data sets), "demo" (demos), "docs" (R documentation), and "vignette" (vignettes).
<code>OS_subdirs</code>	a character vector with the names of OS-specific subdirectories to possibly include in the listing of R code and documentation files. By default, the value of the environment variable <code>R_OSTYPE</code> , or if this is empty, the value of <code>.Platform\$OS.type</code> , is used.

Details

`file_path_as_absolute` turns a possibly relative file path absolute, performing tilde expansion if necessary. Currently, only a single existing path can be given.

`file_path_sans_ext` returns the file paths without extensions. (Only purely alphanumeric extensions are recognized.)

`list_files_with_exts` returns the paths or names of the files in directory `dir` with extension matching one of the elements of `exts`. Note that by default, full paths are returned, and that only visible files are used.

`list_files_with_type` returns the paths of the files in `dir` of the given ‘type’, as determined by the extensions recognized by R. When listing R code and documentation files, files in OS-specific subdirectories are included if present according to the value of `OS_subdirs`. Note that by default, full paths are returned, and that only visible files are used.

See Also

[file.path](#), [file.info](#), [list.files](#)

Examples

```

dir <- file.path(R.home(), "library", "stats")
list_files_with_exts(file.path(dir, "demo"), "R")
list_files_with_type(file.path(dir, "demo"), "demo") # the same
file_path_sans_ext(list.files(file.path(R.home()), "modules"))

```

getDepList

Functions to Retrieve Dependency Information

Description

Given a dependency matrix, will create a `DependsList` object for that package which will include the dependencies for that matrix, which ones are installed, which unresolved dependencies were found online, which unresolved dependencies were not found online, and any R dependencies.

Usage

```
getDepList(depMtrx, instPkgs, recursive = TRUE, local = TRUE,
           reduce = TRUE, lib.loc = NULL)
```

```
pkgDepends(pkg, recursive = TRUE, local = TRUE, reduce = TRUE,
           lib.loc = NULL)
```

Arguments

<code>depMtrx</code>	A dependency matrix as from <code>package.dependencies</code>
<code>pkg</code>	The name of the package
<code>instPkgs</code>	A matrix specifying all packages installed on the local system, as from <code>installed.packages</code>
<code>recursive</code>	Whether or not to include indirect dependencies
<code>local</code>	Whether or not to search only locally
<code>reduce</code>	Whether or not to collapse all sets of dependencies to a minimal value
<code>lib.loc</code>	What libraries to use when looking for installed packages. <code>NULL</code> indicates all library directories in the user's <code>.libPaths()</code> .

Details

The function `pkgDepends` is a convenience function which wraps `getDepList` and takes as input a package name. It will then query `installed.packages` and also generate a dependency matrix, calling `getDepList` with this information and returning the result.

These functions will retrieve information about the dependencies of the matrix, resulting in a `DependsList` object. This is a list with four elements:

Depends A vector of the dependencies for this package.

Installed A vector of the dependencies which have been satisfied by the currently installed packages.

Found A list representing the dependencies which are not in `Installed` but were found online. This list has element names which are the URLs for the repositories in which packages were found and the elements themselves are vectors of package names which were found in the respective repositories. If `local=TRUE`, the `Found` element will always be empty.

R Any R version dependencies.

If `recursive` is `TRUE`, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If `recursive` is `FALSE`, only the dependencies directly stated by the package will be used.

If `local` is `TRUE`, the system will only look at the user's local install and not online to find unresolved dependencies.

If `reduce` is `TRUE`, the system will collapse the fields in the `DependsList` object such that a minimal set of dependencies are specified (for instance if there was `'foo'`, `'foo (>= 1.0.0)'`, `'foo (>= 1.3.0)'`), it would only return `'foo (>= 1.3.0)'`).

Value

An object of class `DependsList`

Author(s)

Jeff Gentry

See Also

[installFoundDepends](#)

Examples

```
pkgDepends("tools", local = FALSE)
```

`installFoundDepends`

A function to install unresolved dependencies

Description

This function will take the `Found` element of a `pkgDependsList` object and attempt to install all of the listed packages from the specified repositories.

Usage

```
installFoundDepends(depPkgList, ...)
```

Arguments

`depPkgList` A `Found` element from a `pkgDependsList` object
`...` Arguments to pass on to [install.packages](#)

Details

This function takes as input the `Found` list from a `pkgDependsList` object. This list will have element names being URLs corresponding to repositories and the elements will be vectors of package names. For each element, [install.packages](#) is called for that URL to install all packages listed in the vector.

Author(s)

Jeff Gentry

See Also[pkgDepends](#), [install.packages](#)**Examples**

```
## Set up a temporary directory to install packages to
tmp <- tempfile()
dir.create(tmp)

pDL <- pkgDepends("tools", local=FALSE)
installFoundDepends(pDL$Found, destdir=tmp)
```

makeLazyLoading *Lazy Loading of Packages*

Description

Tools for lazy loading of packages from a database.

Usage

```
makeLazyLoading(package, lib.loc = NULL, compress = TRUE,
                 keep.source = getOption("keep.source.pkgs"))
```

Arguments

package	package name string
lib.loc	library trees, as in library
keep.source	logical; should sources be kept when saving from source
compress	logical; whether to compress entries on the database.

Details

A tool to set up packages for lazy loading from a database. For packages other than **base** you can use `makeLazyLoading(package)` to convert them to use lazy loading.

Author(s)

Luke Tierney and Brian Ripley

Examples

```
## set up package "splines" for lazy loading -- already done
## Not run:
tools:::makeLazyLoading("splines")
## End(Not run)
```

```
md5sum
```

Compute MD5 Checksums

Description

Compute the 32-byte MD5 checksums of one or more files.

Usage

```
md5sum(files)
```

Arguments

`files` character. The paths of file(s) to be check-summed.

Value

A character vector of the same length as `files`, with names equal to `files`. The elements will be NA for non-existent or unreadable files, otherwise a 32-character string of hexadecimal digits.

On Windows all files are read in binary mode (as the `md5sum` utilities there do): on other OSes the files are read in the default way.

See Also

[checkMD5sums](#)

Examples

```
md5sum(dir(R.home(), pattern="^COPY", full.names=TRUE))
```

```
package.dependencies
```

Check Package Dependencies

Description

Parses and checks the dependencies of a package against the currently installed version of R (and other packages).

Usage

```
package.dependencies(x, check = FALSE,
                    depLevel = c("Depends", "Imports", "Suggests"))
```

Arguments

`x` A matrix of package descriptions as returned by [available.packages](#).

`check` If TRUE, return logical vector of check results. If FALSE, return parsed list of dependencies.

`depLevel` Whether to look for Depends or Suggests level dependencies.

Details

Currently we only check if the package conforms with the currently running version of R. In the future we might add checks for inter-package dependencies.

See Also

[update.packages](#)

 QC

QC Checks for R Code and/or Documentation

Description

Functions for performing various quality checks.

Usage

```
checkDocFiles(package, dir, lib.loc = NULL)
checkDocStyle(package, dir, lib.loc = NULL)
checkReplaceFuns(package, dir, lib.loc = NULL)
checkS3methods(package, dir, lib.loc = NULL)
```

Arguments

<code>package</code>	a character string naming an installed package.
<code>dir</code>	a character string specifying the path to a package's root source directory. This should contain the subdirectories 'R' (for R code) and 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given.
<code>lib.loc</code>	a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .

Details

`checkDocFiles` checks, for all Rd files in a package, whether all arguments shown in the usage sections of the Rd file are documented in its arguments section. It also reports duplicated entries in the arguments section, and 'over-documented' arguments which are given in the arguments section but not in the usage. Note that the match is for the usage section and not a possibly existing synopsis section, as the usage is what gets displayed.

`checkDocStyle` investigates how (S3) methods are shown in the usages of the Rd files in a package. It reports the methods shown by their full name rather than using the Rd `\method` markup for indicating S3 methods. Earlier versions of R also reported about methods shown along with their generic, which typically caused problems for the documentation of the primary argument in the generic and its methods. With `\method` now being expanded in a way that class information is preserved, joint documentation is no longer necessarily a problem. (The corresponding information is still contained in the object returned by `checkDocStyle`.)

`checkReplaceFuns` checks whether replacement functions or S3/S4 replacement methods in the package R code have their final argument named `value`.

`checkS3methods` checks whether all S3 methods defined in the package R code have all arguments of the corresponding generic, with positional arguments of the generics in the same positions

for the method. As an exception, the first argument of a formula method *may* be called `formula` even if this is not the name used by the generic. The rules when `...` is involved are subtle: see the source code. Functions recognized as S3 generics are those with a call to `UseMethod` in their body, internal S3 generics (see [InternalMethods](#)), and S3 group generics (see [Math](#)). Possible dispatch under a different name is not taken into account. The generics are sought first in the given package, then in the **base** package and (currently) the packages **graphics**, **stats**, and **utils** added in R 1.9.0 by splitting the former **base**, and, if an installed package is tested, also in the loaded name spaces/packages listed in the package's 'DESCRIPTION' Depends field.

If using an installed package, the checks needing access to all R objects of the package will load the package (unless it is the **base** package), after possibly detaching an already loaded version of the package.

Value

The functions return objects of class the same as the respective function names containing the information about problems detected. There are `print` methods for nicely displaying the information contained in such objects.

Warning

These functions are still experimental. Names, interfaces and values might change in future versions.

Rdindex

Generate Index from Rd Files

Description

Print a 2-column index table with names and titles from given R documentation files to a given output file or connection. The titles are nicely formatted between two column positions (typically 25 and 72, respectively).

Usage

```
Rdindex(RdFiles, outFile = "", type = NULL,
        width = 0.9 * getOption("width"), indent = NULL)
```

Arguments

<code>RdFiles</code>	a character vector specifying the Rd files to be used for creating the index, either by giving the paths to the files, or the path to a single directory with the sources of a package.
<code>outFile</code>	a connection, or a character string naming the output file to print to. "" (the default) indicates output to the console.
<code>type</code>	a character string giving the documentation type of the Rd files to be included in the index, or NULL (the default). The type of an Rd file is typically specified via the <code>\docType</code> tag; if <code>type</code> is "data", Rd files whose <i>only</i> keyword is <code>datasets</code> are included as well.
<code>width</code>	a positive integer giving the target column for wrapping lines in the output.
<code>indent</code>	a positive integer specifying the indentation of the second column. Must not be greater than <code>width/2</code> , and defaults to <code>width/3</code> .

Details

If a name is not a valid alias, the first alias (or the empty string if there is none) is used instead.

Rdutils

Rd Utilities

Description

Utilities for computing on the information in Rd objects.

Usage

```
Rd_db(package, dir, lib.loc = NULL)
Rd_parse(file, text = NULL)
```

Arguments

<code>package</code>	a character string naming an installed package.
<code>dir</code>	a character string specifying the path to a package's root source directory. This should contain the subdirectory 'man' with R documentation sources (in Rd format). Only used if <code>package</code> is not given.
<code>lib.loc</code>	a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .
<code>file</code>	a connection, or a character string giving the name of a file or a URL to read documentation in Rd format from.
<code>text</code>	character vector with documentation in Rd format. Elements are treated as if they were lines of a file.

Details

`Rd_db` builds a simple database of all Rd sources in a package, as a list of character vectors with the lines of the Rd files in the package. This is particularly useful for working on installed packages, where the individual Rd files in the sources are no longer available.

`Rd_parse` is a simple top-level Rd parser/analyzer. It returns a list with components

meta a list containing the Rd metadata (aliases, concepts, keywords, and documentation type);

data a data frame with the names (`tags`) and corresponding text (`vals`) of the top-level sections in the R documentation object;

rest top-level text not accounted for (currently, silently discarded by `Rdconv`, and hence usually the indication of a problem).

Note that at least for the time being, only the top-level structure is analyzed.

Warning

These functions are still experimental. Names, interfaces and values might change in future versions.

Examples

```
## Build the Rd db for the (installed) base package.
db <- Rd_db("base")
## Run Rd_parse on all entries in the Rd db.
db <- lapply(db, function(txt) Rd_parse(text = txt))
## Extract the metadata.
meta <- lapply(db, "[", "meta")

## Keyword metadata per Rd file.
keywords <- lapply(meta, "[", "keywords")
## Tabulate the keyword entries.
kw_table <- sort(table(unlist(keywords)))
## The 5 most frequent ones:
rev(kw_table)[1 : 5]
## The "most informative" ones:
kw_table[kw_table == 1]

## Concept metadata per Rd file.
concepts <- lapply(meta, "[", "concepts")
## How many files already have \concept metadata?
sum(sapply(concepts, length) > 0)
## How many concept entries altogether?
length(unlist(concepts))
```

read.00Index

Read 00Index-style Files

Description

Read item/description information from 00Index-style files. Such files are description lists rendered in tabular form, and currently used for the ‘INDEX’ and ‘demo/00Index’ files of add-on packages.

Usage

```
read.00Index(file)
```

Arguments

`file` the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (in this case input can be terminated by a blank line). Alternatively, `file` can be a [connection](#), which will be opened if necessary, and if so closed at the end of the function call.

Value

A character matrix with 2 columns named "Item" and "Description" which hold the items and descriptions.

See Also

[formatDL](#) for the inverse operation of creating a 00Index-style file from items and their descriptions.

readNEWS

*Read R's NEWS file or a similar one***Description**

Read R's NEWS file or a similarly formatted one. This is an experimental feature, new in R 2.4.0 and may change in several ways.

Usage

```
readNEWS(file = file.path(R.home(), "NEWS"), trace = FALSE,
         chop = c("first", "1", "par1", "keepAll"))
checkNEWS(file = file.path(R.home(), "NEWS"))
```

Arguments

file	the name of the file which the data are to be read from. Alternatively, file can be a connection , which will be opened if necessary, and can also be a complete URL. For more details, see the file argument of read.table .
trace	logical indicating if the recursive reading should be traced, i.e., print what it is doing.
chop	a character string specifying how the news entries should be <i>chopped</i> ; chop = "keepAll" saves the full entries.

Details

readNEWS() reads a NEWS file; checkNEWS() checks for common errors in formatting. Currently it detects an incorrect number of spaces before the "o" item marker.

Value

readNEWS() returns an (S3) object of class "newsTree"; effectively a [list](#) of lists which is a tree of NEWS entries.

checkNEWS() returns TRUE if no suspected errors are found, or prints a message for each suspected error and returns FALSE.

Note that this is still experimental and may change in the future.

Examples

```
NEWStr <- readNEWS(trace = TRUE)# chop = "first" (= "first non-empty")
## keep the full NEWS entry text i.e. "no chopping":
NEWStrA <- readNEWS(chop = "keepAll")
object.size(NEWStr)
object.size(NEWStrA) ## (no chopping) ==> about double the size

str(NEWStr, max.level = 3)

str(NEWStr[[c("2.3", "2.3.1")]], max.level=2, vec.len=1)

NEWStr [[c("2.3", "2.3.1", "NEW FEATURES")]]
NEWStrA[[c("2.4", "2.4.0", "NEW FEATURES")]]
```

```
# Check the current NEWS file
stopifnot(checkNEWS())
```

showNonASCII *Highlight non-ASCII characters*

Description

This function prints elements of a character vector which contain non-ASCII bytes, printing such bytes as an escape like `<fc>`.

Usage

```
showNonASCII(x)
```

Arguments

`x` a character vector.

Details

This was originally written to help detect non-portable text in files in packages.

It prints all lines of the files which contain non-ASCII characters, preceded by the line number and with non-ASCII bytes highlighted *via* `iconv(sub = "byte")`.

Examples

```
out <- c(
  "fa\xE7ile test of showNonASCII():",
  "\\details{",
  "  This is a good line",
  "  This has an \xfcmlaut in it.",
  "  OK again.",
  "}")
cat(out, file = "my.Rd", sep = "\n")

showNonASCII(readLines("my.Rd"))
unlink("my.Rd")
```

texi2dvi	<i>Compile LaTeX Files</i>
----------	----------------------------

Description

Run `latex` and `bibtex` until all cross-references are resolved and create either a dvi or PDF file.

Usage

```
texi2dvi(file, pdf = FALSE, clean = FALSE, quiet = TRUE,
         texi2dvi = getOption("texi2dvi"), texinputs = NULL)
```

Arguments

<code>file</code>	character. Name of LaTeX source file.
<code>pdf</code>	logical. If <code>TRUE</code> , a PDF file is produced instead of the default dvi file (<code>texi2dvi</code> command line option <code>--pdf</code>).
<code>clean</code>	logical. If <code>TRUE</code> , all auxiliary files are removed (<code>texi2dvi</code> command line option <code>--clean</code>). May not work on some platforms.
<code>quiet</code>	logical. No output unless an error occurs. Ignored if emulation (see the <code>texi2dvi</code> argument) is used.
<code>texi2dvi</code>	character (or <code>NULL</code>). Script or program used to compile a TeX file to dvi or PDF, respectively. The default (selected by <code>NULL</code>) is to look for an executable on the search path and otherwise emulate the script with <code>system</code> calls.
<code>texinputs</code>	<code>NULL</code> or a character vector of paths to add to the LaTeX and bibtex input search paths.

Details

Despite the name, this is used in R to compile LaTeX files, specifically those generated from vignettes. As from R 2.7.1 it ensures that the `'R_HOME/share/texmf'` directory is in the `TEXINPUTS` path, so R style files such as `'Sweave'` and `'Rd'` will be found. The search path used is first the existing `TEXINPUTS` setting (or the current directory if unset), then elements of `texinputs`, then `'R_HOME/share/texmf'` and finally the default path. Analogous changes are made to `BIBINPUTS` and `BSTINPUTS` settings.

tools-deprecated	<i>Deprecated Objects in Package tools</i>
------------------	--

Description

The functions or variables listed here are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

See Also

[Deprecated](#), [Defunct](#)

`undoc`*Find Undocumented Objects*

Description

Finds the objects in a package which are undocumented, in the sense that they are visible to the user (or data objects or S4 classes provided by the package), but no documentation entry exists.

Usage

```
undoc(package, dir, lib.loc = NULL)
```

Arguments

<code>package</code>	a character string naming an installed package.
<code>dir</code>	a character string specifying the path to a package's root source directory. This must contain the subdirectory 'man' with R documentation sources (in Rd format), and at least one of the 'R' or 'data' subdirectories with R code or data objects, respectively.
<code>lib.loc</code>	a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. The specified library trees are used to search for <code>package</code> .

Details

This function is useful for package maintainers mostly. In principle, *all* user-level R objects should be documented.

The **base** package is special as it contains the primitives and these do not have definitions available at code level. We provide equivalent closures in environments `.ArgsEnv` and `.GenericArgsEnv` in the **base** package that are used for various purposes: `undoc("base")` checks that all the primitives that are not language constructs are prototyped in those environments and no others are.

Value

An object of class "undoc" which is a list of character vectors containing the names of the undocumented objects split according to documentation type. This representation is still experimental, and might change in future versions.

There is a `print` method for nicely displaying the information contained in such objects.

See Also

[codoc](#), [QC](#)

Examples

```
undoc("tools")           # Undocumented objects in 'tools'
```

vignetteDepends *Retrieve Dependency Information for a Vignette*

Description

Given a vignette name, will create a DependsList object that reports information about the packages the vignette depends on.

Usage

```
vignetteDepends(vignette, recursive = TRUE, reduce = TRUE,  
                local = TRUE, lib.loc = NULL)
```

Arguments

vignette	The path to the vignette source
recursive	Whether or not to include indirect dependencies
reduce	Whether or not to collapse all sets of dependencies to a minimal value
local	Whether or not to search only locally
lib.loc	What libraries to search in locally

Details

If `recursive` is `TRUE`, any package that is specified as a dependency will in turn have its dependencies included (and so on), these are known as indirect dependencies. If `recursive` is `FALSE`, only the dependencies directly named by the vignette will be used.

If `local` is `TRUE`, the system will only look at the user's local machine and not online to find dependencies.

If `reduce` is `TRUE`, the system will collapse the fields in the `DependsList` to the minimal set of dependencies (for instance if the dependencies were `('foo', 'foo (>= 1.0.0)', 'foo (>= 1.3.0)')`, the return value would be `'foo (>= 1.3.0)'`).

Value

An object of class `DependsList`

Author(s)

Jeff Gentry

See Also

[pkgDepends](#)

Examples

```
gridEx <- system.file("doc", "grid.Snw", package = "grid")  
vignetteDepends(gridEx)
```

write_PACKAGES	<i>Generate PACKAGES files</i>
----------------	--------------------------------

Description

Generate 'PACKAGES' and 'PACKAGES.gz' files for a repository of source or Mac/Windows binary packages.

Usage

```
write_PACKAGES(dir, fields = NULL,
               type = c("source", "mac.binary", "win.binary"),
               verbose = FALSE, unpacked = FALSE, subdirs = FALSE)
```

Arguments

dir	Character vector describing the location of the repository (directory including source or binary packages) to generate the 'PACKAGES' and 'PACKAGES.gz' files from and write them to.
fields	a character vector giving the fields to be used in the 'PACKAGES' and 'PACKAGES.gz' files in addition to the default ones, or NULL (default). The default corresponds to the fields needed by available.packages : "Package", "Bundle", "Priority", "Version", "Depends", "Suggests", "Imports" and "Contains".
type	Type of packages: currently source '.tar.gz' archives, and Mac or Windows binary ('.tgz' or '.zip', respectively) packages are supported. Defaults to "win.binary" on Windows and to "source" otherwise.
verbose	logical. Should packages be listed as they are processed?
unpacked	a logical indicating whether the package contents are available in unpacked form or not (default).
subdirs	either logical (to indicate if subdirectories should be included) or a character vector of subdirectories to include.

Details

type = "win.binary" uses [unz](#) connections to read all 'DESCRIPTION' files contained in the (zipped) binary packages for Windows in the given directory dir, and builds 'PACKAGES' and 'PACKAGES.gz' files from this information.

Value

Invisibly returns the number of packages described in the resulting 'PACKAGES' and 'PACKAGES.gz' files. If 0, no packages were found and no files were written.

Note

Processing '.tar.gz' archives to extract the 'DESCRIPTION' files is quite slow.

This function can be useful on other OSes to prepare a repository to be accessed by Windows machines, so type = "win.binary" should work on all OSes.

Author(s)

Uwe Ligges and R-core.

See Also

See [read.dcf](#) and [write.dcf](#) for reading ‘DESCRIPTION’ files and writing the ‘PACKAGES’ and ‘PACKAGES.gz’ files.

Examples

```
## Not run:
write_PACKAGES("c:/myFolder/myRepository") # on Windows
write_PACKAGES("/pub/RWin/bin/windows/contrib/2.1",
               type="win.binary") # on Linux
## End(Not run)
```

xgettext

Extract Translatable Messages from R Files in a Package

Description

For each file in the ‘R’ directory (including system-specific subdirectories) of a package, extract the unique arguments passed to [stop](#), [warning](#), [message](#), [gettext](#) and [gettextf](#), or to [ngettext](#).

Usage

```
xgettext(dir, verbose = FALSE, asCall = TRUE)

xngettext(dir, verbose = FALSE)

xgettext2pot(dir, potFile)
```

Arguments

<code>dir</code>	the directory of a source package.
<code>verbose</code>	logical: should each file be listed as it is processed?
<code>asCall</code>	logical: if TRUE each argument is returned whole, otherwise the strings within each argument are extracted.
<code>potFile</code>	name of po template file to be produced. Defaults to "R- <i>pkgname</i> .pot" where <i>pkgname</i> is the basename of <code>dir</code> .

Details

Leading and trailing white space (space, tab and linefeed) is removed for calls to [gettext](#), [gettextf](#), [stop](#), [warning](#), and [message](#), as it is by the internal code that passes strings for translation.

We look to see if these functions were called with `domain = NA` and if so omit the call if `asCall = TRUE`: note that the call might contain a call to [gettext](#) which would be visible if `asCall = FALSE`.

`xgettext2pot` calls `xgettext` and then `xngettext`, and writes a PO template file for use with the **GNU Gettext** tools. This ensures that the strings for simple translation are unique in the file (as **GNU Gettext** requires), but does not do so for `ngettext` calls (and the rules are not stated in the Gettext manual).

If applied to the **base** package, this also looks in the `.R` files in `'R_HOME/share/R'`.

Value

For `xgettext`, a list of objects of class `"xgettext"` (which has a `print` method), one per source file that potentially contains translatable strings.

For `xngettext`, a list of objects of class `"xngettext"`, which are themselves lists of length-2 character strings.

Examples

```
## Not run:
## in a source-directory build of R:
xgettext(file.path(R.home(), "src", "library", "splines"))
## End(Not run)
```

Chapter 9

The `utils` package

`utils-package` *The R Utils Package*

Description

R utility functions

Details

This package contains a collection of utility functions.
For a complete list, use `library(help="utils")`.

Author(s)

R Development Core Team and contributors worldwide
Maintainer: R Core Team <R-core@r-project.org>

`alarm` *Alert the user*

Description

Gives an audible or visual signal to the user.

Usage

```
alarm()
```

Details

`alarm()` works by sending a `"\a"` character to the console. On most platforms this will ring a bell, beep, or give some other signal to the user (unless standard output has been redirected).

Value

No useful value is returned.

Examples

```
alarm()
```

```
apropos
```

Find Objects by (Partial) Name

Description

`apropos()` returns a character vector giving the names of all objects in the search list matching `what`.

`find()` is a different user interface to the same task.

Usage

```
apropos(what, where = FALSE, ignore.case = TRUE, mode = "any")
```

```
find(what, mode = "any", numeric = FALSE, simple.words = TRUE)
```

Arguments

<code>what</code>	character string with name of an object, or more generally a regular expression to match against.
<code>where</code> , <code>numeric</code>	a logical indicating whether positions in the search list should also be returned
<code>ignore.case</code>	logical indicating if the search should be case-insensitive, TRUE by default. Note that in R versions prior to 2.5.0, the default was implicitly <code>ignore.case = FALSE</code> .
<code>mode</code>	character; if not "any", only objects whose <code>mode</code> equals <code>mode</code> are searched.
<code>simple.words</code>	logical; if TRUE, the <code>what</code> argument is only searched as whole word.

Details

If `mode != "any"` only those objects which are of mode `mode` are considered. If `where` is TRUE, the positions in the search list are returned as the names attribute.

`find` is a different user interface for the same task as `apropos`. However, by default (`simple.words == TRUE`), only full words are searched with `grep(fixed = TRUE)`.

Note that in R versions prior to 2.5.0, `what` was allowed to be non-character, such that `find(cor)` worked as it does in S. This possibility has been dropped in line with the aim of minimizing all use of non-standard evaluation in R.

Value

For `apropos` character vector, sorted by name, possibly with names giving the (numerical) positions on the search path.

For `find`, either a character vector of environment names, or for `numeric = TRUE`, a numerical vector of positions on the search path, with names giving the names of the corresponding environments.

Author(s)

Kurt Hornik and Martin Maechler (May 1997).

See Also

[glob2rx](#) to convert wildcard patterns to regular expressions.

[objects](#) for listing objects from one place, [help.search](#) for searching the help system, [search](#) for the search path.

Examples

```
require(stats)

## Not run: apropos("lm")
apropos("GLM") # more than a dozen
## that may include internal objects starting '.__C__' if
## methods is attached
apropos("GLM", ignore.case = FALSE) # not one
apropos("lq")

cor <- 1:pi
find("cor") #> ".GlobalEnv" "package:stats"
find("cor", numeric=TRUE) # numbers with these names
find("cor", numeric=TRUE, mode="function") # only the second one
rm(cor)

## Not run: apropos(".", mode="list") # a long list

# need a DOUBLE backslash '\\\'' (in case you don't see it anymore)
apropos("\\[")

## Not run: # everything
length(apropos("."))

# those starting with 'pr'
apropos("^pr")

# the 1-letter things
apropos("^.?$")
# the 1-2-letter things
apropos("^..?$")
# the 2-to-4 letter things
apropos("^{2,4}$")

# the 8-and-more letter things
apropos("^{8,}$")
table(nchar(apropos("^{8,}$")))
## End(Not run)
```

Description

Run R non-interactively with input from `infile` and send output (stdout/stderr) to another file.

Usage

```
R CMD BATCH [options] infile [outfile]
```

Arguments

<code>infile</code>	the name of a file with R code to be executed.
<code>options</code>	a list of R command line options, e.g., for setting the amount of memory available and controlling the load/save process. If <code>infile</code> starts with a '-', use '--' as the final option. The default options are '--restore --save --no-readline'.
<code>outfile</code>	the name of a file to which to write output. If not given, the name used is that of <code>infile</code> , with a possible '.R' extension stripped, and '.Rout' appended.

Details

Use `R CMD BATCH --help` to be reminded of the usage.

By default, the input commands are printed along with the output. To suppress this behavior, add `options(echo = FALSE)` at the beginning of `infile`, or use option '--slave'.

The `infile` can have end of line marked by LF or CRLF (but not just CR), and files with an incomplete last line (missing end of line (EOL) mark) are processed correctly.

A final expression '`proc.time()`' will be executed after the input script unless the latter calls `q(runLast=FALSE)` or is aborted.

Additional options can be set by the environment variable `R_BATCH_OPTIONS`: these come after '--restore --save --no-readline' and before any options given on the command line.

Note

Unlike `Splus BATCH`, this does not run the R process in the background. In most shells, `R CMD BATCH [options] infile [outfile] &` will do so.

Report bugs to r-bugs@r-project.org.

browseEnv

*Browse Objects in Environment***Description**

The `browseEnv` function opens a browser with list of objects currently in `sys.frame()` environment.

Usage

```
browseEnv(envir = .GlobalEnv, pattern,
          excludepatt = "^last\\.warning",
          html = .Platform$OS.type != "mac",
          expanded = TRUE, properties = NULL,
          main = NULL, debugMe = FALSE)
```

Arguments

envir	an environment the objects of which are to be browsed.
pattern	a regular expression for object subselection is passed to the internal <code>ls()</code> call.
excludepatt	a regular expression for <i>dropping</i> objects with matching names.
html	is used on non Macintosh machines to display the workspace on a HTML page in your favorite browser.
expanded	whether to show one level of recursion. It can be useful to switch it to <code>FALSE</code> if your workspace is large. This option is ignored if <code>html</code> is set to <code>FALSE</code> .
properties	a named list of global properties (of the objects chosen) to be showed in the browser; when <code>NULL</code> (as per default), user, date, and machine information is used.
main	a title string to be used in the browser; when <code>NULL</code> (as per default) a title is constructed.
debugMe	logical switch; if true, some diagnostic output is produced.

Details

Very experimental code. Only allows one level of recursion into object structures. The HTML version is not dynamic.

It can be generalized. See sources (`'.../library/base/R/databrowser.R'`) for details.

`wsbrowser()` is currently just an internally used function; its argument list will certainly change.

Most probably, this should rather work through using the 'tkWidget' package (from www.Bioconductor.org).

See Also

[str](#), [ls](#).

Examples

```
if(interactive()) {
  ## create some interesting objects :
  ofa <- ordered(4:1)
  ex1 <- expression(1+ 0:9)
  ex3 <- expression(u,v, 1+ 0:9)
  example(factor, echo = FALSE)
  example(table, echo = FALSE)
  example(ftable, echo = FALSE)
  example(lm, echo = FALSE, ask = FALSE)
  example(str, echo = FALSE)

  ## and browse them:
  browseEnv()

  ## a (simple) function's environment:
  af12 <- approxfun(1:2, 1:2, method = "const")
  browseEnv(envir = environment(af12))
}
```

 browseURL

Load URL into a WWW Browser

Description

Load a given URL into a WWW browser.

Usage

```
browseURL(url, browser = getOption("browser"), encodeIfNeeded = FALSE)
```

Arguments

url	a non-empty character string giving the URL to be loaded.
browser	a non-empty character string giving the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, an R function to be called to invoke the browser.
encodeIfNeeded	Should the URL be encoded by URLencode before passing to the browser? This is not needed (and might be harmful) if the <code>browser</code> program/function itself does encoding, and can be harmful for <code>file://</code> URLs on some systems and for <code>http://</code> URLs passed to some CGI applications. Fortunately, most URLs do not need encoding.

Details

The default browser is set by option "browser", in turn set by the environment variable `R_BROWSER` which is by default set in file '`R_HOME/etc/Renviron`' to a choice made manually or automatically when R was configured. (See [Startup](#) for where to override that default value.)

If `browser` supports remote control and R knows how to perform it, the URL is opened in any already running browser or a new one if necessary. This mechanism currently is available for browsers which support the "`-remote openURL(...)`" interface (which includes Opera 5/6, Mozilla >= 0.9.5 and Mozilla Firefox), Galeon, KDE konqueror (via `kfmclient`) and the GNOME interface to Mozilla. Netscape 7.0 and Opera 7 behave slightly differently, and you will need to open them first. Note that the type of browser is determined from its name, so this mechanism will only be used if the browser is installed under its canonical name.

Because "`-remote`" will use any browser displaying on the X server (whatever machine it is running on), the remote control mechanism is only used if `DISPLAY` points to the local host. This may not allow displaying more than one URL at a time from a remote host.

It is the caller's responsibility to encode `url` if necessary (see [URLencode](#)). This can be tricky for file URLs, where the format accepted can depend on the browser and OS.

Examples

```
## Not run:
## for KDE users who want to open files in a new tab
option(browser="kfmclient newTab")
browseURL("http://www.r-project.org")
## End(Not run)
```

browseVignettes *List Vignettes in an HTML Browser*

Description

List available vignettes in an HTML browser with links to PDF, LaTeX/noweb source, and (tangled) R code (if available).

Usage

```
browseVignettes(package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'browseVignettes':
print(x, ...)
```

Arguments

package	a character vector with the names of packages to search through, or NULL in which "all" packages (as defined by argument all) are searched.
lib.loc	a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known.
all	logical; if TRUE search all available packages in the library trees specified by lib.loc, and if FALSE, search only attached packages.
x	Object of class browseVignettes.
...	Further arguments, ignored by the print method.

Details

Function browseVignettes returns an object of the same class; the print method displays it as an HTML page in a browser (using [browseURL](#)).

See Also

[browseURL](#), [vignette](#)

Examples

```
## Not run:
## List vignettes from all *attached* packages
browseVignettes(all = FALSE)

## List vignettes from a specific package
browseVignettes("grid")
## End(Not run)
```

`bug.report`*Send a Bug Report*

Description

Invokes an editor to write a bug report and optionally mail it to the automated r-bugs repository at (r-bugs@r-project.org). Some standard information on the current version and configuration of R are included automatically.

Usage

```
bug.report(subject = "",
           ccaddress = Sys.getenv("USER"),
           method = getOption("mailer"),
           address = "r-bugs@r-project.org",
           file = "R.bug.report")
```

Arguments

<code>subject</code>	Subject of the email. Please do not use single quotes (') in the subject! File separate bug reports for multiple bugs
<code>ccaddress</code>	Optional email address for copies (default is current user). Use <code>ccaddress = FALSE</code> for no copies.
<code>method</code>	Submission method, one of "mailx", "gnudoit", "none", or "ess".
<code>address</code>	Recipient's email address.
<code>file</code>	File to use for setting up the email (or storing it when method is "none" or sending mail fails).

Details

Currently direct submission of bug reports works only on Unix systems. If the submission method is "mailx", then the default editor is used to write the bug report. Which editor is used can be controlled using `options`, type `getOption("editor")` to see what editor is currently defined. Please use the help pages of the respective editor for details of usage. After saving the bug report (in the temporary file opened) and exiting the editor the report is mailed using a Unix command line mail utility such as `mailx`. A copy of the mail is sent to the current user.

If method is "gnudoit", then an emacs mail buffer is opened and used for sending the email.

If method is "none" or NULL (and in every case on Windows systems), then only an editor is opened to help writing the bug report. The report can then be copied to your favorite email program and be sent to the r-bugs list.

If method is "ess" the body of the mail is simply sent to stdout.

Value

Nothing useful.

When is there a bug?

If R executes an illegal instruction, or dies with an operating system error message that indicates a problem in the program (as opposed to something like “disk full”), then it is certainly a bug.

Taking forever to complete a command can be a bug, but you must make certain that it was really R’s fault. Some commands simply take a long time. If the input was such that you KNOW it should have been processed quickly, report a bug. If you don’t know whether the command should take a long time, find out by looking in the manual or by asking for assistance.

If a command you are familiar with causes an R error message in a case where its usual definition ought to be reasonable, it is probably a bug. If a command does the wrong thing, that is a bug. But be sure you know for certain what it ought to have done. If you aren’t familiar with the command, or don’t know for certain how the command is supposed to work, then it might actually be working right. Rather than jumping to conclusions, show the problem to someone who knows for certain.

Finally, a command’s intended definition may not be best for statistical analysis. This is a very important sort of problem, but it is also a matter of judgement. Also, it is easy to come to such a conclusion out of ignorance of some of the existing features. It is probably best not to complain about such a problem until you have checked the documentation in the usual ways, feel confident that you understand it, and know for certain that what you want is not available. The mailing list `r-devel@r-project.org` is a better place for discussions of this sort than the bug list.

If you are not sure what the command is supposed to do after a careful reading of the manual this indicates a bug in the manual. The manual’s job is to make everything clear. It is just as important to report documentation bugs as program bugs.

If the online argument list of a function disagrees with the manual, one of them must be wrong, so report the bug.

How to report a bug

When you decide that there is a bug, it is important to report it and to report it in a way which is useful. What is most useful is an exact description of what commands you type, from when you start R until the problem happens. Always include the version of R, machine, and operating system that you are using; type `version` in R to print this. To help us keep track of which bugs have been fixed and which are still open please send a separate report for each bug.

The most important principle in reporting a bug is to report FACTS, not hypotheses or categorizations. It is always easier to report the facts, but people seem to prefer to strain to posit explanations and report them instead. If the explanations are based on guesses about how R is implemented, they will be useless; we will have to try to figure out what the facts must have been to lead to such speculations. Sometimes this is impossible. But in any case, it is unnecessary work for us.

For example, suppose that on a data set which you know to be quite large the command `data.frame(x, y, z, monday, tuesday)` never returns. Do not report that `data.frame()` fails for large data sets. Perhaps it fails when a variable name is a day of the week. If this is so then when we got your report we would try out the `data.frame()` command on a large data set, probably with no day of the week variable name, and not see any problem. There is no way in the world that we could guess that we should try a day of the week variable name.

Or perhaps the command fails because the last command you used was a `[` method that had a bug causing R’s internal data structures to be corrupted and making the `data.frame()` command fail from then on. This is why we need to know what other commands you have typed (or read from your startup file).

It is very useful to try and find simple examples that produce apparently the same bug, and somewhat useful to find simple examples that might be expected to produce the bug but actually do not. If you want to debug the problem and find exactly what caused it, that is wonderful. You should still report the facts as well as any explanations or solutions.

Invoking R with the ‘--vanilla’ option may help in isolating a bug. This ensures that the site profile and saved data files are not read.

A bug report can be generated using the `bug.report()` function. This automatically includes the version information and sends the bug to the correct address. Alternatively the bug report can be emailed to `<r-bugs@r-project.org>` or submitted to the Web page at <http://bugs.r-project.org>.

Bug reports on **contributed packages** should be sent to the package maintainer rather than to r-bugs.

capture.output *Send output to a character string or file*

Description

Evaluates its arguments with the output being returned as a character string or sent to a file. Related to `sink` in the same way that `with` is related to `attach`.

Usage

```
capture.output(..., file = NULL, append = FALSE)
```

Arguments

<code>...</code>	Expressions to be evaluated.
<code>file</code>	A file name or a connection, or <code>NULL</code> to return the output as a character vector. If the connection is not open, it will be opened initially and closed on exit.
<code>append</code>	logical. If <code>file</code> a file name or unopened connection, append or overwrite?

Details

An attempt is made to write output as far as possible to `file` if there is an error in evaluating the expressions, but for `file = NULL` all output will be lost.

Value

A character string (if `file=NULL`), or invisible `NULL`.

See Also

[sink](#), [textConnection](#)

Examples

```
require(stats)
glmout <- capture.output(example(glm))
glmout[1:5]
capture.output(1+1, 2+2)
capture.output({1+1; 2+2})
## Not run:
## on Unix with enscript available
ps <- pipe("enscript -o tempout.ps", "w")
capture.output(example(glm), file=ps)
close(ps)
## End(Not run)
```

chooseCRANmirror *Select a CRAN Mirror*

Description

Interact with the user to choose a CRAN mirror.

Usage

```
chooseCRANmirror(graphics = getOption("menu.graphics"))

getCRANmirrors(all = FALSE, local.only = FALSE)
```

Arguments

<code>graphics</code>	Logical. If true and <code>tk</code> and an X server are available, use a Tk widget, or if under the AQUA interface use a MacOS X widget, otherwise use <code>menu</code> .
<code>all</code>	Logical, get all known mirrors or only the ones flagged as OK.
<code>local.only</code>	Logical, try to get most recent list from CRAN or use file on local disk only.

Details

A list of mirrors is stored in file '`R_HOME/doc/CRAN_mirrors.csv`', but first an on-line list of current mirrors is consulted, and the file copy used only if the on-line list is inaccessible.

This function was originally written to support a Windows GUI menu item, but is also called by `contrib.url` if it finds the initial dummy value of `options("repos")`.

Value

None for `chooseCRANmirror()`, this function is invoked for its side effect of updating `options("repos")`.

`getCRANmirrors()` returns a data frame with mirror information.

See Also

`setRepositories`, `contrib.url`.

Description

How to cite R and R packages in publications.

Usage

```
citation(package = "base", lib.loc = NULL)
## S3 method for class 'citation':
toBibtex(object, ...)
## S3 method for class 'citationList':
toBibtex(object, ...)
```

Arguments

package	a character string with the name of a single package. An error occurs if more than one package name is given.
lib.loc	a character vector with path names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
object	return object of <code>citation</code> .
...	currently not used.

Details

The R core development team and the very active community of package authors have invested a lot of time and effort in creating R as it is today. Please give credit where credit is due and cite R and R packages when you use them for data analysis.

Execute function `citation()` for information on how to cite the base R system in publications. If the name of a non-base package is given, the function either returns the information contained in the `CITATION` file of the package or auto-generates citation information. In the latter case the package `'DESCRIPTION'` file is parsed, the resulting citation object may be arbitrarily bad, but is quite useful (at least as a starting point) in most cases.

If only one reference is given, the print method shows both a text version and a BibTeX entry for it, if a package has more than one reference then only the text versions are shown. The BibTeX versions can be obtained using function `toBibtex` (see the examples below).

Value

An object of class `"citationList"`.

See Also

[citEntry](#)

Examples

```
## the basic R reference
citation()

## references for a package -- might not have these installed
if(nchar(system.file(package="lattice"))) citation("lattice")
if(nchar(system.file(package="foreign"))) citation("foreign")

## extract the bibtex entry from the return value
x <- citation()
toBibtex(x)
```

citEntry

Writing Package CITATION Files

Description

The ‘CITATION’ file of R packages contains an annotated list of references that should be used for citing the packages.

Usage

```
citEntry(entry, textVersion, header = NULL, footer = NULL, ...)
citHeader(...)
citFooter(...)
readCitationFile(file, meta = NULL)
```

Arguments

entry	a character string with a BibTeX entry type
textVersion	a character string with a text representation of the reference
header	a character string with optional header text
footer	a character string with optional footer text
file	a file name
...	see details below
meta	a list of package metadata as obtained by packageDescription , or NULL (default).

Details

The ‘CITATION’ file of an R package should be placed in the ‘inst’ subdirectory of the package source. The file is an R source file and may contain arbitrary R commands including conditionals and computations. The file is `source()`ed by the R parser in a temporary environment and all resulting objects of class "citation" (the return value of `citEntry`) are collected.

Typically the file will contain zero or more calls to `citHeader`, then one or more calls to `citEntry`, and finally zero or more calls to `citFooter`. `citHeader` and `citFooter` are simply wrappers to `paste`, and their `...` argument is passed on to `paste` as is.

Value

`citEntry` returns an object of class `"citation"`, `readCitationFile` returns an object of class `"citationList"`.

Entry Types

`citEntry` creates `"citation"` objects, which are modeled after BibTeX entries. The entry should be a valid BibTeX entry type, e.g.,

article: An article from a journal or magazine.

book: A book with an explicit publisher.

inbook: A part of a book, which may be a chapter (or section or whatever) and/or a range of pages.

incollection: A part of a book having its own title.

inproceedings: An article in a conference proceedings.

manual: Technical documentation like a software manual.

mastersthesis: A Master's thesis.

misc: Use this type when nothing else fits.

phdthesis: A PhD thesis.

proceedings: The proceedings of a conference.

techreport: A report published by a school or other institution, usually numbered within a series.

unpublished: A document having an author and title, but not formally published.

Entry Fields

The ... argument of `citEntry` can be any number of BibTeX fields, including

address: The address of the publisher or other type of institution.

author: The name(s) of the author(s), either as a character string in the format described in the LaTeX book, or a `personList` object.

booktitle: Title of a book, part of which is being cited.

chapter: A chapter (or section or whatever) number.

editor: Name(s) of editor(s), same format as `author`.

institution: The publishing institution of a technical report.

journal: A journal name.

note: Any additional information that can help the reader. The first word should be capitalized.

number: The number of a journal, magazine, technical report, or of a work in a series.

pages: One or more page numbers or range of numbers.

publisher: The publisher's name.

school: The name of the school where a thesis was written.

series: The name of a series or set of books.

title: The work's title.

volume: The volume of a journal or multi-volume book.

year: The year of publication.

Examples

```
basecit <- system.file("CITATION", package="base")
source(basecit, echo=TRUE)
readCitationFile(basecit)
```

close.socket	<i>Close a Socket</i>
--------------	-----------------------

Description

Closes the socket and frees the space in the file descriptor table. The port may not be freed immediately.

Usage

```
close.socket(socket, ...)
```

Arguments

socket	A socket object
...	further arguments passed to or from other methods.

Value

logical indicating success or failure

Author(s)

Thomas Lumley

See Also

[make.socket](#), [read.socket](#)

combn	<i>Generate All Combinations of n Elements, Taken m at a Time</i>
-------	---

Description

Generate all combinations of the elements of `x` taken `m` at a time. If `x` is a positive integer, returns all combinations of the elements of `seq(x)` taken `m` at a time. If argument `FUN` is not `NULL`, applies a function given by the argument to each point. If `simplify` is `FALSE`, returns a list; otherwise returns an [array](#), typically a [matrix](#). ... are passed unchanged to the `FUN` function, if specified.

Usage

```
combn(x, m, FUN = NULL, simplify = TRUE, ...)
```

Arguments

<code>x</code>	vector source for combinations, or integer <code>n</code> for <code>x <- seq(n)</code> .
<code>m</code>	number of elements to choose.
<code>FUN</code>	function to be applied to each combination; default <code>NULL</code> means the identity, i.e., to return the combination (vector of length <code>m</code>).
<code>simplify</code>	logical indicating if the result should be simplified to an array (typically a matrix); if <code>FALSE</code> , the function returns a list . Note that when <code>simplify = TRUE</code> as by default, the dimension of the result is simply determined from <code>FUN(\emph{<1st combination>})</code> , for efficiency reasons. This will badly fail if <code>FUN(u)</code> is not of constant length.
<code>...</code>	optionally, further arguments to <code>FUN</code> .

Value

a [list](#) or [array](#) (in nondegenerate cases), see the `simplify` argument above.

Author(s)

Scott Chasalow wrote the original in 1994 for S; R package **combinat** and documentation by Vince Carey <stvjc@channing.harvard.edu>; small changes by the R core team, notably to return an array in all cases of `simplify = TRUE`, e.g., for `combn(5, 5)`.

References

Nijenhuis, A. and Wilf, H.S. (1978) *Combinatorial Algorithms for Computers and Calculators*; Academic Press, NY.

See Also

[choose](#) for fast computation of the *number* of combinations. [expand.grid](#) for creating a data frame from all combinations of factors or vectors.

Examples

```
combn(letters[1:4], 2)
(m <- combn(10, 5, min)) # minimum value in each combination
mm <- combn(15, 6, function(x) matrix(x, 2, 3))
stopifnot(round(choose(10, 5)) == length(m),
           c(2, 3, round(choose(15, 6))) == dim(mm))

## Different way of encoding points:
combn(c(1, 1, 1, 1, 2, 2, 2, 3, 3, 4), 3, tabulate, nbins = 4)

## Compute support points and (scaled) probabilities for a
## Multivariate-Hypergeometric(n = 3, N = c(4, 3, 2, 1)) p.f.:
# table.mat(t(combn(c(1, 1, 1, 1, 2, 2, 2, 3, 3, 4), 3, tabulate, nbins=4)))
```

compareVersion	<i>Compare Two Package Version Numbers</i>
----------------	--

Description

Compare two package version numbers to see which is later.

Usage

```
compareVersion(a, b)
```

Arguments

`a`, `b` Character strings representing package version numbers.

Details

R package version numbers are of the form `x.y-z` for integers `x`, `y` and `z`, with components after `x` optionally missing (in which case the version number is older than those with the components present).

Value

0 if the numbers are equal, -1 if `b` is later and 1 if `a` is later (analogous to the C function `strcmp`).

See Also

[package_version](#), [library](#), [packageStatus](#).

Examples

```
compareVersion("1.0", "1.0-1")
compareVersion("7.2-0", "7.1-12")
```

COMPILE	<i>Compile Files for Use with R</i>
---------	-------------------------------------

Description

Compile given source files so that they can subsequently be collected into a shared library using R CMD SHLIB and be loaded into R using `dyn.load()`.

Usage

```
R CMD COMPILE [options] srcfiles
```

Arguments

srcfiles	A list of the names of source files to be compiled. Currently, C, C++, Objective C, Objective C++ and FORTRAN are supported; the corresponding files should have the extensions '.c', '.cc' (or '.cpp' or '.C'), '.m', '.mm' (or '.M') and '.f', respectively.
options	A list of compile-relevant settings, such as special values for CFLAGS or FFLAGS, or for obtaining information about usage and version of the utility.

Details

Note that Ratfor is not supported. If you have Ratfor source code, you need to convert it to FORTRAN. On many Solaris systems mixing Ratfor and FORTRAN code will work.

Objective C and Objective C++ support is optional and will work only if the corresponding compilers were available at R configure time.

Note

Some binary distributions of R have `COMPILE` in a separate bundle, e.g. an R-devel RPM.

See Also

[SHLIB](#), [dyn.load](#); the section on “Customizing compilation under Unix” in “R Administration and Installation” (see the ‘doc/manual’ subdirectory of the R source tree).

count.fields	<i>Count the Number of Fields per Line</i>
--------------	--

Description

`count.fields` counts the number of fields, as separated by `sep`, in each of the lines of `file` read.

Usage

```
count.fields(file, sep = "", quote = "\"'", skip = 0,
             blank.lines.skip = TRUE, comment.char = "#")
```

Arguments

file	a character string naming an ASCII data file, or a connection , which will be opened if necessary, and if so closed at the end of the function call.
sep	the field separator character. Values on each line of the file are separated by this character. By default, arbitrary amounts of whitespace can separate fields.
quote	the set of quoting characters
skip	the number of lines of the data file to skip before beginning to read data.
blank.lines.skip	logical: if TRUE blank lines in the input are ignored.
comment.char	character: a character vector of length one containing a single character or an empty string.

Details

This used to be used by `read.table` and can still be useful in discovering problems in reading a file by that function.

For the handling of comments, see `scan`.

Value

A vector with the numbers of fields found.

See Also

`read.table`

Examples

```
cat("NAME", "1:John", "2:Paul", file = "foo", sep = "\n")
count.fields("foo", sep = ":")
unlink("foo")
```

data

Data Sets

Description

Loads specified data sets, or list the available data sets.

Usage

```
data(..., list = character(0), package = NULL, lib.loc = NULL,
      verbose = getOption("verbose"), envir = .GlobalEnv)
```

Arguments

<code>...</code>	a sequence of names or literal character strings.
<code>list</code>	a character vector.
<code>package</code>	a character vector giving the package(s) to look in for data sets, or <code>NULL</code> . By default, all packages in the search path are used, then the ‘data’ subdirectory (if present) of the current working directory.
<code>lib.loc</code>	a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.
<code>verbose</code>	a logical. If <code>TRUE</code> , additional diagnostics are printed.
<code>envir</code>	the environment where the data should be loaded.

Details

Currently, four formats of data files are supported:

1. files ending `‘.R’` or `‘.r’` are `source()` d in, with the R working directory changed temporarily to the directory containing the respective file. (`data` ensures that the `utils` package is attached, in case it had been run *via* `utils::data`.)
2. files ending `‘.RData’` or `‘.rda’` are `load()` ed.
3. files ending `‘.tab’`, `‘.txt’` or `‘.TXT’` are read using `read.table(..., header = TRUE)`, and hence result in a data frame.
4. files ending `‘.csv’` or `‘.CSV’` are read using `read.table(..., header = TRUE, sep = ";")`, and also result in a data frame.

If more than one matching file name is found, the first on this list is used.

The data sets to be loaded can be specified as a sequence of names or character strings, or as the character vector `list`, or as both.

For each given data set, the first two types (`‘.R’` or `‘.r’`, and `‘.RData’` or `‘.rda’` files) can create several variables in the load environment, which might all be named differently from the data set. The second two (`‘.tab’`, `‘.txt’`, or `‘.TXT’`, and `‘.csv’` or `‘.CSV’` files) will always result in the creation of a single variable with the same name as the data set.

If no data sets are specified, `data` lists the available data sets. It looks for a new-style data index in the `‘Meta’` or, if this is not found, an old-style `‘00Index’` file in the `‘data’` directory of each specified package, and uses these files to prepare a listing. If there is a `‘data’` area but no index, available data files for loading are computed and included in the listing, and a warning is given: such packages are incomplete. The information about available data sets is returned in an object of class `"packageIQR"`. The structure of this class is experimental. Where the datasets have a different name from the argument that should be used to retrieve them the index will have an entry like `beaver1 (beavers)` which tells us that dataset `beaver1` can be retrieved by the call `data(beaver)`.

If `lib.loc` and `package` are both `NULL` (the default), the data sets are searched for in all the currently loaded packages then in the `‘data’` directory (if any) of the current working directory.

If `lib.loc = NULL` but `package` is specified as a character vector, the specified package(s) are searched for first amongst loaded packages and then in the default library/ies (see `.libPaths`).

If `lib.loc` is specified (and not `NULL`), packages are searched for in the specified library/ies, even if they are already loaded from another library.

To just look in the `‘data’` directory of the current working directory, set `package = character(0)` (and `lib.loc = NULL`, the default).

Value

a character vector of all data sets specified, or information about all available data sets in an object of class `"packageIQR"` if none were specified.

Note

The data files can be many small files. On some file systems it is desirable to save space, and the files in the `‘data’` directory of an installed package can be zipped up as a zip archive `‘Rdata.zip’`. You will need to provide a single-column file `‘filelist’` of file names in that directory.

One can take advantage of the search order and the fact that a `‘.R’` file will change directory. If raw data are stored in `‘mydata.txt’` then one can set up `‘mydata.R’` to read `‘mydata.txt’` and pre-process it, e.g., using `transform`. For instance one can convert numeric vectors to factors with

the appropriate labels. Thus, the '.R' file can effectively contain a metadata specification for the plaintext formats.

See Also

[help](#) for obtaining documentation on data sets, [save](#) for *creating* the second ('.rda') kind of data, typically the most efficient one.

Examples

```
require(utils)
data() # list all available data sets
try(data(package = "rpart") )# list the data sets in the rpart package
data(USArrests, "VADeaths") # load the data sets 'USArrests' and 'VADeaths'
help(USArrests) # give information on data set 'USArrests'
```

dataentry

Spreadsheet Interface for Entering Data

Description

A spreadsheet-like editor for entering or editing data.

Usage

```
data.entry(..., Modes = NULL, Names = NULL)
dataentry(data, modes)
de(..., Modes = list(), Names = NULL)
```

Arguments

...	A list of variables: currently these should be numeric or character vectors or list containing such vectors.
Modes	The modes to be used for the variables.
Names	The names to be used for the variables.
data	A list of numeric and/or character vectors.
modes	A list of length up to that of <code>data</code> giving the modes of (some of) the variables. <code>list()</code> is allowed.

Details

The data entry editor is only available on some platforms and GUIs. Where available it provides a means to visually edit a matrix or a collection of variables (including a data frame) as described in the Notes section.

`data.entry` has side effects, any changes made in the spreadsheet are reflected in the variables. The functions `de`, `de.ncols`, `de.setup` and `de.restore` are designed to help achieve these side effects. If the user passes in a matrix, `X` say, then the matrix is broken into columns before `dataentry` is called. Then on return the columns are collected and glued back together and the result assigned to the variable `X`. If you don't want this behaviour use `dataentry` directly.

The primitive function is `dataentry`. It takes a list of vectors of possibly different lengths and modes (the second argument) and opens a spreadsheet with these variables being the columns. The columns of the dataentry window are returned as vectors in a list when the spreadsheet is closed.

`de.ncols` counts the number of columns which are supplied as arguments to `data.entry`. It attempts to count columns in lists, matrices and vectors. `de.setup` sets things up so that on return the columns can be regrouped and reassigned to the correct name. This is handled by `de.restore`.

Value

`de` and `dataentry` return the edited value of their arguments. `data.entry` invisibly returns a vector of variable names but its main value is its side effect of assigning new version of those variables in the user's workspace.

Resources

The data entry window responds to X resources of class `R_dataentry`. Resources `foreground`, `background` and `geometry` are utilized.

Note

The details of interface to the data grid may differ by platform and GUI. The following description applies to the X11-based implementation under Unix.

You can navigate around the grid using the cursor keys or by clicking with the (left) mouse button on any cell. The active cell is highlighted by thickening the surrounding rectangle. Moving to the right or down will scroll the grid as needed: there is no constraint to the rows or columns currently in use.

There are alternative ways to navigate using the keys. Return and (keypad) Enter and LineFeed all move down. Tab moves right and Shift-Tab move left. Home moves to the top left.

PageDown or Control-F moves down a page, and PageUp or Control-B up by a page. End will show the last used column and the last few rows used (in any column).

Using any other key starts an editing process on the currently selected cell: moving away from that cell enters the edited value whereas Esc cancels the edit and restores the previous value. When the editing process starts the cell is cleared. In numerical columns (the default) only letters making up a valid number (including `- . eE`) are accepted, and entering an invalid edited value (such as blank) enters NA in that cell. The last entered value can be deleted using the BackSpace or Del(ete) key. Only a limited number of characters (currently 29) can be entered in a cell, and if necessary only the start or end of the string will be displayed, with the omissions indicated by `>` or `<`. (The start is shown except when editing.)

Entering a value in a cell further down a column than the last used cell extends the variable and fills the gap (if any) by NAs (not shown on screen).

The column names can only be selected by clicking in them. This gives a popup menu to select the column type (currently Real (numeric) or Character) or to change the name. Changing the type converts the current contents of the column (and converting from Character to Real may generate NAs.) If changing the name is selected the header cell becomes editable (and is cleared). As with all cells, the value is entered by moving away from the cell by clicking elsewhere or by any of the keys for moving down (only).

New columns are created by entering values in them (and not by just assigning a new name). The mode of the column is auto-detected from the first value entered: if this is a valid number it gives a numeric column. Unused columns are ignored, so adding data in `var5` to a three-column grid adds one extra variable, not two.

The Copy button copies the currently selected cell: paste copies the last copied value to the current cell, and right-clicking selects a cell *and* copies in the value. Initially the value is blank, and attempts to paste a blank value will have no effect.

Control-L will refresh the display, recalculating field widths to fit the current entries.

In the default mode the column widths are chosen to fit the contents of each column, with a default of 10 characters for empty columns. you can specify fixed column widths by setting option `de.cellwidth` to the required fixed width (in characters). (set it to zero to return to variable widths). The displayed width of any field is limited to 600 pixels (and by the window width).

See Also

`vi`, `edit`: `edit` uses `dataentry` to edit data frames.

Examples

```
# call data entry with variables x and y
## Not run: data.entry(x,y)
```

debugger

Post-Mortem Debugging

Description

Functions to dump the evaluation environments (frames) and to examine dumped frames.

Usage

```
dump.frames(dumpto = "last.dump", to.file = FALSE)
debugger(dump = last.dump)
```

Arguments

<code>dumpto</code>	a character string. The name of the object or file to dump to.
<code>to.file</code>	logical. Should the dump be to an R object or to a file?
<code>dump</code>	An R dump object created by <code>dump.frames</code> .

Details

To use post-mortem debugging, set the option `error` to be a call to `dump.frames`. By default this dumps to an R object "last.dump" in the workspace, but it can be set to dump to a file (a dump of the object produced by a call to `save`). The dumped object contain the call stack, the active environments and the last error message as returned by `geterrmessage`.

When dumping to file, `dumpto` gives the name of the dumped object and the file name has '.rda' appended.

A dump object of class "dump.frames" can be examined by calling `debugger`. This will give the error message and a list of environments from which to select repeatedly. When an environment is selected, it is copied and the `browser` called from within the copy.

If `dump.frames` is installed as the error handler, execution will continue even in non-interactive sessions. See the examples for how to dump and then quit.

Value

Invisible NULL.

Note

Functions such as `sys.parent` and `environment` applied to closures will not work correctly inside `debugger`.

If the error occurred when computing the default value of a formal argument the debugger will report "recursive default argument reference" when trying to examine that environment.

Of course post-mortem debugging will not work if R is too damaged to produce and save the dump, for example if it has run out of workspace.

See Also

`options` for setting error options; `recover` is an interactive debugger working similarly to `debugger` but directly after the error occurs.

Examples

```
## Not run:
options(error=quote(dump.frames("testdump", TRUE)))

f <- function() {
  g <- function() stop("test dump.frames")
  g()
}
f() # will generate a dump on file "testdump.rda"
options(error=NULL)

## possibly in another R session
load("testdump.rda")
debugger(testdump)
Available environments had calls:
1: f()
2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 1
Browsing in the environment with call:
f()
Called from: debugger.look(ind)
Browse[1]> ls()
[1] "g"
Browse[1]> g
function() stop("test dump.frames")
<environment: 759818>
Browse[1]>
Available environments had calls:
1: f()
```

```

2: g()
3: stop("test dump.frames")

Enter an environment number, or 0 to exit
Selection: 0

## A possible setting for non-interactive sessions
options(error=quote({dump.frames(to.file=TRUE); q()}))
## End(Not run)

```

demo

*Demonstrations of R Functionality***Description**

demo is a user-friendly interface to running some demonstration R scripts. demo() gives the list of available topics.

Usage

```
demo(topic, package = NULL, lib.loc = NULL,
      character.only = FALSE, verbose = getOption("verbose"))
```

Arguments

topic	the topic which should be demonstrated, given as a name or literal character string, or a character string, depending on whether character.only is FALSE (default) or TRUE. If omitted, the list of available topics is displayed.
package	a character vector giving the packages to look into for demos, or NULL. By default, all packages in the search path are used.
lib.loc	a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
character.only	logical; if TRUE, use topic as character string.
verbose	a logical. If TRUE, additional diagnostics are printed.

Details

If no topics are given, demo lists the available demos. The corresponding information is returned in an object of class "packageIQR". The structure of this class is experimental. In earlier versions of R, an empty character vector was returned along with listing available demos.

See Also

[source](#) which is called by demo.

Examples

```
demo() # for attached packages

## All available demos:
demo(package = .packages(all.available = TRUE))

demo(lm.glm, package="stats")
## Not run:
  ch <- "scoping"
  demo(ch, character = TRUE)
## End(Not run)
```

download.file

Download File from the Internet

Description

This function can be used to download a file from the Internet.

Usage

```
download.file(url, destfile, method, quiet = FALSE, mode = "w",
              cacheOK = TRUE)
```

Arguments

url	A character string naming the URL of a resource to be downloaded.
destfile	A character string with the name where the downloaded file is saved. Tilde-expansion is performed.
method	Method to be used for downloading files. Currently download methods "internal", "wget" and "lynx" are available, and there is a value "auto": see 'Details'. The method can also be set through the option "download.file.method": see options() .
quiet	If TRUE, suppress status messages (if any), and the progress bar.
mode	character. The mode with which to write the file. Useful values are "w", "wb" (binary), "a" (append) and "ab". Only used for the "internal" method.
cacheOK	logical. Is a server-side cached value acceptable? Implemented for the "internal" and "wget" methods.

Details

The function `download.file` can be used to download a single file as described by `url` from the internet and store it in `destfile`. The `url` must start with a scheme such as "http://", "ftp://" or "file://".

If `method = "auto"` is chosen (the default), the internal method is chosen for "file://" URLs, and for the others provided `capabilities("http/ftp")` is true (which it almost always is). Otherwise methods "wget" and "lynx" are tried in turn.

`cacheOK = FALSE` is useful for "http://" URLs, and will attempt to get a copy directly from the site rather than from an intermediate cache. (Not all platforms support it.) It is used by [available.packages](#).

The remaining details apply to method "internal" only.

Note that `https://` connections are not supported.

See [url](#) for how "file://" URLs are interpreted, especially on Windows. This function does decode encoded URLs.

The timeout for many parts of the transfer can be set by the option `timeout` which defaults to 60 seconds.

The level of detail provided during transfer can be set by the `quiet` argument and the `internet.info` option. The details depend on the platform and scheme, but setting `internet.info` to 0 gives all available details, including all server responses. Using 2 (the default) gives only serious messages, and 3 or more suppresses all messages.

A progress bar tracks the transfer. If the file length is known, an equals represents 2% of the transfer completed: otherwise a dot represents 10Kb.

Method "wget" can be used with proxy firewalls which require user/password authentication if proxy values are stored in the configuration file for wget.

Value

An (invisible) integer code, 0 for success and non-zero for failure. For the "wget" and "lynx" methods this is the status code returned by the external program. The "internal" method can return 1, but will in most cases throw an error.

Setting Proxies

This applies to the internal code only.

Proxies can be specified via environment variables. Setting "no_proxy" to "*" stops any proxy being tried. Otherwise the setting of "http_proxy" or "ftp_proxy" (or failing that, the all upper-case version) is consulted and if non-empty used as a proxy site. For FTP transfers, the username and password on the proxy can be specified by "ftp_proxy_user" and "ftp_proxy_password". The form of "http_proxy" should be "http://proxy.dom.com/" or "http://proxy.dom.com:8080/" where the port defaults to 80 and the trailing slash may be omitted. For "ftp_proxy" use the form "ftp://proxy.dom.com:3128/" where the default port is 21. These environment variables must be set before the download code is first used: they cannot be altered later by calling [Sys.setenv](#).

Usernames and passwords can be set for HTTP proxy transfers via environment variable `http_proxy_user` in the form `user:passwd`. Alternatively, `http_proxy` can be of the form "http://user:pass@proxy.dom.com:8080/" for compatibility with wget. Only the HTTP/1.0 basic authentication scheme is supported.

Note

Methods "wget" and "lynx" are for historical compatibility. They will block all other activity on the R process.

For methods "wget" and "lynx" a system call is made to the tool given by `method`, and the respective program must be installed on your system and be in the search path for executables.

See Also

[options](#) to set the `HTTPUserAgent`, `timeout` and `internet.info` options.

[url](#) for a finer-grained way to read data from URLs.

[url.show](#), [available.packages](#), [download.packages](#) for applications

edit

*Invoke a Text Editor***Description**

Invoke a text editor on an R object.

Usage

```
## Default S3 method:
edit(name = NULL, file = "", title = NULL,
      editor = getOption("editor"), ...)

vi(name = NULL, file = "")
emacs(name = NULL, file = "")
pico(name = NULL, file = "")
xemacs(name = NULL, file = "")
xedit(name = NULL, file = "")
```

Arguments

<code>name</code>	a named object that you want to edit. If <code>name</code> is missing then the file specified by <code>file</code> is opened for editing.
<code>file</code>	a string naming the file to write the edited version to.
<code>title</code>	a display name for the object being edited.
<code>editor</code>	a string naming the text editor you want to use. On Unix the default is set from the environment variables <code>EDITOR</code> or <code>VISUAL</code> if either is set, otherwise <code>vi</code> is used. On Windows it defaults to <code>notepad</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

`edit` invokes the text editor specified by `editor` with the object `name` to be edited. It is a generic function, currently with a default method and one for data frames and matrices.

`data.entry` can be used to edit data, and is used by `edit` to edit matrices and data frames on systems for which `data.entry` is available.

It is important to realize that `edit` does not change the object called `name`. Instead, a copy of `name` is made and it is that copy which is changed. Should you want the changes to apply to the object `name` you must assign the result of `edit` to `name`. (Try `fix` if you want to make permanent changes to an object.)

In the form `edit(name)`, `edit` deparses `name` into a temporary file and invokes the editor `editor` on this file. Quitting from the editor causes `file` to be parsed and that value returned. Should an error occur in parsing, possibly due to incorrect syntax, no value is returned. Calling `edit()`, with no arguments, will result in the temporary file being reopened for further editing.

Note that deparsing is not perfect, and the object recreated after editing can differ in subtle ways from that deparsed: see `dput` and `.deparseOpts`. (The deparse options used are the same as the defaults for `dump`.) Editing a function will preserve its environment. See `edit.data.frame` for further changes that can occur when editing a data frame or matrix.

Currently only the internal editor in Windows makes use of the `title` option; it displays the given name in the window header.

Note

The functions `vi`, `emacs`, `pico`, `xemacs`, `xedit` rely on the corresponding editor being available and being on the path. This is system-dependent.

See Also

[edit.data.frame](#), [data.entry](#), [fix](#).

Examples

```
## Not run:
# use xedit on the function mean and assign the changes
mean <- edit(mean, editor = "xedit")

# use vi on mean and write the result to file mean.out
vi(mean, file = "mean.out")
## End(Not run)
```

edit.data.frame *Edit Data Frames and Matrices*

Description

Use data editor on data frame or matrix contents.

Usage

```
## S3 method for class 'data.frame':
edit(name, factor.mode = c("character", "numeric"),
      edit.row.names = any(row.names(name) != 1:nrow(name)), ...)

## S3 method for class 'matrix':
edit(name, edit.row.names = !is.null(dn[[1]]), ...)
```

Arguments

<code>name</code>	A data frame or (numeric, logical or character) matrix.
<code>factor.mode</code>	How to handle factors (as integers or using character levels) in a data frame.
<code>edit.row.names</code>	logical. Show the row names (if they exist) be displayed as a separate editable column? It is an error to ask for this on a matrix with <code>NULL</code> row names.
<code>...</code>	further arguments passed to or from other methods.

Details

At present, this only works on simple data frames containing numeric, logical or character vectors and factors, and numeric, logical or character matrices. Any other mode of matrix will give an error, and a warning is given when the matrix has a class (which will be discarded).

Data frame columns are coerced on input to *character* unless numeric (in the sense of `is.numeric`), logical or factor. A warning is given when classes are discarded. Special characters (tabs, non-printing ASCII, etc.) will be displayed as escape sequences.

Factors columns are represented in the spreadsheet as either numeric vectors (which are more suitable for data entry) or character vectors (better for browsing). After editing, vectors are padded with NA to have the same length and factor attributes are restored. The set of factor levels can not be changed by editing in numeric mode; invalid levels are changed to NA and a warning is issued. If new factor levels are introduced in character mode, they are added at the end of the list of levels in the order in which they encountered.

It is possible to use the data-editor's facilities to select the mode of columns to swap between numerical and factor columns in a data frame. Changing any column in a numerical matrix to character will cause the result to be coerced to a character matrix. Changing the mode of logical columns is not supported.

For a data frame, the row names will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged, and from the edited output if `edit.row.names = TRUE` and there are no duplicates. (If the `row.names` column is incomplete, it is extended by entries like `row223`.) In all other cases the row names are replaced by `seq(length=nrows)`.

For a matrix, `colnames` will be added (of the form `col17`) if needed. The `rownames` will be taken from the original object if `edit.row.names = FALSE` and the number of rows is unchanged (otherwise `NULL`), and from the edited output if `edit.row.names = TRUE`. (If the `row.names` column is incomplete, it is extended by entries like `row223`.)

Editing a matrix or data frame will lose all attributes apart from the row and column names.

Value

The edited data frame or matrix.

Note

`fix(dataframe)` works for in-place editing by calling this function.

If the data editor is not available, a dump of the object is presented for editing using the default method of `edit`.

At present the data editor is limited to 65535 rows.

edit(InsectSprays)
edit(InsectSprays, factor.mode="numeric")
## End(Not run)
```

example

*Run an Examples Section from the Online Help***Description**

Run all the R code from the **Examples** part of R's online help topic `topic` with two possible exceptions, `dontrun` and `dontshow`, see 'Details' below.

Usage

```
example(topic, package = NULL, lib.loc = NULL,
        local = FALSE, echo = TRUE,
        verbose = getOption("verbose"),
        setRNG = FALSE, ask = getOption("example.ask"),
        prompt.prefix = abbreviate(topic, 6))
```

Arguments

<code>topic</code>	name or literal character string: the online help topic the examples of which should be run.
<code>package</code>	a character vector giving the package names to look into for example code, or <code>NULL</code> . By default, all packages in the search path are used.
<code>lib.loc</code>	a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
<code>local</code>	logical: if <code>TRUE</code> evaluate locally, if <code>FALSE</code> evaluate in the workspace.
<code>echo</code>	logical; if <code>TRUE</code> , show the R input when sourcing.
<code>verbose</code>	logical; if <code>TRUE</code> , show even more when running example code.
<code>setRNG</code>	logical or expression; if not <code>FALSE</code> , the random number generator state is saved, then initialized to a specified state, the example is run and the (saved) state is restored. <code>setRNG = TRUE</code> sets the same state as R CMD check does for running a package's examples. This is currently equivalent to <code>setRNG = {RNGkind("default", "default"); set.seed(1)}</code> .
<code>ask</code>	logical (or "default") indicating if <code>par(ask=TRUE)</code> and <code>grid.prompt(ask=TRUE)</code> should be called before graphical output happens from the example code. The value "default" (the factory-fresh default) means to ask if <code>echo == TRUE</code> and the graphics device appears to be interactive. This parameter applies both to any currently opened device and to any devices opened by the example code.
<code>prompt.prefix</code>	character; prefixes the prompt to be used if <code>echo = TRUE</code> .

Details

If `lib.loc` is not specified, the packages are searched for amongst those already loaded, then in the specified libraries. If `lib.loc` is specified, they are searched for only in the specified libraries, even if they are already loaded from another library.

An attempt is made to load the package before running the examples, but this will not replace a package loaded from another location.

If `local=TRUE` objects are not created in the workspace and so not available for examination after `example` completes: on the other hand they cannot clobber objects of the same name in the workspace.

As detailed in the manual *Writing R Extensions*, the author of the help page can markup parts of the examples for two exception rules

dontrun encloses code that should not be run.

dontshow encloses code that is invisible on help pages, but will be run both by the package checking tools, and the `example()` function. This was previously `testonly`, and that form is still accepted.

If the examples file contains non-ASCII characters the encoding used will matter. If in a UTF-8 locale `example` first tries UTF-8 and then Latin-1. (This can be overridden by setting the encoding in the `‘.Rd’` file.)

Value

The value of the last evaluated expression.

Note

The examples can be many small files. On some file systems it is desirable to save space, and the files in the `‘R-ex’` directory of an installed package can be zipped up as a zip archive `‘Rex.zip’`.

Examples

```
example(InsectSprays)
## force use of the standard package 'stats':
example("smooth", package="stats", lib.loc=.Library)

## set RNG *before* example as when R CMD check is run:

r1 <- example(quantile, setRNG = TRUE)
x1 <- rnorm(1)
u <- runif(1)
## identical random numbers
r2 <- example(quantile, setRNG = TRUE)
x2 <- rnorm(1)
stopifnot(identical(r1, r2))
## but x1 and x2 differ since the RNG state from before example()
## differs and is restored!
x1; x2
```

`file.edit`*Edit One or More Files*

Description

Edit one or more files in a text editor.

Usage

```
file.edit(..., title = file, editor = getOption("editor"))
```

Arguments

<code>...</code>	one or more character vectors containing the names of the files to be edited.
<code>title</code>	the title to use in the editor; defaults to the filename.
<code>editor</code>	the text editor to be used.

Details

Path expansion (see [path.expand](#)) will be done on names.

The behaviour of this function is very system dependent. Currently files can be opened only one at a time on Unix; on Windows, the internal editor allows multiple files to be opened, but has a limit of 50 simultaneous edit windows.

The `title` argument is used for the window caption in Windows, and is ignored on other platforms.

## Not run:  
# open two R scripts for editing  
file.edit("script1.R", "script2.R")  
## End(Not run)
```

`file_test`*Shell-style Tests on Files*

Description

Utility for shell-style file tests.

Usage

```
file_test(op, x, y)
```

Arguments

<code>op</code>	a character string specifying the test to be performed. Unary tests (only <code>x</code> is used) are <code>"-f"</code> (existence and not being a directory) and <code>"-d"</code> (existence and directory). Binary tests are <code>"-nt"</code> (strictly newer than, using the modification dates) and <code>"-ot"</code> (strictly older than): in both cases the test is false unless both files exist.
<code>x, y</code>	character vectors giving file paths.

Details

'Existence' here means being on the file system and accessible by the `stat` system call (or a 64-bit extension) – on a Unix-like this requires execute permission on all of the directories in the path that leads to the file, but no permissions on the file itself.

See Also

[file.exists](#) which only tests for existence (`test -e` on some systems) but not for not being a directory.

[file.path](#), [file.info](#)

Examples

```
dir <- file.path(R.home(), "library", "stats")
file_test("-d", dir)
file_test("-nt", file.path(dir, "R"), file.path(dir, "demo"))
```

 fix

Fix an Object

Description

`fix` invokes [edit](#) on `x` and then assigns the new (edited) version of `x` in the user's workspace.

Usage

```
fix(x, ...)
```

Arguments

<code>x</code>	the name of an R object, as a name or a character string.
<code>...</code>	arguments to pass to editor: see edit .

Details

The name supplied as `x` need not exist as an R object, in which case a function with no arguments and an empty body is supplied for editing.

Editing an R object may change it in ways other than are obvious: see the comment under [edit](#). See [edit.data.frame](#) for changes that can occur when editing a data frame or matrix.

See Also

[edit](#), [edit.data.frame](#)

Examples

```
## Not run:
## Assume 'my.fun' is a user defined function :
fix(my.fun)
## now my.fun is changed
## Also,
fix(my.data.frame) # calls up data editor
fix(my.data.frame, factor.mode="char") # use of ...
## End(Not run)
```

flush.console	<i>Flush Output to A Console</i>
---------------	----------------------------------

Description

This does nothing except on console-based versions of R. On the Mac OS X and Windows GUIs, it ensures that the display of output in the console is current, even if output buffering is on.

Usage

```
flush.console()
```

format	<i>Format Unordered and Ordered Lists</i>
--------	---

Description

Format unordered (itemize) and ordered (enumerate) lists.

Usage

```
formatUL(x, label = "*", offset = 0,
         width = 0.9 * getOption("width"))
formatOL(x, type = "arabic", offset = 0, start = 1,
         width = 0.9 * getOption("width"))
```

Arguments

x	a character vector of list items.
label	a character string used for labelling the items.
offset	a non-negative integer giving the offset (indentation) of the list.
width	a positive integer giving the target column for wrapping lines in the output.

type	a character string specifying the ‘type’ of the labels in the ordered list. If "arabic" (default), arabic numerals are used. For "Alph" or "alph", single upper or lower case letters are employed (in this case, the number of the last item must not exceed 26. Finally, for "Roman" or "roman", the labels are given as upper or lower case roman numerals (with the number of the last item maximally 3899). type can be given as a unique abbreviation of the above, or as one of the HTML style tokens "1" (arabic), "A"/"a" (alphabetic), or "I"/"i" (roman), respectively.
start	a positive integer specifying the starting number of the first item in an ordered list.

Value

A character vector with the formatted entries.

See Also

[formatDL](#) for formatting description lists.

Examples

```
## A simpler recipe.
x <- c("Mix dry ingredients thoroughly.",
      "Pour in wet ingredients.",
      "Mix for 10 minutes.",
      "Bake for one hour at 300 degrees.")
## Format and output as an unordered list.
writeLines(formatUL(x))
## Format and output as an ordered list.
writeLines(formatOL(x))
## Ordered list using lower case roman numerals.
writeLines(formatOL(x, type = "i"))
## Ordered list using upper case letters and some offset.
writeLines(formatOL(x, type = "A", offset = 5))
```

getAnywhere

Retrieve an R Object, Including from a Name Space

Description

These functions locates all objects with name matching its argument, whether visible on the search path, registered as an S3 method or in a name space but not exported. `getAnywhere()` returns the objects and `argsAnywhere()` returns the arguments of any objects that are functions.

Usage

```
getAnywhere(x)
argsAnywhere(x)
```

Arguments

x a character string or name.

Details

The function looks at all loaded name spaces, whether or not they are associated with a package on the search list.

Where functions are found as an S3 method, an attempt is made to find which name space registered them. This may not be correct, especially if a name space is unloaded.

Value

For `getAnywhere()` an object of class "getAnywhere". This is a list with components

<code>name</code>	the name searched for.
<code>objs</code>	a list of objects found
<code>where</code>	a character vector explaining where the object(s) were found
<code>visible</code>	logical: is the object visible
<code>dups</code>	logical: is the object identical to one earlier in the list.

Normally the structure will be hidden by the `print` method. There is a `[` method to extract one or more of the objects found.

For `argsAnywhere()` one or more argument lists as returned by `args`.

See Also

[get](#), [getFromNamespace](#), [args](#)

Examples

```
getAnywhere("format.dist")
getAnywhere("simpleLoess") # not exported from stats
argsAnywhere(format.dist)
```

`getFromNamespace` *Utility functions for Developing Namespaces*

Description

Utility functions to access and replace the non-exported functions in a name space, for use in developing packages with name spaces.

Usage

```
getFromNamespace(x, ns, pos = -1, envir = as.environment(pos))

assignInNamespace(x, value, ns, pos = -1,
                  envir = as.environment(pos))

fixInNamespace(x, ns, pos = -1, envir = as.environment(pos), ...)
```

Arguments

<code>x</code>	an object name (given as a character string).
<code>value</code>	an R object.
<code>ns</code>	a name space, or character string giving the name space.
<code>pos</code>	where to look for the object: see get .
<code>envir</code>	an alternative way to specify an environment to look in.
<code>...</code>	arguments to pass to the editor: see edit .

Details

The name space can be specified in several ways. Using, for example, `ns = "stats"` is the most direct, but a loaded package with a name space can be specified via any of the methods used for [get](#): `ns` can also be the environment printed as `<namespace:foo>`.

`getFromNamespace` is similar to (but predates) the `:::` operator, but is more flexible in how the name space is specified.

`fixInNamespace` invokes [edit](#) on the object named `x` and assigns the revised object in place of the original object. For compatibility with `fix`, `x` can be unquoted.

Value

`getFromNamespace` returns the object found (or gives an error).

`assignInNamespace` and `fixInNamespace` are invoked for their side effect of changing the object in the name space.

Note

`assignInNamespace` and `fixInNamespace` change the copy in the name space, but not any copies already exported from the name space, in particular an object of that name in the package (if already attached) and any copies already imported into other name spaces. They are really intended to be used *only* for objects which are not exported from the name space. They do attempt to alter a copy registered as an S3 method if one is found.

They can only be used to change the values of objects in the name space, not to create new objects.

See Also

[get](#), [fix](#), [getS3method](#)

Examples

```
getFromNamespace("findGeneric", "utils")
## Not run:
fixInNamespace("predict.ppr", "stats")
stats:::predict.ppr
getS3method("predict", "ppr")
## alternatively
fixInNamespace("predict.ppr", pos = 3)
fixInNamespace("predict.ppr", pos = "package:stats")
## End(Not run)
```

getS3method	<i>Get An S3 Method</i>
-------------	-------------------------

Description

Get a method for an S3 generic, possibly from a name space.

Usage

```
getS3method(f, class, optional = FALSE)
```

Arguments

<code>f</code>	character: name of the generic.
<code>class</code>	character: name of the class.
<code>optional</code>	logical: should failure to find the generic or a method be allowed?

Details

S3 methods may be hidden in packages with name spaces, and will not then be found by `get`: this function can retrieve such functions, primarily for debugging purposes.

Value

The function found, or NULL if no function is found and `optional = TRUE`.

See Also

[methods](#), [get](#)

Examples

```
require(stats)
exists("predict.ppr") # false
getS3method("predict", "ppr")
```

glob2rx	<i>Change Wildcard or Globbing Pattern into Regular Expression</i>
---------	--

Description

Change *wildcard* aka *globbing* patterns into the corresponding regular expressions ([regexp](#)).

Usage

```
glob2rx(pattern, trim.head = FALSE, trim.tail = TRUE)
```

Arguments

<code>pattern</code>	character vector
<code>trim.head</code>	logical specifying if leading " <code>^.*</code> " should be trimmed from the result.
<code>trim.tail</code>	logical specifying if trailing " <code>.*\$</code> " should be trimmed from the result.

Details

This takes a wildcard as used by most shells and returns an equivalent regular expression. `?` is mapped to `.` (match a single character), `*` to `.*` (match any string, including an empty one), and the pattern is anchored (it must start at the beginning and end at the end). Optionally, the resulting regexp is simplified.

Note that now even `(`, `[` and `{` can be used in `pattern`, but `glob2rx()` may not work correctly with arbitrary characters in `pattern`.

Value

A character vector of the same length as the input `pattern` where each wildcard is translated to the corresponding regular expression.

Author(s)

Martin Maechler, Unix/sed based version, 1991; current: 2004

See Also

[regexp](#) about regular expression, [sub](#), etc about substitutions using regexps.

Examples

```
stopifnot(glob2rx("abc.*") == "^abc\\.\"",
  glob2rx("a?b.*") == "^a.b\\.\"",
  glob2rx("a?b.*", trim.tail=FALSE) == "^a.b\\.\\.\\.*$\"",
  glob2rx("*.doc") == "^.*\\.\\.\\.doc$\"",
  glob2rx("*.doc", trim.head=TRUE) == "\\\\.\\.\\.doc$\"",
  glob2rx("*.t*") == "^.*\\.\\.\\.t\"",
  glob2rx("*.t??") == "^.*\\.\\.\\.t..*$\"",
  glob2rx("[*]") == "^.*\\.\\.\\["
)
```

head

Return the First or Last Part of an Object

Description

Returns the first or last parts of a vector, matrix, table, data frame or function. Since `head()` and `tail()` are generic functions, they may also have been extended to other classes.

Usage

```

head(x, ...)
## Default S3 method:
head(x, n = 6, ...)
## S3 method for class 'data.frame':
head(x, n = 6, ...)
## S3 method for class 'matrix':
head(x, n = 6, ...)
## S3 method for class 'ftable':
head(x, n = 6, ...)
## S3 method for class 'table':
head(x, n = 6, ...)
## S3 method for class 'function':
head(x, n = 6, ...)

tail(x, ...)
## Default S3 method:
tail(x, n = 6, ...)
## S3 method for class 'data.frame':
tail(x, n = 6, ...)
## S3 method for class 'matrix':
tail(x, n = 6, addrownums = TRUE, ...)
## S3 method for class 'ftable':
tail(x, n = 6, addrownums = FALSE, ...)
## S3 method for class 'table':
tail(x, n = 6, addrownums = TRUE, ...)
## S3 method for class 'function':
tail(x, n = 6, ...)

```

Arguments

<code>x</code>	an object
<code>n</code>	a single integer. If positive, size for the resulting object: number of elements for a vector (including lists), rows for a matrix or data frame or lines for a function. If negative, all but the <code>n</code> last/first number of elements of <code>x</code> .
<code>addrownums</code>	if there are no row names, create them from the row numbers.
<code>...</code>	arguments to be passed to or from other methods.

Details

For matrices, 2-dim tables and data frames, `head()` (`tail()`) returns the first (last) `n` rows when `n > 0` or all but the last (first) `n` rows when `n < 0`. `head.matrix()` and `tail.matrix()` are exported. For functions, the lines of the deparsed function are returned as character strings.

If a matrix has no row names, then `tail()` will add row names of the form "`[n,]`" to the result, so that it looks similar to the last lines of `x` when printed. Setting `addrownums = FALSE` suppresses this behaviour.

Value

An object (usually) like `x` but generally smaller. For `ftable` objects `x`, a transformed `format(x)`.

Author(s)

Patrick Burns, improved and corrected by R-Core. Negative argument added by Vincent Goulet.

Examples

```
head(letters)
head(letters, n = -6)

head(freeny.x, n = 10)
head(freeny.y)

tail(letters)
tail(letters, n = -6)

tail(freeny.x)
tail(freeny.y)

tail(library)

head(stats::ftable(Titanic))
```

help

Documentation

Description

These functions provide access to documentation. Documentation on a topic with name `name` (typically, an R object or a data set) can be displayed with either `help("name")` or `?name`.

Usage

```
help(topic, offline = FALSE, package = NULL,
      lib.loc = NULL, verbose = getOption("verbose"),
      try.all.packages = getOption("help.try.all.packages"),
      chmhelp = getOption("chmhelp"),
      htmlhelp = getOption("htmlhelp"),
      pager = getOption("pager"))
```

`?topic`

`type?topic`

Arguments

`topic` usually, a [name](#) or character string specifying the topic for which help is sought. A character string (enclosed in explicit single or double quotes) is always taken as naming a topic.

For `help`, if the value of `topic` is a length-one character vector the topic is taken to be the value of the only element. Otherwise `topic` must be a name or a [reserved](#) word (if syntactically valid) or character string.

For `? topic` the `topic` argument may also be a function call, to ask for documentation on a corresponding method: see the section on S4 method documentation. Unlike `help`, all names are deparsed to give the desired topic. The forms `pkg::topic` and `pkg:::topic` are treated specially, and look for help on `topic` in package **package**.

See ‘Details’ for what happens if this is omitted for `help`.

<code>offline</code>	a logical indicating whether documentation should be displayed on-line to the screen (the default) or hardcopy of it should be produced.
<code>package</code>	a name or character vector giving the packages to look into for documentation, or <code>NULL</code> . By default, all packages in the search path are used.
<code>lib.loc</code>	a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
<code>verbose</code>	logical; if <code>TRUE</code> , the file name is reported.
<code>try.all.packages</code>	logical; see Note.
<code>chmhelp</code>	logical (or <code>NULL</code>). Only relevant under Windows. If <code>TRUE</code> the Compiled HTML version of the help on the topic will be shown in a help viewer. If none is available, plain text help will be shown.
<code>htmlhelp</code>	logical (or <code>NULL</code>). If <code>TRUE</code> (which is the default after <code>help.start</code> has been called), the HTML version (if available) of the help on the topic will be shown in the browser specified by <code>options("browser")</code> . See <code>browseURL</code> for details of the browsers that are supported. Where possible an existing browser window is re-used.
<code>pager</code>	the pager to be used for <code>file.show</code> .
<code>type</code>	the special type of documentation to use for this topic; for example, if the type is <code>class</code> , documentation is provided for the class with name <code>topic</code> . The function <code>topicName</code> returns the actual name used in this case. See the section on method documentation for the uses of <code>type</code> to get help on formal methods.

Details

`topic` is not optional: if it is omitted R will give a hint as to suitable topics if a package is specified, to available packages if `lib.loc` only is specified, and help on `help` itself if nothing is specified. (In all cases this will be text help.)

Some topics need to be quoted (by `backticks`) or given as a character string. There include those which cannot syntactically appear on their own such as unary and binary operators, `function` and control-flow `reserved` words (including `if`, `else`, `for`, `in`, `repeat`, `while`, `break` and `next`). The other `reserved` words can be used as if they were names, for example `TRUE`, `NA` and `Inf`.

If multiple help files matching `topic` are found, in interactive use a menu is presented for the user to choose one: otherwise the first on the search path is used. (The menu will be a graphical menu if possible if `getOption("menu.graphics")` is true, the default.)

HTML help works best if `help.start()` has been called in the session. Otherwise there will be a warning about ‘Using non-linked HTML file: hyperlinks may be incorrect’ and cross-library links will most likely not be resolved.

If `offline` is `TRUE`, hardcopy of the documentation is produced by running the LaTeX version of the help page through `latex` and `dvips`. Depending on your `dvips` configuration, hardcopy will be sent to the printer or saved in a file. If the programs are in non-standard locations and hence were not found at compile time, you can either set the options `latexcmd` and `dvipscmd`,

or the environment variables `R_LATEXCMD` and `R_DVIPSCMD` appropriately. The appearance of the output can be customized through a file ‘`Rhelp.cfg`’ somewhere in your LaTeX search path: this will be input as a LaTeX style file after `Rd.sty`. Some [environment variables](#) are consulted, notably `R_PAPERSIZE` (via `getOption("papersize")`) and `R_RD4DVI`

If LaTeX versions of help pages were not built at the installation of the package, the `print` method will ask if conversion with `R CMD Rdconv` (which requires Perl) should be attempted.

S4 Method Documentation

The authors of formal (‘S4’) methods can provide documentation on specific methods, as well as overall documentation on the methods of a particular function. The “?” operator allows access to this documentation in three ways.

The expression `methods ? f` will look for the overall documentation methods for the function `f`. Currently, this means the documentation file containing the alias `f-methods`.

There are two different ways to look for documentation on a particular method. The first is to supply the `topic` argument in the form of a function call, omitting the `type` argument. The effect is to look for documentation on the method that would be used if this function call were actually evaluated. See the examples below. If the function is not a generic (no S4 methods are defined for it), the help reverts to documentation on the function name.

The “?” operator can also be called with `type` supplied as “method”; in this case also, the `topic` argument is a function call, but the arguments are now interpreted as specifying the class of the argument, not the actual expression that will appear in a real call to the function. See the examples below.

The first approach will be tedious if the actual call involves complicated expressions, and may be slow if the arguments take a long time to evaluate. The second approach avoids these difficulties, but you do have to know what the classes of the actual arguments will be when they are evaluated.

Both approaches make use of any inherited methods; the signature of the method to be looked up is found by using `selectMethod` (see the documentation for [getMethod](#)).

Note

Unless `lib.loc` is specified explicitly, the loaded packages are searched before those in the specified libraries. This ensures that if a library is loaded from a library not in the known library trees, then the help from the loaded library is used. If `lib.loc` is specified explicitly, the loaded packages are *not* searched.

If this search fails and argument `try.all.packages` is `TRUE` and neither `packages` nor `lib.loc` is specified, then all the packages in the known library trees are searched for help on `topic` and a list of (any) packages where help may be found is printed (but no help is shown). **N.B.** searching all packages can be slow.

The help files can be many small files. On some file systems it is desirable to save space, and the text files in the ‘help’ directory of an installed package can be zipped up as a zip archive ‘`Rhelp.zip`’. Ensure that file ‘`AnIndex`’ remains un-zipped. Similarly, all the files in the ‘`latex`’ directory can be zipped to ‘`Rhelp.zip`’.

See Also

`help.search()` or `??` for finding help pages on a vague topic; `help.start()` which opens the HTML version of the R help pages; `library()` for listing available packages and the user-level objects they contain; `data()` for listing available data sets; `methods()`.

See `prompt()` to get a prototype for writing help pages of private packages.

Examples

```

help()
help(help)           # the same

help(lapply)
?lapply             # the same

help("for")         # or ?"for", but quotes/backticks are needed
?`+`

help(package="splines") # get help even when package is not loaded

data()              # list all available data sets
?women              # information about data set "women"

topi <- "women"
help(topi)

try(help("bs", try.all.packages=FALSE)) # reports not found (an error)
help("bs", try.all.packages=TRUE)       # reports can be found
                                         # in package 'splines'

## Not run:
require(methods)
## define a S4 generic function and some methods
combo <- function(x, y) c(x, y)
setGeneric("combo")
setMethod("combo", c("numeric", "numeric"), function(x, y) x+y)

## assume we have written some documentation
## for combo, and its methods ....

?combo ## produces the function documentation

methods?combo ## looks for the overall methods documentation

method?combo("numeric", "numeric") ## documentation for the method above

?combo(1:10, rnorm(10)) ## ... the same method, selected according to
                        ## the arguments (one integer, the other numeric)

?combo(1:10, letters) ## documentation for the default method
## End(Not run)

```

Description

Prompts the user to check they have done all that is expected of them before sending a post to the R-help mailing list, provides a template for the post with session information included and optionally sends the email (on Unix systems).

Usage

```
help.request(subject = "",
             ccaddress = Sys.getenv("USER"),
             method = getOption("mailer"),
             address = "r-help@R-project.org",
             file = "R.help.request")
```

Arguments

subject	subject of the email. Please do not use single quotes (') in the subject! Post separate help requests for multiple queries.
ccaddress	optional email address for copies (default is current user). Use ccaddress = FALSE for no copies.
method	submission method: for Unix one of "mailx", "gnudoit", "none" or "ess"; for Windows either "none" (default) or "mailto".
address	recipient's email address.
file	file to use for setting up the email (or storing it when method is "none" or sending mail fails).

Details

This function is not intended to replace the posting guide. Please read the guide before posting to R-help or using this function (see <http://www.r-project.org/posting-guide.html>).

The help.request function:

- asks whether the user has consulted relevant resources, stopping and opening the relevant url if a negative response if given.
- checks whether the current version of R is being used and whether the add-on packages are up-to-date, giving the option of updating where necessary.
- asks whether the user has prepared appropriate (minimal, reproducible, self-contained, commented) example code ready to paste into the post.

Once this checklist has been completed a template post is prepared including current session information.

If method is "none" or NULL, then the default text editor is opened for the user to complete the post. Which editor is used can be controlled using `options`, type `getOption("editor")` to see what editor is currently defined. Please use the help pages of the respective editor for details of usage. The report can then be copied to your favorite email program and sent to the r-help list.

On Windows systems there is an experimental "mailto" option, which sends the template post to the system's default email program for the user to edit and send.

On Unix systems there are three options for direct submission of the post. If the submission method is "mailx", then the default editor is used to write the help request. After saving the help request (in the temporary file opened) and exiting the editor the report is mailed using a Unix command line mail utility such as mailx. A copy of the mail is sent to the current user. If method is "gnudoit",

then an emacs mail buffer is opened and used for sending the email. If method is "ess" the body of the mail is simply sent to stdout.

Value

Nothing useful.

Author(s)

Heather Turner, based on code and help page of [bug.report\(\)](#).

help.search

Search the Help System

Description

Allows for searching the help system for documentation matching a given character string in the (file) name, alias, title, concept or keyword entries (or any combination thereof), using either [fuzzy matching](#) or [regular expression matching](#). Names and titles of the matched help entries are displayed nicely formatted.

Usage

```
help.search(pattern, fields = c("alias", "concept", "title"),
            apropos, keyword, whatis, ignore.case = TRUE,
            package = NULL, lib.loc = NULL,
            help.db = getOption("help.db"),
            verbose = getOption("verbose"),
            rebuild = FALSE, agrep = NULL)

??pattern
field??pattern
```

Arguments

pattern	a character string to be matched in the specified fields. If this is given, the arguments <code>apropos</code> , <code>keyword</code> , and <code>whatis</code> are ignored.
fields	a character vector specifying the fields of the help data bases to be searched. The entries must be abbreviations of "name", "title", "alias", "concept", and "keyword", corresponding to the help page's (file) name, its title, the topics and concepts it provides documentation for, and the keywords it can be classified to.
apropos	a character string to be matched in the help page topics and title.
keyword	a character string to be matched in the help page 'keywords'. 'Keywords' are really categories: the standard categories are listed in file 'RHOME/doc/KEYWORDS' (see also the example) and some package writers have defined their own. If <code>keyword</code> is specified, <code>agrep</code> defaults to <code>FALSE</code> .

<code>what.is</code>	a character string to be matched in the help page topics.
<code>ignore.case</code>	a logical. If TRUE, case is ignored during matching; if FALSE, pattern matching is case sensitive.
<code>package</code>	a character vector with the names of packages to search through, or NULL in which case <i>all</i> available packages in the library trees specified by <code>lib.loc</code> are searched.
<code>lib.loc</code>	a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.
<code>help.db</code>	a character string giving the file path to a previously built and saved help data base, or NULL.
<code>verbose</code>	logical; if TRUE, the search process is traced.
<code>rebuild</code>	a logical indicating whether the help data base should be rebuilt. This will be done automatically if <code>lib.loc</code> or the search path is changed, or if <code>package</code> is used and a value is not found.
<code>agrep</code>	if NULL (the default unless <code>keyword</code> is used) and the character string to be matched consists of alphanumeric characters, whitespace or a dash only, approximate (fuzzy) matching via <code>agrep</code> is used unless the string has fewer than 5 characters; otherwise, it is taken to contain a regular expression to be matched via <code>grep</code> . If FALSE, approximate matching is not used. Otherwise, one can give a numeric or a list specifying the maximal distance for the approximate match, see argument <code>max.distance</code> in the documentation for <code>agrep</code> .
<code>field</code>	a single value of <code>fields</code> to search.

Details

Upon installation of a package, a pre-built help.search index is serialized as 'hsearch.rds' in the 'Meta' directory (provided the package has any help pages). These files are used to create the data base.

The arguments `apropos` and `what.is` play a role similar to the Unix commands with the same names.

Searching with `agrep = FALSE` will be several times faster than the default.

If possible, the help data base is saved in memory or (if memory limits have been set: see `mem.limits`) to a file in the session temporary directory for use by subsequent calls in the session.

Note that currently the aliases in the matching help files are not displayed.

Matching by `agrep` is by bytes even in multi-byte locales: character-by-character matching will be too slow with a thousand or more packages.

As with `?`, in `??` the pattern may be prefixed with a package name followed by `::` or `:::` to limit the search to that package.

Value

The results are returned in a list object of class "hsearch", which has a print method for nicely formatting the results of the query. This mechanism is experimental, and may change in future versions of R.

In R.app on Mac OS X, this will show up a browser with selectable items. On exiting this browser, the help pages for the selected items will be shown in separate help windows.

The internal format of the class is undocumented and subject to change.

See Also

[help](#); [help.start](#) for starting the hypertext (currently HTML) version of R's online documentation, which offers a similar search mechanism.

[RSiteSearch](#) to access an on-line search of R resources.

[apropos](#) uses regexps and has nice examples.

Examples

```
help.search("linear models")      # In case you forgot how to fit linear
                                # models
help.search("non-existent topic")

??utils::help # All the topics matching "help" in the utils package

## Not run:
help.search("print")             # All help pages with topics or title
                                # matching 'print'
help.search(apropos = "print")   # The same

help.search(keyword = "hplot")   # All help pages documenting high-level
                                # plots.
file.show(file.path(R.home(), "doc", "KEYWORDS")) # show all keywords

## Help pages with documented topics starting with 'try'.
help.search("\\btry", fields = "alias")
## End(Not run)
```

help.start

Hypertext Documentation

Description

Start the hypertext (currently HTML) version of R's online documentation.

Usage

```
help.start(gui = "irrelevant", browser = getOption("browser"),
           remote = NULL, searchEngine = FALSE)
```

Arguments

gui	just for compatibility with S-PLUS.
browser	the name of the program to be used as hypertext browser. It should be in the PATH, or a full path specified. Alternatively, it can be a function which will be called with an URL as its only argument.
remote	A character giving a valid URL for the ' <i>R_HOME</i> ' directory on a remote location.
searchEngine	logical: if true go directly to the search engine page. A workaround for Firefox 3 users (see 'Notes').

Details

All the packages in the known library trees are linked to directory `‘.R’` in the per-session temporary directory. The links are re-made each time `make.packages.html` or `help.start` is run, which should be done after packages are installed, updated or removed.

A side effect is to set `options(htmlhelp = TRUE)` so that future help requests (by default) are sent to the browser.

If the browser named by the `browser` argument is different from the default browser as specified by `options("browser")`, the default is changed to the given browser so that it gets used for all future help requests. (This only holds when `browser` is a name, not a function.)

Note

There is a Java-based search facility available from the HTML page that `help.start` brings up. Should this not work, please consult the ‘R Installation and Administration’ manual which is linked from that page.

Note to users of Firefox 3: the search results have links that are resolved incorrectly by that browser if starting from the normal HTML index page. The workaround is to start with `help.start(searchEngine = TRUE)`

See Also

`help()` for on- and off-line help in ASCII/Editor or PostScript format.

`browseURL` for how the help file is displayed.

`RSiteSearch` to access an on-line search of R resources.

Examples

```
## Not run:  
help.start()  
## End(Not run)
```

index.search

Search Indices for Help Files

Description

Used to search the indices for help files, possibly under aliases.

Usage

```
index.search(topic, path, file="AnIndex", type = "help")
```

Arguments

<code>topic</code>	The keyword to be searched for in the indices.
<code>path</code>	The path(s) to the packages to be searched.
<code>file</code>	The index file to be searched. Normally <code>“AnIndex”</code> .
<code>type</code>	The type of file required.

Details

For each package in `path`, examine the file `file` in directory ‘`type`’, and look up the matching file stem for topic `topic`, if any.

Value

A character vector of matching files, as if they are in directory `type` of the corresponding package. In the special cases of `type = "html"`, `"R-ex"` and `"latex"` the file extensions `".html"`, `".R"` and `".tex"` are added.

[help, example](#)

 INSTALL

Install Add-on Packages

Description

Utility for installing add-on packages.

Usage

```
R CMD INSTALL [options] [-l lib] pkgs
```

Arguments

<code>pkgs</code>	A space-separated list with the path names of the packages to be installed.
<code>lib</code>	the path name of the R library tree to install to.
<code>options</code>	a space-separated list of options through which in particular the process for building the help files can be controlled. Options should only be given once. Use <code>R CMD INSTALL --help</code> for the current list of options.

Details

This will stop at the first error, so if you want all the `pkgs` to be tried, call this via a shell `for` or `foreach` loop.

If used as `R CMD INSTALL pkgs` without explicitly specifying `lib`, packages are installed into the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To install into the library tree `lib`, use `R CMD INSTALL -l lib pkgs`. This prepends `lib` to `R_LIBS` for duration of the install, so required packages in the installation directory will be found (and used in preference to those in other libraries).

Both `lib` and the elements of `pkgs` may be absolute or relative path names of directories. `pkgs` may also contain names of package/bundle archive files of the form ‘`pkg_version.tar.gz`’ as obtained from CRAN: these are then extracted in a temporary directory. Finally, binary package/bundle archive files (as created by `R CMD build --binary` can be supplied.

Some package sources contain a ‘`configure`’ script that can be passed arguments or variables via the option ‘`--configure-args`’ and ‘`--configure-vars`’, respectively, if necessary. The

latter is useful in particular if libraries or header files needed for the package are in non-system directories. In this case, one can use the configure variables `LIBS` and `CPPFLAGS` to specify these locations (and set these via `--configure-vars`), see section “Configuration variables” in “R Installation and Administration” for more information. (If these are used more than once on the command line, only the last instance is used.) One can bypass the configure mechanism using the option `--no-configure`.

If `--no-docs` is given, no help files are built. Options `--no-text`, `--no-html`, and `--no-latex` suppress creating the text, HTML, and LaTeX versions, respectively. The default is to build help files in all three versions.

If the attempt to install the package fails, leftovers are removed. If the package was already installed, the old version is restored. This happens either if a command encounters an error or if the install is interrupted from the keyboard: after cleaning up the script terminates.

Use `R CMD INSTALL --help` for more usage information.

Packages using the methods package

Packages that require the methods package and make use functions such as `setMethod` or `setClass`, should be installed using lazy-loading (or, deprecated, by creating a binary image): use the field `LazyLoad` in the ‘DESCRIPTION’ file to ensure this.

Note

Some parts of the operation of `INSTALL` depend on `/tmp` having both write and execution access to the account running R. This is usually the case, but if `/tmp` has been mounted as `noexec`, environment variable `TMPDIR` needs to be set to a directory from which execution is allowed.

See Also

`REMOVE` and `library` for information on using several library trees; `update.packages` for automatic update of packages using the internet (or other R level installation of packages, such as by `install.packages`).

The section on “Add-on packages” in “R Installation and Administration” and the chapter on “Creating R packages” in “Writing R Extensions” (see `RShowDoc` and the ‘doc/manual’ subdirectory of the R source tree).

`installed.packages` *Find Installed Packages*

Description

Find (or retrieve) details of all packages installed in the specified libraries.

Usage

```
installed.packages(lib.loc = NULL, priority = NULL,
                  noCache = FALSE, fields = NULL)
```

Arguments

<code>lib.loc</code>	character vector describing the location of R library trees to search through.
<code>priority</code>	character vector or NULL (default). If non-null, used to select packages; "high" is equivalent to <code>c("base", "recommended")</code> . To select all packages without an assigned priority use <code>priority = "NA"</code> .
<code>noCache</code>	Do not use cached information.
<code>fields</code>	a character vector giving the fields to extract from each package's DESCRIPTION file in addition to the default ones, or NULL (default). Unavailable fields result in NA values.

Details

`installed.packages` scans the 'DESCRIPTION' files of each package found along `lib.loc` and returns a matrix of package names, library paths and version numbers.

Note: this works with package names, not bundle names, and for versioned installs with the name under which the package is installed, in the style `mypkg_1.3-7`.

The information found is cached (by library) for the R session and specified `fields` argument, and updated only if the top-level library directory has been altered, for example by installing or removing a package. If the cached information becomes confused, it can be refreshed by running `installed.packages(noCache = TRUE)`.

Value

A matrix with one row per package, row names the package names and column names "Package", "LibPath", "Version", "Priority", "Bundle", "Contains", "Depends", "Suggests", "Imports" and "Built" (the R version the package was built under). Additional columns can be specified using the `fields` argument.

See Also

[update.packages](#), [INSTALL](#), [REMOVE](#).

Examples

```
str(ip <- installed.packages(priority = "high"))
ip[, c(1,3:5)]
plic <- installed.packages(priority = "high", fields="License")
## what licenses are there:
table( plic["License"] )
```

LINK

Create Executable Programs

Description

Front-end for creating executable programs.

Usage

```
R CMD LINK [options] linkcmd
```

Arguments

<code>linkcmd</code>	a list of commands to link together suitable object files (include library objects) to create the executable program.
<code>options</code>	further options to control the linking, or for obtaining information about usage and version.

Details

The linker front-end is useful in particular when linking against the R shared library, in which case `linkcmd` must contain `-lR` but need not specify its library path.

Currently only works if the C compiler is used for linking, and no C++ code is used.

Use `R CMD LINK --help` for more usage information.

Note

Some binary distributions of R have `LINK` in a separate bundle, e.g. an `R-devel` RPM.

`localeToCharset` *Select a Suitable Encoding Name from a Locale Name*

Description

This functions aims to find a suitable coding for the locale named, by default the current locale, and if it is a UTF-8 locale a suitable single-byte encoding.

Usage

```
localeToCharset(locale = Sys.getlocale("LC_CTYPE"))
```

Arguments

<code>locale</code>	character string naming a locale.
---------------------	-----------------------------------

Details

The operation differs by OS. Locale names are normally like `es_MX.iso88591`. If final component indicates an encoding and it is not `utf8` we just need to look up the equivalent encoding name. Otherwise, the language (here `es`) is used to choose a primary or fallback encoding.

In the C locale the answer will be `"ASCII"`.

Value

A character vector naming an encoding and possibly a fallback single-encoding, `NA` if unknown.

Note

The encoding names are those used by `libiconv`, and ought also to work with `glibc` but maybe not with commercial Unixen.

See Also

[Sys.getlocale](#), [iconv](#).

Examples

```
localeToCharset()
```

```
ls.str
```

List Objects and their Structure

Description

`ls.str` and `lsf.str` are variations of `ls` applying `str()` to each matched name: see section [Value](#).

Usage

```
ls.str(pos = -1, name, envir, all.names = FALSE,
       pattern, mode = "any")
```

```
lsf.str(pos = -1, envir, ...)
```

```
## S3 method for class 'ls_str':
print(x, max.level = 1, give.attr = FALSE, ...)
```

Arguments

<code>pos</code>	integer indicating search path position.
<code>name</code>	optional name indicating search path position, see ls .
<code>envir</code>	environment to use, see ls .
<code>all.names</code>	logical indicating if names which begin with a <code>.</code> are omitted; see ls .
<code>pattern</code>	a regular expression passed to ls . Only names matching <code>pattern</code> are considered.
<code>max.level</code>	maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default 0: Display all nesting levels.
<code>give.attr</code>	logical; if TRUE (default), show attributes as sub structures.
<code>mode</code>	character specifying the mode of objects to consider. Passed to exists and get .
<code>x</code>	an object of class "ls_str".
<code>...</code>	further arguments to pass. and <code>lsf.str</code> passes them to <code>ls.str</code> which passes them on to <code>ls</code> . The (non-exported) print method <code>print.ls_str</code> passes them to <code>str</code> .

Value

`ls.str` and `lsf.str` return an object of class "ls_str", basically the character vector of matching names (functions only for `lsf.str`), similarly to `ls`, with a `print()` method that calls `str()` on each object.

Author(s)

Martin Maechler

See Also[str](#), [summary](#), [args](#).**Examples**

```
require(stats)

lsf.str()#- how do the functions look like which I am using?
ls.str(mode = "list") #- what are the structured objects I have defined?

## create a few objects
example(glm, echo = FALSE)
ll <- as.list(LETTERS)
print(ls.str(), max.level = 0)# don't show details

## which base functions have "file" in their name ?
lsf.str(pos = length(search()), pattern = "file")

## demonstrating that ls.str() works inside functions
## ["browser/debug mode"]:
tt <- function(x, y=1) { aa <- 7; r <- x + y; ls.str() }
(nms <- sapply(strsplit(capture.output(tt(2)), " *: *"), `[`, 1))
stopifnot(nms == c("aa", "r", "x", "y"))
```

make.packages.html *Update HTML Documentation Files*

Description

Functions to link and (optionally) re-create the HTML documentation files to reflect all installed packages.

Usage

```
make.packages.html(lib.loc = .libPaths(), packages = TRUE)
```

Arguments

`lib.loc` character vector. List of libraries to be included.
`packages` logical: should package indices be create.

Details

This sets up the links from packages in libraries to the `‘.R’` subdirectory of the per-session directory (see [tempdir](#)) and optionally creates the `‘packages.html’` and `‘index.txt’` files to point to those links. The slow part is creating those files (as all the package `‘DESCRIPTION’` files are read).

If a package is available in more than one library tree, all the copies are linked, after the first with suffix `.1` etc.

Value

Invisible logical, indicating if the files were created.

See Also

[help.start](#)

Examples

```
## Not run:
# to prefer HTML help, put in your .Rprofile
options(htmlhelp=TRUE)
make.packages.html(packages=FALSE)
# this can be slow for large numbers of installed packages.
## End(Not run)
```

make.socket

Create a Socket Connection

Description

With `server = FALSE` attempts to open a client socket to the specified port and host. With `server = TRUE` listens on the specified port for a connection and then returns a server socket. It is a good idea to use [on.exit](#) to ensure that a socket is closed, as you only get 64 of them.

Usage

```
make.socket(host = "localhost", port, fail = TRUE, server = FALSE)
```

Arguments

host	name of remote host
port	port to connect to/listen on
fail	failure to connect is an error?
server	a server socket?

Value

An object of class "socket".

socket	socket number. This is for internal use
port	port number of the connection
host	name of remote computer

Warning

I don't know if the connecting host name returned when `server = TRUE` can be trusted. I suspect not.

Author(s)

Thomas Lumley

References

Adapted from Luke Tierney's code for XLISP-Stat, in turn based on code from Robbins and Robbins "Practical UNIX Programming"

See Also

[close.socket](#), [read.socket](#)

Examples

```
daytime <- function(host = "localhost"){
  a <- make.socket(host, 13)
  on.exit(close.socket(a))
  read.socket(a)
}
## Official time (UTC) from US Naval Observatory
## Not run: daytime("tick.usno.navy.mil")
```

memory.size

Report on Memory Allocation

Description

`memory.size` and `memory.limit` are used to manage the total memory allocation on Windows. On other platforms these are stubs which report infinity with a warning.

Usage

```
memory.size(max = FALSE)
```

```
memory.limit(size = NA)
```

Arguments

`max` logical. If true the maximum amount of memory obtained from the OS is reported, otherwise the amount currently in use.

`size` numeric. If NA report the memory size, otherwise request a new limit, in Mb.

Details

To restrict memory usage on a Unix-alike use the facilities of the shell used to launch R, e.g. `limit` or `ulimit`.

Value

Size in bytes: always Inf.

See Also

[Memory-limits](#) for other limits.

menu

Menu Interaction Function

Description

`menu` presents the user with a menu of choices labelled from 1 to the number of choices. To exit without choosing an item one can select '0'.

Usage

```
menu(choices, graphics = FALSE, title = "")
```

Arguments

<code>choices</code>	a character vector of choices
<code>graphics</code>	a logical indicating whether a graphics menu should be used if available.
<code>title</code>	a character string to be used as the title of the menu. NULL is also accepted.

Details

If `graphics = TRUE` and a windowing system is available (Windows, MacOS X or X11 via Tcl/Tk) a listbox widget is used, otherwise a text menu.

Ten or fewer items will be displayed in a single column, more in multiple columns if possible within the current display width.

No title is displayed if `title` is NULL or "".

Value

The number corresponding to the selected item, or 0 if no choice was made.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`select.list`, which is used to implement the graphical menu, and allows multiple selections.

Examples

```
## Not run:
switch(menu(c("List letters", "List LETTERS")) + 1,
        cat("Nothing done\n"), letters, LETTERS)
## End(Not run)
```

 methods

List Methods for S3 Generic Functions or Classes

Description

List all available methods for an S3 generic function, or all methods for a class.

Usage

```
methods(generic.function, class)
```

Arguments

<code>generic.function</code>	a generic function, or a character string naming a generic function.
<code>class</code>	a symbol or character string naming a class: only used if <code>generic.function</code> is not supplied.

Details

Function `methods` can be used to find out about the methods for a particular generic function or class. The functions listed are those which *are named like methods* and may not actually be methods (known exceptions are discarded in the code). Note that the listed methods may not be user-visible objects, but often help will be available for them.

If `class` is used, we check that a matching generic can be found for each user-visible object named. If `generic.function` is given, there is a warning if it appears not to be a generic function. (The check for being generic used can be fooled.)

Value

An object of class "MethodsFunction", a character vector of function names with an "info" attribute. There is a `print` method which marks with an asterisk any methods which are not visible: such functions can be examined by `getS3method` or `getAnywhere`.

The "info" attribute is a data frame, currently with a logical column, `visible` and a factor column `from` (indicating where the methods were found).

Note

This scheme is called *S3* (S version 3). For new projects, it is recommended to use the more flexible and robust *S4* scheme provided in the **methods** package. Functions can have both S3 and S4 methods, and function `showMethods` will list the S4 methods (possibly none).

The original `methods` function was written by Martin Maechler.

References

For [S4](#), [showMethods](#), [Methods](#).

Examples

```
require(stats)

methods(summary)
methods(class = "aov")
methods("[[" # uses C-internal dispatching
methods("$")
methods("$<-") # replacement function
methods("+") # binary operator
methods("Math") # group generic
require(graphics)
methods("axis") # looks like it has methods, but not generic
## Not run:
methods(print) # over 100
## End(Not run)
## --> help(showMethods) for related examples
```

mirrorAdmin

Managing Repository Mirrors

Description

Functions helping to maintain CRAN, some of them may also be useful for administrators of other repository networks.

Usage

```
mirror2html(mirrors = NULL, file = "mirrors.html",
            head = "mirrors-head.html", foot = "mirrors-foot.html")
checkCRAN(method)
```

Arguments

mirrors	A data frame, by default the CRAN list of mirrors is used.
file	A connection object or a character string.
head	Name of optional header file.
foot	Name of optional footer file.
method	Download method, see download.file .

Details

`mirror2html` creates the HTML file for the CRAN list of mirrors and invisibly returns the HTML text.

`checkCRAN` performs a sanity checks on all CRAN mirrors.

modifyList	<i>Recursively Modify Elements of a List</i>
------------	--

Description

Modifies a possibly nested list recursively by changing a subset of elements at each level to match a second list.

Usage

```
modifyList(x, val)
```

Arguments

x	a named <code>list</code> , possibly empty.
val	a named list with components to replace corresponding components in x.

Value

A modified version of x, with the modifications determined as follows (here, list elements are identified by their names). Elements in val which are missing from x are added to x. For elements that are common to both but are not both lists themselves, the component in x is replaced by the one in val. For common elements that are both lists, x[[name]] is replaced by modifyList(x[[name]], val[[name]]).

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

Examples

```
foo <- list(a = 1, b = list(c = "a", d = FALSE))
bar <- modifyList(foo, list(e = 2, b = list(d = TRUE)))
str(foo)
str(bar)
```

normalizePath	<i>Express File Paths in Canonical Form</i>
---------------	---

Description

Convert file paths to canonical form for the platform, to display them in a user-understandable form.

Usage

```
normalizePath(path)
```

Arguments

path	character vector of file paths.
------	---------------------------------

Details

Where the platform supports it this turns paths into absolute paths in their canonical form (no ./, ../ nor symbolic links).

If the path is not a real path the result is undefined. On Unix-alikes, this will likely be the corresponding input element. On Windows, it will likely result in an error being signalled.

Value

A character vector.

Examples

```
cat(normalizePath(c(R.home(), tempdir())), sep = "\n")
```

nsl

Look up the IP Address by Hostname

Description

Interface to gethostbyname.

Usage

```
nsl(hostname)
```

Arguments

hostname the name of the host.

Value

The IP address, as a character string, or NULL if the call fails.

Note

This was included as a test of internet connectivity, to fail if the node running R is not connected. It will also return NULL if BSD networking is not supported, including the header file 'arpa/inet.h'.

Examples

```
## Not run: nsl("www.r-project.org")
```

`object.size`*Report the Space Allocated for an Object*

Description

Provides an estimate of the memory that is being used to store an R object.

Usage

```
object.size(x)
```

Arguments

`x` An R object.

Details

Exactly which parts of the memory allocation should be attributed to which object is not clear-cut. This function merely provides a rough indication: it should be reasonably accurate for atomic vectors, but does not detect if elements of a list are shared, for example. (Sharing amongst elements of a character vector is taken into account, but not that between character vectors in a single object.)

The calculation is of the size of the object, and excludes the space needed to store its name in the symbol table.

Associated space (e.g. the environment of a function and what the pointer in a `EXTPTRSXP` points to) is not included in the calculation.

Object sizes are larger on 64-bit platforms than 32-bit ones, but will very likely be the same on different platforms with the same word length and pointer size.

Value

An estimate of the memory allocation attributable to the object, in bytes.

See Also

[Memory-limits](#) for the design limitations on object size.

Examples

```
object.size(letters)
object.size(ls)
## find the 10 largest objects in the base package
z <- sapply(ls("package:base"), function(x)
            object.size(get(x, envir = baseenv())))
as.matrix(rev(sort(z)) [1:10])
```

package.skeleton *Create a Skeleton for a New Source Package*

Description

`package.skeleton` automates some of the setup for a new source package. It creates directories, saves functions, data, and R code files to appropriate places, and creates skeleton help files and a ‘Read-and-delete-me’ file describing further steps in packaging.

Usage

```
package.skeleton(name = "anRpackage", list,
                 environment = .GlobalEnv,
                 path = ".", force = FALSE, namespace = FALSE,
                 code_files = character())
```

Arguments

<code>name</code>	character string: the package name and directory name for your package.
<code>list</code>	character vector naming the R objects to put in the package. Usually, at most one of <code>list</code> , <code>environment</code> , or <code>code_files</code> will be supplied. See ‘Details’.
<code>environment</code>	an environment where objects are looked for. See ‘Details’.
<code>path</code>	path to put the package directory in.
<code>force</code>	If <code>FALSE</code> will not overwrite an existing directory.
<code>namespace</code>	a logical indicating whether to add a name space for the package. If <code>TRUE</code> , a <code>NAMESPACE</code> file is created to export all objects whose names begin with a letter, plus all S4 methods and classes.
<code>code_files</code>	a character vector with the paths to R code files to build the package around. See ‘Details’.

Details

The arguments `list`, `environment`, and `code_files` provide alternative ways to initialize the package. If `code_files` is supplied, the files so named will be sourced to form the environment, then used to generate the package skeleton. Otherwise `list` defaults to the non-hidden files in `environment` (those whose name does not start with `.`), but can be supplied to select a subset of the objects in that environment.

Stubs of help files are generated for functions, data objects, and S4 classes and methods, using the `prompt`, `promptClass`, and `promptMethods` functions.

The package sources are placed in subdirectory `name` of `path`. If `code_files` is supplied, these files are copied; otherwise, objects will be dumped into individual source files. The file names in `code_files` should have suffix `".R"` and be in the current working directory.

The filenames created for source and documentation try to be valid for all OSes known to run R. Invalid characters are replaced by `'_'`, invalid names are preceded by `'zz'`, and finally the converted names are made unique by `make.unique` (`sep = "_"`). This can be done for code and help files but not data files (which are looked for by name). Also, the code and help files should have names starting with an ASCII letter or digit, and this is checked and if necessary `z` prepended.

When you are done, delete the ‘Read-and-delete-me’ file, as it should not be distributed.

Value

Used for its side-effects.

References

Read the *Writing R Extensions* manual for more details.

Once you have created a *source* package you need to install it: see the *R Installation and Administration* manual, [INSTALL](#) and [install.packages](#).

See Also

[prompt](#), [promptClass](#), and [promptMethods](#).

Examples

```
require(stats)
## two functions and two "data sets" :
f <- function(x,y) x+y
g <- function(x,y) x-y
d <- data.frame(a=1, b=2)
e <- rnorm(1000)

package.skeleton(list=c("f", "g", "d", "e"), name="mypkg")
```

packageDescription *Package Description*

Description

Parses and returns the ‘DESCRIPTION’ file of a package.

Usage

```
packageDescription(pkg, lib.loc = NULL, fields = NULL,
                  drop = TRUE, encoding = "")
```

Arguments

pkg	a character string with the package name.
lib.loc	a character vector of directory names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.
fields	a character vector giving the tags of fields to return (if other fields occur in the file they are ignored).
drop	If TRUE and the length of fields is 1, then a single character string with the value of the respective field is returned instead of an object of class "packageDescription".
encoding	If there is an Encoding field, to what encoding should re-encoding be attempted? If NA, no re-encoding. The other values are as used by iconv , so the default "" indicates the encoding of the current locale.

Details

A package will not be ‘found’ unless it has a ‘DESCRIPTION’ file which contains a valid `Version` field. Different warnings are given when no package directory is found and when there is a suitable directory but no valid ‘DESCRIPTION’ file.

An [attached](#) environment named to look like a package (e.g. `package:utils2`) will be ignored as from R 2.6.0.

Value

If a ‘DESCRIPTION’ file for the given package is found and can successfully be read, `packageDescription` returns an object of class `"packageDescription"`, which is a named list with the values of the (given) fields as elements and the tags as names, unless `drop = TRUE`.

If parsing the ‘DESCRIPTION’ file was not successful, it returns a named list of NAs with the field tags as names if `fields` is not null, and NA otherwise.

See Also

[read.dcf](#)

Examples

```
packageDescription("stats")
packageDescription("stats", fields = c("Package", "Version"))

packageDescription("stats", fields = "Version")
packageDescription("stats", fields = "Version", drop = FALSE)
```

packageStatus

Package Management Tools

Description

Summarize information about installed packages and packages available at various repositories, and automatically upgrade outdated packages.

Usage

```
packageStatus(lib.loc = NULL, repositories = NULL, method,
              type = getOption("pkgType"))

## S3 method for class 'packageStatus':
summary(object, ...)
```

```
## S3 method for class 'packageStatus':
update(object, lib.loc = levels(object$inst$LibPath),
        repositories = levels(object$avail$Repository), ...)
```

```
## S3 method for class 'packageStatus':
upgrade(object, ask = TRUE, ...)
```

Arguments

<code>lib.loc</code>	a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.
<code>repositories</code>	a character vector of URLs describing the location of R package repositories on the Internet or on the local machine.
<code>method</code>	Download method, see download.file .
<code>type</code>	type of package distribution: see install.packages .
<code>object</code>	an object of class "packageStatus" as returned by <code>packageStatus</code> .
<code>ask</code>	if TRUE, the user is prompted which packages should be upgraded and which not.
<code>...</code>	currently not used.

Details

The URLs in `repositories` should be full paths to the appropriate contrib sections of the repositories. The default is `contrib.url(getOption("repos"))`.

There are `print` and `summary` methods for the "packageStatus" objects: the `print` method gives a brief tabular summary and the `summary` method prints the results.

The `update` method updates the "packageStatus" object. The `upgrade` method is similar to [update.packages](#): it offers to install the current versions of those packages which are not currently up-to-date.

Value

An object of class "packageStatus". This is a list with two components

<code>inst</code>	a data frame with columns as the <i>matrix</i> returned by installed.packages plus "Status", a factor with levels <code>c("ok", "upgrade")</code> . Only the newest version of each package is reported, in the first repository in which it appears.
<code>avail</code>	a data frame with columns as the <i>matrix</i> returned by available.packages plus "Status", a factor with levels <code>c("installed", "not installed", "unavailable")</code> .

See Also

[installed.packages](#), [available.packages](#)

Examples

```
## Not run:
x <- packageStatus()
print(x)
summary(x)
upgrade(x)
x <- update(x)
print(x)
## End(Not run)
```

page

Invoke a Pager on an R Object

Description

Displays a representation of the object named by `x` in a pager via `file.show`.

Usage

```
page(x, method = c("dput", "print"), ...)
```

Arguments

<code>x</code>	An R object, or a character string naming an object.
<code>method</code>	The default method is to dump the object via <code>dput</code> . An alternative is to use <code>print</code> and capture the output to be shown in the pager.
<code>...</code>	additional arguments for <code>dput</code> , <code>print</code> or <code>file.show</code> (such as <code>title</code>).

Details

If `x` is a length-one character vector, it is used as the name of an object to look up in the environment from which `page` is called. All other objects are displayed directly.

A default value of `title` is passed to `file.show` if one is not supplied in `...`

See Also

`file.show`, `edit`, `fix`.

To go to a new page when graphing, see `frame`.

Examples

```
## Not run:
## four ways to look at the code of 'page'
page(page)           # as an object
page("page")        # a character string
v <- "page"; page(v) # a length-one character vector
page(utils::page)    # a call
## End(Not run)
```

person

Person Names and Contact Information

Description

A class and utility methods for holding information about persons like name and email address.

Usage

```

person(first = "", last = "", middle = "", email = "")
personList(...)
as.person(x)
as.personList(x)

## S3 method for class 'person':
as.character(x, ...)
## S3 method for class 'personList':
as.character(x, ...)

## S3 method for class 'person':
toBibtex(object, ...)
## S3 method for class 'personList':
toBibtex(object, ...)

```

Arguments

first	character string, first name
middle	character string, middle name(s)
last	character string, last name
email	character string, email address
...	for personList an arbitrary number of person objects
x	a character string or an object of class person or personList
object	an object of class person or personList

Examples

```

## create a person object directly
p1 <- person("Karl", "Pearson", email = "pearson@stats.heaven")
p1

## convert a string
p2 <- as.person("Ronald Aylmer Fisher")
p2

## create one object holding both
p <- personList(p1, p2)
ps <- as.character(p)
ps
as.personList(ps)

## convert to BibTeX author field
toBibtex(p)

```

Description

Utilities for checking whether the sources of an R add-on package work correctly, and for building a source or binary package from them.

Usage

```
R CMD build [options] pkgdirs
R CMD check [options] pkgdirs
```

Arguments

pkgdirs	a list of names of directories with sources of R add-on packages.
options	further options to control the processing, or for obtaining information about usage and version of the utility.

Details

R CMD check checks R add-on packages from their sources, performing a wide variety of diagnostic checks.

R CMD build builds R source or binary packages from their sources. The name(s) of the packages are taken from the ‘DESCRIPTION’ files and not from the directory names.

Use R CMD foo --help to obtain usage information on utility foo.

Several of the options to build --binary are passed to [INSTALL](#) so consult its help for the details.

See Also

The sections on “Checking and building packages” and “Processing Rd format” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

[INSTALL](#) is called by build --binary.

prompt

*Produce Prototype of an R Documentation File***Description**

Facilitate the constructing of files documenting R objects.

Usage

```
prompt(object, filename = NULL, name = NULL, ...)

## Default S3 method:
prompt(object, filename = NULL, name = NULL,
        force.function = FALSE, ...)

## S3 method for class 'data.frame':
prompt(object, filename = NULL, name = NULL, ...)
```

Arguments

<code>object</code>	an R object, typically a function for the default method.
<code>filename</code>	usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is <code>name</code> followed by ".Rd". Can also be NA (see below).
<code>name</code>	a character string specifying the name of the object.
<code>force.function</code>	a logical. If TRUE, treat <code>object</code> as function in any case.
<code>...</code>	further arguments passed to or from other methods.

Details

Unless `filename` is NA, a documentation shell for `object` is written to the file specified by `filename`, and a message about this is given. For function objects, this shell contains the proper function and argument names. R documentation files thus created still need to be edited and moved into the 'man' subdirectory of the package containing the object to be documented.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

When `prompt` is used in `for` loops or scripts, the explicit name specification will be useful.

Value

If `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Warning

The default filename may not be a valid filename under limited file systems (e.g. those on Windows).

Currently, calling `prompt` on a non-function object assumes that the object is in fact a data set and hence documents it as such. This may change in future versions of R. Use `promptData` to create documentation skeletons for data sets.

Note

The documentation file produced by `prompt.data.frame` does not have the same format as many of the data frame documentation files in the **base** package. We are trying to settle on a preferred format for the documentation.

Author(s)

Douglas Bates for `prompt.data.frame`

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[promptData](#), [help](#) and the chapter on “Writing R documentation” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

For creation of many help pages (for a package), see [package.skeleton](#).

To prompt the user for input, see [readline](#).

Examples

```
require(graphics)
prompt(plot.default)
prompt(interactive, force.function = TRUE)
unlink("plot.default.Rd")
unlink("interactive.Rd")

prompt(women) # data.frame
unlink("women.Rd")

prompt(sunspots) # non-data.frame data
unlink("sunspots.Rd")
```

promptData

Generate a Shell for Documentation of Data Sets

Description

Generates a shell of documentation for a data set.

Usage

```
promptData(object, filename = NULL, name = NULL)
```

Arguments

object	an R object to be documented as a data set.
filename	usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is name followed by ".Rd". Can also be NA (see below).
name	a character string specifying the name of the object.

Details

Unless filename is NA, a documentation shell for object is written to the file specified by filename, and a message about this is given.

If filename is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where x is the list-style representation.

Currently, only data frames are handled explicitly by the code.

Value

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Warning

This function is still experimental. Both interface and value might change in future versions. In particular, it may be preferable to use a character string naming the data set and optionally a specification of where to look for it instead of using `object/name` as we currently do. This would be different from `prompt`, but consistent with other `prompt`-style functions in package **methods**, and also allow prompting for data set documentation without explicitly having to load the data set.

See Also

`prompt`

Examples

```
promptData(sunspots)
unlink("sunspots.Rd")
```

promptPackage

Generate a Shell for Documentation of a Package

Description

Generates a shell of documentation for an installed or source package.

Usage

```
promptPackage(package, lib.loc = NULL, filename = NULL,
              name = NULL, final = FALSE)
```

Arguments

<code>package</code>	the name of an <i>installed</i> or <i>source</i> package to be documented.
<code>lib.loc</code>	a character vector describing the location of R library trees to search through, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. For a source package this should specify the parent directory of the package's sources.
<code>filename</code>	usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is <code>name</code> followed by <code>".Rd"</code> . Can also be <code>NA</code> (see below).
<code>name</code>	a character string specifying the name of the help topic, typically of the form <code><pkg>-package</code> .
<code>final</code>	a logical value indicating whether to attempt to create a usable version of the help topic, rather than just a shell.

Details

Unless `filename` is `NA`, a documentation shell for `package` is written to the file specified by `filename`, and a message about this is given.

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

If `final` is `TRUE`, the generated documentation will not include the place-holder slots for manual editing, it will be usable as-is. In most cases a manually edited file is preferable (but `final = TRUE` is certainly less work).

Value

If `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

promptPackage("utils", filename = filename)
file.show(filename)
unlink(filename)
```

rcompgen

A Completion Generator for R

Description

This package provides a mechanism to generate relevant completions from a partially completed command line. It is not intended to be useful by itself, but rather in conjunction with other mechanisms that use it as a backend. The functions listed in the usage section provide a simple control and query mechanism. The actual interface consists of a few unexported functions described further down.

Usage

```
rc.settings(ops, ns, args, func, ipck, S3, data, help,
            argdb, files)

rc.status()

rc.getOption(name)

rc.options(...)
```

Arguments

`ops`, `ns`, `args`, `func`, `ipck`, `S3`, `data`, `help`, `argdb`, `files`
 logical, turning some optional completion features on and off.

ops: activates completion after the `$` and `@` operators

ns: controls name space related completions

args: enables completion of function arguments

func: enables detection of functions. If enabled, a customizable extension ("`"` by default) is appended to function names. The process of determining whether a potential completion is a function requires evaluation, including for lazy loaded symbols. This is extremely undesirable for large objects, because of potentially wasteful use of memory in addition to the time overhead associated with loading. For this reason, this feature is disabled by default.

S3: when `args=TRUE`, activates completion on arguments of all S3 methods (otherwise just the generic, which usually has very few arguments)

ipck: enables completion of installed package names inside `library` and `require`

data: enables completion of data sets (including those already visible) inside `data`

help: enables completion of help requests starting with a question mark, by looking inside help index files

argdb: when `args=TRUE`, completion is attempted on function arguments. Generally, the list of valid arguments is determined by dynamic calls to `args`. While this gives results that are technically correct, the use of the `...` argument often hides some useful arguments. To give more flexibility in this regard, `rcompgen` internally retains an optional table of valid arguments names for specific functions. Setting `argdb=TRUE` enables preferential lookup in this internal data base for functions with an entry in it. Of course, this is useful only when the data base contains information about the function of interest. Some functions are included in the package (the maintainer is happy to add more upon request), and more can be added by the user through the unexported function `.addFunctionInfo` (see below).

files: enables filename completion in R code. This is initially set to `FALSE`, in which case the underlying completion front-end can take over (and hopefully do a better job than we would have done). For systems where no such facilities exist, this can be set to `TRUE` if file name completion is desired. This is currently experimental and may not work very well.

All settings are turned on by default except `ipck`, `func` and `files`. Turn more off if your CPU cycles are valuable; you will still retain basic completion on names of objects in the search list. See below for additional details.

`name`, ... user-settable options. Currently valid names are

function.suffix: default "`"`

funarg.suffix: default "`=`"

package.suffix: default "`::`"

See `options` for detailed usage description

Details

There are several types of completion, some of which can be disabled using `rc.settings`. The most basic level, which can not be turned off once the package is loaded, provides completion on names visible on the search path, along with a few special keywords (e.g. `TRUE`). This type of completion is not attempted if the partial ‘word’ (a.k.a. token) being completed is empty (since there would be too many completions). The more advanced types of completion are described below.

Completion after extractors `$` and `@`: When the `ops` setting is turned on, completion after `$` and `@` is attempted. This requires the prefix to be evaluated, which is attempted unless it involves an explicit function call (implicit function calls involving the use of `[`, `$`, etc *do not* inhibit evaluation).

Completion inside name spaces: When the `ns` setting is turned on, completion inside name spaces is attempted when a token is preceded by the `::` or `:::` operators. Additionally, the basic completion mechanism is extended to include attached name spaces, or more precisely, `foopkg::` becomes a valid completion of `foo` if the return value of `search()` includes the string `"package:foopkg"`.

The completion of package name spaces applies only to attached packages, i.e. if `MASS` is not attached (whether or not it is loaded), `MAS` will not complete to `MASS::`. However, attempted completion *inside* an apparent name space will attempt to load the name space if it is not already loaded, e.g. trying to complete on `MASS::fr` will load `MASS` (but not necessarily attach it) even if it is not already loaded.

Completion of function arguments: When the `args` setting is turned on, completion on function arguments is attempted whenever deemed appropriate. The mechanism used will currently fail if the relevant function (at the point where completion is requested) was entered on a previous prompt (which implies in particular that the current line is being typed in response to a continuation prompt, usually `+`). Note that separation by newlines is fine.

The list of possible argument completions that is generated can be misleading. There is no problem for non-generic functions (except that `...` is listed as a completion; this is intentional as it signals the fact that the function can accept further arguments). However, for generic functions, it is practically impossible to give a reliable argument list without evaluating arguments (and not even then, in some cases), which is risky (in addition to being difficult to code, which is the real reason it hasn’t even been tried), especially when that argument is itself an inline function call. Our compromise is to consider arguments of *all* currently available methods of that generic. This has two drawbacks. First, not all listed completions may be appropriate in the call currently being constructed. Second, for generics with many methods (like `print` and `plot`), many matches will need to be considered, which may take a noticeable amount of time. Despite these drawbacks, we believe this behaviour to be more useful than the only other practical alternative, which is to list arguments of the generic only.

Only S3 methods are currently supported in this fashion, and that can be turned off using the `S3` setting.

Since arguments can be unnamed in R function calls, other types of completion are also appropriate whenever argument completion is. Since there are usually many many more visible objects than formal arguments of any particular function, possible argument completions are often buried in a bunch of other possibilities. However, recall that basic completion is suppressed for blank tokens. This can be useful to list possible arguments of a function. For example, trying to complete `seq([TAB]` and `seq(from = 1, [TAB])` will both list only the arguments of `seq` (or any of its methods), whereas trying to complete `seq(length[TAB]` will list both the `length.out` argument and the `length()` function as possible completions. Note that no attempt is made to remove arguments already supplied, as that would incur a further speed penalty.

Special functions: For a few special functions (`library`, `data`, etc), the first argument is treated specially, in the sense that normal completion is suppressed, and some function specific completions are enabled if so requested by the settings. The `ipck` setting, which controls whether `library` and `require` will complete on *installed packages*, is disabled by default because the first call to `installed.packages` is potentially time consuming (e.g. when packages are installed on a remote network file server). Note, however, that the results of a call to `installed.packages` is cached, so subsequent calls are usually fast, so turning this option on is not particularly onerous even in such situations.

Value

`rc.status` returns, as a list, the contents of an internal (unexported) environment that is used to record the results of the last completion attempt. This can be useful for debugging. For such use, one must resist the temptation to use completion when typing the call to `rc.status` itself, as that then becomes the last attempt by the time the call is executed.

The items of primary interest in the returned list are:

<code>comps</code>	the possible completions generated by the last call to <code>.completeToken</code> , as a character vector
<code>token</code>	the token that was (or, is to be) completed, as set by the last call to <code>.assignToken</code> (possibly inside a call to <code>.guessTokenFromLine</code>)
<code>linebuffer</code>	the full line, as set by the last call to <code>.assignLinebuffer</code>
<code>start</code>	the start position of the token in the line buffer, as set by the last call to <code>.assignStart</code>
<code>end</code>	the end position of the token in the line buffer, as set by the last call to <code>.assignEnd</code>
<code>fileName</code>	logical, indicating whether the cursor is currently inside quotes. If so, no completion is attempted. A reasonable default behaviour for the backend in that case is to fall back to filename completion.
<code>fguess</code>	the name of the function <code>rcompgen</code> thinks the cursor is currently inside
<code>isFirstArg</code>	logical. If cursor is inside a function, is it the first argument?

In addition, the components `settings` and `options` give the current values of settings and options respectively.

`rc.getOption` and `rc.options` behave much like `getOption` and `options` respectively.

Unexported API

There are several unexported functions in the package. Of these, a few are special because they provide the API through which other mechanisms can make use of the facilities provided by this package (they are unexported because they are not meant to be called directly by users). The usage of these functions are:

```
.assignToken(text)
.assignLinebuffer(line)
.assignStart(start)
.assignEnd(end)

.completeToken()
.retrieveCompletions()
```

```
.getFileComp()

.guessTokenFromLine()
.win32consoleCompletion(linebuffer, cursorPosition,
                        check.repeat = TRUE,
                        minlength = -1)

.addFunctionInfo(...)
```

The first four functions set up a completion attempt by specifying the token to be completed (`text`), and indicating where (`start` and `end`, which should be integers) the token is placed within the complete line typed so far (`line`).

Potential completions of the token are generated by `.completeToken`, and the completions can be retrieved as an R character vector using `.retrieveCompletions`.

If the cursor is inside quotes, no completion is attempted. The function `.getFileComp` can be used after a call to `.completeToken` to determine if this is the case (returns `TRUE`), and alternative completions generated as deemed useful. In most cases, filename completion is a reasonable fallback.

The `.guessTokenFromLine` function is provided for use with backends that do not already break a line into tokens. It requires the `linebuffer` and endpoint (cursor position) to be already set, and itself sets the token and the start position. It returns the token as a character string. (This is used by the ESS completion hook example given in the `examples/altesscomp.el` file.)

The `.win32consoleCompletion` is similar in spirit, but is more geared towards the Windows GUI (or rather, any front-end that has no completion facilities of its own). It requires the `linebuffer` and cursor position as arguments, and returns a list with three components, `addition`, `possible` and `comps`. If there is an unambiguous extension at the current position, `addition` contains the additional text that should be inserted at the cursor. If there is more than one possibility, these are available either as a character vector of preformatted strings in `possible`, or as a single string in `comps`. `possible` consists of lines formatted using the current `width` option, so that printing them on the console one line at a time will be a reasonable way to list them. `comps` is a space separated (collapsed) list of the same completions, in case the front-end wishes to display it in some other fashion.

The `minlength` argument can be used to suppress completion when the token is too short (which can be useful if the front-end is set up to try completion on every keypress). If `check.repeat` is `TRUE`, it is detected if the same completion is being requested more than once in a row, and ambiguous completions are returned only in that case. This is an attempt to emulate GNU Readline behaviour, where a single TAB completes upto any unambiguous part, and multiple possibilities are reported only on two consecutive TABs.

As the various front-end interfaces evolve, the details of these functions are likely to change as well.

The function `.addFunctionInfo` can be used to add information about the permitted argument names for specific functions. Multiple named arguments are allowed in calls to it, where the tags are names of functions and values are character vectors representing valid arguments. When the `argdb` setting is `TRUE`, these are used as a source of valid argument names for the relevant functions.

Note

If you are uncomfortable with unsolicited evaluation of pieces of code, you should set `ops = FALSE`. Otherwise, trying to complete `foo@ba` will evaluate `foo`, trying to complete `foo[i,1:10]$ba` will evaluate `foo[i,1:10]`, etc. This should not be too bad, as explicit function calls (involving parentheses) are not evaluated in this manner. However, this *will* affect lazy loaded symbols (and presumably other promise type thingies).

 read.DIF

Data Input from Spreadsheet

Description

Reads a file in Data Interchange Format (DIF) and creates a data frame from it. DIF is a format for data matrices such as single spreadsheets.

Usage

```
read.DIF(file, header = FALSE,
         dec = ".", row.names, col.names,
         as.is = !stringsAsFactors,
         na.strings = "NA", colClasses = NA, nrows = -1,
         skip = 0, check.names = TRUE,
         blank.lines.skip = TRUE,
         stringsAsFactors = default.stringsAsFactors(),
         transpose = FALSE)
```

Arguments

file	the name of the file which the data are to be read from, or a connection, or a complete URL.
header	a logical value indicating whether the spreadsheet contains the names of the variables as its first line. If missing, the value is determined from the file format: header is set to TRUE if and only if the first row contains only character values and the top left cell is empty.
dec	the character used in the file for decimal points.
row.names	a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names. If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered. Using row.names = NULL forces row numbering.
col.names	a vector of optional names for the variables. The default is to use "V" followed by the column number.
as.is	the default behavior of read.DIF is to convert character variables (which are not converted to logical, numeric or complex) to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors. Note: to suppress all conversions including those of numeric columns, set colClasses = "character". Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.

<code>na.strings</code>	a character vector of strings which are to be interpreted as <code>NA</code> values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.
<code>colClasses</code>	character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be <code>NA</code> . Possible values are <code>NA</code> (when <code>type.convert</code> is used), <code>"NULL"</code> (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or <code>"factor"</code> , <code>"Date"</code> or <code>"POSIXct"</code> . Otherwise there needs to be an <code>as</code> method (from package methods) for conversion from <code>"character"</code> to the specified formal class. Note that <code>colClasses</code> is specified per column (not per variable) and so includes the column of row names (if any).
<code>nrows</code>	the maximum number of rows to read in. Negative values are ignored.
<code>skip</code>	the number of lines of the data file to skip before beginning to read data.
<code>check.names</code>	logical. If <code>TRUE</code> then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by <code>make.names</code>) so that they are, and also to ensure that there are no duplicates.
<code>blank.lines.skip</code>	logical: if <code>TRUE</code> blank lines in the input are ignored.
<code>stringsAsFactors</code>	logical: should character vectors be converted to factors?
<code>transpose</code>	logical, indicating if the row and column interpretation should be transposed. Microsoft's Excel has been known to produce (non-standard conforming) DIF files which would need <code>transpose = TRUE</code> to be read correctly.

Value

A data frame (`data.frame`) containing a representation of the data in the file. Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame.

Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).
Less memory will be used if `colClasses` is specified as one of the six atomic vector classes.

Author(s)

R Core; `transpose` option by Christoph Buser, ETH Zurich

References

The DIF format specification can be found by searching on <http://www.wotsit.org/>; the optional header fields are ignored. See also http://en.wikipedia.org/wiki/Data_Interchange_Format.

The term is likely to lead to confusion: Windows will have a 'Windows Data Interchange Format (DIF) data format' as part of its WinFX system, which may or may not be compatible.

See Also

The *R Data Import/Export* manual.

[scan](#), [type.convert](#), [read.fwf](#) for reading fixed width formatted input; [read.table](#); [data.frame](#).

Examples

```
## read.DIF() needs transpose=TRUE for file exported from Excel
udir <- system.file("misc", package="utils")
dd <- read.DIF(file.path(udir, "exDIF.dif"), header= TRUE, transpose=TRUE)
dc <- read.csv(file.path(udir, "exDIF.csv"), header= TRUE)
stopifnot(identical(dd,dc), dim(dd) == c(4,2))
```

read.fortran	<i>Read fixed-format data</i>
--------------	-------------------------------

Description

Read fixed-format data files using Fortran-style format specifications.

Usage

```
read.fortran(file, format, ..., as.is = TRUE, colClasses = NA)
```

Arguments

file	File or connection to read from
format	Character vector or list of vectors. See ‘Details’ below.
...	Other arguments for read.table
as.is	Keep characters as characters?
colClasses	Variable classes to override defaults. See read.table for details.

Details

The format for a field is of one of the following forms: `rFl.d`, `rDl.d`, `rXl`, `rAl`, `rIl`, where `l` is the number of columns, `d` is the number of decimal places, and `r` is the number of repeats. `F` and `D` are numeric formats, `A` is character, `I` is integer, and `X` indicates columns to be skipped. The repeat code `r` and decimal place code `d` are always optional. The length code `l` is required except for `X` formats when `r` is present.

For a single-line record, `format` should be a character vector. For a multiline record it should be a list with a character vector for each line.

Skipped (`X`) columns are not passed to [read.table](#), so `colClasses`, `col.names`, and similar arguments passed to [read.table](#) should not reference these columns.

Value

A data frame

See Also

[read.fwf](#), [read.csv](#)

Examples

```
ff <- tempfile()
cat(file=ff, "123456", "987654", sep="\n")
read.fortran(ff, c("F2.1", "F2.0", "I2"))
read.fortran(ff, c("2F1.0", "2X", "2A1"))
unlink(ff)
cat(file=ff, "123456AB", "987654CD", sep="\n")
read.fortran(ff, list(c("2F3.1", "A2"), c("3I2", "2X")))
unlink(ff)
```

read.fwf

Read Fixed Width Format Files

Description

Read a table of fixed width formatted data into a [data.frame](#).

Usage

```
read.fwf(file, widths, header = FALSE, sep = "\t",
         skip = 0, row.names, col.names, n = -1,
         buffersize = 2000, ...)
```

Arguments

<code>file</code>	the name of the file which the data are to be read from. Alternatively, <code>file</code> can be a connection , which will be opened if necessary, and if so closed at the end of the function call.
<code>widths</code>	integer vector, giving the widths of the fixed-width fields (of one line), or list of integer vectors giving widths for multiline records.
<code>header</code>	a logical value indicating whether the file contains the names of the variables as its first line. If present, the names must be delimited by <code>sep</code> .
<code>sep</code>	character; the separator used internally; should be a character that does not occur in the file (except in the header).
<code>skip</code>	number of initial lines to skip; see read.table .
<code>row.names</code>	see read.table .
<code>col.names</code>	see read.table .
<code>n</code>	the maximum number of records (lines) to be read, defaulting to no limit.
<code>buffersize</code>	Maximum number of lines to read at one time
<code>...</code>	further arguments to be passed to read.table . Useful further arguments include <code>as.is</code> , <code>na.strings</code> , <code>colClasses</code> and <code>strip.white</code> .

Details

Multiline records are concatenated to a single line before processing. Fields that are of zero-width or are wholly beyond the end of the line in `file` are replaced by NA.

Negative-width fields are used to indicate columns to be skipped, eg `-5` to skip 5 columns. These fields are not seen by `read.table` and so should not be included in a `col.names` or `colClasses` argument (nor in the header line, if present).

Reducing the `buffer.size` argument may reduce memory use when reading large files with long lines. Increasing `buffer.size` may result in faster processing when enough memory is available.

Value

A `data.frame` as produced by `read.table` which is called internally.

Author(s)

Brian Ripley for R version: original Perl by Kurt Hornik.

See Also

`scan` and `read.table`.

Examples

```
ff <- tempfile()
cat(file=ff, "123456", "987654", sep="\n")
read.fwf(ff, widths=c(1,2,3)) #> 1 23 456 \ 9 87 654
read.fwf(ff, widths=c(1,-2,3)) #> 1 456 \ 9 654
unlink(ff)
cat(file=ff, "123", "987654", sep="\n")
read.fwf(ff, widths=c(1,0, 2,3)) #> 1 NA 23 NA \ 9 NA 87 654
unlink(ff)
cat(file=ff, "123456", "987654", sep="\n")
read.fwf(ff, widths=list(c(1,0, 2,3), c(2,2,2))) #> 1 NA 23 456 98 76 54
unlink(ff)
```

read.socket

Read from or Write to a Socket

Description

`read.socket` reads a string from the specified socket, `write.socket` writes to the specified socket. There is very little error checking done by either.

Usage

```
read.socket(socket, maxlen = 256, loop = FALSE)
write.socket(socket, string)
```

Arguments

socket	a socket object
maxlen	maximum length of string to read
loop	wait for ever if there is nothing to read?
string	string to write to socket

Value

read.socket returns the string read.

read.table

Data Input

Description

Reads a file in table format and creates a data frame from it, with cases corresponding to lines and variables to fields in the file.

Usage

```
read.table(file, header = FALSE, sep = "", quote = "\"'",
           dec = ".", row.names, col.names,
           as.is = !stringsAsFactors,
           na.strings = "NA", colClasses = NA, nrows = -1,
           skip = 0, check.names = TRUE, fill = !blank.lines.skip,
           strip.white = FALSE, blank.lines.skip = TRUE,
           comment.char = "#",
           allowEscapes = FALSE, flush = FALSE,
           stringsAsFactors = default.stringsAsFactors(),
           encoding = "unknown")

read.csv(file, header = TRUE, sep = ",", quote="\"", dec=".",
         fill = TRUE, comment.char=" ", ...)

read.csv2(file, header = TRUE, sep = ";", quote="\"", dec=".",
          fill = TRUE, comment.char=" ", ...)

read.delim(file, header = TRUE, sep = "\t", quote="\"", dec=".",
           fill = TRUE, comment.char=" ", ...)

read.delim2(file, header = TRUE, sep = "\t", quote="\"", dec=".",
            fill = TRUE, comment.char=" ", ...)
```

Arguments

file the name of the file which the data are to be read from. Each row of the table appears as one line of the file. If it does not contain an *absolute* path, the file name is *relative* to the current working directory, `getwd()`. Tilde-expansion is performed where supported.

Alternatively, `file` can be a readable text-mode `connection` (which will be opened for reading if necessary, and if so `closed` (and hence destroyed) at the end of the function call). (If `stdin()` is used, the prompts for lines may be somewhat confusing. Terminate input with a blank line or an EOF signal, `Ctrl-D` on Unix and `Ctrl-Z` on Windows. Any pushback on `stdin()` will be cleared before return.)

`file` can also be a complete URL.

To read a data file not in the current encoding (for example a Latin-1 file in a UTF-8 locale or conversely) use a `file` connection setting the encoding argument.

header a logical value indicating whether the file contains the names of the variables as its first line. If missing, the value is determined from the file format: `header` is set to `TRUE` if and only if the first row contains one fewer field than the number of columns.

sep the field separator character. Values on each line of the file are separated by this character. If `sep = ""` (the default for `read.table`) the separator is ‘white space’, that is one or more spaces, tabs, newlines or carriage returns.

quote the set of quoting characters. To disable quoting altogether, use `quote = ""`. See `scan` for the behaviour on quotes embedded in quotes. Quoting is only considered for columns read as character, which is all of them unless `colClasses` is specified.

dec	the character used in the file for decimal points.
row.names	<p>a vector of row names. This can be a vector giving the actual row names, or a single number giving the column of the table which contains the row names, or character string giving the name of the table column containing the row names.</p> <p>If there is a header and the first row contains one fewer field than the number of columns, the first column in the input is used for the row names. Otherwise if row.names is missing, the rows are numbered.</p> <p>Using row.names = NULL forces row numbering. Missing or NULL row.names generate row names that are considered to be ‘automatic’ (and not preserved by as.matrix).</p>
col.names	a vector of optional names for the variables. The default is to use "V" followed by the column number.
as.is	<p>the default behavior of read.table is to convert character variables (which are not converted to logical, numeric or complex) to factors. The variable as.is controls the conversion of columns not otherwise specified by colClasses. Its value is either a vector of logicals (values are recycled if necessary), or a vector of numeric or character indices which specify which columns should not be converted to factors.</p> <p>Note: to suppress all conversions including those of numeric columns, set colClasses = "character".</p> <p>Note that as.is is specified per column (not per variable) and so includes the column of row names (if any) and any columns to be skipped.</p>
na.strings	a character vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.
colClasses	<p>character. A vector of classes to be assumed for the columns. Recycled as necessary, or if the character vector is named, unspecified values are taken to be NA.</p> <p>Possible values are NA (when type.convert is used), "NULL" (when the column is skipped), one of the atomic vector classes (logical, integer, numeric, complex, character, raw), or "factor", "Date" or "POSIXct". Otherwise there needs to be an as method (from package methods) for conversion from "character" to the specified formal class.</p> <p>Note that colClasses is specified per column (not per variable) and so includes the column of row names (if any).</p>
nrows	integer: the maximum number of rows to read in. Negative and other invalid values are ignored.
skip	integer: the number of lines of the data file to skip before beginning to read data.
check.names	logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names. If necessary they are adjusted (by make.names) so that they are, and also to ensure that there are no duplicates.
fill	logical. If TRUE then in case the rows have unequal length, blank fields are implicitly added. See ‘Details’.
strip.white	logical. Used only when sep has been specified, and allows the stripping of leading and trailing white space from character fields (numeric fields are always stripped). See scan for further details, remembering that the columns may include the row names.

<code>blank.lines.skip</code>	logical: if TRUE blank lines in the input are ignored.
<code>comment.char</code>	character: a character vector of length one containing a single character or an empty string. Use "" to turn off the interpretation of comments altogether.
<code>allowEscapes</code>	logical. Should C-style escapes such as <code>\n</code> be processed or read verbatim (the default)? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). For more details see scan .
<code>flush</code>	logical: if TRUE, <code>scan</code> will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field.
<code>stringsAsFactors</code>	logical: should character vectors be converted to factors? Note that this is overridden by <code>as.is</code> and <code>colClasses</code> , both of which allow finer control.
<code>encoding</code>	encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input. For an example of how to do so, see the examples under file .
<code>...</code>	Further arguments to be passed to <code>read.table</code> .

Details

This function is the principal means of reading tabular data into R.

A field or line is ‘blank’ if it contains nothing (except whitespace if no separator is specified) before a comment character or the end of the field or line.

If `row.names` is not specified and the header line has one less entry than the number of columns, the first column is taken to be the row names. This allows data frames to be read in from the format in which they are printed. If `row.names` is specified and does not refer to the first column, that column is discarded from such files.

The number of data columns is determined by looking at the first five lines of input (or the whole file if it has less than five lines), or from the length of `col.names` if it is specified and is longer. This could conceivably be wrong if `fill` or `blank.lines.skip` are true, so specify `col.names` if necessary.

`read.csv` and `read.csv2` are identical to `read.table` except for the defaults. They are intended for reading ‘comma separated value’ files (‘.CSV’) or (`read.csv2`) the variant used in countries that use a comma as decimal point and a semicolon as field separator. Similarly, `read.delim` and `read.delim2` are for reading delimited files, defaulting to the TAB character for the delimiter. Notice that `header = TRUE` and `fill = TRUE` in these variants, and that the comment character is disabled.

The rest of the line after a comment character is skipped; quotes are not processed in comments. Complete comment lines are allowed provided `blank.lines.skip = TRUE`; however, comment lines prior to the header must have the comment character in the first non-blank column.

Quoted fields with embedded newlines are supported except after a comment character.

Note that unless `colClasses` is specified, all columns are read as character columns and then converted. This means that quotes are interpreted in all fields and that a column of values like "42" will result in an integer column.

Value

A data frame ([data.frame](#)) containing a representation of the data in the file.

Empty input is an error unless `col.names` is specified, when a 0-row data frame is returned: similarly giving just a header line if `header = TRUE` results in a 0-row data frame. Note that in either case the columns will be logical unless `colClasses` was supplied.

Character strings in the result (including factor levels) will have a declared encoding if `encoding` is `"latin1"` or `"UTF-8"`.

Note

The columns referred to in `as.is` and `colClasses` include the column of row names (if any).

Less memory will be used if `colClasses` is specified as one of the six [atomic](#) vector classes. This can be particularly so when reading a column that takes many distinct numeric values, as storing each distinct value as a character string can take up to 14 times as much memory as storing it as an integer.

Using `nrows`, even as a mild over-estimate, will help memory usage.

Using `comment.char = ""` will be appreciably faster than the `read.table` default.

`read.table` is not the right tool for reading large matrices, especially those with many columns: it is designed to read *data frames* which may have columns of very different classes. Use [scan](#) instead.

[count.fields](#) can be useful to determine problems with reading files which result in reports of incorrect record lengths.

recover

Browsing after an Error

Description

This function allows the user to browse directly on any of the currently active function calls, and is suitable as an error option. The expression `options(error=recover)` will make this the error option.

Usage

```
recover()
```

Details

When called, `recover` prints the list of current calls, and prompts the user to select one of them. The standard R [browser](#) is then invoked from the corresponding environment; the user can type ordinary S language expressions to be evaluated in that environment.

When finished browsing in this call, type `c` to return to `recover` from the browser. Type another frame number to browse some more, or type `0` to exit `recover`.

The use of `recover` largely supersedes `dump.frames` as an error option, unless you really want to wait to look at the error. If `recover` is called in non-interactive mode, it behaves like `dump.frames`. For computations involving large amounts of data, `recover` has the advantage that it does not need to copy out all the environments in order to browse in them. If you do decide to quit interactive debugging, call `dump.frames` directly while browsing in any frame (see the examples).

Value

Nothing useful is returned. However, you *can* invoke `recover` directly from a function, rather than through the error option shown in the examples. In this case, execution continues after you type 0 to exit `recover`.

Compatibility Note

The R `recover` function can be used in the same way as the S-Plus function of the same name; therefore, the error option shown is a compatible way to specify the error action. However, the actual functions are essentially unrelated and interact quite differently with the user. The navigating commands `up` and `down` do not exist in the R version; instead, exit the browser and select another frame.

References

2:lm.wfit(x, y, w, offset = offset, ...)
Selection: 0 # exit recover
>

## End(Not run)

```

relist

*Allow Re-Listing an unlist()ed Object***Description**

`relist()` is an S3 generic function with a few methods in order to allow easy inversion of `unlist(obj)` when that is used with an object `obj` of (S3) class "relistable".

Usage

```

relist(flesh, skeleton)
## Default S3 method:
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'factor':
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'list':
relist(flesh, skeleton = attr(flesh, "skeleton"))
## S3 method for class 'matrix':
relist(flesh, skeleton = attr(flesh, "skeleton"))

as.relistable(x)
is.relistable(x)

## S3 method for class 'relistable':
unlist(x, recursive = TRUE, use.names = TRUE)

```

Arguments

<code>flesh</code>	a vector to be relisted
<code>skeleton</code>	a list, the structure of which determines the structure of the result
<code>x</code>	an R object, typically a list (or vector).
<code>recursive</code>	logical. Should unlisting be applied to list components of <code>x</code> ?
<code>use.names</code>	logical. Should names be preserved?

Details

Some functions need many parameters, which are most easily represented in complex structures, e.g., nested lists. Unfortunately, many mathematical functions in R, including `optim` and `nlm` can only operate on functions whose domain is a vector. R has `unlist()` to convert nested list objects into a vector representation. `relist()`, its methods and the functionality mentioned here provide

the inverse operation to convert vectors back to the convenient structural representation. This allows structured functions (such as `optim()`) to have simple mathematical interfaces.

For example, a likelihood function for a multivariate normal model needs a variance-covariance matrix and a mean vector. It would be most convenient to represent it as a list containing a vector and a matrix. A typical parameter might look like

```
list(mean=c(0, 1), vcov=cbind(c(1, 1), c(1, 0))).
```

However, `optim` cannot operate on functions that take lists as input; it only likes numeric vectors. The solution is conversion. Given a function `mvdnorm(x, mean, vcov, log=FALSE)` which computes the required probability density, then

```
ipar <- list(mean=c(0, 1), vcov=cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)

ll <- function(param.vector)
{
  param <- relist(param.vector, skeleton=ipar)
  -sum(mvdnorm(x, mean = param$mean, vcov = param$vcov,
              log = TRUE))
}

optim(unlist(initial.param), ll)
```

`relist` takes two parameters: `skeleton` and `flesh`. `Skeleton` is a sample object that has the right shape but the wrong content. `flesh` is a vector with the right content but the wrong shape. Invoking

```
relist(flesh, skeleton)
```

will put the content of `flesh` on the `skeleton`. You don't need to specify `skeleton` explicitly if the `skeleton` is stored as an attribute inside `flesh`. In particular, if `flesh` was created from some object `obj` with `unlist(as.relistable(obj))` then the `skeleton` attribute is automatically set. (Note that this does not apply to the example here, as `optim` is creating a new vector to pass to `ll` and not its `par` argument.)

As long as `skeleton` has the right shape, it should be a precise inverse of `unlist`. These equalities hold:

```
relist(unlist(x), x) == x
unlist(relist(y, skeleton)) == y

x <- as.relistable(x)
relist(unlist(x)) == x
```

Value

an object of (S3) class "relistable" (and "list").

Author(s)

R Core, based on a code proposal by Andrew Clausen.

See Also

[unlist](#)

Examples

```
ipar <- list(mean=c(0, 1), vcov=cbind(c(1, 1), c(1, 0)))
initial.param <- as.relistable(ipar)
ul <- unlist(initial.param)
relist(ul)
stopifnot(identical(relist(ul), initial.param))
```

REMOVE

Remove Add-on Packages

Description

Utility for removing add-on packages.

Usage

```
R CMD REMOVE [options] [-l lib] pkgs
```

Arguments

<code>pkgs</code>	a list with the names of the packages to be removed.
<code>lib</code>	the path name of the R library tree to remove from. May be absolute or relative.
<code>options</code>	further options.

Details

If used as `R CMD REMOVE pkgs` without explicitly specifying `lib`, packages are removed from the library tree rooted at the first directory in the library path which would be used by R run in the current environment.

To remove from the library tree `lib`, use `R CMD REMOVE -l lib pkgs`.

Use `R CMD REMOVE --help` for more usage information.

Note

Some binary distributions of R have `INSTALL` in a separate bundle, e.g. an R-devel RPM.

See Also

[INSTALL](#), [remove.packages](#)

`remove.packages` *Remove Installed Packages*

Description

Removes installed packages/bundles and updates index information as necessary.

Usage

```
remove.packages(pkgs, lib, version)
```

Arguments

<code>pkgs</code>	a character vector with the names of the package(s) or bundle(s) to be removed.
<code>lib</code>	a character vector giving the library directories to remove the packages from. If missing, defaults to the first element in <code>.libPaths()</code> .
<code>version</code>	A character vector specifying version(s) with versioned installs of the package(s) to remove. If none is provided, the system will remove an unversioned install of the package if one is found, otherwise the latest versioned install.

Details

If an element of `pkgs` matches a bundle name, all the packages in the bundle will be removed. This takes precedence over matching a package name.

`pkgs` and `version` will be recycled if necessary to the length of the longer one.

See Also

[REMOVE](#) for a command line version; [install.packages](#) for installing packages.

RHOME

R Home Directory

Description

Returns the location of the R home directory, which is the root of the installed R tree.

Usage

```
R RHOME
```

`roman`*Roman Numerals*

Description

Manipulate integers as roman numerals.

Usage

```
as.roman(x)
```

Arguments

`x` a numeric vector, or a character vector of arabic or roman numerals.

Details

`as.roman` creates objects of class "roman" which are internally represented as integers, and have suitable methods for printing, formatting, subsetting, and coercion to character.

Only numbers between 1 and 3899 have a unique representation as roman numbers.

References

Wikipedia contributors (2006). Roman numerals. Wikipedia, The Free Encyclopedia. http://en.wikipedia.org/w/index.php?title=Roman_numerals&oldid=78252134. Accessed September 29, 2006.

Examples

```
## First five roman 'numbers'.
(y <- as.roman(1 : 5))
## Middle one.
y[3]
## Current year as a roman number.
(y <- as.roman(format(Sys.Date(), "%Y")))
## 10 years ago ...
y - 10
```

`Rprof`*Enable Profiling of R's Execution*

Description

Enable or disable profiling of the execution of R expressions.

Usage

```
Rprof(filename = "Rprof.out", append = FALSE, interval = 0.02,
       memory.profiling=FALSE)
```

Arguments

filename	The file to be used for recording the profiling results. Set to NULL or "" to disable profiling.
append	logical: should the file be over-written or appended to?
interval	real: time interval between samples.
memory.profiling	logical: write memory use information to the file?

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling works by writing out the call stack every `interval` seconds, to the file specified. Either the [summaryRprof](#) function or the Perl script `R CMD Rprof` can be used to process the output file to produce a summary of the usage; use `R CMD Rprof --help` for usage information.

Note that the timing interval cannot be too small: once the timer goes off, the information is not recorded until the next timing click (probably in the range 1–10msecs).

Note

Profiling is not available on all platforms. By default, it is attempted to compile support for profiling. Configure R with `--disable-R-profiling` to change this.

As R profiling uses the same mechanisms as C profiling, the two cannot be used together, so do not use `Rprof` in an executable built for profiling.

See Also

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

[summaryRprof](#)

[tracemem](#), [Rprofmem](#) for other ways to track memory use.

Examples

```
## Not run:
Rprof()
## some code to be profiled
Rprof(NULL)
## some code NOT to be profiled
Rprof(append=TRUE)
## some code to be profiled
Rprof(NULL)
...
## Now post-process the output as described in Details
## End(Not run)
```

`Rprofmem`*Enable Profiling of R's Memory Use*

Description

Enable or disable reporting of memory allocation in R.

Usage

```
Rprofmem(filename = "Rprofmem.out", append = FALSE, threshold = 0)
```

Arguments

<code>filename</code>	The file to be used for recording the memory allocations. Set to <code>NULL</code> or <code>" "</code> to disable reporting.
<code>append</code>	logical: should the file be over-written or appended to?
<code>threshold</code>	numeric: allocations on R's "large vector" heap larger than this number of bytes will be reported.

Details

Enabling profiling automatically disables any existing profiling to another or the same file.

Profiling writes the call stack to the specified file every time `malloc` is called to allocate a large vector object or to allocate a page of memory for small objects. The size of a page of memory and the size above which `malloc` is used for vectors are compile-time constants, by default 2000 and 128 bytes respectively.

The profiler tracks allocations, some of which will be to previously used memory and will not increase the total memory use of R.

Value

None

Note

The memory profiler slows down R even when not in use, and so is a compile-time option. The memory profiler can be used at the same time as other R and C profilers.

See Also

The R sampling profiler, [Rprof](#) also collects memory information.

[tracemem](#) traces duplications of specific objects.

The "Writing R Extensions" manual section on "Tidying and profiling R code"

Examples

```
## Not run:
## not supported unless R is compiled to support it.
Rprofmem("Rprofmem.out", threshold=1000)
example(glm)
Rprofmem(NULL)
noquote(readLines("Rprofmem.out", n=5))
## End(Not run)
```

Rscript

Scripting Front-End for R

Description

This is an alternative front end for use in `#!` scripts and other scripting applications.

Usage

```
Rscript [options] [-e expression] file [args]
```

Arguments

options	A list of options beginning with <code>--</code> . These can be any of the options of the standard R front-end, and also those described in the details.
expression	a R expression.
file	The name of a file containing R commands. <code>-</code> indicates ‘stdin’.
args	Arguments to be passed to the script in <code>file</code> .

Details

`Rscript --help` gives details of usage, and `Rscript --version` gives the version of Rscript.

Other invocations invoke the R front-end with selected options. This front-end is convenient for writing `#!` scripts since it is an executable and takes `file` directly as an argument. Options `--slave` `--no-restore` are always supplied: these imply `--no-save`.

Either one or more ‘`-e`’ options or `file` should be supplied. When using ‘`-e`’ options be aware of the quoting rules in the shell used: see the examples.

Additional options accepted (before `file` or `args`) are

`--verbose` gives details of what Rscript is doing. Also passed on to R.

`--default-packages=list` where `list` is a comma-separated list of package names or NULL. Sets the environment variable `R_DEFAULT_PACKAGES` which determines the packages loaded on startup. The default for Rscript omits **methods** as it takes about 60% of the startup time.

Normally the version of R is determined at installation, but this can be overridden by setting the environment variable `RHOME`.

`stdin()` refers to the input file, and `file("stdin")` to the `stdin` file stream of the process.

Note

Rscript is only supported on systems with the `execv` system call.

Examples

```
## Not run:
Rscript -e 'date()' -e 'format(Sys.time(), "%a %b %d %X %Y")'

## example #! script for a Unix-alike

#! /path/to/Rscript --vanilla --default-packages=utils
args <- commandArgs(TRUE)
res <- try(install.packages(args))
if(inherits(res, "try-error")) q(status=1) else q()

## End(Not run)
```

RShowDoc

Show R Manuals and Other Documentation

Description

Utility function to find and display R documentation.

Usage

```
RShowDoc(what, type = c("pdf", "html", "txt"), package)
```

Arguments

<code>what</code>	a character string: see ‘Details’.
<code>type</code>	an optional character string giving the preferred format.
<code>package</code>	an optional character string specifying the name of a package within which to look for documentation.

Details

`what` can specify one of several different sources of documentation, including the R manuals (R-admin, R-data, R-exts, R-intro, R-ints, R-lang), NEWS, COPYING (the GPL licence), FAQ (also available as R-FAQ), and the files in ‘[R_HOME/doc](#)’.

If `package` is supplied, documentation is looked for in the ‘doc’ and top-level directories of an installed package of that name.

If `what` is missing a brief usage message is printed.

The documentation types are tried in turn starting with the first specified in `type` (or "pdf" if none is specified).

Value

A invisible character string given the path to the file found.

Examples

```
## Not run:
RShowDoc("R-lang")
RShowDoc("FAQ", type="html")
RShowDoc("frame", package="grid")
RShowDoc("changes.txt", package="grid")
RShowDoc("NEWS", package="MASS")
## End(Not run)
```

RSiteSearch	<i>Search for Key Words or Phrases in the R-help Mailing List Archives or Documentation</i>
-------------	---

Description

Search for key words or phrases in the R-help mailing list archives, or R manuals and help pages, using the search engine at <http://search.r-project.org> and view them in a web browser.

Usage

```
RSiteSearch(string,
            restrict = c("Rhelp02a", "functions", "docs"),
            format = c("normal", "short"),
            sortby = c("score", "date:late", "date:early",
                    "subject", "subject:descending",
                    "from", "from:descending",
                    "size", "size:descending"),
            matchesPerPage = 20)
```

Arguments

string	word(s) or phrase to search. If the words are to be searched as one entity, enclose all words in braces (see example).
restrict	a character vector, typically of length larger than one: What areas to search in: Rhelp02a for R-help mailing list archive since 2002, Rhelp01 for mailing list archive before 2002, docs for R manuals, functions for help pages. R-devel for R-devel mailing list. Use <code>c()</code> to specify more than one.
format	normal or short (no excerpts); can be abbreviated.
sortby	character string (can be abbreviated) indicating how to sort the search results: (score, date:late for sorting by date with latest results first, date:early for earliest first, subject for subject in alphabetical order, subject:descending for reverse alphabetical order, from or from:descending for sender (when applicable), size or size:descending for size.)
matchesPerPage	How many items to show per page.

Details

This function is designed to work with the search site at <http://search.r-project.org>, and depends on that site continuing to be made available (thanks to Jonathan Baron and the School of Arts and Sciences of the University of Pennsylvania).

Unique partial matches will work for all arguments. Each new browser window will stay open unless you close it.

Value

(Invisibly) the complete URL passed to the browser, including the query string.

Author(s)

Andy Liaw and Jonathan Baron

See Also

[help.search](#), [help.start](#) for local searches.

[browseURL](#) for how the help file is displayed.

Examples

```
# need Internet connection
RSiteSearch("{logistic regression}") # matches exact phrase
Sys.sleep(5) # allow browser to open, take a quick look
RSiteSearch("Baron Liaw", restrict = "Rhelp02a")
## Search in R-devel archive and documents (and store the query-string):
Sys.sleep(5)
fullquery <- RSiteSearch("S4", restrict = c("R-dev", "docs"))
fullquery # a string of ~ 116 characters
## the latest purported bug reports, responses ...
Sys.sleep(5)
RSiteSearch("bug", restrict = "R-devel", sortby = "date:late")
```

Rtangle

R Driver for Stangle

Description

A driver for [Stangle](#) that extracts R code chunks.

Usage

```
Rtangle()
RtangleSetup(file, syntax, output = NULL, annotate = TRUE,
             split = FALSE, prefix = TRUE, quiet = FALSE)
```

Arguments

<code>file</code>	Name of Sweave source file.
<code>syntax</code>	An object of class <code>SweaveSyntax</code> .
<code>output</code>	Name of output file, default is to remove extension <code>.nw</code> , <code>.Rnw</code> or <code>.Snw</code> and to add extension <code>.R</code> . Any directory names in <code>file</code> are also removed such that the output is created in the current working directory.
<code>annotate</code>	By default, code chunks are separated by comment lines specifying the names and numbers of the code chunks. If <code>FALSE</code> , only the code chunks without any decorating comments are extracted.
<code>split</code>	Split output in single files per code chunk?
<code>prefix</code>	If <code>split = TRUE</code> , prefix the chunk labels by the basename of the input file to get output file names?
<code>quiet</code>	If <code>TRUE</code> all progress messages are suppressed.

RweaveLatex

R/LaTeX Driver for Sweave

Description

A driver for [Sweave](#) that translates R code chunks in LaTeX files.

Usage

```
RweaveLatex()
```

```
RweaveLatexSetup(file, syntax, output = NULL, quiet = FALSE,
                  debug = FALSE, echo = TRUE, eval = TRUE,
                  keep.source = FALSE, split = FALSE,
                  stylepath, pdf = TRUE, eps = TRUE)
```

Arguments

<code>file</code>	Name of Sweave source file.
<code>syntax</code>	An object of class <code>SweaveSyntax</code> .
<code>output</code>	Name of output file, default is to remove extension <code>.nw</code> , <code>.Rnw</code> or <code>.Snw</code> and to add extension <code>.tex</code> . Any directory names in <code>file</code> are also removed such that the output is created in the current working directory.
<code>quiet</code>	If <code>TRUE</code> all progress messages are suppressed.
<code>debug</code>	If <code>TRUE</code> , input and output of all code chunks is copied to the console.
<code>stylepath</code>	See ‘Details’.
<code>echo</code>	set default for option <code>echo</code> , see details below.
<code>eval</code>	set default for option <code>eval</code> , see details below.
<code>keep.source</code>	set default for option <code>keep.source</code> , see details below.
<code>split</code>	set default for option <code>split</code> , see details below.
<code>pdf</code>	set default for option <code>pdf</code> , see details below.
<code>eps</code>	set default for option <code>eps</code> , see details below.

Details

The LaTeX file generated needs to contain `\usepackage{Sweave}`, and if this is not present in the Sweave source file, it is inserted by the `RweaveLatex` driver. If `stylepath = TRUE`, a hard-coded path to the file ‘`Sweave.sty`’ in the R installation is set in place of `Sweave`. The hard-coded path makes the TeX file less portable, but avoids the problem of installing the current version of ‘`Sweave.sty`’ to some place in your TeX input path. However, TeX may not be able to process the hard-coded path if it contains spaces (as it often will under Windows) or TeX special characters.

The default in R prior to 2.7.0 was `stylepath = TRUE`. It is now taken from the environment variable `SWEAVE_STYLEPATH_DEFAULT`, or is `FALSE` if that is unset or empty. If set, it should be exactly `TRUE` or `FALSE`: any other values are taken as `FALSE`.

Supported Options

`RweaveLatex` supports the following options for code chunks (the values in parentheses show the default values):

echo: logical (`TRUE`). Include S code in the output file?

keep.source: logical (`FALSE`). When echoing, if `keep.source == TRUE` the original source is copied to the file. Otherwise, deparsed source is echoed.

eval: logical (`TRUE`). If `FALSE`, the code chunk is not evaluated, and hence no text or graphical output produced.

results: character string (`verbatim`). If `verbatim`, the output of S commands is included in the `verbatim`-like `Soutput` environment. If `tex`, the output is taken to be already proper latex markup and included as is. If `hide` then all output is completely suppressed (but the code executed during the weave).

print: logical (`FALSE`) If `TRUE`, each expression in the code chunk is wrapped into a `print()` statement before evaluation, such that the values of all expressions become visible.

term: logical (`TRUE`). If `TRUE`, visibility of values emulates an interactive R session: values of assignments are not printed, values of single objects are printed. If `FALSE`, output comes only from explicit `print` or `cat` statements.

- split:** logical (FALSE). If TRUE, text output is written to separate files for each code chunk.
- strip.white:** character string (false). If true, blank lines at the beginning and end of output are removed. If all, then all blank lines are removed from the output.
- prefix:** logical (TRUE). If TRUE generated filenames of figures and output have a common prefix.
- prefix.string:** a character string, default is the name of the '.Snw' source file.
- include:** logical (TRUE), indicating whether input statements for text output and includegraphics statements for figures should be auto-generated. Use `include = FALSE` if the output should appear in a different place than the code chunk (by placing the input line manually).
- fig:** logical (FALSE), indicating whether the code chunk produces graphical output. Note that only one figure per code chunk can be processed this way.
- eps:** logical (TRUE), indicating whether EPS figures should be generated. Ignored if `fig = FALSE`.
- pdf:** logical (TRUE), indicating whether PDF figures should be generated. Ignored if `fig = FALSE`.
- pdf.version, pdf.encoding:** passed to `pdf` to set the version and encoding. Defaults taken from `pdf.options()`.
- width:** numeric (6), width of figures in inches.
- height:** numeric (6), height of figures in inches.
- expand:** logical (TRUE). Expand references to other chunks so that only R code appears in the output file. If FALSE, the chunk reference (e.g. `<<chunkname>>`) will appear. The `expand=FALSE` option requires `keep.source = TRUE` or it will have no effect.
- concordance:** logical (FALSE). Write a concordance file to link the input line numbers to the output line numbers. This is an experimental feature; see the source code for the output format, which is subject to change in future releases.

savehistory

Load or Save or Display the Commands History

Description

Load or save or display the commands history.

Usage

```
loadhistory(file = ".Rhistory")
savehistory(file = ".Rhistory")

history(max.show = 25, reverse = FALSE, pattern, ...)

timestamp(stamp = date(),
          prefix = "##----- ", suffix = " -----##",
          quiet = FALSE)
```

Arguments

<code>file</code>	The name of the file in which to save the history, or from which to load it. The path is relative to the current working directory.
<code>max.show</code>	The maximum number of lines to show. <code>Inf</code> will give all of the currently available history.
<code>reverse</code>	logical. If true, the lines are shown in reverse order. Note: this is not useful when there are continuation lines.
<code>pattern</code>	A character string to be matched against the lines of the history
<code>...</code>	Arguments to be passed to <code>grep</code> when doing the matching.
<code>stamp</code>	A value or vector of values to be written into the history.
<code>prefix</code>	A prefix to apply to each line.
<code>suffix</code>	A suffix to apply to each line.
<code>quiet</code>	If TRUE, suppress printing timestamp to the console.

Details

There are several history mechanisms available for the different R consoles, which work in similar but not identical ways. Other uses of R, in particular embedded uses, may have no history. This works under the `readline` and GNOME and MacOS X consoles, but not otherwise (for example, in batch use or in an embedded application).

The `readline` history mechanism is controlled by two environment variables: `R_HISTSIZE` controls the number of lines that are saved (default 512), and `R_HISTFILE` sets the filename used for the loading/saving of history if requested at the beginning/end of a session (but not the default for these functions). There is no limit on the number of lines of history retained during a session, so setting `R_HISTSIZE` to a large value has no penalty unless a large file is actually generated.

These variables are read at the time of saving, so can be altered within a session by the use of `Sys.setenv`.

`history` shows only unique matching lines if `pattern` is supplied.

The `timestamp` function writes a timestamp (or other message) into the history and echos it to the console. On platforms that do not support a history mechanism (where the mechanism does not yet support timestamps) only the console message is printed.

Note

If you want to save the history (almost) every session, you can put a call to `savehistory()` in `.Last`. See the examples.

Examples

```
## Not run:
.Last <- function()
  if(interactive()) try(savehistory("~/Rhistory"))
## End(Not run)
```

select.list	<i>Select Items from a List</i>
-------------	---------------------------------

Description

Select item(s) from a character vector.

Usage

```
select.list(list, preselect = NULL, multiple = FALSE, title = NULL)
```

Arguments

list	character. A list of items.
preselect	a character vector, or NULL. If non-null and if the string(s) appear in the list, the item(s) are selected initially.
multiple	logical: can more than one item be selected?
title	optional character string for window title.

Details

Under the AQUA interface for MacOS X this brings up a modal dialog box with a (scrollable) list of items, which can be selected by the mouse.

Otherwise it displays a text list from which the user can choose by number(s). The `multiple = FALSE` case uses [menu](#). Preselection is only supported for `multiple = TRUE`, where it is indicated by a "+" preceding the item.

Value

A character vector of selected items. If `multiple` is false and no item was selected (or Cancel was used), "" is returned. If `multiple` is true and no item was selected (or Cancel was used) then a character vector of length 0 is returned.

See Also

[menu](#), [tk_select.list](#) for a graphical version using Tcl/Tk.

Examples

```
## Not run:
select.list(sort(.packages(all.available = TRUE)))
## End(Not run)
```

sessionInfo	<i>Collect Information About the Current R Session</i>
-------------	--

Description

Print version information about R and attached or loaded packages.

Usage

```
sessionInfo(package=NULL)
## S3 method for class 'sessionInfo':
print(x, ...)
## S3 method for class 'sessionInfo':
toLatex(object, ...)
```

Arguments

package	a character vector naming installed packages. By default all attached packages are used.
x	an object of class "sessionInfo".
object	an object of class "sessionInfo".
...	currently not used.

See Also

[R.version](#)

Examples

```
sessionInfo()
toLatex(sessionInfo())
```

setRepositories	<i>Select Package Repositories</i>
-----------------	------------------------------------

Description

Interact with the user to choose the package repositories to be used.

Usage

```
setRepositories(graphics = getOption("menu.graphics"), ind = NULL)
```

Arguments

graphics	Logical. If true and tk and an X server are available, use a Tk widget, or if under the AQUA interface use a MacOS X widget, otherwise use a text list in the console.
ind	NULL or a vector of integer indices, which have the same effect as if they were entered at the prompt for graphics=FALSE.

Details

The default list of known repositories is stored in the file `'R_HOME/etc/repositories'`. That file can be edited for a site, or a user can have a personal copy in `'HOME/.R/repositories'` which will take precedence.

The items that are preselected are those that are currently in `options("repos")` plus those marked as default in the list of known repositories.

This function requires the R session to be interactive unless `ind` is supplied.

Value

This function is invoked mainly for its side effect of updating `options("repos")`. It returns (invisibly) the previous `repos` options setting (as a `list` with component `repos`) or `NULL` if no changes were applied.

See Also

`chooseCRANmirror`, `install.packages`.

 SHLIB

Build Shared Library for Dynamic Loading

Description

Compile the given source files and then link all specified object files into a shared library which can be loaded into R using `dyn.load` or `library.dynam`.

Usage

```
R CMD SHLIB [options] [-o libname] files
```

Arguments

<code>files</code>	a list specifying the object files to be included in the shared library. You can also include the name of source files (for which the object files are automatically made from their sources) and library linking commands.
<code>libname</code>	the full name of the shared library to be built, including the extension (typically <code>'.so'</code> on Unix systems). If not given, the name of the library is taken from the first file.
<code>options</code>	Further options to control the processing. Use <code>R CMD SHLIB --help</code> for a current list.

Details

`R CMD SHLIB` is the mechanism used by `INSTALL` to compile source code in packages. Please consult section 'Creating shared objects' in the manual 'Writing R Extensions' for how to customize it (for example to add `cpp` flags and to add libraries to the link step) and for details of some of its quirks.

Items in `files` with extensions `'.c'`, `'.cpp'`, `'.cc'`, `'.C'`, `'.f'`, `'.f90'`, `'.f95'`, `'.m'`, `'.M'` and `'.mm'` are regarded as source files, and those with extension `'.O'` as object files. All other items are passed to the linker.

Note

Some binary distributions of R have SHLIB in a separate bundle, e.g., an R-devel RPM.

See Also

[COMPILE](#), [dyn.load](#), [library.dynam](#).

The section on “Customizing compilation under Unix” in “R Administration and Installation” (see the ‘doc/manual’ subdirectory of the R source tree).

The ‘R Installation and Administration’ and ‘Writing R Extensions’ manuals.

Examples

```
## Not run:
R CMD SHLIB -o mylib.so a.f b.f -L/opt/acml3.5.0/gnu64/lib -lacml
## End(Not run)
```

stack

Stack or Unstack Vectors from a Data Frame or List

Description

Stacking vectors concatenates multiple vectors into a single vector along with a factor indicating where each observation originated. Unstacking reverses this operation.

Usage

```
stack(x, ...)
## Default S3 method:
stack(x, ...)
## S3 method for class 'data.frame':
stack(x, select, ...)

unstack(x, ...)
## Default S3 method:
unstack(x, form, ...)
## S3 method for class 'data.frame':
unstack(x, form, ...)
```

Arguments

x	object to be stacked or unstacked
select	expression, indicating variables to select from a data frame
form	a two-sided formula whose left side evaluates to the vector to be unstacked and whose right side evaluates to the indicator of the groups to create. Defaults to <code>formula(x)</code> in <code>unstack.data.frame</code> .
...	further arguments passed to or from other methods.

Details

The `stack` function is used to transform data available as separate columns in a data frame or list into a single column that can be used in an analysis of variance model or other linear model. The `unstack` function reverses this operation.

Value

`unstack` produces a list of columns according to the formula `form`. If all the columns have the same length, the resulting list is coerced to a data frame.

`stack` produces a data frame with two columns

values the result of concatenating the selected vectors in `x`

ind a factor indicating from which vector in `x` the observation originated

Author(s)

Douglas Bates

Examples

```
require(stats)
formula(PlantGrowth)            # check the default formula
pg <- unstack(PlantGrowth)      # unstack according to this formula
pg
stack(pg)                        # now put it back together
stack(pg, select = -ctrl)       # omitting one vector
```

str

Compactly Display the Structure of an Arbitrary R Object

Description

Compactly display the internal **structure** of an R object, a diagnostic function and an alternative to [summary](#) (and to some extent, [dput](#)). Ideally, only one line for each ‘basic’ structure is displayed. It is especially well suited to compactly display the (abbreviated) contents of (possibly nested) lists. The idea is to give reasonable output for **any** R object. It calls [args](#) for (non-primitive) function objects.

`strOptions()` is a convenience function for setting `options(str = .)`, see the examples.

Usage

```
str(object, ...)
```

S3 method for class 'data.frame':

```
str(object, ...)
```

Default S3 method:

```

str(object, max.level = NA,
     vec.len = strO$vec.len, digits.d = strO$digits.d,
     nchar.max = 128, give.attr = TRUE,
     give.head = TRUE, give.length = give.head,
     width = getOption("width"), nest.lev = 0,
     indent.str = paste(rep.int(" ", max(0, nest.lev + 1)),
                        collapse = ".."),
     comp.str="$ ", no.list = FALSE, envir = baseenv(),
     strict.width = strO$strict.width,
     formatNum = strO$formatNum, ...)

strOptions(strict.width = "no", digits.d = 3, vec.len = 4,
           formatNum = function(x, ...)
             format(x, trim=TRUE, drop0trailing=TRUE, ...))

```

Arguments

object	any R object about which you want to have some information.
max.level	maximal level of nesting which is applied for displaying nested structures, e.g., a list containing sub lists. Default NA: Display all nesting levels.
vec.len	numeric (≥ 0) indicating how many ‘first few’ elements are displayed of each vector. The number is multiplied by different factors (from .5 to 3) depending on the kind of vector. Defaults to the <code>vec.len</code> component of option "str" (see options) which defaults to 4.
digits.d	number of digits for numerical components (as for print). Defaults to the <code>digits.d</code> component of option "str" which defaults to 3.
nchar.max	maximal number of characters to show for character strings. Longer strings are truncated, see <code>longch</code> example below.
give.attr	logical; if TRUE (default), show attributes as sub structures.
give.length	logical; if TRUE (default), indicate length (as <code>[1:...]</code>).
give.head	logical; if TRUE (default), give (possibly abbreviated) mode/class and length (as <code><type>[1:...]</code>).
width	the page width to be used. The default is the currently active options ("width"); note that this has only a weak effect, unless <code>strict.width</code> is not "no".
nest.lev	current nesting level in the recursive calls to <code>str</code> .
indent.str	the indentation string to use.
comp.str	string to be used for separating list components.
no.list	logical; if true, no ‘list of ...’ nor the class are printed.
envir	the environment to be used for <i>promise</i> (see delayedAssign) objects only.
strict.width	string indicating if the <code>width</code> argument’s specification should be followed strictly, one of the values <code>c("no", "cut", "wrap")</code> . Defaults to the <code>strict.width</code> component of option "str" (see options) which defaults to "no" for back compatibility reasons; "wrap" uses <code>strwrap</code> (*, width=width) whereas "cut" cuts directly to width. Note that a small <code>vec.length</code> may be better than setting <code>strict.width = "wrap"</code> .
formatNum	a function such as format for formatting numeric vectors. It defaults to the <code>formatNum</code> component of option "str", see “Usage” of <code>strOptions()</code> above, which is almost back compatible to R version $\leq 2.7.x$, however, using formatC may be slightly better.

... potential further arguments (required for Method/Generic reasons).

Value

`str` does not return anything, for efficiency reasons. The obvious side effect is output to the terminal.

Author(s)

Martin Maechler <maechler@stat.math.ethz.ch> since 1990.

See Also

str(ls)
str(args) #- more useful than args(args) !
str(freeny)
str(str)
str(.Machine, digits.d = 20)
str( lsfit(1:9,1:9) )
str( lsfit(1:9,1:9), max.level = 1 )
str( lsfit(1:9,1:9), width = 60, strict.width = "cut" )
str( lsfit(1:9,1:9), width = 60, strict.width = "wrap" )
op <- options(); str(op) # save first;
                        # otherwise internal options() is used.
need.dev <-
  !exists(".Device") || is.null(.Device) || .Device == "null device"
{ if(need.dev) postscript()
  str(par())
  if(need.dev) graphics.off()
}
ch <- letters[1:12]; is.na(ch) <- 3:5
str(ch) # character NA's

nchar(longch <- paste(rep(letters,100), collapse=""))
str(longch)
str(longch, nchar.max = 52)

str(longch, strict.width = "wrap")

## Settings for narrow transcript :
op <- options(width = 60,
              str = strOptions(strict.width = "wrap"))
str(lsfit(1:9,1:9))
str(options())
## reset to previous:
options(op)

str(quote( { A+B; list(C,D) } ))
```

```
## S4 classes :
require(stats4)
x <- 0:10; y <- c(26, 17, 13, 12, 20, 5, 9, 8, 5, 4, 8)
ll <- function(y, lambda=y/(1+x/xh), log=TRUE)
  -sum(dpois(y, lambda=y/(1+x/xh), log=TRUE))
fit <- mle(ll)
str(fit)
```

summaryRprof

*Summarise Output of R Sampling Profiler***Description**

Summarise the output of the `Rprof` function to show the amount of time used by different R functions.

Usage

```
summaryRprof(filename = "Rprof.out", chunksize = 5000,
             memory=c("none", "both", "tseries", "stats"),
             index=2, diff=TRUE, exclude=NULL)
```

Arguments

<code>filename</code>	Name of a file produced by <code>Rprof()</code>
<code>chunksize</code>	Number of lines to read at a time
<code>memory</code>	Summaries for memory information. See ‘Details’ below
<code>index</code>	How to summarize the stack trace for memory information. See ‘Details’ below.
<code>diff</code>	If <code>TRUE</code> memory summaries use change in memory rather than current memory
<code>exclude</code>	Functions to exclude when summarizing the stack trace for memory summaries

Details

This function is an alternative to R CMD `Rprof`. It provides the convenience of an all-R implementation but will be slower for large files.

As the profiling output file could be larger than available memory, it is read in blocks of `chunksize` lines. Increasing `chunksize` will make the function run faster if sufficient memory is available.

When called with `memory.profiling=TRUE`, the profiler writes information on three aspects of memory use: vector memory in small blocks on the R heap, vector memory in large blocks (from `malloc`), memory in nodes on the R heap. It also records the number of calls to the internal function `duplicate` in the time interval. `duplicate` is called by C code when arguments need to be copied. Note that the profiler does not track which function actually allocated the memory.

With `memory="both"` the change in total memory (truncated at zero) is reported in addition to timing data.

With `memory="tseries"` or `memory="stats"` the `index` argument specifies how to summarize the stack trace. A positive number specifies that many calls from the bottom of

the stack; a negative number specifies the number of calls from the top of the stack. With `memory="tseries"` the index is used to construct labels and may be a vector to give multiple sets of labels. With `memory="stats"` the index must be a single number and specifies how to aggregate the data to the maximum and average of the memory statistics. With both `memory="tseries"` and `memory="stats"` the argument `diff=TRUE` asks for summaries of the increase in memory use over the sampling interval and `diff=FALSE` asks for the memory use at the end of the interval.

Value

If `memory="none"`, a list with components

<code>by.self</code>	Timings sorted by ‘self’ time
<code>by.total</code>	Timings sorted by ‘total’ time
<code>sampling.time</code>	Total length of profiling run

If `memory="both"` the same list but with memory consumption in Mb in addition to the timings.

If `memory="tseries"` a data frame giving memory statistics over time

If `memory="stats"` a `by` object giving memory statistics by function.

See Also

The chapter on “Tidying and profiling R code” in “Writing R Extensions” (see the ‘doc/manual’ subdirectory of the R source tree).

[Rprof](#)

[tracemem](#) traces copying of an object via the C function `duplicate`.

[Rprofmem](#) is a non-sampling memory use profiler.

<http://developer.r-project.org/memory-profiling.html>

Examples

```
## Not run:
## Rprof() is not available on all platforms
Rprof(tmp <- tempfile())
example(glm)
Rprof()
summaryRprof(tmp)
unlink(tmp)
## End(Not run)
```

Description

Sweave provides a flexible framework for mixing text and S code for automatic report generation. The basic idea is to replace the S code with its output, such that the final document only contains the text and the output of the statistical analysis.

Usage

```
Sweave(file, driver = RweaveLatex(),
        syntax = getOption("SweaveSyntax"), ...)

Stangle(file, driver = Rtangle(),
        syntax = getOption("SweaveSyntax"), ...)
```

Arguments

<code>file</code>	Name of Sweave source file.
<code>driver</code>	The actual workhorse, see details below.
<code>syntax</code>	An object of class <code>SweaveSyntax</code> or a character string with its name. The default installation provides <code>SweaveSyntaxNoweb</code> and <code>SweaveSyntaxLatex</code> .
<code>...</code>	Further arguments passed to the driver's setup function.

Details

Automatic generation of reports by mixing word processing markup (like latex) and S code. The S code gets replaced by its output (text or graphs) in the final markup file. This allows a report to be re-generated if the input data change and documents the code to reproduce the analysis in the same file that also produces the report.

Sweave combines the documentation and code chunks together (or their output) into a single document. Stangle extracts only the code from the Sweave file creating a valid S source file (that can be run using `source`). Code inside `\Sexpr{}` statements is ignored by Stangle.

Stangle is just a frontend to Sweave using a simple driver by default, which discards the documentation and concatenates all code chunks the current S engine understands.

Hook Functions

Before each code chunk is evaluated, a number of hook functions can be executed. If `getOption("SweaveHooks")` is set, it is taken to be a collection of hook functions. For each logical option of a code chunk (`echo`, `print`, ...) a hook can be specified, which is executed if and only if the respective option is `TRUE`. Hooks must be named elements of the list returned by `getOption("SweaveHooks")` and be functions taking no arguments. E.g., if option "SweaveHooks" is defined as `list(fig = foo)`, and `foo` is a function, then it would be executed before the code in each figure chunk. This is especially useful to set defaults for the graphical parameters in a series of figure chunks.

Note that the user is free to define new Sweave options and associate arbitrary hooks with them. E.g., one could define a hook function for option `clean` that removes all objects in the global environment. Then all code chunks with `clean = TRUE` would start operating on an empty workspace.

Syntax Definition

Sweave allows a very flexible syntax framework for marking documentation and text chunks. The default is a noweb-style syntax, as alternative a latex-style syntax can be used. See the user manual for details.

Examples

```
testfile <- system.file("Sweave", "Sweave-test-1.Rnw", package = "utils")

## enforce par(ask=FALSE)
options(device.ask.default=FALSE)

## create a LaTeX file
Sweave(testfile)

## This can be compiled to PDF by
## Not run: tools::texi2dvi("Sweave-test-1.tex", pdf=TRUE)
## or outside R by
## R CMD texi2dvi Sweave-test-1.tex
## which sets the appropriate TEXINPUTS path.

## create an S source file from the code chunks
Stangle(testfile)
## which can be sourced, e.g.
source("Sweave-test-1.R")
```

SweaveSyntConv

Convert Sweave Syntax

Description

This function converts the syntax of files in [Sweave](#) format to another Sweave syntax definition.

Usage

```
SweaveSyntConv(file, syntax, output = NULL)
```

Arguments

<code>file</code>	Name of Sweave source file.
<code>syntax</code>	An object of class <code>SweaveSyntax</code> or a character string with its name giving the target syntax to which the file is converted.
<code>output</code>	Name of output file, default is to remove the extension from the input file and to add the default extension of the target syntax. Any directory names in <code>file</code> are also removed such that the output is created in the current working directory.

## and run it through Sweave
Sweave("Sweave-test-1.Stex")
```

`toLatex`*Converting R Objects to BibTeX or LaTeX*

Description

These methods convert R objects to character vectors with BibTeX or LaTeX markup.

Usage

```
toBibtex(object, ...)
toLatex(object, ...)
## S3 method for class 'Bibtex':
print(x, prefix="", ...)
## S3 method for class 'Latex':
print(x, prefix="", ...)
```

Arguments

<code>object</code>	object of a class for which a <code>toBibtex</code> or <code>toLatex</code> method exists.
<code>x</code>	object of class "Bibtex" or "Latex".
<code>prefix</code>	a character string which is printed at the beginning of each line, mostly used to insert whitespace for indentation.
<code>...</code>	currently not used in the print methods.

Details

Objects of class "Bibtex" or "Latex" are simply character vectors where each element holds one line of the corresponding BibTeX or LaTeX file.

[citEntry](#) and [sessionInfo](#) for examples

txtProgressBar *Text Progress Bar*

Description

Text progress bar in the R console.

Usage

```
txtProgressBar(min = 0, max = 1, initial = 0, char = "=",
              width = NA, title, label, style = 1)

getTxtProgressBar(pb)
setTxtProgressBar(pb, value, title = NULL, label = NULL)
## S3 method for class 'txtProgressBar':
close(con, ...)
```

Arguments

<code>min, max</code>	(finite) numeric values for the extremes of the progress bar.
<code>initial, value</code>	initial or new value for the progress bar.
<code>char</code>	the character (or character string) to form the progress bar.
<code>width</code>	the width of the progress bar, as a multiple of the width of <code>char</code> . If <code>NA</code> , the default, the number of characters is that which fits into <code>getOption("width")</code> .
<code>style</code>	the 'style' of the bar – see 'Details'.
<code>pb, con</code>	an object of class "txtProgressBar".
<code>title, label</code>	ignored, for compatibility with other progress bars.
<code>...</code>	for consistency with the generic.

Details

`txtProgressBar` will display a progress bar on the R console via a text representation.

`setTxtProgressBar` will update the value. Missing (`NA`) and out-of-range values of `value` will be (silently) ignored.

The progress bar should be closed when finished with: this outputs the final newline character.

`style = 1` and `style = 2` just shows a line of `char`. They differ in that `style = 2` redraws the line each time, which is useful if other code might be writing to the R console. `style = 3` marks the end of the range by `|` and gives a percentage to the right of the bar.

Value

For `txtProgressBar` an object of class "txtProgressBar".

For `getTxtProgressBar` and `setTxtProgressBar`, a length-one numeric vector giving the previous value (invisibly for `setTxtProgressBar`).

Note

Using `style 2` or `3` or reducing the value with `style = 1` uses `\r` to return to the left margin – the interpretation of carriage return is up to the terminal or console in which **R** is running.

See Also

[tkProgressBar](#)

Examples

```
# slow
testit <- function(x = sort(runif(20)), ...)
{
  pb <- txtProgressBar(...)
  for(i in c(0, x, 1)) {Sys.sleep(0.5); setTxtProgressBar(pb, i)}
  Sys.sleep(1)
  close(pb)
}
testit()
testit(runif(10))
testit(style=3)
```

type.convert

Type Conversion on Character Variables

Description

Convert a character vector to logical, integer, numeric, complex or factor as appropriate.

Usage

```
type.convert(x, na.strings = "NA", as.is = FALSE, dec = ".")
```

Arguments

<code>x</code>	a character vector.
<code>na.strings</code>	a vector of strings which are to be interpreted as NA values. Blank fields are also considered to be missing values in logical, integer, numeric or complex vectors.
<code>as.is</code>	logical. See ‘Details’.
<code>dec</code>	the character to be assumed for decimal points.

Details

This is principally a helper function for `read.table`. Given a character vector, it attempts to convert it to logical, integer, numeric or complex, and failing that converts it to factor unless `as.is = TRUE`. The first type that can accept all the non-missing values is chosen.

Vectors which are entirely missing values are converted to logical, since **NA** is primarily logical.

Since this is a helper function, the caller should always pass an appropriate value of `as.is`.

Value

A vector of the selected class, or a factor.

update.packages	<i>Download Packages from CRAN-like repositories</i>
-----------------	--

Description

These functions can be used to automatically compare the version numbers of installed packages with the newest available version on the repositories and update outdated packages on the fly.

Usage

```
update.packages(lib.loc = NULL, repos = getOption("repos"),
               contriburl = contrib.url(repos, type),
               method, instlib = NULL,
               ask = TRUE, available = NULL,
               oldPkgs = NULL, ...,
               checkBuilt = FALSE, type = getOption("pkgType"))

available.packages(contriburl = contrib.url(getOption("repos")),
                  method, fields = NULL)

old.packages(lib.loc = NULL, repos = getOption("repos"),
             contriburl = contrib.url(repos),
             instPkgs = installed.packages(lib.loc = lib.loc),
             method, available = NULL, checkBuilt = FALSE)

new.packages(lib.loc = NULL, repos = getOption("repos"),
             contriburl = contrib.url(repos, type),
             instPkgs = installed.packages(lib.loc = lib.loc),
             method, available = NULL, ask = FALSE, ...,
             type = getOption("pkgType"))

download.packages(pkgs, destdir, available = NULL,
                 repos = getOption("repos"),
                 contriburl = contrib.url(repos, type),
                 method, type = getOption("pkgType"), ...)

install.packages(pkgs, lib, repos = getOption("repos"),
                contriburl = contrib.url(repos, type),
                method, available = NULL, destdir = NULL,
                installWithVers = FALSE, dependencies = NA,
                type = getOption("pkgType"),
                configure.args = character(0),
                clean = FALSE, ...)

contrib.url(repos, type = getOption("pkgType"))
```

Arguments

<code>lib.loc</code>	character vector describing the location of R library trees to search through (and update packages therein).
<code>repos</code>	character vector, the base URL(s) of the repositories to use, i.e., the URL of the CRAN master such as "http://cran.r-project.org" or its Statlib mirror, "http://lib.stat.cmu.edu/R/CRAN". Can be NULL to install from local files ('.tar.gz' for source packages).
<code>contriburl</code>	URL(s) of the contrib sections of the repositories. Use this argument only if your repository mirror is incomplete, e.g., because you burned only the 'contrib' section on a CD. Overrides argument <code>repos</code> . As <code>repos</code> , can also be NULL to install from local files.
<code>method</code>	Download method, see download.file .
<code>pkgs</code>	character vector of the short names of packages/bundles whose current versions should be downloaded from the repositories. If <code>repos = NULL</code> , a character vector of file paths of '.tar.gz' files. These can be source archives or binary package/bundle archive files (as created by R CMD <code>build --binary</code>). Tilde-expansion will be done on the file paths. If this is a zero-length character vector, a listbox of available packages (including those contained in bundles) is presented where possible.
<code>destdir</code>	directory where downloaded packages are stored.
<code>available</code>	an object listing packages available at the repositories as returned by <code>available.packages</code> .
<code>lib</code>	character vector giving the library directories where to install the packages. Recycled as needed. If missing, defaults to <code>.libPaths()[1]</code> .
<code>ask</code>	logical indicating whether to ask user before packages are actually downloaded and installed, or the character string "graphics", which brings up a widget to allow the user to (de-)select from the list of packages which could be updated. The latter only works on systems with a GUI version of <code>select.list</code> , and is otherwise equivalent to <code>ask = TRUE</code> .
<code>installWithVers</code>	If TRUE, will invoke the install of the package such that it can be referenced by package version.
<code>checkBUILT</code>	If TRUE, a package built under an earlier minor version of R is considered to be 'old'.
<code>instlib</code>	character string giving the library directory where to install the packages.
<code>dependencies</code>	logical indicating to also install uninstalled packages on which these packages depend/suggest/import (and so on recursively). Not used if <code>repos = NULL</code> . Can also be a character vector, a subset of <code>c("Depends", "Imports", "Suggests")</code> . Note that only if the dependent package is <i>installed</i> is checked, not if it meets the version requirements. Only supported if <code>lib</code> is of length one (or missing), so it is unambiguous where to install the dependent packages. The default, NA, means <code>c("Depends", "Imports")</code> if <code>lib</code> is unambiguous, and FALSE otherwise.
<code>configure.args</code>	a character vector or a named list. If a character vector with no names is supplied, the elements are concatenated into a single string (separated by a space) and used as the value for the <code>--configure-args</code> flag in the call to R CMD

	INSTALL. If the character vector has names, these are assumed to identify values for <code>--configure-args</code> for individual packages. This allows one to specify settings for an entire collection of packages which will be used if any of those packages are installed. These settings can therefore be reused and act as default settings. A named list can be used also to the same effect, and that allows multi-element character strings for each package which are concatenated to a single string to be used as the value for <code>--configure-args</code> .
<code>oldPkgs</code>	if specified as non-NULL, <code>update.packages()</code> only considers these packages for updating.
<code>instPkgs</code>	by default all installed packages, <code>installed.packages(lib.loc=lib.loc)</code> . A subset can be specified; currently this must be in the same (character matrix) format as returned by <code>installed.packages()</code> .
<code>...</code>	(for <code>update.packages</code>). Arguments such as <code>destdir</code> , <code>installWithVers</code> and dependencies to be passed to <code>install.packages</code> . (for <code>new.packages</code>). Arguments such as <code>destdir</code> and dependencies to be passed to <code>install.packages</code> . (for <code>install.packages</code> and <code>download.packages</code>) arguments to be passed to <code>download.file</code> .
<code>type</code>	character, indicating the type of package to download and install. Possible values are "source" (the default except under the CRAN Mac OS X build), "mac.binary" and "win.binary" (which can be downloaded but not installed).
<code>clean</code>	a logical value indicating whether to specify to add the <code>--clean</code> flag to the call to <code>R CMD INSTALL</code> . This is sometimes used to perform additional operations at the end of the package installation in addition to removing intermediate files.
<code>fields</code>	a character vector giving the fields to extract from the <code>PACKAGES</code> file(s) in addition to the default ones, or NULL (default). Unavailable fields result in NA values.

Details

All of these functions work with the names of a package or bundle (and not the component packages of a bundle, except for `install.packages` if the repository provides the necessary information).

`available.packages` returns a matrix of details corresponding to packages/bundles currently available at one or more repositories. The current list of packages is downloaded over the internet (or copied from a local mirror). It returns only packages whose version requirements are met by the running version of R.

`old.packages` compares the information from `available.packages` with that from `instPkgs` (`installed.packages` by default) and reports installed packages/bundles that have newer versions on the repositories or, if `checkBuilt = TRUE`, that were built under an earlier minor version of R (for example built under 2.0.x when running R 2.1.1).

`new.packages` does the same comparison but reports uninstalled packages/bundles that are available at the repositories. (It checks the front-end package **gnomeGUI** separately.) It will give warnings about incompletely installed bundles (provided the information is available) and bundles whose contents has changed. If `ask != FALSE` it asks which packages should be installed in the first element of `lib.loc`. NB: versioned installs are not installs of a named package.

`download.packages` takes a list of package/bundle names and a destination directory, downloads the newest versions and saves them in `destdir`. If the list of available packages is not

given as argument, it is obtained from repositories. If a repository is local, i.e. the URL starts with "file:", then the packages are not downloaded but used directly. Both "file:" and "file:///" are allowed as prefixes to a file path. Use the latter only for URLs: see [url](#) for their interpretation. (Other forms of "file://" URLs are not supported.)

The main function of the set is `update.packages`. First a list of all packages/bundles found in `lib.loc` is created and compared with those available at the repositories. If `ask = TRUE` (the default) packages/bundles with a newer version are reported and for each one the user can specify if it should be updated. If so, the package sources are downloaded from the repositories and installed in the respective library path (or `instlib` if specified) using the R [INSTALL](#) mechanism.

`install.packages` can be used to install new packages/bundles. It takes a vector of names and a destination library, downloads the packages from the repositories and installs them. (If the library is omitted it defaults to the first directory in `.libPaths()`, with a warning if there is more than one.) If `lib` is omitted or is of length one and is not a (group) writeable directory, the code offers to create a personal library tree (the first element of `Sys.getenv("R_LIBS_USER")`) and install there.

If a repository is used (rather than local `.tar.gz` files), an attempt is made to install the packages in an order that respects their dependencies. This does assume that all the entries in `lib` are on the default library path for installs (set by `R_LIBS`).

`contrib.url` adds the appropriate type-specific path within a repository to each URL in `repos`.

For `install.packages`, `destdir` is the directory to which packages will be downloaded. If it is `NULL` (the default) a directory `downloaded_packages` of the session temporary directory will be used (and the files will be deleted at the end of the session).

If `repos` or `contriburl` is a vector of length greater than one, the newest version of the package compatible with this version of R is fetched from the first repository on the list within which it is found.

Value

For `available.packages`, a matrix with one row per package/bundle, row names the package names and column names "Package", "Version", "Priority", "Bundle", "Depends", "Imports", "Suggests", "Contains" and "Repository". Additional columns can be specified using the `fields` argument.

For `old.packages`, `NULL` or a matrix with one row per package/bundle, row names the package names and column names "Package", "LibPath", "Installed" (the version), "Built" (the version built under), "ReposVer" and "Repository".

For `new.packages` a character vector of package/bundle names, *after* any have been installed.

For `download.packages`, a two-column matrix of names and destination file names, for those packages/bundles successfully downloaded. If packages are not available or there is a problem with the download, suitable warnings are given.

`install.packages` and `update.packages` have no return value.

Warning

Take care when using dependencies with `update.packages`, for it is unclear where new dependencies should be installed. The current implementation will only allow it if all the packages to be updated are in a single library, when that library will be used.

You are advised to run `update.packages` before `install.packages` to ensure that any installed dependencies have their latest versions.

Note

Some binary distributions of R have `INSTALL` in a separate bundle, e.g. an R-devel RPM. `install.packages` will give an error if called on such a system.

See Also

[installed.packages](#), [remove.packages](#)

See [download.file](#) for how to handle proxies and other options to monitor file transfers.

[INSTALL](#), [REMOVE](#), [library](#), [.packages](#), [read.dcf](#)

The ‘R Installation and Administration’ manual for how to set up a repository.

Examples

```
## Not run:
install.packages(
  c("XML_0.99-5.tar.gz",
    "../Interfaces/Perl/RSPerl_0.8-0.tar.gz"),
  repos = NULL,
  configure.args = c(XML = '--with-xml-config=xml-config',
                    RSPerl = "--with-modules='IO Fcntl'"))
## End(Not run)
```

url.show

Display a text URL

Description

Extension of [file.show](#) to display text files from a remote server.

Usage

```
url.show(url, title = url, file = tempfile(),
         delete.file = TRUE, method, ...)
```

Arguments

<code>url</code>	The URL to read from.
<code>title</code>	Title for the browser.
<code>file</code>	File to copy to.
<code>delete.file</code>	Delete the file afterwards?
<code>method</code>	File transfer method: see download.file
<code>...</code>	Arguments to pass to file.show .

See Also

[url](#), [file.show](#), [download.file](#)

Examples

```
## Not run: url.show("http://lib.stat.cmu.edu/datasets/csb/ch3a.txt")
```

URLEncode

Encode or Decode a (partial) URL

Description

Functions to encode or decode characters in URLs.

Usage

```
URLEncode(URL, reserved = FALSE)
URLdecode(URL)
```

Arguments

URL	A character string.
reserved	should reserved characters be encoded? See ‘Details’.

Details

Characters in a URL other than the English alphanumeric characters and \$ - _ . + ! * ' () , should be encoded as % plus a two-digit hexadecimal representation, and any single-byte character can be so encoded. (Multi-byte characters are encoded as byte-by-byte.)

In addition, ; / ? : @ = & are reserved characters, and should be encoded unless used in their reserved sense, which is scheme specific. The default in URLEncode is to leave them alone, which is appropriate for file:// URLs, but probably not for http:// ones.

Value

A character string.

References

RFC1738, <http://www.rfc-editor.org/rfc/rfc1738.txt>

Examples

```
(y <- URLEncode("a url with spaces and / and @"))
URLdecode(y)
(y <- URLEncode("a url with spaces and / and @", reserved=TRUE))
URLdecode(y)
URLdecode("ab%20cd")
```

utils-deprecated *Deprecated Functions in Package utils*

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as of the next release.

Usage

```
CRAN.packages(CRAN = getOption("repos"), method,
              contriburl = contrib.url(CRAN))
```

Arguments

CRAN	character, an earlier way to specify a repository.
method	Download method, see download.file .
contriburl	URL(s) of the contrib section of the repositories. Use this argument only if your CRAN mirror is incomplete, e.g., because you burned only the ‘contrib’ section on a CD. Overrides argument <code>repos</code> .

See Also

[Deprecated](#), [Defunct](#)

View *Invoke a Data Viewer*

Description

Invoke a spreadsheet-style data viewer on a matrix-like R object.

Usage

```
View(x, title)
```

Arguments

x	an R object which can be coerced to a data frame with non-zero numbers of rows and columns.
title	title for viewer window. Defaults to name of x.

Details

Object `x` is coerced (if possible) to a data frame, and all non-numeric columns are then coerced to character. The object is then viewed in a spreadsheet-like data viewer, a read-only version of [data.entry](#).

If there are row names on the data frame that are not `1:nrow`, they are displayed in a separate first column called `row.names`.

Objects with zero columns or zero rows are not accepted.

The array of cells can be navigated by the cursor keys and Home, End, Page Up and Page Down (where supported by X11) as well as Enter and Tab.

Value

Invisible `NULL`. The function puts up a window and returns immediately: the window can be closed via its controls or menus.

See Also

[edit.data.frame](#), [data.entry](#).

vignette

View or List Vignettes

Description

View a specified vignette, or list the available ones.

Usage

```
vignette(topic, package = NULL, lib.loc = NULL, all = TRUE)

## S3 method for class 'vignette':
print(x, ...)
## S3 method for class 'vignette':
edit(name, ...)
```

Arguments

<code>topic</code>	a character string giving the (base) name of the vignette to view. If omitted, all vignettes from all installed packages are listed.
<code>package</code>	a character vector with the names of packages to search through, or <code>NULL</code> in which "all" packages (as defined by argument <code>all</code>) are searched.
<code>lib.loc</code>	a character vector of directory names of R libraries, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known.
<code>all</code>	logical; if <code>TRUE</code> search all available packages in the library trees specified by <code>lib.loc</code> , and if <code>FALSE</code> , search only attached packages.
<code>x, name</code>	Object of class <code>vignette</code> .
<code>...</code>	Ignored by the <code>print</code> method, passed on to file.edit by the <code>edit</code> method.

Details

Function `vignette` returns an object of the same class, the print method opens a viewer for it. Currently, only PDF versions of vignettes can be viewed. The program specified by the `pdfviewer` option is used for this. If several vignettes have PDF versions with base name identical to `topic`, the first one found is used.

If no topics are given, all available vignettes are listed. The corresponding information is returned in an object of class `"packageIQR"`.

The `edit` method extracts the R code from the vignette to a temporary file and opens the file in an editor (see [edit](#)). This makes it very easy to execute the commands line by line, modify them in any way you want to help you test variants, etc.. An alternative way of extracting the R code from the vignette is to run [Stangle](#) on the source code of the vignette, see the examples below.

Examples

```
## List vignettes from all *attached* packages
vignette(all = FALSE)

## List vignettes from all *installed* packages (can take a long time!):
vignette(all = TRUE)

## Not run:
## Open the grid intro vignette
vignette("grid")

## The same
v1 <- vignette("grid")
print(v1)

## Now let us have a closer look at the code
edit(v1)

## An alternative way of extracting the code,
## R file is written to current working directory
Stangle(v1$file)

## A package can have more than one vignette (package grid has several):
vignette(package="grid")
vignette("rotated")
## The same, but without searching for it:
vignette("rotated", package="grid")
## End(Not run)
```

withVisible

Return both a value and its visibility

Description

This function evaluates an expression, returning it in a two element list containing its value and a flag showing whether it would automatically print.

Usage

```
withVisible(x)
```

Arguments

`x` An expression to be evaluated.

Details

The argument is evaluated in the caller's context.

Value

`value` The value of `x` after evaluation.
`visible` logical; whether the value would auto-print.

See Also

[invisible](#), [eval](#)

Examples

```
x <- 1
withVisible(x <- 1)
x
withVisible(x)

# Wrap the call in evalq() for special handling

df <- data.frame(a=1:5, b=1:5)
evalq(withVisible(a + b), envir=df)
```

write.table

Data Output

Description

`write.table` prints its required argument `x` (after converting it to a data frame if it is not one nor a matrix) to a file or connection.

Usage

```
write.table(x, file = "", append = FALSE, quote = TRUE, sep = " ",
            eol = "\n", na = "NA", dec = ".", row.names = TRUE,
            col.names = TRUE, qmethod = c("escape", "double"))

write.csv(...)
write.csv2(...)
```

Arguments

<code>x</code>	the object to be written, preferably a matrix or data frame. If not, it is attempted to coerce <code>x</code> to a data frame.
<code>file</code>	either a character string naming a file or a connection open for writing. "" indicates output to the console.
<code>append</code>	logical. Only relevant if <code>file</code> is a character string. If <code>TRUE</code> , the output is appended to the file. If <code>FALSE</code> , any existing file of the name is destroyed.
<code>quote</code>	a logical value (<code>TRUE</code> or <code>FALSE</code>) or a numeric vector. If <code>TRUE</code> , any character or factor columns will be surrounded by double quotes. If a numeric vector, its elements are taken as the indices of columns to quote. In both cases, row and column names are quoted if they are written. If <code>FALSE</code> , nothing is quoted.
<code>sep</code>	the field separator string. Values within each row of <code>x</code> are separated by this string.
<code>eol</code>	the character(s) to print at the end of each line (row). For example, <code>eol="\r\n"</code> will produce Windows' line endings on a Unix-alike OS, and <code>eol="\r"</code> will produce files as expected by MacOS Excel 2004.
<code>na</code>	the string to use for missing values in the data.
<code>dec</code>	the string to use for decimal points in numeric or complex columns: must be a single character.
<code>row.names</code>	either a logical value indicating whether the row names of <code>x</code> are to be written along with <code>x</code> , or a character vector of row names to be written.
<code>col.names</code>	either a logical value indicating whether the column names of <code>x</code> are to be written along with <code>x</code> , or a character vector of column names to be written. See the section on 'CSV files' for the meaning of <code>col.names = NA</code> .
<code>qmethod</code>	a character string specifying how to deal with embedded double quote characters when quoting strings. Must be one of "escape" (default), in which case the quote character is escaped in C style by a backslash, or "double", in which case it is doubled. You can specify just the initial letter.
<code>...</code>	arguments to <code>write.table</code> : <code>col.names</code> , <code>sep</code> , <code>dec</code> and <code>qmethod</code> cannot be altered.

Details

If the table has no columns the rownames will be written only if `row.names=TRUE`, and *vice versa*.

Real and complex numbers are written to the maximal possible precision.

If a data frame has matrix-like columns these will be converted to multiple columns in the result (*via* `as.matrix`) and so a character `col.names` or a numeric `quote` should refer to the columns in the result, not the input. Such matrix-like columns are unquoted by default.

Any columns in a data frame which are lists or have a class (e.g. dates) will be converted by the appropriate `as.character` method: such columns are unquoted by default. On the other hand, any class information for a matrix is discarded and non-atomic (e.g. list) matrices are coerced to character.

Only columns which have been converted to character will be quoted if specified by `quote`.

The `dec` argument only applies to columns that are not subject to conversion to character because they have a class or are part of a matrix-like column (or matrix), in particular to columns protected by `I()`. Use `options("OutDec")` to control such conversions.

In almost all cases the conversion of numeric quantities is governed by the option "scipen" (see [options](#)), but with the internal equivalent of `digits=15`. For finer control, use `format` to make a character matrix/data frame, and call `write.table` on that.

These functions check for a user interrupt every 1000 lines of output.

If `file` is not open for writing, an attempt is made to open it and then close it after use.

CSV files

By default there is no column name for a column of row names. If `col.names = NA` and `row.names = TRUE` a blank column name is added, which is the convention used for CSV files to be read by spreadsheets.

`write.csv` and `write.csv2` provide convenience wrappers for writing CSV files. They set `sep`, `dec` and `qmethod`, and `col.names` to `NA` if `row.names = TRUE` and `TRUE` otherwise.

`write.csv` uses "." for the decimal point and a comma for the separator.

`write.csv2` uses a comma for the decimal point and a semicolon for the separator, the Excel convention for CSV files in some Western European locales.

These wrappers are deliberately inflexible: they are designed to ensure that the correct conventions are used to write a valid file. Attempts to change `col.names`, `sep`, `dec` or `qmethod` are ignored, with a warning.

Note

`write.table` can be slow for data frames with large numbers (hundreds or more) of columns: this is inevitable as each column could be of a different class and so must be handled separately. If they are all of the same class, consider using a matrix instead.

See Also

The 'R Data Import/Export' manual.

[read.table](#), [write](#).

[write.matrix](#) in package **MASS**.

Examples

```
## Not run:
## To write a CSV file for input to Excel one might use
x <- data.frame(a = I("a \" quote"), b = pi)
write.table(x, file = "foo.csv", sep = ",", col.names = NA,
            qmethod = "double")
## and to read this file back into R one needs
read.table("foo.csv", header = TRUE, sep = ",", row.names = 1)
## NB: you do need to specify a separator if qmethod = "double".

### Alternatively
write.csv(x, file = "foo.csv")
read.csv("foo.csv", row.names = 1)
## or without row names
write.csv(x, file = "foo.csv", row.names = FALSE)
read.csv("foo.csv")
## End(Not run)
```

zip.file.extract *Extract File from a Zip Archive*

Description

This will extract the file named `file` from the zip archive, if possible, and write it in a temporary location.

Usage

```
zip.file.extract(file, zipname = "R.zip",
                unzip = getOption("unzip"))
```

Arguments

<code>file</code>	A file name. (If a path is given, see 'Note'.)
<code>zipname</code>	The file name (not path) of a zip archive, including the ".zip" extension if required.
<code>unzip</code>	character string: the method to be used, an empty string indicates "internal".

Details

All platforms support an "internal" unzip: this is the default under Windows and the fall-back under Unix if no unzip program was found during configuration and `R_UNZIPCMD` is not set.

The file will be extracted if it is in the archive and any required unzip utility is available. It will be extracted to the directory given by `tempdir`, overwriting any existing file of that name.

Value

The name of the original or extracted file. Success is indicated by returning a different name.

Note

The "internal" method is very simple, and will not set file dates.

This is a helper function for [help](#), [example](#) and [data](#). As such, it handles file paths in an unusual way. Any path component of `zipname` is ignored, and the path to `file` is used only to determine the directory within which to find `zipname`.

Part II

Chapter 10

The KernSmooth package

bkde

Compute a Binned Kernel Density Estimate

Description

Returns x and y coordinates of the binned kernel density estimate of the probability density of the data.

Usage

```
bkde(x, kernel = "normal", canonical = FALSE, bandwidth,  
      gridsize = 401, range.x, truncate = TRUE)
```

Arguments

x	vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
bandwidth	the kernel bandwidth smoothing parameter. Larger values of <code>bandwidth</code> make smoother estimates, smaller values of <code>bandwidth</code> make less smooth estimates. The default is a bandwidth computed from the variance of <code>x</code> , specifically the ‘oversmoothed bandwidth selector’ of Wand and Jones (1995, page 61).
kernel	character string which determines the smoothing kernel. <code>kernel</code> can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density.
canonical	logical flag: if TRUE, canonically scaled kernels are used.
gridsize	the number of equally spaced points at which to estimate the density.
range.x	vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
truncate	logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.

Details

This is the binned approximation to the ordinary kernel density estimate. Linear binning is used to obtain the bin counts. For each x value in the sample, the kernel is centered on that x and the heights of the kernel at each datapoint are summed. This sum, after a normalization, is the corresponding y value in the output.

Value

a list containing the following components:

x	vector of sorted x values at which the estimate was computed.
y	vector of density estimates at the corresponding x .

Background

Density estimation is a smoothing operation. Inevitably there is a trade-off between bias in the estimate and the estimate's variability: large bandwidths will produce smooth estimates that may hide local features of the density; small bandwidths may introduce spurious bumps into the estimate.

References

See Also

[density](#), [dpik](#), [hist](#), [ksmooth](#).

Examples

```
data(geyser, package="MASS")
x <- geyser$duration
est <- bkde(x, bandwidth=0.25)
plot(est, type="l")
```

bkde2D

Compute a 2D Binned Kernel Density Estimate

Description

Returns the set of grid points in each coordinate direction, and the matrix of density estimates over the mesh induced by the grid points. The kernel is the standard bivariate normal density.

Usage

```
bkde2D(x, bandwidth, gridsize=c(51, 51), range.x, truncate=TRUE)
```

Arguments

<code>x</code>	a two-column matrix containing the observations from the distribution whose density is to be estimated. Missing values are not allowed.
<code>bandwidth</code>	vector containing the bandwidth to be used in each coordinate direction.
<code>gridsize</code>	vector containing the number of equally spaced points in each direction over which the density is to be estimated.
<code>range.x</code>	a list containing two vectors, where each vector contains the minimum and maximum values of <code>x</code> at which to compute the estimate for each direction. The default minimum in each direction is minimum data value minus 1.5 times the bandwidth for that direction. The default maximum is the maximum data value plus 1.5 times the bandwidth for that direction
<code>truncate</code>	logical flag: if TRUE, data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.

Value

a list containing the following components:

<code>x1</code>	vector of values of the grid points in the first coordinate direction at which the estimate was computed.
<code>x2</code>	vector of values of the grid points in the second coordinate direction at which the estimate was computed.
<code>fhat</code>	matrix of density estimates over the mesh induced by <code>x1</code> and <code>x2</code> .

Details

This is the binned approximation to the 2D kernel density estimate. Linear binning is used to obtain the bin counts and the Fast Fourier Transform is used to perform the discrete convolutions. For each `x1,x2` pair the bivariate Gaussian kernel is centered on that location and the heights of the kernel, scaled by the bandwidths, at each datapoint are summed. This sum, after a normalization, is the corresponding `fhat` value in the output.

Examples

```
data(geyser, package="MASS")
x <- cbind(geyser$duration, geyser$waiting)
est <- bkde2D(x, bandwidth=c(0.7,7))
contour(est$x1, est$x2, est$fhat)
persp(est$fhat)
```

bkfe

*Compute a Binned Kernel Functional Estimate***Description**

Returns an estimate of a binned approximation to the kernel estimate of the specified density functional. The kernel is the standard normal density.

Usage

```
bkfe(x, drv, bandwidth, gridsize = 401, range.x, binned = FALSE,
      truncate = TRUE)
```

Arguments

<code>x</code>	vector of observations from the distribution whose density is to be estimated. Missing values are not allowed.
<code>drv</code>	order of derivative in the density functional. Must be a non-negative even integer.
<code>bandwidth</code>	the kernel bandwidth smoothing parameter. Must be supplied.
<code>gridsize</code>	the number of equally-spaced points over which binning is performed.
<code>range.x</code>	vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values, extended by the support of the kernel.
<code>binned</code>	logical flag: if <code>TRUE</code> , then <code>x</code> and <code>y</code> are taken to be grid counts rather than raw data.
<code>truncate</code>	logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.

Details

The density functional of order `drv` is the integral of the product of the density and its `drv`th derivative. The kernel estimates of such quantities are computed using a binned implementation, and the kernel is the standard normal density.

Value

the estimated functional.

Background

Estimates of this type were proposed by Sheather and Jones (1991).

References

Sheather, S. J. and Jones, M. C. (1991). A reliable data-based bandwidth selection method for kernel density estimation. *Journal of the Royal Statistical Society, Series B*, **53**, 683–690.

Examples

```
data(geyser, package="MASS")
x <- geyser$duration
est <- bkfe(x, drv=4, bandwidth=0.3)
```

dph

*Select a Histogram Bin Width***Description**

Uses direct plug-in methodology to select the bin width of a histogram.

Usage

```
dph(x, scalest="minim", level=2, gridsize=401,
    range.x=range(x), truncate=TRUE)
```

Arguments

<code>x</code>	vector containing the sample on which the histogram is to be constructed.
<code>scalest</code>	estimate of scale. "stdev" - standard deviation is used. "iqr" - inter-quartile range divided by 1.349 is used. "minim" - minimum of "stdev" and "iqr" is used.
<code>level</code>	number of levels of functional estimation used in the plug-in rule.
<code>gridsize</code>	number of grid points used in the binned approximations to functional estimates.
<code>range.x</code>	range over which functional estimates are obtained. The default is the minimum and maximum data values.
<code>truncate</code>	if <code>truncate</code> is TRUE then observations outside of the interval specified by <code>range.x</code> are omitted. Otherwise, they are used to weight the extreme grid points.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bin width and bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bin width.

Background

This method for selecting the bin width of a histogram is described in Wand (1995). It is an extension of the normal scale rule of Scott (1979) and uses plug-in ideas from bandwidth selection for kernel density estimation (e.g. Sheather and Jones, 1991).

```

dpik

Select a Bandwidth for Kernel Density Estimation

Description

Use direct plug-in methodology to select the bandwidth of a kernel density estimate.

Usage

```
dpik(x, scalest="minim", level=2, kernel="normal",
     canonical=FALSE, gridsize=401, range.x=range(x),
     truncate=TRUE)
```

Arguments

x	vector containing the sample on which the kernel density estimate is to be constructed.
scalest	estimate of scale. "stdev" - standard deviation is used. "iqr" - inter-quartile range divided by 1.349 is used. "minim" - minimum of "stdev" and "iqr" is used.
level	number of levels of functional estimation used in the plug-in rule.
kernel	character string which determines the smoothing kernel. kernel can be: "normal" - the Gaussian density function (the default). "box" - a rectangular box. "epanech" - the centred beta(2,2) density. "biweight" - the centred beta(3,3) density. "triweight" - the centred beta(4,4) density.
canonical	logical flag: if TRUE, canonically scaled kernels are used
gridsize	the number of equally-spaced points over which binning is performed to obtain kernel functional approximation.

<code>range.x</code>	vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate. The default is the minimum and maximum data values.
<code>truncate</code>	logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The normal distribution is used to provide an initial estimate.

Value

the selected bandwidth.

Background

This method for selecting the bandwidth of a kernel density estimate was proposed by Sheather and Jones (1991) and is described in Section 3.6 of Wand and Jones (1995).

References

Sheather, S. J. and Jones, M. C. (1991). A reliable data-based bandwidth selection method for kernel density estimation. *Journal of the Royal Statistical Society, Series B*, **53**, 683–690.

plot(est, type="l")
```

dpill

Select a Bandwidth for Local Linear Regression

Description

Use direct plug-in methodology to select the bandwidth of a local linear Gaussian kernel regression estimate, as described by Ruppert, Sheather and Wand (1995).

Usage

```
dpill(x, y, blockmax = 5, divisor = 20, trim = 0.01, proptrun = 0.05,
      gridsize = 401, range.x, truncate = TRUE)
```

Arguments

<code>x</code>	vector of x data. Missing values are not accepted.
<code>y</code>	vector of y data. This must be same length as <code>x</code> , and missing values are not accepted.
<code>blockmax</code>	the maximum number of blocks of the data for construction of an initial parametric estimate.
<code>divisor</code>	the value that the sample size is divided by to determine a lower limit on the number of blocks of the data for construction of an initial parametric estimate.
<code>trim</code>	the proportion of the sample trimmed from each end in the x direction before application of the plug-in methodology.
<code>proptrun</code>	the proportion of the range of x at each end truncated in the functional estimates.
<code>gridsize</code>	number of equally-spaced grid points over which the function is to be estimated.
<code>range.x</code>	vector containing the minimum and maximum values of x at which to compute the estimate. For density estimation the default is the minimum and maximum data values with 5% of the range added to each end. For regression estimation the default is the minimum and maximum data values.
<code>truncate</code>	logical flag: if TRUE, data with x values outside the range specified by <code>range.x</code> are ignored.

Details

The direct plug-in approach, where unknown functionals that appear in expressions for the asymptotically optimal bandwidths are replaced by kernel estimates, is used. The kernel is the standard normal density. Least squares quartic fits over blocks of data are used to obtain an initial estimate. Mallows's C_p is used to select the number of blocks.

Value

the selected bandwidth.

Warning

If there are severe irregularities (i.e. outliers, sparse regions) in the x values then the local polynomial smooths required for the bandwidth selection algorithm may become degenerate and the function will crash. Outliers in the y direction may lead to deterioration of the quality of the selected bandwidth.

[ksmooth](#), [locpoly](#).

Examples

```

data(geyser, package = "MASS")
x <- geyser$duration
y <- geyser$waiting
plot(x, y)
h <- dpill(x, y)
fit <- locpoly(x, y, bandwidth = h)
lines(fit)

```

locpoly

*Estimate Functions Using Local Polynomials***Description**

Estimates a probability density function, regression function or their derivatives using local polynomials. A fast binned implementation over an equally-spaced grid is used.

Usage

```

locpoly(x, y, drv = 0, degree =, kernel = "normal",
        bandwidth, gridsize = 401, bwdisc = 25,
        range.x, binned = FALSE, truncate = TRUE)

```

Arguments

<code>x</code>	vector of <code>x</code> data. Missing values are not accepted.
<code>bandwidth</code>	the kernel bandwidth smoothing parameter. It may be a single number or an array having length <code>gridsize</code> , representing a bandwidth that varies according to the location of estimation.
<code>y</code>	vector of <code>y</code> data. This must be same length as <code>x</code> , and missing values are not accepted.
<code>drv</code>	order of derivative to be estimated.
<code>degree</code>	degree of local polynomial used. Its value must be greater than or equal to the value of <code>drv</code> . The default value is of degree is <code>drv + 1</code> .
<code>kernel</code>	"normal" - the Gaussian density function.
<code>gridsize</code>	number of equally-spaced grid points over which the function is to be estimated.
<code>bwdisc</code>	number of logarithmically-equally-spaced bandwidths on which <code>bandwidth</code> is discretised, to speed up computation.
<code>range.x</code>	vector containing the minimum and maximum values of <code>x</code> at which to compute the estimate.
<code>binned</code>	logical flag: if <code>TRUE</code> , then <code>x</code> and <code>y</code> are taken to be grid counts rather than raw data.
<code>truncate</code>	logical flag: if <code>TRUE</code> , data with <code>x</code> values outside the range specified by <code>range.x</code> are ignored.

Value

if y is specified, a local polynomial regression estimate of $E[Y|X]$ (or its derivative) is computed. If y is missing, a local polynomial estimate of the density of x (or its derivative) is computed.

a list containing the following components:

x	vector of sorted x values at which the estimate was computed.
y	vector of smoothed estimates for either the density or the regression at the corresponding x .

Details

Local polynomial fitting with a kernel weight is used to estimate either a density, regression function or their derivatives. In the case of density estimation, the data are binned and the local fitting procedure is applied to the bin counts. In either case, binned approximations over an equally-spaced grid is used for fast computation. The bandwidth may be either scalar or a vector of length `gridsize`.

 addterm

Try All One-Term Additions to a Model

Description

Try fitting all models that differ from the current model by adding a single term from those supplied, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

Usage

```
addterm(object, ...)

## Default S3 method:
addterm(object, scope, scale = 0, test = c("none", "Chisq"),
        k = 2, sorted = FALSE, trace = FALSE, ...)
## S3 method for class 'lm':
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
        k = 2, sorted = FALSE, ...)
## S3 method for class 'glm':
addterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
        k = 2, sorted = FALSE, trace = FALSE, ...)
```

Arguments

<code>object</code>	An object fitted by some model-fitting function.
<code>scope</code>	a formula specifying a maximal model which should include the current one. All additional terms in the maximal model with all marginal terms in the original model are tried.
<code>scale</code>	used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>aov</code> and <code>glm</code> models. Specifying <code>scale</code> asserts that the residual standard error or dispersion is known.
<code>test</code>	should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>aov</code> models, and perhaps for some over-dispersed <code>glm</code> models. The Chisq test can be an exact test (<code>lm</code> models with known scale) or a likelihood-ratio test depending on the method.
<code>k</code>	the multiple of the number of degrees of freedom used for the penalty. Only <code>k=2</code> gives the genuine AIC: <code>k = log(n)</code> is sometimes referred to as BIC or SBC.
<code>sorted</code>	should the results be sorted on the value of AIC?
<code>trace</code>	if TRUE additional information may be given on the fits as they are tried.
<code>...</code>	arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (l_m models with specified scale) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

addterm(quine.lo, quine.hi, test="F")

house.glm0 <- glm(Freq ~ Infl*Type*Cont + Sat, family=poisson,
                 data=housing)
addterm(house.glm0, ~. + Sat:(Infl+Type+Cont), test="Chisq")
house.glm1 <- update(house.glm0, . ~ . + Sat*(Infl+Type+Cont))
addterm(house.glm1, ~. + Sat:(Infl+Type+Cont)^2, test = "Chisq")
```

Aids2

Australian AIDS Survival Data

Description

Data on patients diagnosed with AIDS in Australia before 1 July 1991.

Usage

```
Aids2
```

Format

This data frame contains 2843 rows and the following columns:

state Grouped state of origin: "NSW" includes ACT and "other" is WA, SA, NT and TAS.

sex Sex of patient.

diag (Julian) date of diagnosis.

death (Julian) date of death or end of observation.

status "A" (alive) or "D" (dead) at end of observation.

T.categ Reported transmission category.

age Age (years) at diagnosis.

Note

This data set has been slightly jittered as a condition of its release, to ensure patient confidentiality.

`anova.negbin`*Likelihood Ratio Tests for Negative Binomial GLMs*

Description

Method function to perform sequential likelihood ratio tests for Negative Binomial generalized linear models.

Usage

```
## S3 method for class 'negbin':  
anova(object, ..., test = "Chisq")
```

Arguments

object	Fitted model object of class "negbin", inheriting from classes "glm" and "lm", specifying a Negative Binomial fitted GLM. Typically the output of <code>glm.nb()</code> .
...	Zero or more additional fitted model objects of class "negbin". They should form a nested sequence of models, but need not be specified in any particular order.
test	Argument to match the <code>test</code> argument of <code>anova.glm</code> . Ignored (with a warning if changed) if a sequence of two or more Negative Binomial fitted model objects is specified, but possibly used if only one object is specified.

Details

This function is a method for the generic function `anova()` for class "negbin". It can be invoked by calling `anova(x)` for an object `x` of the appropriate class, or directly by calling `anova.negbin(x)` regardless of the class of the object.

Note

If only one fitted model object is specified, a sequential analysis of deviance table is given for the fitted model. The `theta` parameter is kept fixed. If more than one fitted model object is specified they must all be of class "negbin" and likelihood ratio tests are done of each model within the next. In this case `theta` is assumed to have been re-estimated for each model.

[glm.nb](#), [negative.binomial](#), [summary.negbin](#)

Examples

```
m1 <- glm.nb(Days ~ Eth*Age*Lrn*Sex, quine, link = log)
m2 <- update(m1, . ~ . - Eth:Age:Lrn:Sex)
anova(m2, m1)
anova(m2)
```

area

Adaptive Numerical Integration

Description

Integrate a function of one variable over a finite range using a recursive adaptive method. This function is mainly for demonstration purposes.

Usage

```
area(f, a, b, ..., fa = f(a, ...), fb = f(b, ...),
     limit = 10, eps = 1e-05)
```

Arguments

f	The integrand as an S function object. The variable of integration must be the first argument.
a	Lower limit of integration.
b	Upper limit of integration.
...	Additional arguments needed by the integrand.
fa	Function value at the lower limit.
fb	Function value at the upper limit.
limit	Limit on the depth to which recursion is allowed to go.
eps	Error tolerance to control the process.

Details

The method divides the interval in two and compares the values given by Simpson's rule and the trapezium rule. If these are within eps of each other the Simpson's rule result is given, otherwise the process is applied separately to each half of the interval and the results added together.

Value

The integral from a to b of $f(x)$.

Examples

```
area(sin, 0, pi) # integrate the sin function from 0 to pi.
```

bacteria

Presence of Bacteria after Drug Treatments

Description

Tests of the presence of the bacteria *H. influenzae* in children with otitis media in the Northern Territory of Australia.

Usage

```
bacteria
```

Format

This data frame has 220 rows and the following columns:

y presence or absence: a factor with levels n and y.

ap active/placebo: a factor with levels a and p.

hilo hi/low compliance: a factor with levels hi and lo.

week numeric: week of test.

ID subject ID: a factor.

trt a factor with levels placebo, drug and drug+, a re-coding of ap and hilo.

Details

Dr A. Leach tested the effects of a drug on 50 children with a history of otitis media in the Northern Territory of Australia. The children were randomized to the drug or the a placebo, and also to receive active encouragement to comply with taking the drug.

The presence of *H. influenzae* was checked at weeks 0, 2, 4, 6 and 11: 30 of the checks were missing and are not included in this data frame.

coxph(Surv(Time, unclass(y)) ~ I(week > 2) + strata(ID),
  data = bacteria, method = "exact")

# PQL glmm analysis
library(nlme)
summary(glmmPQL(y ~ trt + I(week > 2), random = ~ 1 | ID,
  family = binomial, data = bacteria))
```

bandwidth.nrd *Bandwidth for density() via Normal Reference Distribution*

Description

A well-supported rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator.

Usage

```
bandwidth.nrd(x)
```

Arguments

x A data vector.

Value

A bandwidth on a scale suitable for the `width` argument of `density`.

References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Springer, equation (5.5) on page 130.

Examples

```
# The function is currently defined as
function(x)
{
  r <- quantile(x, c(0.25, 0.75))
  h <- (r[2] - r[1])/1.34
  4 * 1.06 * min(sqrt(var(x)), h) * length(x)^(-1/5)
}
```

bcv *Biased Cross-Validation for Bandwidth Selection*

Description

Uses biased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

Usage

```
bcv(x, nb = 1000, lower, upper)
```

Arguments

x a numeric vector
nb number of bins to use.
lower, upper Range over which to minimize. The default is almost always satisfactory.

Value

a bandwidth

 beav1

Body Temperature Series of Beaver 1

Description

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

Usage

```
beav1
```

Format

The `beav1` data frame has 114 rows and 4 columns. This data frame contains the following columns:

day Day of observation (in days since the beginning of 1990), December 12–13.

time Time of observation, in the form 0330 for 3.30am.

temp Measured body temperature in degrees Celsius.

activ Indicator of activity outside the retreat.

Note

The observation at 22:20 is missing.

```
biopsy
```

```
Biopsy Data on Breast Cancer Patients
```

Description

This breast cancer database was obtained from the University of Wisconsin Hospitals, Madison from Dr. William H. Wolberg. He assessed biopsies of breast tumours for 699 patients up to 15 July 1992; each of nine attributes has been scored on a scale of 1 to 10, and the outcome is also known. There are 699 rows and 11 columns.

Usage

```
biopsy
```

Format

This data frame contains the following columns:

- ID** sample code number (not unique).
- V1** clump thickness.
- V2** uniformity of cell size.
- V3** uniformity of cell shape.
- V4** marginal adhesion.
- V5** single epithelial cell size.
- V6** bare nuclei (16 values are missing).
- V7** bland chromatin.
- V8** normal nucleoli.
- V9** mitoses.
- class** "benign" or "malignant".

 birthwt

Risk Factors Associated with Low Infant Birth Weight

Description

The `birthwt` data frame has 189 rows and 10 columns. The data were collected at Baystate Medical Center, Springfield, Mass during 1986.

Usage

```
birthwt
```

Format

This data frame contains the following columns:

low indicator of birth weight less than 2.5 kg.

age mother's age in years.

lwt mother's weight in pounds at last menstrual period.

race mother's race (1 = white, 2 = black, 3 = other).

smoke smoking status during pregnancy.

pt1 number of previous premature labours.

ht history of hypertension.

ui presence of uterine irritability.

ftv number of physician visits during the first trimester.

bwt birth weight in grams.

```

 Boston

Housing Values in Suburbs of Boston

Description

The Boston data frame has 506 rows and 14 columns.

Usage

Boston

Format

This data frame contains the following columns:

crim per capita crime rate by town.

zn proportion of residential land zoned for lots over 25,000 sq.ft.

indus proportion of non-retail business acres per town.

chas Charles River dummy variable (= 1 if tract bounds river; 0 otherwise).

nox nitrogen oxides concentration (parts per 10 million).

rm average number of rooms per dwelling.

age proportion of owner-occupied units built prior to 1940.

dis weighted mean of distances to five Boston employment centres.

rad index of accessibility to radial highways.

tax full-value property-tax rate per \$10,000.

ptratio pupil-teacher ratio by town.

black $1000(Bk - 0.63)^2$ where Bk is the proportion of blacks by town.

lstat lower status of the population (percent).

medv median value of owner-occupied homes in \$1000s.

 boxcox

Box-Cox Transformations for Linear Models

Description

Computes and optionally plots profile log-likelihoods for the parameter of the Box-Cox power transformation.

Usage

```
boxcox(object, ...)

## Default S3 method:
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp, eps = 1/50, xlab = expression(lambda),
        ylab = "log-Likelihood", ...)

## S3 method for class 'formula':
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp, eps = 1/50, xlab = expression(lambda),
        ylab = "log-Likelihood", ...)

## S3 method for class 'lm':
boxcox(object, lambda = seq(-2, 2, 1/10), plotit = TRUE,
        interp, eps = 1/50, xlab = expression(lambda),
        ylab = "log-Likelihood", ...)
```

Arguments

object	a formula or fitted model object. Currently only <code>lm</code> and <code>aov</code> objects are handled.
lambda	vector of values of <code>lambda</code> – default $(-2, 2)$ in steps of 0.1.
plotit	logical which controls whether the result should be plotted.
interp	logical which controls whether spline interpolation is used. Default to <code>TRUE</code> if plotting with <code>lambda</code> of length less than 100.
eps	Tolerance for <code>lambda = 0</code> ; defaults to 0.02.
xlab	defaults to <code>"lambda"</code> .
ylab	defaults to <code>"log-Likelihood"</code> .
...	additional parameters to be used in the model fitting.

Value

A list of the `lambda` vector and the computed profile log-likelihood vector, invisibly if the result is plotted.

Side Effects

If `plotit = TRUE` plots `loglik vs lambda` and indicates a 95% confidence interval about the maximum observed value of `lambda`. If `interp = TRUE`, spline interpolation is used to give a smoother plot.

Examples

```
boxcox(Volume ~ log(Height) + log(Girth), data = trees,
       lambda = seq(-0.25, 0.25, length = 10))
```

```
boxcox(Days+1 ~ Eth*Sex*Age*Lrn, data = quine,
       lambda = seq(-0.05, 0.45, len = 20))
```

cabbages

Data from a cabbage field trial

Description

The cabbages data set has 60 observations and 4 variables

Usage

```
cabbages
```

Format

This data frame contains the following columns:

Cult Factor giving the cultivar of the cabbage, two levels: `c39` and `c52`.

Date Factor specifying one of three planting dates: `d16`, `d20` or `d21`.

HeadWt Weight of the cabbage head, presumably in kg.

VitC Ascorbic acid content, in undefined units.

```

Cars93*Data from 93 Cars on Sale in the USA in 1993*

Description

The Cars93 data frame has 93 rows and 27 columns.

Usage

Cars93

Format

This data frame contains the following columns:

Manufacturer Manufacturer.

Model Model.

Type Type: a factor with levels "Small", "Sporty", "Compact", "Midsize", "Large" and "Van".

Min.Price Minimum Price (in \$1,000): price for a basic version.

Price Midrange Price (in \$1,000): average of Min.Price and Max.Price.

Max.Price Maximum Price (in \$1,000): price for "a premium version".

MPG.city City MPG (miles per US gallon by EPA rating).

MPG.highway Highway MPG.

AirBags Air Bags standard. Factor: none, driver only, or driver & passenger.

DriveTrain Drive train type: rear wheel, front wheel or 4WD; (factor).

Cylinders Number of cylinders (missing for Mazda RX-7, which has a rotary engine).

EngineSize Engine size (litres).

Horsepower Horsepower (maximum).

RPM RPM (revs per minute at maximum horsepower).

Rev.per.mile Engine revolutions per mile (in highest gear).

Man.trans.avail Is a manual transmission version available? (yes or no, Factor).

Fuel.tank.capacity Fuel tank capacity (US gallons).

Passengers Passenger capacity (persons)

Length Length (inches).

Wheelbase Wheelbase (inches).

Width Width (inches).

Turn.circle U-turn space (feet).

Rear.seat.room Rear seat room (inches) (missing for 2-seater vehicles).

Luggage.room Luggage capacity (cubic feet) (missing for vans).

Weight Weight (pounds).

Origin Of non-USA or USA company origins? (factor).

Make Combination of Manufacturer and Model (character).

Details

Cars were selected at random from among 1993 passenger car models that were listed in both the *Consumer Reports* issue and the *PACE Buying Guide*. Pickup trucks and Sport/Utility vehicles were eliminated due to incomplete information in the *Consumer Reports* source. Duplicate models (e.g., Dodge Shadow and Plymouth Sundance) were listed at most once.

Further description can be found in Lock (1993).

cement

Heat Evolved by Setting Cements

Description

Experiment on the heat evolved in the setting of each of 13 cements.

Usage

cement

Format

x1, **x2**, **x3**, **x4** Proportions (%) of active ingredients.

y heat evolved in cal/gm.

Details

Thirteen samples of Portland cement were set. For each sample, the percentages of the four main chemical ingredients was accurately measured. While the cement was setting the amount of heat evolved was also measured.

Source

`con2tr`*Convert Lists to Data Frames for use by Lattice*

Description

Convert lists to data frames for use by lattice.

Usage

```
con2tr(obj)
```

Arguments

`obj` A list of components `x`, `y` and `z` as passed to `contour`.

Details

`con2tr` repeats the `x` and `y` components suitably to match the vector `z`.

Value

A data frame suitable for passing to lattice (formerly trellis) functions.

References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

`confint-MASS`*Confidence Intervals for Model Parameters*

Description

Computes confidence intervals for one or more parameters in a fitted model. Package **MASS** adds methods for `glm` and `nls` fits.

Usage

```
## S3 method for class 'glm':
confint(object, parm, level = 0.95, trace = FALSE, ...)

## S3 method for class 'nls':
confint(object, parm, level = 0.95, ...)
```

Arguments

object	a fitted model object. Methods currently exist for the classes "glm", "nls" and for profile objects from these classes.
parm	a specification of which parameters are to be given confidence intervals, either a vector of numbers or a vector of names. If missing, all parameters are considered.
level	the confidence level required.
trace	logical. Should profiling be traced?
...	additional argument(s) for methods.

Details

`confint` is a generic function in package `base`.

These `confint` methods calls the appropriate profile method, then finds the confidence intervals by interpolation in the profile traces. If the profile object is already available it should be used as the main argument rather than the fitted model object itself.

Value

A matrix (or vector) with columns giving lower and upper confidence limits for each parameter. These will be labelled as $(1 - \text{level})/2$ and $1 - (1 - \text{level})/2$ in % (by default 2.5% and 97.5%).

```

 contr.sdif

Successive Differences contrast coding

Description

A coding for unordered factors based on successive differences.

Usage

```
contr.sdif(n, contrasts = TRUE)
```

Arguments

<code>n</code>	The number of levels required.
<code>contrasts</code>	Should there be $n - 1$ columns orthogonal to the mean (the default) or n columns spanning the space.

Details

The contrast coefficients are chosen so that the coded coefficients in a one-way layout are the differences between the means of the second and first levels, the third and second levels, and so on.

Value

If `contrasts` is `TRUE`, a matrix with n rows and $n - 1$ columns, and the n by n identity matrix if `contrasts` is `FALSE`.

`corresp`*Simple Correspondence Analysis*

Description

Find the principal canonical correlation and corresponding row- and column-scores from a correspondence analysis of a two-way contingency table.

Usage

```
corresp(x, ...)

## S3 method for class 'matrix':
corresp(x, nf = 1, ...)

## S3 method for class 'factor':
corresp(x, y, ...)

## S3 method for class 'data.frame':
corresp(x, ...)

## S3 method for class 'xtabs':
corresp(x, ...)

## S3 method for class 'formula':
corresp(formula, data, ...)
```

Arguments

<code>x</code> , <code>formula</code>	The function is generic, accepting various forms of the principal argument for specifying a two-way frequency table. Currently accepted forms are matrices, data frames (coerced to frequency tables), objects of class " <code>xtabs</code> " and formulae of the form $\sim F1 + F2$, where <code>F1</code> and <code>F2</code> are factors.
<code>nf</code>	The number of factors to be computed. Note that although 1 is the most usual, one school of thought takes the first two singular vectors for a sort of biplot.
<code>y</code>	a second factor for a cross-classification.
<code>data</code>	a data frame against which to preferentially resolve variables in the formula.
<code>...</code>	If the principal argument is a formula, a data frame may be specified as well from which variables in the formula are preferentially satisfied.

Details

See Venables & Ripley (2002). The `plot` method produces a graphical representation of the table if `nf=1`, with the *areas* of circles representing the numbers of points. If `nf` is two or more the `biplot` method is called, which plots the second and third columns of the matrices $A = D r^{(-1/2)} U L$ and $B = D c^{(-1/2)} V L$ where the singular value decomposition is $U L V$. Thus the x-axis is the canonical correlation times the row and column scores. Although this is called a biplot, it does *not* have any useful inner product relationship between the row and column scores. Think of this as an equally-scaled plot with two unrelated sets of labels. The origin is marked on the plot with a cross. (For other versions of this plot see the book.)

Value

An list object of class "`correspondence`" for which `print`, `plot` and `biplot` methods are supplied. The main components are the canonical correlation(s) and the row and column scores.

corresp(caith)
biplot(corresp(caith, nf = 2))
```

 cov.rob

Resistant Estimation of Multivariate Location and Scatter

Description

Compute a multivariate location and scale estimate with a high breakdown point – this can be thought of as estimating the mean and covariance of the `good` part of the data. `cov.mve` and `cov.mcd` are compatibility wrappers.

Usage

```
cov.rob(x, cor = FALSE, quantile.used = floor((n + p + 1)/2),
        method = c("mve", "mcd", "classical"),
        nsamp = "best", seed)

cov.mve(...)
cov.mcd(...)
```

Arguments

<code>x</code>	a matrix or data frame.
<code>cor</code>	should the returned result include a correlation matrix?
<code>quantile.used</code>	the minimum number of the data points regarded as good points.
<code>method</code>	the method to be used – minimum volume ellipsoid, minimum covariance determinant or classical product-moment. Using <code>cov.mve</code> or <code>cov.mcd</code> forces <code>mve</code> or <code>mcd</code> respectively.
<code>nsamp</code>	the number of samples or "best" or "exact" or "sample". If "sample" the number chosen is $\min(5 \cdot p, 3000)$, taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples: if "exact" exhaustive enumeration will be attempted however many samples are needed.
<code>seed</code>	the seed to be used for random sampling: see RNGkind . The current value of <code>.Random.seed</code> will be preserved if it is set.
<code>...</code>	arguments to <code>cov.rob</code> other than <code>method</code> .

Details

For method "mve", an approximate search is made of a subset of size `quantile.used` with an enclosing ellipsoid of smallest volume; in method "mcd" it is the volume of the Gaussian confidence ellipsoid, equivalently the determinant of the classical covariance matrix, that is minimized. The mean of the subset provides a first estimate of the location, and the rescaled covariance matrix a first estimate of scatter. The Mahalanobis distances of all the points from the location estimate for this covariance matrix are calculated, and those points within the 97.5% point under Gaussian assumptions are declared to be `good`. The final estimates are the mean and rescaled covariance of the `good` points.

The rescaling is by the appropriate percentile under Gaussian data; in addition the first covariance matrix has an *ad hoc* finite-sample correction given by Marazzi.

For method "mve" the search is made over ellipsoids determined by the covariance matrix of `p` of the data points. For method "mcd" an additional improvement step suggested by Rousseeuw and van Driessen (1999) is used, in which once a subset of size `quantile.used` is selected, an ellipsoid based on its covariance is tested (as this will have no larger a determinant, and may be smaller).

Value

A list with components

<code>center</code>	the final estimate of location.
<code>cov</code>	the final estimate of scatter.
<code>cor</code>	(only is <code>cor = TRUE</code>) the estimate of the correlation matrix.
<code>sing</code>	message giving number of singular samples out of total
<code>crit</code>	the value of the criterion on log scale. For MCD this is the determinant, and for MVE it is proportional to the volume.
<code>best</code>	the subset used. For MVE the best sample, for MCD the best set of size <code>quantile.used</code> .
<code>n.obs</code>	total number of observations.

cov.trob

*Covariance Estimation for Multivariate t Distribution***Description**

Estimates a covariance or correlation matrix assuming the data came from a multivariate t distribution: this provides some degree of robustness to outlier without giving a high breakdown point.

Usage

```
cov.trob(x, wt = rep(1, n), cor = FALSE, center = TRUE, nu = 5,
         maxit = 25, tol = 0.01)
```

Arguments

x	data matrix. Missing values (NAs) are not allowed.
wt	A vector of weights for each case: these are treated as if the case <i>i</i> actually occurred <i>wt[i]</i> times.
cor	Flag to choose between returning the correlation (<code>cor = TRUE</code>) or covariance (<code>cor = FALSE</code>) matrix.
center	a logical value or a numeric vector providing the location about which the covariance is to be taken. If <code>center = FALSE</code> , no centering is done; if <code>center = TRUE</code> the MLE of the location vector is used.
nu	'degrees of freedom' for the multivariate t distribution. Must exceed 2 (so that the covariance matrix is finite).
maxit	Maximum number of iterations in fitting.
tol	Convergence tolerance for fitting.

Value

A list with the following components

cov	the fitted covariance matrix.
center	the estimated or specified location vector.
wt	the specified weights: only returned if the <code>wt</code> argument was given.
n.obs	the number of cases used in the fitting.
cor	the fitted correlation matrix: only returned if <code>cor = TRUE</code> .
call	The matched call.
iter	The number of iterations used.

crabs

Morphological Measurements on Leptograpsus Crabs

Description

The `crabs` data frame has 200 rows and 8 columns, describing 5 morphological measurements on 50 crabs each of two colour forms and both sexes, of the species *Leptograpsus variegatus* collected at Fremantle, W. Australia.

Usage

```
crabs
```

Format

This data frame contains the following columns:

sp species - "B" or "O" for blue or orange.

sex as it says.

index index 1 : 50 within each of the four groups.

FL frontal lobe size (mm).

RW rear width (mm).

CL carapace length (mm).

CW carapace width (mm).

BD body depth (mm).

Cushings

Diagnostic Tests on Patients with Cushing's Syndrome

Description

Cushing's syndrome is a hypertensive disorder associated with over-secretion of cortisol by the adrenal gland. The observations are urinary excretion rates of two steroid metabolites.

Usage

```
Cushings
```

Format

The `Cushings` data frame has 27 rows and 3 columns:

Tetrahydrocortisone urinary excretion rate (mg/24hr) of Tetrahydrocortisone.

Pregnanetriol urinary excretion rate (mg/24hr) of Pregnanetriol.

Type underlying type of syndrome, coded a (adenoma) , b (bilateral hyperplasia), c (carcinoma) or u for unknown.

denumerate

Transform an Allowable Formula for 'loglm' into one for 'terms'

Description

`loglm` allows dimension numbers to be used in place of names in the formula. `denumerate` modifies such a formula into one that `terms` can process.

Usage

```
denumerate(x)
```

Arguments

`x` A formula conforming to the conventions of `loglm`, that is, it may allow dimension numbers to stand in for names when specifying a log-linear model.

Details

The model fitting function `loglm` fits log-linear models to frequency data using iterative proportional scaling. To specify the model the user must nominate the margins in the data that remain fixed under the log-linear model. It is convenient to allow the user to use dimension numbers, 1, 2, 3, ... for the first, second, third, ..., margins in a similar way to variable names. As the model formula has to be parsed by `terms`, which treats 1 in a special way and requires parsable variable names, these formulae have to be modified by giving genuine names for these margin, or dimension numbers. `denumerate` replaces these numbers with names of a special form, namely `n` is replaced by `.vn`. This allows `terms` to parse the formula in the usual way.

Value

A linear model formula like that presented, except that where dimension numbers, say `n`, have been used to specify fixed margins these are replaced by names of the form `.vn` which may be processed by `terms`.

dose.p

*Predict Doses for Binomial Assay model***Description**

Calibrate binomial assays, generalizing the calculation of LD50.

Usage

```
dose.p(obj, cf = 1:2, p = 0.5)
```

Arguments

`obj` A fitted model object of class inheriting from "glm".

`cf` The terms in the coefficient vector giving the intercept and coefficient of (log-)dose

`p` Probabilities at which to predict the dose needed.

Value

An object of class "glm.dose" giving the prediction (attribute "p" and standard error (attribute "SE") at each response probability.

References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Springer.

Examples

dropterm

Try All One-Term Deletions from a Model

Description

Try fitting all models that differ from the current model by dropping a single term, maintaining marginality.

This function is generic; there exist methods for classes `lm` and `glm` and the default method will work for many other classes.

Usage

```
dropterm (object, ...)

## Default S3 method:
dropterm(object, scope, scale = 0, test = c("none", "Chisq"),
         k = 2, sorted = FALSE, trace = FALSE, ...)

## S3 method for class 'lm':
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
         k = 2, sorted = FALSE, ...)

## S3 method for class 'glm':
dropterm(object, scope, scale = 0, test = c("none", "Chisq", "F"),
         k = 2, sorted = FALSE, trace = FALSE, ...)
```

Arguments

<code>object</code>	A object fitted by some model-fitting function.
<code>scope</code>	a formula giving terms which might be dropped. By default, the model formula. Only terms that can be dropped and maintain marginality are actually tried.
<code>scale</code>	used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> , <code>aoV</code> and <code>glm</code> models. Specifying <code>scale</code> asserts that the residual standard error or dispersion is known.
<code>test</code>	should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>aoV</code> models, and perhaps for some over-dispersed <code>glm</code> models. The Chisq test can be an exact test (<code>lm</code> models with known scale) or a likelihood-ratio test depending on the method.
<code>k</code>	the multiple of the number of degrees of freedom used for the penalty. Only <code>k = 2</code> gives the genuine AIC: <code>k = log(n)</code> is sometimes referred to as BIC or SBC.

sorted	should the results be sorted on the value of AIC?
trace	if TRUE additional information may be given on the fits as they are tried.
...	arguments passed to or from other methods.

Details

The definition of AIC is only up to an additive constant: when appropriate (lm models with specified scale) the constant is taken to be that used in Mallows' Cp statistic and the results are labelled accordingly.

Value

A table of class "anova" containing at least columns for the change in degrees of freedom and AIC (or Cp) for the models. Some methods will give further information, for example sums of squares, deviances, log-likelihoods and test statistics.

epil

Seizure Counts for Epileptics

Description

Thall and Vail (1990) give a data set on two-week seizure counts for 59 epileptics. The number of seizures was recorded for a baseline period of 8 weeks, and then patients were randomly assigned to a treatment group or a control group. Counts were then recorded for four successive two-week periods. The subject's age is the only covariate.

Usage

epil

Format

This data frame has 236 rows and the following 9 columns:

y the count for the 2-week period.
trt treatment, "placebo" or "progabide".
base the counts in the baseline 8-week period.
age subject's age, in years.
V4 0/1 indicator variable of period 4.
subject subject number, 1 to 59.
period period, 1 to 4.
lbase log-counts for the baseline period, centred to have zero mean.
lage log-ages, centred to have zero mean.

```

`eqsplot`*Plots with Geometrically Equal Scales*

Description

Version of a scatterplot with scales chosen to be equal on both axes, that is 1cm represents the same units on each

Usage

```
eqsplot(x, y, ratio = 1, tol = 0.04, uin, ...)
```

Arguments

<code>x</code>	vector of x values, or a 2-column matrix, or a list with components <code>x</code> and <code>y</code>
<code>y</code>	vector of y values
<code>ratio</code>	desired ratio of units on the axes. Units on the y axis are drawn at <code>ratio</code> times the size of units on the x axis. Ignored if <code>uin</code> is specified and of length 2.
<code>tol</code>	proportion of white space at the margins of plot
<code>uin</code>	desired values for the units-per-inch parameter. If of length 1, the desired units per inch on the x axis.
<code>...</code>	further arguments for <code>plot</code> and graphical parameters. Note that <code>par(xaxs="i", yaxs="i")</code> is enforced, and <code>xlim</code> and <code>ylim</code> will be adjusted accordingly.

Details

Limits for the x and y axes are chosen so that they include the data. One of the sets of limits is then stretched from the midpoint to make the units in the ratio given by `ratio`. Finally both are stretched by $1 + \text{tol}$ to move points away from the axes, and the points plotted.

Value

invisibly, the values of `uin` used for the plot.

Side Effects

performs the plot.

Note

Arguments `ratio` and `uin` were suggested by Bill Dunlap.

farms

Ecological Factors in Farm Management

Description

The `farms` data frame has 20 rows and 4 columns. The rows are farms on the Dutch island of Terschelling and the columns are factors describing the management of grassland.

Usage

```
farms
```

Format

This data frame contains the following columns:

Mois Five levels of soil moisture – level 3 does not occur at these 20 farms.

Manag Grassland management type (SF = standard, BF = biological, HF = hobby farming, NM = nature conservation).

Use Grassland use (U1 = hay production, U2 = intermediate, U3 = grazing).

Manure Manure usage – classes C0 to C4.

Examples

```
farms.mca <- mca(farms, abbrev = TRUE) # Use levels as names
eqscplot(farms.mca$cs, type = "n")
text(farms.mca$rs, cex = 0.7)
text(farms.mca$cs, labels = dimnames(farms.mca$cs)[[1]], cex = 0.7)
```

fgl

*Measurements of Forensic Glass Fragments***Description**

The `fgl` data frame has 214 rows and 10 columns. It was collected by B. German on fragments of glass collected in forensic work.

Usage

```
fgl
```

Format

This data frame contains the following columns:

RI refractive index; more precisely the refractive index is 1.518xxxx.

The next 8 measurements are percentages by weight of oxides.

Na sodium.

Mg manganese.

Al aluminium.

Si silicon.

K potassium.

Ca calcium.

Ba barium.

Fe iron.

type The fragments were originally classed into seven types, one of which was absent in this dataset. The categories which occur are window float glass (`WinF: 70`), window non-float glass (`WinNF: 76`), vehicle window glass (`Veh: 17`), containers (`Con: 13`), tableware (`Tabl: 9`) and vehicle headlamps (`Head: 29`).

fitdistr

*Maximum-likelihood Fitting of Univariate Distributions***Description**

Maximum-likelihood fitting of univariate distributions, allowing parameters to be held fixed if desired.

Usage

```
fitdistr(x, densfun, start, ...)
```

Arguments

<code>x</code>	A numeric vector.
<code>densfun</code>	Either a character string or a function returning a density evaluated at its first argument. Distributions "beta", "cauchy", "chi-squared", "exponential", "f", "gamma", "geometric", "log-normal", "lognormal", "logistic", "negative binomial", "normal", "Poisson", "t" and "weibull" are recognised, case being ignored.
<code>start</code>	A named list giving the parameters to be optimized with initial values. This can be omitted for some of the named distributions and must be for others (see Details).
<code>...</code>	Additional parameters, either for <code>densfun</code> or for <code>optim</code> . In particular, it can be used to specify bounds via <code>lower</code> or <code>upper</code> or both. If arguments of <code>densfun</code> (or the density function corresponding to a character-string specification) are included they will be held fixed.

Details

For the Normal, log-Normal, exponential and Poisson distributions the closed-form MLEs (and exact standard errors) are used, and `start` should not be supplied.

For all other distributions, direct optimization of the log-likelihood is performed using `optim`. The estimated standard errors are taken from the observed information matrix, calculated by a numerical approximation. For one-dimensional problems the Nelder-Mead method is used and for multi-dimensional problems the BFGS method, unless arguments named `lower` or `upper` are supplied when `L-BFGS-B` is used or `method` is supplied explicitly.

For the "t" named distribution the density is taken to be the location-scale family with location `m` and scale `s`.

For the following named distributions, reasonable starting values will be computed if `start` is omitted or only partially specified: "cauchy", "gamma", "logistic", "negative binomial" (parametrized by `mu` and `size`), "t" and "weibull". Note that these starting values may not be good enough if the fit is poor: in particular they are not resistant to outliers unless the fitted distribution is long-tailed.

There are `print`, `coef` and `logLik` methods for class "fitdistr".

Value

An object of class "fitdistr", a list with three components,

<code>estimate</code>	the parameter estimates,
<code>sd</code>	the estimated standard errors, and
<code>loglik</code>	the log-likelihood.

Examples

```

set.seed(123)
x <- rgamma(100, shape = 5, rate = 0.1)
fitdistr(x, "gamma")
## now do this directly with more control.
fitdistr(x, dgamma, list(shape = 1, rate = 0.1), lower = 0.01)

set.seed(123)
x2 <- rt(250, df = 9)
fitdistr(x2, "t", df = 9)
## allow df to vary: not a very good idea!
fitdistr(x2, "t")
## now do fixed-df fit directly with more control.
mydt <- function(x, m, s, df) dt((x-m)/s, df)/s
fitdistr(x2, mydt, list(m = 0, s = 1), df = 9, lower = c(-Inf, 0))

set.seed(123)
x3 <- rweibull(100, shape = 4, scale = 100)
fitdistr(x3, "weibull")

set.seed(123)
x4 <- rnegbin(500, mu = 5, theta = 4)
fitdistr(x4, "Negative Binomial") # R only

```

forbes

Forbes' Data on Boiling Points in the Alps

Description

A data frame with 17 observations on boiling point of water and barometric pressure in inches of mercury.

Usage

```
forbes
```

Format

bp boiling point (degrees Farenheit).
pres barometric pressure in inches of mercury.

Source

S. Weisberg (1980) *Applied Linear Regression*. Wiley.

fractions

*Rational Approximation***Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage

```
fractions(x, cycles = 10, max.denominator = 2000, ...)
```

Arguments

`x` Any object of mode numeric. Missing values are now allowed.

`cycles` The maximum number of steps to be used in the continued fraction approximation process.

`max.denominator` An early termination criterion. If any partial denominator exceeds `max.denominator` the continued fraction stops at that point.

`...` arguments passed to or from other methods.

Details

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1/(p_1 + 1/(p_2 + \dots))$$

where p_1, p_2, \dots are positive integers, terminating either at `cycles` terms or when a $p_j > \text{max.denominator}$. The continued fraction is then re-arranged to retrieve the numerator and denominator as integers.

The numerators and denominators are then combined into a character vector that becomes the "fracs" attribute and used in printed representations.

Arithmetic operations on "fractions" objects have full floating point accuracy, but the character representation printed out may not.

Value

An object of class "fractions". A structure with `.Data` component the same as the input numeric `x`, but with the rational approximations held as a character vector attribute, "fracs". Arithmetic operations on "fractions" objects are possible.

GAGurine

*Level of GAG in Urine of Children***Description**

Data were collected on the concentration of a chemical GAG in the urine of 314 children aged from zero to seventeen years. The aim of the study was to produce a chart to help a paediatrician to assess if a child's GAG concentration is 'normal'.

Usage

GAGurine

Format

This data frame contains the following columns:

Age age of child in years.

GAG concentration of GAG (the units have been lost).

Source

Mrs Susan Prosser, Paediatrics Department, University of Oxford, via Department of Statistics Consulting Service.

References

galaxies

*Velocities for 82 Galaxies***Description**

A numeric vector of velocities in km/sec of 82 galaxies from 6 well-separated conic sections of an unfilled survey of the Corona Borealis region. Multimodality in such surveys is evidence for voids and superclusters in the far universe.

Usage

galaxies

Note

There is an 83rd measurement of 5607 km/sec in the Postman *et al.* paper which is omitted in Roeder (1990) and from the dataset here.

There is also a typo: this dataset has 78th observation 26690 which should be 26960.

lines(density(gal, width = 2.56, n = 200), lty = 3)
```

gamma.dispersion

*Calculate the MLE of the Gamma Dispersion Parameter in a GLM Fit***Description**

A front end to `gamma.shape` for convenience. Finds the reciprocal of the estimate of the shape parameter only.

Usage

```
gamma.dispersion(object, ...)
```

Arguments

```
object      Fitted model object giving the gamma fit.
...         Additional arguments passed on to gamma.shape.
```

Value

The MLE of the dispersion parameter of the gamma distribution.

References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

See Also

[gamma.shape.glm](#), including the example on its help page.

gamma.shape	<i>Estimate the Shape Parameter of the Gamma Distribution in a GLM Fit</i>
-------------	--

Description

Find the maximum likelihood estimate of the shape parameter of the gamma distribution after fitting a Gamma generalized linear model.

Usage

```
## S3 method for class 'glm':
gamma.shape(object, it.lim = 10,
            eps.max = .Machine$double.eps^0.25, verbose = FALSE, ...)
```

Arguments

```
object      Fitted model object from a Gamma family or quasi family with variance
            = "mu^2".
it.lim      Upper limit on the number of iterations.
eps.max     Maximum discrepancy between approximations for the iteration process to con-
            tinue.
verbose     If TRUE, causes successive iterations to be printed out. The initial estimate is
            taken from the deviance.
...         further arguments passed to or from other methods.
```

Details

A glm fit for a Gamma family correctly calculates the maximum likelihood estimate of the mean parameters but provides only a crude estimate of the dispersion parameter. This function takes the results of the glm fit and solves the maximum likelihood equation for the reciprocal of the dispersion parameter, which is usually called the shape (or exponent) parameter.

Value

List of two components

alpha	the maximum likelihood estimate
SE	the approximate standard error, the square-root of the reciprocal of the observed information.

genotype

Rat Genotype Data

Description

Data from a foster feeding experiment with rat mothers and litters of four different genotypes: A, B, I and J. Rat litters were separated from their natural mothers at birth and given to foster mothers to rear.

Usage

genotype

Format

The data frame has the following components:

Litter genotype of the litter.

Mother genotype of the foster mother.

Wt Litter average weight gain of the litter, in grams at age 28 days. (The source states that the within-litter variability is negligible.)

geyser

Old Faithful Geysers Data

Description

A version of the eruptions data from the 'Old Faithful' geyser in Yellowstone National Park, Wyoming. This version comes from Azzalini and Bowman (1990) and is of continuous measurement from August 1 to August 15, 1985.

Some nocturnal duration measurements were coded as 2, 3 or 4 minutes, having originally been described as 'short', 'medium' or 'long'.

Usage

geyser

Format

A data frame with 299 observations on 2 variables.

duration	numeric	Eruption time in mins
waiting	numeric	Waiting time to next eruption

References

gilgais

Line Transect of Soil in Gilgai Territory

Description

This dataset was collected on a line transect survey in gilgai territory in New South Wales, Australia. Gilgais are natural gentle depressions in otherwise flat land, and sometimes seem to be regularly distributed. The data collection was stimulated by the question: are these patterns reflected in soil properties? At each of 365 sampling locations on a linear grid of 4 meters spacing, samples were taken at depths 0-10 cm, 30-40 cm and 80-90 cm below the surface. pH, electrical conductivity and chloride content were measured on a 1:5 soil:water extract from each sample.

Usage

gilgais

Format

This data frame contains the following columns:

pH00 pH at depth 0–10 cm.

pH30 pH at depth 30–40 cm.

pH80 pH at depth 80–90 cm.

e00 electrical conductivity in mS/cm (0–10 cm).

e30 electrical conductivity in mS/cm (30–40 cm).

e80 electrical conductivity in mS/cm (80–90 cm).

c00 chloride content in ppm (0–10 cm).

c30 chloride content in ppm (30–40 cm).

c80 chloride content in ppm (80–90 cm).

```

`glm.convert`*Change a Negative Binomial fit to a GLM fit*

Description

This function modifies an output object from `glm.nb()` to one that looks like the output from `glm()` with a negative binomial family. This allows it to be updated keeping the theta parameter fixed.

Usage

```
glm.convert(object)
```

Arguments

`object` An object of class "negbin", typically the output from `glm.nb()`.

Details

Convenience function needed to effect some low level changes to the structure of the fitted model object.

Value

An object of class "glm" with negative binomial family. The theta parameter is then fixed at its present estimate.

See Also

[glm.nb](#), [negative.binomial](#), [glm](#)

Examples

```
quine.nb1 <- glm.nb(Days ~ Sex/(Age + Eth*Lrn), data = quine)
quine.nbA <- glm.convert(quine.nb1)
quine.nbB <- update(quine.nb1, . ~ . + Sex:Age:Lrn)
anova(quine.nbA, quine.nbB)
```

`glm.nb`*Fit a Negative Binomial Generalized Linear Model*

Description

A modification of the system function `glm()` to include estimation of the additional parameter, `theta`, for a Negative Binomial generalized linear model.

Usage

```
glm.nb(formula, data, weights, subset, na.action,
       start = NULL, etastart, mustart,
       control = glm.control(...), method = "glm.fit",
       model = TRUE, x = FALSE, y = TRUE, contrasts = NULL, ...,
       init.theta, link = log)
```

Arguments

`formula`, `data`, `weights`, `subset`, `na.action`, `start`, `etastart`, `mustart`, `control`, `method`, `model`, `x`, `y`, `contrasts`, `...`, `init.theta`, `link`

arguments for the `glm()` function. Note that these exclude family and offset (but `offset()` can be used).

`init.theta` Optional initial value for the theta parameter. If omitted a moment estimator after an initial fit using a Poisson GLM is used.

`link` The link function. Currently must be one of `log`, `sqrt` or `identity`.

Details

An alternating iteration process is used. For given `theta` the GLM is fitted using the same process as used by `glm()`. For fixed means the `theta` parameter is estimated using score and information iterations. The two are alternated until convergence of both. (The number of alternations and the number of iterations when estimating `theta` are controlled by the `maxit` parameter of `glm.control()`.)

Setting `trace > 0` traces the alternating iteration process. Setting `trace > 1` traces the `glm` fit, and setting `trace > 2` traces the estimation of `theta`.

Value

A fitted model object of class `negbin` inheriting from `glm` and `lm`. The object is like the output of `glm` but contains three additional components, namely `theta` for the ML estimate of `theta`, `SE.theta` for its approximate standard error (using observed rather than expected information), and `twologlik` for twice the log-likelihood function.

anova(quine.nb1, quine.nb2, quine.nb3)
```

 glmmPQL

Fit Generalized Linear Mixed Models via PQL

Description

Fit a GLMM model with multivariate normal random effects, using Penalized Quasi-Likelihood.

Usage

```
glmmPQL(fixed, random, family, data, correlation, weights,
        control, niter = 10, verbose = TRUE, ...)
```

Arguments

<code>fixed</code>	a two-sided linear formula giving fixed-effects part of the model.
<code>random</code>	a formula or list of formulae describing the random effects.
<code>family</code>	a GLM family.
<code>data</code>	an optional data frame used as the first place to find variables in the formulae.
<code>correlation</code>	an optional correlation structure.
<code>weights</code>	optional case weights as in <code>glm</code> .
<code>control</code>	an optional argument to be passed to <code>lme</code> .
<code>niter</code>	maximum number of iterations.
<code>verbose</code>	logical: print out record of iterations?
<code>...</code>	Further arguments for <code>lme</code> .

Details

`glmmPQL` works by repeated calls to `lme`, so package `nlme` will be loaded at first use if necessary.

Value

A object of class "lme": see `lmeObject`.

 hills

Record Times in Scottish Hill Races

Description

The record times in 1984 for 35 Scottish hill races.

Usage

```
hills
```

Format

The components are:

dist distance in miles (on the map).

climb total height gained during the route, in feet.

time record time in minutes.

 hist.scott

Plot a Histogram with Automatic Bin Width Selection

Description

Plot a histogram with automatic bin width selection, using the Scott or Freedman–Diaconis formulae.

Usage

```
hist.scott(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
hist.FD(x, prob = TRUE, xlab = deparse(substitute(x)), ...)
```

Arguments

`x` A data vector
`prob` Should the plot have unit area, so be a density estimate?
`xlab, ...` Further arguments to `hist`.

Value

For the `nclass.*` functions, the suggested number of classes.

Side Effects

Plot a histogram.

housing

Frequency Table from a Copenhagen Housing Conditions Survey

Description

The housing data frame has 72 rows and 5 variables.

Usage

```
housing
```

Format

Sat Satisfaction of householders with their present housing circumstances, (High, Medium or Low, ordered factor).

Infl Perceived degree of influence householders have on the management of the property (High, Medium, Low).

Type Type of rental accommodation, (Tower, Atrium, Apartment, Terrace).

Cont Contact residents are afforded with other residents, (Low, High).

Freq Frequencies: the numbers of residents in each class.

immer

Yields from a Barley Field Trial

Description

The `immer` data frame has 30 rows and 4 columns. Five varieties of barley were grown in six locations in each of 1931 and 1932.

Usage

```
immer
```

Format

This data frame contains the following columns:

Loc The location.

Var The variety of barley ("manchuria", "svansota", "velvet", "trebi" and "peatland").

Y1 Yield in 1931.

Y2 Yield in 1932.

```

 Insurance

Numbers of Car Insurance claims

Description

The data given in data frame `Insurance` consist of the numbers of policyholders of an insurance company who were exposed to risk, and the numbers of car insurance claims made by those policyholders in the third quarter of 1973.

Usage

```
Insurance
```

Format

This data frame contains the following columns:

District district of policyholder (1 to 4): 4 is major cities.

Group group of car (1 to 4), <1 litre, 1–1.5 litre, 1.5–2 litre, >2 litre.

Age of driver in 4 ordered groups, <25, 25–29, 30–35, >35.

Holders numbers of policyholders.

Claims numbers of claims

## main-effects fit as Poisson GLM with offset
glm(Claims ~ District + Group + Age + offset(log(Holders)),
     data = Insurance, family = poisson)

# same via loglm
loglm(Claims ~ District + Group + Age + offset(log(Holders)),
      data = Insurance)
```

isoMDS

*Kruskal's Non-metric Multidimensional Scaling***Description**

One form of non-metric multidimensional scaling

Usage

```
isoMDS(d, y = cmdscale(d, k), k = 2, maxit = 50, trace = TRUE,
      tol = 1e-3, p = 2)
```

```
Shepard(d, x, p = 2)
```

Arguments

d	distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. Both missing and infinite values are allowed.
y	An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution, unless there are missing or infinite dissimilarities.
k	The desired dimension for the solution, passed to <code>cmdscale</code> .
maxit	The maximum number of iterations.
trace	Logical for tracing optimization. Default <code>TRUE</code> .
tol	convergence tolerance.
p	Power for Minkowski distance in the configuration space.
x	A final configuration.

Details

This chooses a k -dimensional (default $k = 2$) configuration to minimize the stress, the square root of the ratio of the sum of squared differences between the input distances and those of the configuration to the sum of configuration distances squared. However, the input distances are allowed a monotonic transformation.

An iterative algorithm is used, which will usually converge in around 10 iterations. As this is necessarily an $O(n^2)$ calculation, it is slow for large datasets. Further, since for the default $p = 2$ the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine.

Value

Two components:

points	A k -column vector of the fitted configuration.
stress	The final stress achieved (in percent).

Side Effects

If `trace` is true, the initial stress and the current stress are printed out every 5 iterations.

kde2d

Two-Dimensional Kernel Density Estimation

Description

Two-dimensional kernel density estimation with an axis-aligned bivariate normal kernel, evaluated on a square grid.

Usage

```
kde2d(x, y, h, n = 25, lims = c(range(x), range(y)))
```

Arguments

x	x coordinate of data
y	y coordinate of data
h	vector of bandwidths for x and y directions. Defaults to normal reference bandwidth (see bandwidth.nrd).
n	Number of grid points in each direction.
lims	The limits of the rectangle covered by the grid as <code>c(xl, xu, yl, yu)</code> .

Value

A list of three components.

x, y	The x and y coordinates of the grid points, vectors of length n.
z	An n x n matrix of the evaluated density.

detach("geyser")

```

lda

Linear Discriminant Analysis

Description

Linear discriminant analysis.

Usage

```

lda(x, ...)

## S3 method for class 'formula':
lda(formula, data, ..., subset, na.action)

## Default S3 method:
lda(x, grouping, prior = proportions, tol = 1.0e-4,
    method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame':
lda(x, ...)

## S3 method for class 'matrix':
lda(x, grouping, ..., subset, na.action)

```

Arguments

<code>formula</code>	A formula of the form <code>groups ~ x1 + x2 + ...</code> . That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
<code>data</code>	Data frame from which variables specified in <code>formula</code> are preferentially to be taken.
<code>x</code>	(required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
<code>grouping</code>	(required if no formula principal argument is given.) a factor specifying the class for each observation.
<code>prior</code>	the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If present, the probabilities should be specified in the order of the factor levels.
<code>tol</code>	A tolerance to decide if a matrix is singular; it will reject variables and linear combinations of unit-variance variables whose variance is less than <code>tol^2</code> .
<code>subset</code>	An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
<code>na.action</code>	A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
<code>method</code>	"moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a <i>t</i> distribution.
<code>CV</code>	If true, returns results (classes and posterior probabilities) for leave-one-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
<code>nu</code>	degrees of freedom for <code>method = "t"</code> .
<code>...</code>	arguments passed to or from other methods.

Details

The function tries hard to detect if the within-class covariance matrix is singular. If any variable has within-group variance less than `tol^2` it will stop and report the variable as constant. This could result from poor scaling of the problem, but is more likely to result from constant variables.

Specifying the `prior` will affect the classification unless over-ridden in `predict.lda`. Unlike in most statistical packages, it will also affect the rotation of the linear discriminants within their space, as a weighted between-groups covariance matrix is used. Thus the first few linear discriminants emphasize the differences between groups with the weights given by the prior, which may differ from their prevalence in the dataset.

If one or more groups is missing in the supplied data, they are dropped with a warning, but the classifications produced are with respect to the original set of levels.

Value

If `CV = TRUE` the return value is a list with components `class`, the MAP classification (a factor), and `posterior`, posterior probabilities for the classes.

Otherwise it is an object of class "lda" containing the following components:

`prior` the prior probabilities used.

means	the group means.
scaling	a matrix which transforms observations to discriminant functions, normalized so that within groups covariance matrix is spherical.
svd	the singular values, which give the ratio of the between- and within-group standard deviations on the linear discriminant variables. Their squares are the canonical F-statistics.
N	The number of observations used.
call	The (matched) function call.

Note

This function may be called giving either a formula and optional data frame, or a matrix and grouping factor as the first two arguments. All other arguments are optional, but `subset=` and `na.action=`, if required, must be fully named.

If a formula is given as the principal argument the object may be modified using `update()` in the usual way.

## [61] v v v v v v v v v v v v v v v
(z1 <- update(z, . ~ . - Petal.W.))
```

Description

Plot histograms or density plots of data on a single Fisher linear discriminant.

Usage

```
ldahist(data, g, nbins = 25, h, x0 = - h/1000, breaks,
        xlim = range(breaks), ymax = 0, width,
        type = c("histogram", "density", "both"),
        sep = (type != "density"),
        col = 5, xlab = deparse(substitute(data)), bty = "n", ...)
```

Arguments

data	vector of data. Missing values (NAs) are allowed and omitted.
g	factor or vector giving groups, of the same length as data.
nbins	Suggested number of bins to cover the whole range of the data.
h	The bin width (takes precedence over nbins).
x0	Shift for the bins - the breaks are at $x0 + h * (... , -1, 0, 1, ...)$
breaks	The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).
xlim	The limits for the x-axis.
ymax	The upper limit for the y-axis.
width	Bandwidth for density estimates. If missing, the Sheather-Jones selector is used for each group separately.
type	Type of plot.
sep	Whether there is a separate plot for each group, or one combined plot.
col	The colour number for the bar fill.
xlab	label for the plot x-axis. By default, this will be the name of data.
bty	The box type for the plot - defaults to none.
...	additional arguments to polygon.

Side Effects

Histogram and/or density plots are plotted on the current device.

leuk

Survival Times and White Blood Counts for Leukaemia Patients

Description

A data frame of data from 33 leukaemia patients.

Usage

leuk

Format

A data frame with columns:

wbc white blood count.

ag a test result, "present" or "absent".

time survival time in weeks.

Details

Survival times are given for 33 patients who died from acute myelogenous leukaemia. Also measured was the patient's white blood cell count at the time of diagnosis. The patients were also factored into 2 groups according to the presence or absence of a morphologic characteristic of white blood cells. Patients termed AG positive were identified by the presence of Auer rods and/or significant granulation of the leukaemic cells in the bone marrow at the time of diagnosis.

Examples

```
library(survival)
plot(survfit(Surv(time) ~ ag, data = leuk), lty = 2:3, col = 2:3)

# now Cox models
leuk.cox <- coxph(Surv(time) ~ ag + log(wbc), leuk)
summary(leuk.cox)
```

lm.gls

*Fit Linear Models by Generalized Least Squares***Description**

Fit linear models by Generalized Least Squares

Usage

```
lm.gls(formula, data, W, subset, na.action, inverse = FALSE,
        method = "qr", model = FALSE, x = FALSE, y = FALSE,
        contrasts = NULL, ...)
```

Arguments

formula	a formula expression as for regression models, of the form <code>response ~ predictors</code> . See the documentation of <code>formula</code> for other details.
data	an optional data frame in which to interpret the variables occurring in <code>formula</code> .
W	a weight matrix.
subset	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
na.action	a function to filter missing data.
inverse	logical: if true <code>W</code> specifies the inverse of the weight matrix: this is appropriate if a variance matrix is used.
method	method to be used by <code>lm.fit</code> .
model	should the model frame be returned?
x	should the design matrix be returned?
y	should the response be returned?
contrasts	a list of contrasts to be used for some or all of
...	additional arguments to <code>lm.fit</code> .

Details

The problem is transformed to uncorrelated form and passed to `lm.fit`.

Value

An object of class `"lm.gls"`, which is similar to an `"lm"` object. There is no `"weights"` component, and only a few `"lm"` methods will work correctly. As from version 7.1-22 the residuals and fitted values refer to the untransformed problem.

See Also

`gls`, `lm`, `lm.ridge`

lm.ridge	<i>Ridge Regression</i>
----------	-------------------------

Description

Fit a linear model by ridge regression.

Usage

```
lm.ridge(formula, data, subset, na.action, lambda = 0, model = FALSE,
         x = FALSE, y = FALSE, contrasts = NULL, ...)
```

Arguments

formula	a formula expression as for regression models, of the form <code>response ~ predictors</code> . See the documentation of <code>formula</code> for other details. offset terms are allowed.
data	an optional data frame in which to interpret the variables occurring in <code>formula</code> .
subset	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
na.action	a function to filter missing data.
lambda	A scalar or vector of ridge constants.
model	should the model frame be returned?
x	should the design matrix be returned?
y	should the response be returned?
contrasts	a list of contrasts to be used for some or all of factor terms in the formula. See the <code>contrasts.arg</code> of model.matrix.default .
...	additional arguments to lm.fit .

Details

If an intercept is present in the model, its coefficient is not penalized. (If you want to penalized an intercept, put in your own constant term and remove the intercept.)

Value

A list with components

coef	matrix of coefficients, one row for each value of <code>lambda</code> . Note that these are not on the original scale and are for use by the <code>coef</code> method.
scales	scalings used on the X matrix.
Inter	was intercept included?
lambda	vector of <code>lambda</code> values
ym	mean of <code>y</code>
xm	column means of <code>x</code> matrix
GCV	vector of GCV values
kHKB	HKB estimate of the ridge constant.
kLW	L-W estimate of the ridge constant.

```

loglm

Fit Log-Linear Models by Iterative Proportional Scaling

Description

This function provides a front-end to the standard function, `loglin`, to allow log-linear models to be specified and fitted in a manner similar to that of other fitting functions, such as `glm`.

Usage

```
loglm(formula, data, subset, na.action, ...)
```

Arguments

<code>formula</code>	A linear model formula specifying the log-linear model. If the left-hand side is empty, the <code>data</code> argument is required and must be a (complete) array of frequencies. In this case the variables on the right-hand side may be the names of the <code>dimnames</code> attribute of the frequency array, or may be the positive integers: 1, 2, 3, ... used as alternative names for the 1st, 2nd, 3rd, ... dimension (classifying factor). If the left-hand side is not empty it specifies a vector of frequencies. In this case the <code>data</code> argument, if present, must be a data frame from which the left-hand side vector and the classifying factors on the right-hand side are (preferentially) obtained. The usual abbreviation of a <code>.</code> to stand for 'all other variables in the data frame' is allowed. Any non-factors on the right-hand side of the formula are coerced to factor.
<code>data</code>	Numeric array or data frame. In the first case it specifies the array of frequencies; in the second it provides the data frame from which the variables occurring in the formula are preferentially obtained in the usual way. This argument may be the result of a call to xtabs .
<code>subset</code>	Specifies a subset of the rows in the data frame to be used. The default is to take all rows.
<code>na.action</code>	Specifies a method for handling missing observations. The default is to fail if missing values are present.
<code>...</code>	May supply other arguments to the function loglm1 .

Details

If the left-hand side of the formula is empty the `data` argument supplies the frequency array and the right-hand side of the formula is used to construct the list of fixed faces as required by `loglin`. Structural zeros may be specified by giving a `start` argument with those entries set to zero, as described in the help information for `loglin`.

If the left-hand side is not empty, all variables on the right-hand side are regarded as classifying factors and an array of frequencies is constructed. If some cells in the complete array are not specified they are treated as structural zeros. The right-hand side of the formula is again used to construct the list of faces on which the observed and fitted totals must agree, as required by `loglin`. Hence terms such as `a:b`, `a*b` and `a/b` are all equivalent.

Value

An object of class "loglm" conveying the results of the fitted log-linear model. Methods exist for the generic functions `print`, `summary`, `deviance`, `fitted`, `coef`, `resid`, `anova` and `update`, which perform the expected tasks. Only log-likelihood ratio tests are allowed using `anova`.

The deviance is simply an alternative name for the log-likelihood ratio statistic for testing the current model within a saturated model, in accordance with standard usage in generalized linear models.

Warning

If structural zeros are present, the calculation of degrees of freedom may not be correct. `loglin` itself takes no action to allow for structural zeros. `loglm` deducts one degree of freedom for each structural zero, but cannot make allowance for gains in error degrees of freedom due to loss of dimension in the model space. (This would require checking the rank of the model matrix, but since iterative proportional scaling methods are developed largely to avoid constructing the model matrix explicitly, the computation is at least difficult.)

When structural zeros (or zero fitted values) are present the estimated coefficients will not be available due to infinite estimates. The deviances will normally continue to be correct, though.

logtrans

Estimate log Transformation Parameter

Description

Find and optionally plot the marginal (profile) likelihood for alpha for a transformation model of the form $\log(y + \alpha) \sim x_1 + x_2 + \dots$

Usage

```
logtrans(object, ...)

## Default S3 method:
logtrans(object, ..., alpha = seq(0.5, 6, by = 0.25) - min(y),
         plotit = TRUE, interp =, xlab = "alpha",
         ylab = "log Likelihood")

## S3 method for class 'formula':
logtrans(object, data, ...)

## S3 method for class 'lm':
logtrans(object, ...)
```

Arguments

object	Fitted linear model object, or formula defining the untransformed model that is $y \sim x_1 + x_2 + \dots$. The function is generic.
...	If <code>object</code> is a formula, this argument may specify a data frame as for <code>lm</code> .
alpha	Set of values for the transformation parameter, <code>alpha</code> .
plotit	Should plotting be done?
interp	Should the marginal log-likelihood be interpolated with a spline approximation? (Default is <code>TRUE</code> if plotting is to be done and the number of real points is less than 100.)
xlab	as for <code>plot</code> .
ylab	as for <code>plot</code> .
data	optional data argument for <code>lm</code> fit.

Value

List with components `x` (for `alpha`) and `y` (for the marginal log-likelihood values).

Side Effects

A plot of the marginal log-likelihood is produced, if requested, together with an approximate mle and 95% confidence interval.

         alpha = seq(0.75, 6.5, len=20))
```

lqs	<i>Resistant Regression</i>
-----	-----------------------------

Description

Fit a regression to the *good* points in the dataset, thereby achieving a regression estimator with a high breakdown point. `lmsreg` and `ltsreg` are compatibility wrappers.

Usage

```
lqs(x, ...)

## S3 method for class 'formula':
lqs(formula, data, ...,
     method = c("lts", "lqs", "lms", "S", "model.frame"),
     subset, na.action, model = TRUE,
     x.ret = FALSE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
lqs(x, y, intercept = TRUE, method = c("lts", "lqs", "lms", "S"),
     quantile, control = lqs.control(...), k0 = 1.548, seed, ...)

lmsreg(...)
ltsreg(...)
```

Arguments

<code>formula</code>	a formula of the form $y \sim x_1 + x_2 + \dots$
<code>data</code>	data frame from which variables specified in <code>formula</code> are preferentially to be taken.
<code>subset</code>	an index vector specifying the cases to be used in fitting. (NOTE: If given, this argument must be named exactly.)
<code>na.action</code>	function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. Alternatives include <code>na.omit</code> and <code>na.exclude</code> , which lead to omission of cases with missing values on any required variable. (NOTE: If given, this argument must be named exactly.)
<code>model, x.ret, y.ret</code>	logical. If TRUE the model frame, the model matrix and the response are returned, respectively.
<code>contrasts</code>	an optional list. See the <code>contrasts.arg</code> of <code>model.matrix.default</code> .
<code>x</code>	a matrix or data frame containing the explanatory variables.
<code>y</code>	the response: a vector of length the number of rows of <code>x</code> .
<code>intercept</code>	should the model include an intercept?
<code>method</code>	the method to be used. <code>model.frame</code> returns the model frame: for the others see the <i>Details</i> section. Using <code>lmsreg</code> or <code>ltsreg</code> forces "lms" and "lts" respectively.
<code>quantile</code>	the quantile to be used: see <i>Details</i> . This is over-ridden if <code>method = "lms"</code> .

<code>control</code>	additional control items: see <code>Details</code> .
<code>k0</code>	the cutoff / tuning constant used for $\chi()$ and $\psi()$ functions when <code>method = "S"</code> , currently corresponding to Tukey's 'biweight'.
<code>seed</code>	the seed to be used for random sampling: see <code>.Random.seed</code> . The current value of <code>.Random.seed</code> will be preserved if it is set..
<code>...</code>	arguments to be passed to <code>lqs.default</code> or <code>lqs.control</code> , see <code>control</code> above and <code>Details</code> .

Details

Suppose there are n data points and p regressors, including any intercept.

The first three methods minimize some function of the sorted squared residuals. For methods "lqs" and "lms" is the quantile squared residual, and for "lts" it is the sum of the quantile smallest squared residuals. "lqs" and "lms" differ in the defaults for `quantile`, which are `floor((n+p+1)/2)` and `floor((n+1)/2)` respectively. For "lts" the default is `floor(n/2) + floor((p+1)/2)`.

The "S" estimation method solves for the scale s such that the average of a function χ of the residuals divided by s is equal to a given constant.

The `control` argument is a list with components

psamp: the size of each sample. Defaults to p .

nsamp: the number of samples or "best" (the default) or "exact" or "sample". If "sample" the number chosen is `min(5*p, 3000)`, taken from Rousseeuw and Hubert (1997). If "best" exhaustive enumeration is done up to 5000 samples; if "exact" exhaustive enumeration will be attempted however many samples are needed.

adjust: should the intercept be optimized for each sample? Defaults to `TRUE`.

Value

An object of class "lqs". This is a list with components

<code>crit</code>	the value of the criterion for the best solution found, in the case of <code>method == "S"</code> before IWLS refinement.
<code>sing</code>	character. A message about the number of samples which resulted in singular fits.
<code>coefficients</code>	of the fitted linear model
<code>bestone</code>	the indices of those points fitted by the best sample found (prior to adjustment of the intercept, if requested).
<code>fitted.values</code>	the fitted values.
<code>residuals</code>	the residuals.
<code>scale</code>	estimate(s) of the scale of the error. The first is based on the fit criterion. The second (not present for <code>method == "S"</code>) is based on the variance of those residuals whose absolute value is less than 2.5 times the initial estimate.

Note

There seems no reason other than historical to use the `lms` and `lqs` options. LMS estimation is of low efficiency (converging at rate $n^{-1/3}$) whereas LTS has the same asymptotic efficiency as an M estimator with trimming at the quartiles (Marazzi, 1993, p.201). LQS and LTS have the same maximal breakdown value of $(\text{floor}((n-p)/2) + 1)/n$ attained if $\text{floor}((n+p)/2) \leq \text{quantile} \leq \text{floor}((n+p+1)/2)$. The only drawback mentioned of LTS is greater computation, as a sort was thought to be required (Marazzi, 1993, p.201) but this is not true as a partial sort can be used (and is used in this implementation).

Adjusting the intercept for each trial fit does need the residuals to be sorted, and may be significant extra computation if n is large and p small.

Opinions differ over the choice of `psamp`. Rousseeuw and Hubert (1997) only consider p ; Marazzi (1993) recommends $p+1$ and suggests that more samples are better than adjustment for a given computational limit.

The computations are exact for a model with just an intercept and adjustment, and for LQS for a model with an intercept plus one regressor and exhaustive search with adjustment. For all other cases the minimization is only known to be approximate.

 mca

Multiple Correspondence Analysis

Description

Computes a multiple correspondence analysis of a set of factors.

Usage

```
mca(df, nf = 2, abbrev = FALSE)
```

Arguments

df	A data frame containing only factors
nf	The number of dimensions for the MCA. Rarely 3 might be useful.
abbrev	Should the vertex names be abbreviated? By default these are of the form ‘factor.level’ but if <code>abbrev = TRUE</code> they are just ‘level’ which will suffice if the factors have distinct levels.

Value

An object of class "mca", with components

rs	The coordinates of the rows, in <code>nf</code> dimensions.
cs	The coordinates of the column vertices, one for each level of each factor.
fs	Weights for each row, used to interpolate additional factors in <code>predict.mca</code> .
p	The number of factors
d	The singular values for the <code>nf</code> dimensions.
call	The matched call.

 Melanoma

Survival from Malignant Melanoma

Description

The Melanoma data frame has data on 205 patients in Denmark with malignant melanoma.

Usage

Melanoma

Format

This data frame contains the following columns:

time survival time in days, possibly censored.

status 1 died from melanoma, 2 alive, 3 dead from other causes.

sex 1 = male, 0 = female.

age age in years.

year of operation.

thickness tumour thickness in mm.

ulcer 1 = presence, 0 = absence.

 menarche

Age of Menarche in Warsaw

Description

Proportions of female children at various ages during adolescence who have reached menarche.

Usage

menarche

Format

This data frame contains the following columns:

Age Average age of the group. (The groups are reasonably age homogeneous.)

Total Total number of children in the group.

Menarche Number who have reached menarche.

```

 michelson

Michelson's Speed of Light Data

Description

Measurements of the speed of light in air, made between 5th June and 2nd July, 1879. The data consists of five experiments, each consisting of 20 consecutive runs. The response is the speed of light in km/s, less 299000. The currently accepted value, on this scale of measurement, is 734.5.

Usage

```
michelson
```

Format

The data frame contains the following components:

Expt The experiment number, from 1 to 5.

Run The run number within each experiment.

Speed Speed-of-light measurement.

muscle

Effect of Calcium Chloride on Muscle Contraction in Rat Hearts

Description

The purpose of this experiment was to assess the influence of calcium in solution on the contraction of heart muscle in rats. The left auricle of 21 rat hearts was isolated and on several occasions a constant-length strip of tissue was electrically stimulated and dipped into various concentrations of calcium chloride solution, after which the shortening of the strip was accurately measured as the response.

Usage

muscle

Format

This data frame contains the following columns:

Strip which heart muscle strip was used?

Conc concentration of calcium chloride solution, in multiples of 2.2 mM.

Length the change in length (shortening) of the strip, (allegedly) in mm.

    panel.xyplot(x, Muscle$logLength[subscripts], ...)
  })
```

mvrnorm

Simulate from a Multivariate Normal Distribution

Description

Produces one or more samples from the specified multivariate normal distribution.

Usage

```
mvrnorm(n = 1, mu, Sigma, tol = 1e-6, empirical = FALSE)
```

Arguments

<code>n</code>	the number of samples required.
<code>mu</code>	a vector giving the means of the variables.
<code>Sigma</code>	a positive-definite symmetric matrix specifying the covariance matrix of the variables.
<code>tol</code>	tolerance (relative to largest variance) for numerical lack of positive-definiteness in <code>Sigma</code> .
<code>empirical</code>	logical. If true, <code>mu</code> and <code>Sigma</code> specify the empirical not population mean and covariance matrix.

Details

The matrix decomposition is done via `eigen`; although a Choleski decomposition might be faster, the eigendecomposition is stabler.

Value

If `n = 1` a vector of the same length as `mu`, otherwise an `n` by `length(mu)` matrix with one sample in each row.

Side Effects

Causes creation of the dataset `.Random.seed` if it does not already exist, otherwise its value is updated.

negative.binomial *Family function for Negative Binomial GLMs*

Description

Specifies the information required to fit a Negative Binomial generalized linear model, with known `theta` parameter, using `glm()`.

Usage

```
negative.binomial(theta = stop("'theta' must be specified"), link = "log")
```

Arguments

theta	The known value of the additional parameter, <code>theta</code> .
link	The link function, as a character string, name or one-element character vector specifying one of <code>log</code> , <code>sqrt</code> or <code>identity</code> , or an object of class " link-glm ".

Value

An object of class "`family`", a list of functions and expressions needed by `glm()` to fit a Negative Binomial generalized linear model.

newcomb

Newcomb's Measurements of the Passage Time of Light

Description

A numeric vector giving the 'Third Series' of measurements of the passage time of light recorded by Newcomb in 1882. The given values divided by 1000 plus 24 give the time in millionths of a second for light to traverse a known distance. The 'true' value is now considered to be 33.02.

Usage

```
newcomb
```

nlschools

*Eighth-Grade Pupils in the Netherlands***Description**

Snijders and Bosker (1999) use as a running example a study of 2287 eighth-grade pupils (aged about 11) in 132 classes in 131 schools in the Netherlands. Only the variables used in our examples are supplied.

Usage

```
nlschools
```

Format

This data frame contains 2287 rows and the following columns:

lang language test score.

IQ verbal IQ.

class class ID.

GS class size: number of eighth-grade pupils recorded in the class (there may be others: see COMB, and some may have been omitted with missing values).

SES social-economic status of pupil's family.

COMB were the pupils taught in a multi-grade class (0/1)? Classes which contained pupils from grades 7 and 8 are coded 1, but only eighth-graders were tested.

```

npk

Classical N, P, K Factorial Experiment

Description

A classical N, P, K (nitrogen, phosphate, potassium) factorial experiment on the growth of peas conducted on 6 blocks. Each half of a fractional factorial design confounding the NPK interaction was used on 3 of the plots.

Usage

npk

Format

The npk data frame has 24 rows and 5 columns:

block which block (label 1 to 6).

N indicator (0/1) for the application of nitrogen.

P indicator (0/1) for the application of phosphate.

K indicator (0/1) for the application of potassium.

yield Yield of peas, in pounds/plot (the plots were (1/70) acre).

npr1

*US Naval Petroleum Reserve No. 1 data***Description**

Data on the locations, porosity and permeability (a measure of oil flow) on 104 oil wells in the US Naval Petroleum Reserve No. 1 in California.

Usage

npr1

Format

This data frame contains the following columns:

x, **y** x and y coordinates, in miles from an arbitrary origin.

perm permeability in milli-Darcies.

por porosity (%).

Null

*Null Spaces of Matrices***Description**

Given a matrix, M , find a matrix N giving a basis for the null space. That is $(N) \%*\% M$ is the zero and N has the maximum number of linearly independent columns.

Usage

Null(M)

Arguments

M Input matrix. A vector is coerced to a 1-column matrix.

Value

The matrix N with the basis for the null space, or an empty vector if the matrix M is square and of maximal rank.

oats

Data from an Oats Field Trial

Description

The yield of oats from a split-plot field trial using three varieties and four levels of manurial treatment. The experiment was laid out in 6 blocks of 3 main plots, each split into 4 sub-plots. The varieties were applied to the main plots and the manurial treatments to the sub-plots.

Usage

```
oats
```

Format

This data frame contains the following columns:

B Blocks, levels I, II, III, IV, V and VI.

V Varieties, 3 levels.

N Nitrogen (manurial) treatment, levels 0.0cwt, 0.2cwt, 0.4cwt and 0.6cwt, showing the application in cwt/acre.

Y Yields in 1/4lbs per sub-plot, each of area 1/80 acre.

OME

*Tests of Auditory Perception in Children with OME***Description**

Experiments were performed on children on their ability to differentiate a signal in broad-band noise. The noise was played from a pair of speakers and a signal was added to just one channel; the subject had to turn his/her head to the channel with the added signal. The signal was either coherent (the amplitude of the noise was increased for a period) or incoherent (independent noise was added for the same period to form the same increase in power).

The threshold used in the original analysis was the stimulus loudness needs to get 75% correct responses. Some of the children had suffered from otitis media with effusion (OME).

Usage

OME

Format

The OME data frame has 1129 rows and 7 columns:

ID Subject ID (1 to 99, with some IDs missing). A few subjects were measured at different ages.

OME "low" or "high" or "N/A" (at ages other than 30 and 60 months).

Age Age of the subject (months).

Loud Loudness of stimulus, in decibels.

Noise Whether the signal in the stimulus was "coherent" or "incoherent".

Correct Number of correct responses from `Trials` trials.

Trials Number of trials performed.

Background

The experiment was to study otitis media with effusion (OME), a very common childhood condition where the middle ear space, which is normally air-filled, becomes congested by a fluid. There is a concomitant fluctuating, conductive hearing loss which can result in various language, cognitive and social deficits. The term 'binaural hearing' is used to describe the listening conditions in which the brain is processing information from both ears at the same time. The brain computes differences in the intensity and/or timing of signals arriving at each ear which contributes to sound localisation and also to our ability to hear in background noise.

Some years ago, it was found that children of 7–8 years with a history of significant OME had significantly worse binaural hearing than children without such a history, despite having equivalent sensitivity. The question remained as to whether it was the timing, the duration, or the degree of severity of the otitis media episodes during critical periods, which affected later binaural hearing. In an attempt to begin to answer this question, 95 children were monitored for the presence of effusion every month since birth. On the basis of OME experience in their first two years, the test population was split into one group of high OME prevalence and one of low prevalence.

painters

The Painter's Data of de Piles

Description

The subjective assessment, on a 0 to 20 integer scale, of 54 classical painters. The painters were assessed on four characteristics: composition, drawing, colour and expression. The data is due to the Eighteenth century art critic, de Piles.

Usage

```
painters
```

Format

The row names of the data frame are the painters. The components are:

Composition Composition score.

Drawing Drawing score.

Colour Colour score.

Expression Expression score.

School The school to which a painter belongs, as indicated by a factor level code as follows:
 "A": Renaissance; "B": Mannerist; "C": Seicento; "D": Venetian; "E": Lombard; "F":
 Sixteenth Century; "G": Seventeenth Century; "H": French.

`pairs.lda`*Produce Pairwise Scatterplots from an 'lda' Fit*

Description

Pairwise scatterplot of the data on the linear discriminants.

Usage

```
## S3 method for class 'lda':  
pairs(x, labels = colnames(x), panel = panel.lda,  
      dimen, abbrev = FALSE, ..., cex=0.7, type = c("std", "trellis"))
```

Arguments

<code>x</code>	Object of class "lda".
<code>labels</code>	vector of character strings for labelling the variables.
<code>panel</code>	panel function to plot the data in each panel.
<code>dimen</code>	The number of linear discriminants to be used for the plot; if this exceeds the number determined by <code>x</code> the smaller value is used.
<code>abbrev</code>	whether the group labels are abbreviated on the plots. If <code>abbrev > 0</code> this gives <code>minlength</code> in the call to <code>abbreviate</code> .
<code>...</code>	additional arguments for <code>pairs.default</code> .
<code>cex</code>	graphics parameter <code>cex</code> for labels on plots.
<code>type</code>	type of plot. The default is in the style of <code>pairs.default</code> ; the style "trellis" uses the Trellis function <code>splom</code> .

Details

This function is a method for the generic function `pairs()` for class "lda". It can be invoked by calling `pairs(x)` for an object `x` of the appropriate class, or directly by calling `pairs.lda(x)` regardless of the class of the object.

parcoord

Parallel Coordinates Plot

Description

Parallel coordinates plot

Usage

```
parcoord(x, col = 1, lty = 1, var.label = FALSE, ...)
```

Arguments

x	a matrix or data frame whose columns represent variables. Missing values are allowed.
col	A vector of colours, recycled as necessary for each observation.
lty	A vector of line types, recycled as necessary for each observation.
var.label	If TRUE, each variable's axis is labelled with maximum and minimum values.
...	Further graphics parameters which are passed to <code>matplot</code> .

Side Effects

a parallel coordinates plot is drawn.

ir <- rbind(iris3[,1], iris3[,2], iris3[,3])  
parcoord(log(ir)[, c(3, 4, 2, 1)], col = 1 + (0:149)%/%50)
```

 petrol

N. L. Prater's Petrol Refinery Data

Description

The yield of a petroleum refining process with four covariates. The crude oil appears to come from only 10 distinct samples.

These data were originally used by Prater (1956) to build an estimation equation for the yield of the refining process of crude oil to gasoline.

Usage

```
petrol
```

Format

The variables are as follows

No crude oil sample identification label. (Factor.)

SG specific gravity, degrees API. (Constant within sample.)

VP vapour pressure in pounds per square inch. (Constant within sample.)

V10 volatility of crude; ASTM 10% point. (Constant within sample.)

EP desired volatility of gasoline. (The end point. Varies within sample.)

Y yield as a percentage of crude.

Source

N. H. Prater (1956) Estimate gasoline yields from crudes. *Petroleum Refiner* **35**, 236–238.

This dataset is also given in D. J. Hand, F. Daly, K. McConway, D. Lunn and E. Ostrowski (eds) (1994) *A Handbook of Small Data Sets*. Chapman & Hall.

References

Pima.tr

Diabetes in Pima Indian Women

Description

A population of women who were at least 21 years old, of Pima Indian heritage and living near Phoenix, Arizona, was tested for diabetes according to World Health Organization criteria. The data were collected by the US National Institute of Diabetes and Digestive and Kidney Diseases. We used the 532 complete records after dropping the (mainly missing) data on serum insulin.

Usage

Pima.tr
Pima.tr2
Pima.te

Format

These data frames contains the following columns:

npreg number of pregnancies.
glu plasma glucose concentration in an oral glucose tolerance test.
bp diastolic blood pressure (mm Hg).
skin triceps skin fold thickness (mm).
bmi body mass index (weight in kg/(height in m)²).
ped diabetes pedigree function.
age age in years.
type Yes or No, for diabetic according to WHO criteria.

Details

The training set `Pima.tr` contains a randomly selected set of 200 subjects, and `Pima.te` contains the remaining 322 subjects. `Pima.tr2` contains `Pima.tr` plus 100 subjects with missing values in the explanatory variables.

plot.lda

*Plot Method for Class 'lda'***Description**

Plots a set of data on one, two or more linear discriminants.

Usage

```
## S3 method for class 'lda':
plot(x, panel = panel.lda, ..., cex = 0.7, dimen,
      abbrev = FALSE, xlab = "LD1", ylab = "LD2")
```

Arguments

x	An object of class "lda".
panel	the panel function used to plot the data.
...	additional arguments to pairs, ldahist or eqscplot.
cex	graphics parameter cex for labels on plots.
dimen	The number of linear discriminants to be used for the plot; if this exceeds the number determined by x the smaller value is used.
abbrev	whether the group labels are abbreviated on the plots. If abbrev > 0 this gives minlength in the call to abbreviate.
xlab	label for the x axis
ylab	label for the y axis

Details

This function is a method for the generic function `plot()` for class "lda". It can be invoked by calling `plot(x)` for an object `x` of the appropriate class, or directly by calling `plot.lda(x)` regardless of the class of the object.

The behaviour is determined by the value of `dimen`. For `dimen > 2`, a `pairs` plot is used. For `dimen = 2`, an equiscaled scatter plot is drawn. For `dimen = 1`, a set of histograms or density plots are drawn. Use argument `type` to match "histogram" or "density" or "both".

plot.mca	<i>Plot Method for Objects of Class 'mca'</i>
----------	---

Description

Plot a multiple correspondence analysis.

Usage

```
## S3 method for class 'mca':
plot(x, rows = TRUE, col, cex = par("cex"), ...)
```

Arguments

x	An object of class "mca".
rows	Should the coordinates for the rows be plotted, or just the vertices for the levels?
col, cex	The colours and cex to be used for the row points and level vertices respectively.
...	Additional parameters to plot.

References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

See Also

```

plot.profile	<i>Plottig Functions for 'profile' Objects</i>
--------------	--

Description

[plot](#) and [pairs](#) methods for objects of class "profile".

Usage

```
## S3 method for class 'profile':
plot(x, ...)
## S3 method for class 'profile':
pairs(x, colours = 2:3, ...)
```

Arguments

x	an object inheriting from class "profile".
colours	Colours to be used for the mean curves conditional on x and y respectively.
...	arguments passed to or from other methods.

Details

This is the main `plot` method for objects created by `profile.glm`. It can also be called on objects created by `profile.nls`, but they have a specific method, `plot.profile.nls`.

The `pairs` method shows, for each pair of parameters x and y , two curves intersecting at the maximum likelihood estimate, which give the loci of the points at which the tangents to the contours of the bivariate profile likelihood become vertical and horizontal, respectively. In the case of an exactly bivariate normal profile likelihood, these two curves would be straight lines giving the conditional means of $y|x$ and $x|y$, and the contours would be exactly elliptical.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

See Also

`profile.glm`, `profile.nls`.

Examples

```
## see ?profile.glm for an example using glm fits.

## a version of example(profile.nls) from R >= 2.8.0
fm1 <- nls(demand ~ SSasymptOrig(Time, A, lrc), data = BOD)
pr1 <- profile(fm1, alpha = 0.1)
MASS:::plot.profile(pr1)
pairs(pr1) # a little odd since the parameters are highly correlated

## an example from ?nls
x <- -(1:100)/10
y <- 100 + 10 * exp(x / 2) + rnorm(x)/10
nlmod <- nls(y ~ Const + A * exp(B * x), start=list(Const=100, A=10, B=1))
pairs(profile(nlmod))
```

polr

Ordered Logistic or Probit Regression

Description

Fits a logistic or probit regression model to an ordered factor response. The default logistic case is *proportional odds logistic regression*, after which the function is named.

Usage

```
polr(formula, data, weights, start, ..., subset, na.action,
      contrasts = NULL, Hess = FALSE, model = TRUE,
      method = c("logistic", "probit", "cloglog", "cauchit"))
```

Arguments

<code>formula</code>	a formula expression as for regression models, of the form <code>response ~ predictors</code> . The response should be a factor (preferably an ordered factor), which will be interpreted as an ordinal response, with levels ordered as in the factor. The model must have an intercept: attempts to remove one will lead to a warning and be ignored. An offset may be used. See the documentation of <code>formula</code> for other details.
<code>data</code>	an optional data frame in which to interpret the variables occurring in <code>formula</code> .
<code>weights</code>	optional case weights in fitting. Default to 1.
<code>start</code>	initial values for the parameters. This is in the format <code>c(coefficients, zeta)</code> : see the Values section.
<code>...</code>	additional arguments to be passed to <code>optim</code> , most often a <code>control</code> argument.
<code>subset</code>	expression saying which subset of the rows of the data should be used in the fit. All observations are included by default.
<code>na.action</code>	a function to filter missing data.
<code>contrasts</code>	a list of contrasts to be used for some or all of the factors appearing as variables in the model formula.
<code>Hess</code>	logical for whether the Hessian (the observed information matrix) should be returned. Use this if you intend to call <code>summary</code> or <code>vcov</code> on the fit.
<code>model</code>	logical for whether the model matrix should be returned.
<code>method</code>	logistic or probit or complementary log-log or <code>cauchit</code> (corresponding to a Cauchy latent variable).

Details

This model is what Agresti (2002) calls a *cumulative link* model. The basic interpretation is as a *coarsened* version of a latent variable Y_i which has a logistic or normal or extreme-value or Cauchy distribution with scale parameter one and a linear model for the mean. The ordered factor which is observed is which bin Y_i falls into with breakpoints

$$\zeta_0 = -\infty < \zeta_1 < \dots < \zeta_K = \infty$$

This leads to the model

$$\text{logit}P(Y \leq k|x) = \zeta_k - \eta$$

with *logit* replaced by *probit* for a normal latent variable, and η being the linear predictor, a linear function of the explanatory variables (with no intercept). Note that it is quite common for other software to use the opposite sign for η (and hence the coefficients `beta`).

In the logistic case, the left-hand side of the last display is the log odds of category k or less, and since these are log odds which differ only by a constant for different k , the odds are proportional. Hence the term *proportional odds logistic regression*.

In the complementary log-log case, we have a *proportional hazards* model for grouped survival times.

There are methods for the standard model-fitting functions, including `predict`, `summary`, `vcov`, `anova`, `model.frame` and an `extractAIC` method for use with `stepAIC`. There are also `profile` and `confint` methods.

Value

A object of class "polr". This has components

coefficients	the coefficients of the linear predictor, which has no intercept.
zeta	the intercepts for the class boundaries.
deviance	the residual deviance.
fitted.values	a matrix, with a column for each level of the response.
lev	the names of the response levels.
terms	the terms structure describing the model.
df.residual	the number of residual degrees of freedoms, calculated using the weights.
edf	the (effective) number of degrees of freedom used by the model
n, nobs	the (effective) number of observations, calculated using the weights. (nobs is for use by <code>stepAIC</code>).
call	the matched call.
method	the matched method used.
convergence	the convergence code returned by <code>optim</code> .
niter	the number of function and gradient evaluations used by <code>optim</code> .
Hessian	(if <code>Hess</code> is true).
model	(if <code>model</code> is true).

predict.glmmPQL *Predict Method for glmmPQL Fits*

Description

Obtains predictions from a fitted generalized linear model with random effects.

Usage

```
## S3 method for class 'glmmPQL':
predict(object, newdata = NULL, type = c("link", "response"),
        level, na.action = na.pass, ...)
```

Arguments

object	a fitted object of class inheriting from "glmmPQL".
newdata	optionally, a data frame in which to look for variables with which to predict.
type	the type of prediction required. The default is on the scale of the linear predictors; the alternative "response" is on the scale of the response variable. Thus for a default binomial model the default predictions are of log-odds (probabilities on logit scale) and type = "response" gives the predicted probabilities.
level	an optional integer vector giving the level(s) of grouping to be used in obtaining the predictions. Level values increase from outermost to innermost grouping, with level zero corresponding to the population predictions. Defaults to the highest or innermost level of grouping.
na.action	function determining what should be done with missing values in newdata. The default is to predict NA.
...	further arguments passed to or from other methods.

Value

If level is a single integer, a vector otherwise a data frame.

See Also

[glmmPQL](#), [predict.lme](#).

Examples

```
fit <- glmmPQL(y ~ trt + I(week > 2), random = ~1 | ID,
              family = binomial, data = bacteria)
predict(fit, bacteria, level = 0, type="response")
predict(fit, bacteria, level = 1, type="response")
```

predict.lda

*Classify Multivariate Observations by Linear Discrimination***Description**

Classify multivariate observations in conjunction with `lda`, and also project data onto the linear discriminants.

Usage

```
## S3 method for class 'lda':
predict(object, newdata, prior = object$prior, dimen,
        method = c("plug-in", "predictive", "debiased"), ...)
```

Arguments

<code>object</code>	object of class "lda"
<code>newdata</code>	data frame of cases to be classified or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>lda</code> object.
<code>prior</code>	The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to <code>lda</code> .
<code>dimen</code>	the dimension of the space to be used. If this is less than $\min(p, ng-1)$, only the first <code>dimen</code> discriminant components are used (except for <code>method="predictive"</code>), and only those dimensions are returned in <code>x</code> .
<code>method</code>	This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior.
<code>...</code>	arguments based from or to other methods

Details

This function is a method for the generic function `predict()` for class "lda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

This version centres the linear discriminants so that the weighted mean (weighted by `prior`) of the group centroids is at the origin.

Value

a list with components

<code>class</code>	The MAP classification (a factor)
<code>posterior</code>	posterior probabilities for the classes
<code>x</code>	the scores of test cases on up to <code>dimen</code> discriminant variables

predict(z, test)$class
```

predict.lqs

Predict from an lqs Fit

Description

Predict from an resistant regression fitted by lqs.

Usage

```
## S3 method for class 'lqs':
predict(object, newdata, na.action = na.pass, ...)
```

Arguments

object	object inheriting from class "lqs"
newdata	matrix or data frame of cases to be predicted or, if object has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If newdata is missing, an attempt will be made to retrieve the data used to fit the lqs object.
na.action	function determining what should be done with missing values in newdata. The default is to predict NA.
...	arguments to be passed from or to other methods.

Details

This function is a method for the generic function `predict()` for class `lqs`. It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.lqs(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the linear fit cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

Value

A vector of predictions.

fm <- lqs(stack.loss ~ ., data = stackloss, method = "S", nsamp = "exact")
predict(fm, stackloss)
```

predict.mca

Predict Method for Class 'mca'

Description

Used to compute coordinates for additional rows or additional factors in a multiple correspondence analysis.

Usage

```
## S3 method for class 'mca':
predict(object, newdata, type = c("row", "factor"), ...)
```

Arguments

object	An object of class "mca", usually the result of a call to <code>mca</code> .
newdata	A data frame containing <i>either</i> additional rows of the factors used to fit <code>object</code> <i>or</i> additional factors for the cases used in the original fit.
type	Are predictions required for further rows or for new factors?
...	Additional arguments from <code>predict</code> : unused.

Value

If `type = "row"`, the coordinates for the additional rows.

If `type = "factor"`, the coordinates of the column vertices for the levels of the new factors.

References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

predict.qda *Classify from Quadratic Discriminant Analysis*

Description

Classify multivariate observations in conjunction with `qda`

Usage

```
## S3 method for class 'qda':
predict(object, newdata, prior = object$prior,
        method = c("plug-in", "predictive", "debiased", "looCV"), ...)
```

Arguments

<code>object</code>	object of class "qda"
<code>newdata</code>	data frame of cases to be classified or, if <code>object</code> has a formula, a data frame with columns of the same names as the variables used. A vector will be interpreted as a row vector. If <code>newdata</code> is missing, an attempt will be made to retrieve the data used to fit the <code>qda</code> object.
<code>prior</code>	The prior probabilities of the classes, by default the proportions in the training set or what was set in the call to <code>qda</code> .
<code>method</code>	This determines how the parameter estimation is handled. With "plug-in" (the default) the usual unbiased parameter estimates are used and assumed to be correct. With "debiased" an unbiased estimator of the log posterior probabilities is used, and with "predictive" the parameter estimates are integrated out using a vague prior. With "looCV" the leave-one-out cross-validation fits to the original dataset are computed and returned.
<code>...</code>	arguments based from or to other methods

Details

This function is a method for the generic function `predict()` for class "qda". It can be invoked by calling `predict(x)` for an object `x` of the appropriate class, or directly by calling `predict.qda(x)` regardless of the class of the object.

Missing values in `newdata` are handled by returning `NA` if the quadratic discriminants cannot be evaluated. If `newdata` is omitted and the `na.action` of the fit omitted cases, these will be omitted on the prediction.

Value

	a list with components
<code>class</code>	The MAP classification (a factor)
<code>posterior</code>	posterior probabilities for the classes

References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

zq <- qda(train, cl)
predict(zq, test)$class
```

profile.glm

Method for Profiling glm Objects

Description

Investigates the profile log-likelihood function for a fitted model of class "glm".

Usage

```
## S3 method for class 'glm':
profile(fitted, which = 1:p, alpha = 0.01, maxsteps = 10,
       del = zmax/5, trace = FALSE, ...)
```

Arguments

fitted	the original fitted model object.
which	the original model parameters which should be profiled. This can be a numeric or character vector. By default, all parameters are profiled.
alpha	highest significance level allowed for the profile t-statistics.
maxsteps	maximum number of points to be used for profiling each parameter.
del	suggested change on the scale of the profile t-statistics. Default value chosen to allow profiling at about 10 parameter values.
trace	logical: should the progress of profiling be reported?
...	further arguments passed to or from other methods.

Details

The profile t-statistic is defined as the square root of change in sum-of-squares divided by residual standard error with an appropriate sign.

Value

A list of classes "profile.glm" and "profile" with an element for each parameter being profiled. The elements are data-frames with two variables

par.vals	a matrix of parameter values for each fitted model.
tau	the profile t-statistics.

Author(s)

Originally, D. M. Bates and W. N. Venables. (For S in 1996.)

sex <- factor(rep(c("M", "F"), c(6, 6)))
SF <- cbind(numdead, numalive = 20 - numdead)
budworm.lg <- glm(SF ~ sex*ldose, family = binomial)
pr1 <- profile(budworm.lg)
plot(pr1)
pairs(pr1)
```

qda

Quadratic Discriminant Analysis

Description

Quadratic discriminant analysis.

Usage

```
qda(x, ...)

## S3 method for class 'formula':
qda(formula, data, ..., subset, na.action)

## Default S3 method:
qda(x, grouping, prior = proportions,
     method, CV = FALSE, nu, ...)

## S3 method for class 'data.frame':
qda(x, ...)

## S3 method for class 'matrix':
qda(x, grouping, ..., subset, na.action)
```

Arguments

formula	A formula of the form $\text{groups} \sim x_1 + x_2 + \dots$. That is, the response is the grouping factor and the right hand side specifies the (non-factor) discriminators.
data	Data frame from which variables specified in <code>formula</code> are preferentially to be taken.

<code>x</code>	(required if no formula is given as the principal argument.) a matrix or data frame or Matrix containing the explanatory variables.
<code>grouping</code>	(required if no formula principal argument is given.) a factor specifying the class for each observation.
<code>prior</code>	the prior probabilities of class membership. If unspecified, the class proportions for the training set are used. If specified, the probabilities should be specified in the order of the factor levels.
<code>subset</code>	An index vector specifying the cases to be used in the training sample. (NOTE: If given, this argument must be named.)
<code>na.action</code>	A function to specify the action to be taken if NAs are found. The default action is for the procedure to fail. An alternative is <code>na.omit</code> , which leads to rejection of cases with missing values on any required variable. (NOTE: If given, this argument must be named.)
<code>method</code>	"moment" for standard estimators of the mean and variance, "mle" for MLEs, "mve" to use <code>cov.mve</code> , or "t" for robust estimates based on a t distribution.
<code>CV</code>	If true, returns results (classes and posterior probabilities) for leave-out-out cross-validation. Note that if the prior is estimated, the proportions in the whole dataset are used.
<code>nu</code>	degrees of freedom for <code>method = "t"</code> .
<code>...</code>	arguments passed to or from other methods.

Details

Uses a QR decomposition which will give an error message if the within-group variance is singular for any group.

Value

an object of class "qda" containing the following components:

<code>prior</code>	the prior probabilities used.
<code>means</code>	the group means.
<code>scaling</code>	for each group <code>i</code> , <code>scaling[, , i]</code> is an array which transforms observations so that within-groups covariance matrix is spherical.
<code>ldet</code>	a vector of half log determinants of the dispersion matrix.
<code>lev</code>	the levels of the grouping factor.
<code>terms</code>	(if formula is a formula) an object of mode expression and class term summarizing the formula.
<code>call</code>	the (matched) function call.
<code>class</code>	The MAP classification (a factor)
<code>posterior</code>	posterior probabilities for the classes

quine

Absenteeism from School in Rural New South Wales

Description

The `quine` data frame has 146 rows and 5 columns. Children from Walgett, New South Wales, Australia, were classified by Culture, Age, Sex and Learner status and the number of days absent from school in a particular school year was recorded.

Usage

`quine`

Format

This data frame contains the following columns:

Eth ethnic background: Aboriginal or Not, ("A" or "N").

Sex sex: factor with levels ("F" or "M").

Age age group: Primary ("F0"), or forms "F1", "F2" or "F3".

Lrn learner status: factor with levels Average or Slow learner, ("AL" or "SL").

Days days absent from school in the year.

Source

Rabbit

*Blood Pressure in Rabbits***Description**

Five rabbits were studied on two occasions, after treatment with saline (control) and after treatment with the $5-HT_3$ antagonist MDL 72222. After each treatment ascending doses of phenylbiguanide were injected intravenously at 10 minute intervals and the responses of mean blood pressure measured. The goal was to test whether the cardiogenic chemoreflex elicited by phenylbiguanide depends on the activation of $5-HT_3$ receptors.

Usage

Rabbit

Format

This data frame contains 60 rows and the following variables:

BPchange change in blood pressure relative to the start of the experiment.

Dose dose of Phenylbiguanide in micrograms.

Run label of run ("C1" to "C5", then "M1" to "M5").

Treatment placebo or the $5-HT_3$ antagonist MDL 72222.

Animal label of animal used ("R1" to "R5").

rational

*Rational Approximation***Description**

Find rational approximations to the components of a real numeric object using a standard continued fraction method.

Usage

```
rational(x, cycles = 10, max.denominator = 2000, ...)
```

Arguments

<code>x</code>	Any object of mode numeric. Missing values are now allowed.
<code>cycles</code>	The maximum number of steps to be used in the continued fraction approximation process.
<code>max.denominator</code>	An early termination criterion. If any partial denominator exceeds <code>max.denominator</code> the continued fraction stops at that point.
<code>...</code>	arguments passed to or from other methods.

Details

Each component is first expanded in a continued fraction of the form

$$x = \text{floor}(x) + 1/(p_1 + 1/(p_2 + \dots))$$

where p_1, p_2, \dots are positive integers, terminating either at `cycles` terms or when a $p_j > \text{max.denominator}$. The continued fraction is then re-arranged to retrieve the numerator and denominator as integers and the ratio returned as the value.

Value

A numeric object with the same attributes as `x` but with entries rational approximations to the values. This effectively rounds relative to the size of the object and replaces very small entries by zero.

renumerate	<i>Convert a Formula Transformed by 'denumerate'</i>
------------	--

Description

`denumerate` converts a formula written using the conventions of `loglm` into one that `terms` is able to process. `renumerate` converts it back again to a form like the original.

Usage

```
renumerate(x)
```

Arguments

`x` A formula, normally as modified by `denumerate`.

Details

This is an inverse function to `denumerate`. It is only needed since `terms` returns an expanded form of the original formula where the non-marginal terms are exposed. This expanded form is mapped back into a form corresponding to the one that the user originally supplied.

Value

A formula where all variables with names of the form `.vn`, where `n` is an integer, converted to numbers, `n`, as allowed by the formula conventions of `loglm`.

See Also

[denumerate](#)

Examples

```
denumerate(~(1+2+3)^3 + a/b)
## ~ (.v1 + .v2 + .v3)^3 + a/b
renumerate(.Last.value)
## ~ (1 + 2 + 3)^3 + a/b
```

rlm	<i>Robust Fitting of Linear Models</i>
-----	--

Description

Fit a linear model by robust regression using an M estimator.

Usage

```

rlm(x, ...)

## S3 method for class 'formula':
rlm(formula, data, weights, ..., subset, na.action,
     method = c("M", "MM", "model.frame"),
     wt.method = c("inv.var", "case"),
     model = TRUE, x.ret = TRUE, y.ret = FALSE, contrasts = NULL)

## Default S3 method:
rlm(x, y, weights, ..., w = rep(1, nrow(x)),
     init = "ls", psi = psi.huber,
     scale.est = c("MAD", "Huber", "proposal 2"), k2 = 1.345,
     method = c("M", "MM"), wt.method = c("inv.var", "case"),
     maxit = 20, acc = 1e-4, test.vec = "resid", lqs.control = NULL)

psi.huber(u, k = 1.345, deriv = 0)
psi.hampel(u, a = 2, b = 4, c = 8, deriv = 0)
psi.bisquare(u, c = 4.685, deriv = 0)

```

Arguments

<code>formula</code>	a formula of the form $y \sim x_1 + x_2 + \dots$
<code>data</code>	data frame from which variables specified in <code>formula</code> are preferentially to be taken.
<code>weights</code>	a vector of prior weights for each case.
<code>subset</code>	An index vector specifying the cases to be used in fitting.
<code>na.action</code>	A function to specify the action to be taken if NAs are found. The ‘factory-fresh’ default action in R is <code>na.omit</code> , and can be changed by <code>options(na.action=)</code> .
<code>x</code>	a matrix or data frame containing the explanatory variables.
<code>y</code>	the response: a vector of length the number of rows of <code>x</code> .
<code>method</code>	currently either M-estimation or MM-estimation or (for the <code>formula</code> method only) find the model frame. MM-estimation is M-estimation with Tukey’s bi-weight initialized by a specific S-estimator. See the ‘Details’ section.
<code>wt.method</code>	are the weights case weights (giving the relative importance of case, so a weight of 2 means there are two of these) or the inverse of the variances, so a weight of two means this error is half as variable?
<code>model</code>	should the model frame be returned in the object?
<code>x.ret</code>	should the model matrix be returned in the object?
<code>y.ret</code>	should the response be returned in the object?
<code>contrasts</code>	optional contrast specifications: see lm .
<code>w</code>	(optional) initial down-weighting for each case.
<code>init</code>	(optional) initial values for the coefficients OR a method to find initial values OR the result of a fit with a <code>coef</code> component. Known methods are <code>"ls"</code> (the default) for an initial least-squares fit using weights <code>w*weights</code> , and <code>"lts"</code> for an unweighted least-trimmed squares fit with 200 samples.

<code>psi</code>	the <code>psi</code> function is specified by this argument. It must give (possibly by name) a function <code>g(x, ..., deriv)</code> that for <code>deriv=0</code> returns <code>psi(x)/x</code> and for <code>deriv=1</code> returns <code>psi'(x)</code> . Tuning constants will be passed in via <code>...</code>
<code>scale.est</code>	method of scale estimation: re-scaled MAD of the residuals (default) or Huber's proposal 2 (which can be selected by either "Huber" or "proposal 2").
<code>k2</code>	tuning constant used for Huber proposal 2 scale estimation.
<code>maxit</code>	the limit on the number of IWLS iterations.
<code>acc</code>	the accuracy for the stopping criterion.
<code>test.vec</code>	the stopping criterion is based on changes in this vector.
<code>...</code>	additional arguments to be passed to <code>rlm.default</code> or to the <code>psi</code> function.
<code>lqs.control</code>	An optional list of control values for <code>lqs</code> .
<code>u</code>	numeric vector of evaluation points.
<code>k, a, b, c</code>	tuning constants.
<code>deriv</code>	0 or 1: compute values of the <code>psi</code> function or of its first derivative.

Details

Fitting is done by iterated re-weighted least squares (IWLS).

`Psi` functions are supplied for the Huber, Hampel and Tukey bisquare proposals as `psi.huber`, `psi.hampel` and `psi.bisquare`. Huber's corresponds to a convex optimization problem and gives a unique solution (up to collinearity). The other two will have multiple local minima, and a good starting point is desirable.

Selecting `method = "MM"` selects a specific set of options which ensures that the estimator has a high breakdown point. The initial set of coefficients and the final scale are selected by an S-estimator with `k0 = 1.548`; this gives (for $n \gg p$) breakdown point 0.5. The final estimator is an M-estimator with Tukey's biweight and fixed scale that will inherit this breakdown point provided $c > k0$; this is true for the default value of `c` that corresponds to 95% relative efficiency at the normal. Case weights are not supported for `method = "MM"`.

Value

An object of class "rlm" inheriting from "lm". The additional components not in an `lm` object are

<code>s</code>	the robust scale estimate used
<code>w</code>	the weights used in the IWLS process
<code>psi</code>	the <code>psi</code> function with parameters substituted
<code>conv</code>	the convergence criteria at each iteration
<code>converged</code>	did the IWLS converge?
<code>wresid</code>	a working residual, weighted for "inv.var" weights only.

 rms.curv

Relative Curvature Measures for Non-Linear Regression

Description

Calculates the root mean square parameter effects and intrinsic relative curvatures, c^θ and c^t , for a fitted nonlinear regression, as defined in Bates & Watts, section 7.3, p. 253 et seq.

Usage

```
rms.curv(obj)
```

Arguments

`obj` Fitted model object of class "nls". The model must be fitted using the default algorithm.

Details

The method of section 7.3.1 of Bates & Watts is implemented. The function `deriv3` should be used generate a model function with first derivative (gradient) matrix and second derivative (Hessian) array attributes. This function should then be used to fit the nonlinear regression model.

A print method, `print.rms.curv`, prints the `pc` and `ic` components only, suitably annotated.

If either `pc` or `ic` exceeds some threshold (0.3 has been suggested) the curvature is unacceptably high for the planar assumption.

Value

A list of class `rms.curv` with components `pc` and `ic` for parameter effects and intrinsic relative curvatures multiplied by \sqrt{F} , `ct` and `ci` for c^θ and c^t (unmultiplied), and `C` the C-array as used in section 7.3.1 of Bates & Watts.

rnegbin

*Simulate Negative Binomial Variates***Description**

Function to generate random outcomes from a Negative Binomial distribution, with mean μ and variance $\mu + \mu^2/\theta$.

Usage

```
rnegbin(n, mu = n, theta = stop("'theta' must be specified"))
```

Arguments

n	If a scalar, the number of sample values required. If a vector, length(n) is the number required and n is used as the mean vector if mu is not specified.
mu	The vector of means. Short vectors are recycled.
theta	Vector of values of the theta parameter. Short vectors are recycled.

Details

The function uses the representation of the Negative Binomial distribution as a continuous mixture of Poisson distributions with Gamma distributed means. Unlike `rnbinom` the index can be arbitrary.

Value

Vector of random Negative Binomial variate values.

Side Effects

Changes `.Random.seed` in the usual way.

Examples

```
# Negative Binomials with means fitted(fm) and theta = 4.5
fm <- glm.nb(Days ~ ., data = quine)
dummy <- rnegbin(fitted(fm), theta = 4.5)
```

road	<i>Road Accident Deaths in US States</i>
------	--

Description

A data frame with the annual deaths in road accidents for half the US states.

Usage

```
road
```

Format

Columns are:

state name.

deaths number of deaths.

drivers number of drivers (in 10,000s).

popden population density in people per square mile.

rural length of rural roads, in 1000s of miles.

temp average daily maximum temperature in January.

fuel fuel consumption in 10,000,000 US gallons per year.

sammon

Sammon's Non-Linear Mapping

Description

One form of non-metric multidimensional scaling.

Usage

```
sammon(d, y = cmdscale(d, k), k = 2, niter = 100, trace = TRUE,  
       magic = 0.2, tol = 1e-4)
```

Arguments

<code>d</code>	distance structure of the form returned by <code>dist</code> , or a full, symmetric matrix. Data are assumed to be dissimilarities or relative distances, but must be positive except for self-distance. This can contain missing values.
<code>y</code>	An initial configuration. If none is supplied, <code>cmdscale</code> is used to provide the classical solution. (If there are missing values in <code>d</code> , an initial configuration must be provided.) This must not have duplicates.
<code>k</code>	The dimension of the configuration.
<code>niter</code>	The maximum number of iterations.
<code>trace</code>	Logical for tracing optimization. Default <code>TRUE</code> .
<code>magic</code>	initial value of the step size constant in diagonal Newton method.
<code>tol</code>	Tolerance for stopping, in units of stress.

Details

This chooses a two-dimensional configuration to minimize the stress, the sum of squared differences between the input distances and those of the configuration, weighted by the distances, the whole sum being divided by the sum of input distances to make the stress scale-free.

An iterative algorithm is used, which will usually converge in around 50 iterations. As this is necessarily an $O(n^2)$ calculation, it is slow for large datasets. Further, since the configuration is only determined up to rotations and reflections (by convention the centroid is at the origin), the result can vary considerably from machine to machine. In this release the algorithm has been modified by adding a step-length search (`magic`) to ensure that it always goes downhill.

Value

Two components:

<code>points</code>	A two-column vector of the fitted configuration.
<code>stress</code>	The final stress achieved.

Side Effects

If `trace` is true, the initial stress and the current stress are printed out every 10 iterations.

snails

Snail Mortality Data

Description

Groups of 20 snails were held for periods of 1, 2, 3 or 4 weeks in carefully controlled conditions of temperature and relative humidity. There were two species of snail, A and B, and the experiment was designed as a 4 by 3 by 4 by 2 completely randomized design. At the end of the exposure time the snails were tested to see if they had survived; the process itself is fatal for the animals. The object of the exercise was to model the probability of survival in terms of the stimulus variables, and in particular to test for differences between species.

The data are unusual in that in most cases fatalities during the experiment were fairly small.

Usage

```
snails
```

Format

The data frame contains the following components:

Species snail species A (1) or B (2).

Exposure exposure in weeks.

Rel.Hum relative humidity (4 levels).

Temp temperature, in degrees Celsius (3 levels).

Deaths number of deaths.

N number of snails exposed.

 stepAIC

Choose a model by AIC in a Stepwise Algorithm

Description

Performs stepwise model selection by AIC.

Usage

```
stepAIC(object, scope, scale = 0,
        direction = c("both", "backward", "forward"),
        trace = 1, keep = NULL, steps = 1000, use.start = FALSE,
        k = 2, ...)
```

Arguments

object	an object representing a model of an appropriate class. This is used as the initial model in the stepwise search.
scope	defines the range of models examined in the stepwise search. This should be either a single formula, or a list containing components <code>upper</code> and <code>lower</code> , both formulae. See the details for how to specify the formulae and how they are used.
scale	used in the definition of the AIC statistic for selecting the models, currently only for <code>lm</code> and <code>aov</code> models (see <code>extractAIC</code> for details).
direction	the mode of stepwise search, can be one of "both", "backward", or "forward", with a default of "both". If the <code>scope</code> argument is missing the default for <code>direction</code> is "backward".
trace	if positive, information is printed during the running of <code>stepAIC</code> . Larger values may give more information on the fitting process.
keep	a filter function whose input is a fitted model object and the associated AIC statistic, and whose output is arbitrary. Typically <code>keep</code> will select a subset of the components of the object and return them. The default is not to keep anything.
steps	the maximum number of steps to be considered. The default is 1000 (essentially as many as required). It is typically used to stop the process early.
use.start	if true the updated fits are done starting at the linear predictor for the currently selected model. This may speed up the iterative calculations for <code>glm</code> (and other fits), but it can also slow them down. Not used in R.
k	the multiple of the number of degrees of freedom used for the penalty. Only $k = 2$ gives the genuine AIC: $k = \log(n)$ is sometimes referred to as BIC or SBC.
...	any additional arguments to <code>extractAIC</code> . (None are currently used.)

Details

The set of models searched is determined by the `scope` argument. The right-hand-side of its lower component is always included in the model, and right-hand-side of the model is included in the upper component. If `scope` is a single formula, it specifies the upper component, and the lower model is empty. If `scope` is missing, the initial model is used as the upper model.

Models specified by `scope` can be templates to update `object` as used by `update.formula`.

There is a potential problem in using `glm` fits with a variable `scale`, as in that case the deviance is not simply related to the maximized log-likelihood. The `glm` method for `extractAIC` makes the appropriate adjustment for a gaussian family, but may need to be amended for other cases. (The binomial and poisson families have fixed `scale` by default and do not correspond to a particular maximum-likelihood problem for variable `scale`.)

Where a conventional deviance exists (e.g. for `lm`, `aov` and `glm` fits) this is quoted in the analysis of variance table: it is the *unscaled* deviance.

Value

the stepwise-selected model is returned, with up to two additional components. There is an "anova" component corresponding to the steps taken in the search, as well as a "keep" component if the `keep=` argument was supplied in the call. The "Resid. Dev" column of the analysis of deviance table refers to a constant minus twice the maximized log likelihood: it will be a deviance only in cases where a saturated model is well-defined (thus excluding `lm`, `aov` and `survreg` fits, for example).

Note

The model fitting must apply the models to the same dataset. This may be a problem if there are missing values and an `na.action` other than `na.fail` is used (as is the default in R). We suggest you remove the missing values first.

stormer

The Stormer Viscometer Data

Description

The stormer viscometer measures the viscosity of a fluid by measuring the time taken for an inner cylinder in the mechanism to perform a fixed number of revolutions in response to an actuating weight. The viscometer is calibrated by measuring the time taken with varying weights while the mechanism is suspended in fluids of accurately known viscosity. The data comes from such a calibration, and theoretical considerations suggest a nonlinear relationship between time, weight and viscosity, of the form $\text{Time} = (B1 * \text{Viscosity}) / (\text{Weight} - B2) + E$ where $B1$ and $B2$ are unknown parameters to be estimated, and E is error.

Usage

```
stormer
```

Format

The data frame contains the following components:

Viscosity viscosity of fluid.

Wt actuating weight.

Time time taken.

Source

 summary.loglm

Summary Method Function for Objects of Class 'loglm'

Description

Returns a summary list for log-linear models fitted by iterative proportional scaling using `loglm`.

Usage

```
## S3 method for class 'loglm':
summary(object, fitted = FALSE, ...)
```

Arguments

`object` a fitted `loglm` model object.
`fitted` if TRUE return observed and expected frequencies in the result. Using `fitted = TRUE` may necessitate re-fitting the object.
`...` arguments to be passed to or from other methods.

Details

This function is a method for the generic function `summary()` for class "loglm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.loglm(x)` regardless of the class of the object.

Value

a list is returned for use by `print.summary.loglm`. This has components

<code>formula</code>	the formula used to produce <code>object</code>
<code>tests</code>	the table of test statistics (likelihood ratio, Pearson) for the fit.
<code>oe</code>	if <code>fitted = TRUE</code> , an array of the observed and expected frequencies, otherwise <code>NULL</code> .

[loglm](#), [summary](#)

summary.negbin

Summary Method Function for Objects of Class 'negbin'

Description

Identical to `summary.glm`, but with three lines of additional output: the ML estimate of theta, its standard error, and twice the log-likelihood function.

Usage

```
## S3 method for class 'negbin':
summary(object, dispersion = 1, correlation = FALSE, ...)
```

Arguments

<code>object</code>	fitted model object of class <code>negbin</code> inheriting from <code>glm</code> and <code>lm</code> . Typically the output of <code>glm.nb</code> .
<code>dispersion</code>	as for <code>summary.glm</code> , with a default of 1.
<code>correlation</code>	as for <code>summary.glm</code> .
<code>...</code>	arguments passed to or from other methods.

Details

`summary.glm` is used to produce the majority of the output and supply the result. This function is a method for the generic function `summary()` for class "negbin". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.negbin(x)` regardless of the class of the object.

Value

As for `summary.glm`; the additional lines of output are not included in the resultant object.

Side Effects

A summary table is produced as for `summary.glm`, with the additional information described above.

summary.rlm

Summary Method for Robust Linear Models

Description

`summary` method for objects of class "rlm"

Usage

```
## S3 method for class 'rlm':
summary(object, method = c("XtX", "XtWX"), correlation = FALSE, ...)
```

Arguments

<code>object</code>	the fitted model. This is assumed to be the result of some fit that produces an object inheriting from the class <code>rlm</code> , in the sense that the components returned by the <code>rlm</code> function will be available.
<code>method</code>	Should the weighted (by the IWLS weights) or unweighted cross-products matrix be used?
<code>correlation</code>	logical. Should correlations be computed (and printed)?
<code>...</code>	arguments passed to or from other methods.

Details

This function is a method for the generic function `summary()` for class "rlm". It can be invoked by calling `summary(x)` for an object `x` of the appropriate class, or directly by calling `summary.rlm(x)` regardless of the class of the object.

Value

If printing takes place, only a null value is returned. Otherwise, a list is returned with the following components. Printing always takes place if this function is invoked automatically as a method for the `summary` function.

`correlation` The computed correlation coefficient matrix for the coefficients in the model.

`cov.unscaled` The unscaled covariance matrix; i.e, a matrix such that multiplying it by an estimate of the error variance produces an estimated covariance matrix for the coefficients.

`sigma` The scale estimate.

`stddev` A scale estimate used for the standard errors.

`df` The number of degrees of freedom for the model and for residuals.

`coefficients` A matrix with three columns, containing the coefficients, their standard errors and the corresponding t statistic.

`terms` The terms object used in fitting this model.

## End(Not run)
```

survey

Student Survey Data

Description

This data frame contains the responses of 237 Statistics I students at the University of Adelaide to a number of questions.

Usage

```
survey
```

Format

The components of the data frame are:

Sex The sex of the student. (Factor with levels "Male" and "Female".)

Wr.Hnd span (distance from tip of thumb to tip of little finger of spread hand) of writing hand, in centimetres.

NW.Hnd span of non-writing hand.

W.Hnd writing hand of student. (Factor, with levels "Left" and "Right".)

Fold "Fold your arms! Which is on top" (Factor, with levels "R on L", "L on R", "Neither".)

Pulse pulse rate of student (beats per minute).

Clap "Clap your hands! Which hand is on top?" (Factor, with levels "Right", "Left", "Neither".)

Exer how often the student exercises. (Factor, with levels "Freq" (frequently), "Some", "None".)

Smoke how much the student smokes. (Factor, levels "Heavy", "Regul" (regularly), "Occas" (occasionally), "Never".)

Height height of the student in centimetres.

M.I whether the student expressed height in imperial (feet/inches) or metric (centimetres/metres) units. (Factor, levels "Metric", "Imperial".)

Age age of the student in years.

 synth.tr

Synthetic Classification Problem

Description

The `synth.tr` data frame has 250 rows and 3 columns. The `synth.te` data frame has 100 rows and 3 columns. It is intended that `synth.tr` be used from training and `synth.te` for testing.

Usage

```
synth.tr
synth.te
```

Format

These data frames contains the following columns:

xs x-coordinate
ys y-coordinate
yc class, coded as 0 or 1.

Source

 theta.md

Estimate theta of the Negative Binomial

Description

Given the estimated mean vector, estimate `theta` of the Negative Binomial Distribution.

Usage

```
theta.md(y, mu, dfr, weights, limit = 20, eps = .Machine$double.eps^0.25)
theta.ml(y, mu, n, weights, limit = 10, eps = .Machine$double.eps^0.25,
         trace = FALSE)
theta.mm(y, mu, dfr, weights, limit = 10, eps = .Machine$double.eps^0.25)
```

Arguments

<code>y</code>	Vector of observed values from the Negative Binomial.
<code>mu</code>	Estimated mean vector.
<code>n</code>	Number of data points (defaults to the sum of weights)
<code>dfr</code>	Residual degrees of freedom (assuming <code>theta</code> known). For a weighted fit this is the sum of the weights minus the number of fitted parameters.
<code>weights</code>	Case weights. If missing, taken as 1.
<code>limit</code>	Limit on the number of iterations.
<code>eps</code>	Tolerance to determine convergence.
<code>trace</code>	logical: should iteration progress be printed?

Details

`theta.md` estimates by equating the deviance to the residual degrees of freedom, an analogue of a moment estimator.

`theta.ml` uses maximum likelihood.

`theta.mm` calculates the moment estimator of `theta` by equating the Pearson chi-square $sum((y - \mu)^2 / (\mu + \mu^2 / \theta))$ to the residual degrees of freedom.

Value

The required estimate of `theta`, as a scalar. For `theta.ml`, the standard error is given as attribute "SE".

`Traffic`*Effect of Swedish Speed Limits on Accidents*

Description

An experiment was performed in Sweden in 1961–2 to assess the effect of a speed limit on the motorway accident rate. The experiment was conducted on 92 days in each year, matched so that day *j* in 1962 was comparable to day *j* in 1961. On some days the speed limit was in effect and enforced, while on other days there was no speed limit and cars tended to be driven faster. The speed limit days tended to be in contiguous blocks.

Usage

```
Traffic
```

Format

This data frame contains the following columns:

year 1961 or 1962.

day of year.

limit was there a speed limit?

y traffic accident count for that day.

Source

truehist	<i>Plot a Histogram</i>
----------	-------------------------

Description

Creates a histogram on the current graphics device.

Usage

```
truehist(data, nbins = "Scott", h, x0 = -h/1000,
          breaks, prob = TRUE, xlim = range(breaks),
          ymax = max(est), col,
          xlab = deparse(substitute(data)), bty = "n", ...)
```

Arguments

data	numeric vector of data for histogram. Missing values (NAs) are allowed and omitted.
nbins	The suggested number of bins. Either a positive integer, or a character string naming a rule: "Scott" or "Freedman-Diaconis" or "FD". (Case is ignored.)
h	The bin width, a strictly positive number (takes precedence over nbins).
x0	Shift for the bins - the breaks are at $x_0 + h * (\dots, -1, 0, 1, \dots)$
breaks	The set of breakpoints to be used. (Usually omitted, takes precedence over h and nbins).
prob	If true (the default) plot a true histogram. The vertical axis has a <i>relative frequency density</i> scale, so the product of the dimensions of any panel gives the relative frequency. Hence the total area under the histogram is 1 and it is directly comparable with most other estimates of the probability density function. If false plot the counts in the bins.
xlim	The limits for the x-axis.
ymax	The upper limit for the y-axis.
col	The colour number for the bar fill.
xlab	label for the plot x-axis. By default, this will be the name of data.
bty	The box type for the plot - defaults to none.
...	additional arguments to rect or plot .

Details

This plots a true histogram, a density estimate of total area 1. If `breaks` is specified, those break-points are used. Otherwise if `h` is specified, a regular grid of bins is used with width `h`. If neither `breaks` nor `h` is specified, `nbins` is used to select a suitable `h`.

Side Effects

A histogram is plotted on the current device.

ucv

Unbiased Cross-Validation for Bandwidth Selection

Description

Uses unbiased cross-validation to select the bandwidth of a Gaussian kernel density estimator.

Usage

```
ucv(x, nb = 1000, lower, upper)
```

Arguments

`x` a numeric vector
`nb` number of bins to use.
`lower, upper` Range over which to minimize. The default is almost always satisfactory.

Value

a bandwidth.

`UScereal`*Nutritional and Marketing Information on US Cereals*

Description

The `UScereal` data frame has 65 rows and 11 columns. The data come from the 1993 ASA Statistical Graphics Exposition, and are taken from the mandatory F&DA food label. The data have been normalized here to a portion of one American cup.

Usage`UScereal`**Format**

This data frame contains the following columns:

mfr Manufacturer, represented by its first initial: G=General Mills, K=Kelloggs, N=Nabisco, P=Post, Q=Quaker Oats, R=Ralston Purina.

calories number of calories in one portion.

protein grams of protein in one portion.

fat grams of fat in one portion.

sodium milligrams of sodium in one portion.

fibre grams of dietary fibre in one portion.

carbo grams of complex carbohydrates in one portion.

sugars grams of sugars in one portion.

shelf display shelf (1, 2, or 3, counting from the floor).

potassium grams of potassium.

vitamins vitamins and minerals (none, enriched, or 100%).

UScrime

*The Effect of Punishment Regimes on Crime Rates***Description**

Criminologists are interested in the effect of punishment regimes on crime rates. This has been studied using aggregate data on 47 states of the USA for 1960 given in this data frame. The variables seem to have been re-scaled to convenient numbers.

Usage

UScrime

Format

This data frame contains the following columns:

- M** percentage of males aged 14–24.
- So** indicator variable for a Southern state.
- Ed** mean years of schooling.
- Po1** police expenditure in 1960.
- Po2** police expenditure in 1959.
- LF** labour force participation rate.
- M.F** number of males per 1000 females.
- Pop** state population.
- NW** number of non-whites per 1000 people.
- U1** unemployment rate of urban males 14–24.
- U2** unemployment rate of urban males 35–39.
- GDP** gross domestic product per head.
- Ineq** income inequality.
- Prob** probability of imprisonment.
- Time** average time served in state prisons.
- y** rate of crimes in a particular category per head of population.

whiteside

*House Insulation: Whiteside's Data***Description**

Mr Derek Whiteside of the UK Building Research Station recorded the weekly gas consumption and average external temperature at his own house in south-east England for two heating seasons, one of 26 weeks before, and one of 30 weeks after cavity-wall insulation was installed. The object of the exercise was to assess the effect of the insulation on gas consumption.

Usage

whiteside

Format

The whiteside data frame has 56 rows and 3 columns.:

Insul A factor, before or after insulation.

Temp Purportedly the average outside temperature in degrees Celsius. (These values is far too low for any 56-week period in the 1960s in South-East England. It might be the weekly average of daily minima.)

Gas The weekly gas consumption in 1000s of cubic feet.

Source

A data set collected in the 1960s by Mr Derek Whiteside of the UK Building Research Station. Reported by

Hand, D. J., Daly, F., McConway, K., Lunn, D. and Ostrowski, E. eds (1993) *A Handbook of Small Data Sets*. Chapman & Hall, p. 69.

Examples

```
require(lattice)
xyplot(Gas ~ Temp | Insul, whiteside, panel =
  function(x, y, ...) {
    panel.xyplot(x, y, ...)
    panel.lmline(x, y, ...)
  }, xlab = "Average external temperature (deg. C)",
  ylab = "Gas consumption (1000 cubic feet)", aspect = "xy",
  strip = function(...) strip.default(..., style = 1))

gasB <- lm(Gas ~ Temp, whiteside, subset = Insul=="Before")
gasA <- update(gasB, subset = Insul=="After")
summary(gasB)
summary(gasA)
gasBA <- lm(Gas ~ Insul/Temp - 1, whiteside)
summary(gasBA)
```

```
gasQ <- lm(Gas ~ Insul/(Temp + I(Temp^2)) - 1, whiteside)
coef(summary(gasQ))

gasPR <- lm(Gas ~ Insul + Temp, whiteside)
anova(gasPR, gasBA)
options(contrasts = c("contr.treatment", "contr.poly"))
gasBA1 <- lm(Gas ~ Insul*Temp, whiteside)
coef(summary(gasBA1))
```

width.SJ

*Bandwidth Selection by Pilot Estimation of Derivatives***Description**

Uses the method of Sheather & Jones (1991) to select the bandwidth of a Gaussian kernel density estimator.

Usage

```
width.SJ(x, nb = 1000, lower, upper, method = c("ste", "dpi"))
```

Arguments

x	a numeric vector
nb	number of bins to use.
upper, lower	range over which to search for solution if method = "ste".
method	Either "ste" ("solve-the-equation") or "dpi" ("direct plug-in").

Value

a bandwidth.

`write.matrix` *Write a Matrix or Data Frame*

Description

Writes a matrix or data frame to a file or the console, using column labels and a layout respecting columns.

Usage

```
write.matrix(x, file = "", sep = " ", blocksize)
```

Arguments

<code>x</code>	matrix or data frame.
<code>file</code>	name of output file. The default ("") is the console.
<code>sep</code>	The separator between columns.
<code>blocksize</code>	If supplied and positive, the output is written in blocks of <code>blocksize</code> rows. Choose as large as possible consistent with the amount of memory available.

Details

If `x` is a matrix, supplying `blocksize` is more memory-efficient and enables larger matrices to be written, but each block of rows might be formatted slightly differently.

If `x` is a data frame, the conversion to a matrix may negate the memory saving.

Side Effects

A formatted file is produced, with column headings (if `x` has them) and columns of data.

`wtloss` *Weight Loss Data from an Obese Patient*

Description

The data frame gives the weight, in kilograms, of an obese patient at 52 time points over an 8 month period of a weight rehabilitation programme.

Usage

```
wtloss
```

Format

This data frame contains the following columns:

Days time in days since the start of the programme.

Weight weight in kilograms of the patient.

Source

Dr T. Davies, Adelaide.

References

Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

Examples

```
wtloss.fm <- nls(Weight ~ b0 + b1*2^(-Days/th),  
  data = wtloss, start = list(b0=90, b1=95, th=120),  
  trace = TRUE)
```

Chapter 12

The boot package

abc.ci

Nonparametric ABC Confidence Intervals

Description

Calculate equi-tailed two-sided nonparametric approximate bootstrap confidence intervals for a parameter, given a set of data and an estimator of the parameter, using numerical differentiation.

Usage

```
abc.ci(data, statistic, index=1, strata=rep(1, n), conf=0.95,  
       eps=0.001/n, ...)
```

Arguments

data	A data set expressed as a vector, matrix or data frame.
statistic	A function which returns the statistic of interest. The function must take at least 2 arguments; the first argument should be the data and the second a vector of weights. The weights passed to <code>statistic</code> will be normalized to sum to 1 within each stratum. Any other arguments should be passed to <code>abc.ci</code> as part of the <code>...{}</code> argument.
index	If <code>statistic</code> returns a vector of length greater than 1, then this indicates the position of the variable of interest within that vector.
strata	A factor or numerical vector indicating to which sample each observation belongs in multiple sample problems. The default is the one-sample case.
conf	A scalar or vector containing the confidence level(s) of the required interval(s).
eps	The value of epsilon to be used for the numerical differentiation.
...	Any other arguments for <code>statistic</code> . These will be passed unchanged to <code>statistic</code> each time it is called within <code>abc.ci</code> .

Details

This function is based on the function `abcnon` written by R. Tibshirani. A listing of the original function is available in DiCiccio and Efron (1996). The function uses numerical differentiation for the first and second derivatives of the statistic and then uses these values to approximate the bootstrap BCa intervals. The total number of evaluations of the statistic is $2 * n + 2 + 2 * \text{length}(\text{conf})$ where n is the number of data points (plus calculation of the original value of the statistic). The function works for the multiple sample case without the need to rewrite the statistic in an artificial form since the stratified normalization is done internally by the function.

Value

A `length(conf)` by 3 matrix where each row contains the confidence level followed by the lower and upper end-points of the ABC interval at that level.

acme

Monthly Excess Returns

Description

The `acme` data frame has 60 rows and 3 columns.

The excess return for the Acme Cleveland Corporation are recorded along with those for all stocks listed on the New York and American Stock Exchanges were recorded over a five year period. These excess returns are relative to the return on a risk-less investment such a U.S. Treasury bills.

Usage

acme

Format

This data frame contains the following columns:

month A character string representing the month of the observation.

market The excess return of the market as a whole.

acme The excess return for the Acme Cleveland Corporation.

Source

The data were obtained from

Simonoff, J.S. and Tsai, C.-L. (1994) Use of modified profile likelihood for improved tests of constancy of variance in regression. *Applied Statistics*, **43**, 353–370.

aids

Delay in AIDS Reporting in England and Wales

Description

The `aids` data frame has 570 rows and 6 columns.

Although all cases of AIDS in England and Wales must be reported to the Communicable Disease Surveillance Centre, there is often a considerable delay between the time of diagnosis and the time that it is reported. In estimating the prevalence of AIDS, account must be taken of the unknown number of cases which have been diagnosed but not reported. The data set here records the reported cases of AIDS diagnosed from July 1983 and until the end of 1992. The data are cross-classified by the date of diagnosis and the time delay in the reporting of the cases.

Usage

aids

Format

This data frame contains the following columns:

year The year of the diagnosis.

quarter The quarter of the year in which diagnosis was made.

delay The time delay (in months) between diagnosis and reporting. 0 means that the case was reported within one month. Longer delays are grouped in 3 month intervals and the value of `delay` is the midpoint of the interval (therefore a value of 2 indicates that reporting was delayed for between 1 and 3 months).

dud An indicator of censoring. These are categories for which full information is not yet available and the number recorded is a lower bound only.

time The time interval of the diagnosis. That is the number of quarters from July 1983 until the end of the quarter in which these cases were diagnosed.

y The number of AIDS cases reported.

Source

The data were obtained from

De Angelis, D. and Gilks, W.R. (1994) Estimating acquired immune deficiency syndrome accounting for reporting delay. *Journal of the Royal Statistical Society, A*, **157**, 31–40.

aircondit

Failures of Air-conditioning Equipment

Description

Proschan (1963) reported on the times between failures of the air-conditioning equipment in 10 Boeing 720 aircraft. The `aircondit` data frame contains the intervals for the ninth aircraft while `aircondit7` contains those for the seventh aircraft.

Both data frames have just one column. Note that the data have been sorted into increasing order.

Usage

```
aircondit
```

Format

The data frames contain the following column:

hours The time interval in hours between successive failures of the air-conditioning equipment

Source

The data were taken from

Cox, D.R. and Snell, E.J. (1981) *Applied Statistics: Principles and Examples*. Chapman and Hall.

References

`amis`*Car Speeding and Warning Signs*

Description

The `amis` data frame has 8437 rows and 4 columns.

In a study into the effect that warning signs have on speeding patterns, Cambridgeshire County Council considered 14 pairs of locations. The locations were paired to account for factors such as traffic volume and type of road. One site in each pair had a sign erected warning of the dangers of speeding and asking drivers to slow down. No action was taken at the second site. Three sets of measurements were taken at each site. Each set of measurements was nominally of the speeds of 100 cars but not all sites have exactly 100 measurements. These speed measurements were taken before the erection of the sign, shortly after the erection of the sign, and again after the sign had been in place for some time.

Usage

```
amis
```

Format

This data frame contains the following columns:

speed Speeds of cars (in miles per hour).

period A numeric column indicating the time that the reading was taken. A value of 1 indicates a reading taken before the sign was erected, a 2 indicates a reading taken shortly after erection of the sign and a 3 indicates a reading taken after the sign had been in place for some time.

warning A numeric column indicating whether the location of the reading was chosen to have a warning sign erected. A value of 1 indicates presence of a sign and a value of 2 indicates that no sign was erected.

pair A numeric column giving the pair number at which the reading was taken. Pairs were numbered from 1 to 14.

Source

The data were kindly made available by Mr. Graham Amis, Cambridgeshire County Council, U.K.

`aml`*Remission Times for Acute Myelogenous Leukaemia*

Description

The `aml` data frame has 23 rows and 3 columns.

A clinical trial to evaluate the efficacy of maintenance chemotherapy for acute myelogenous leukaemia was conducted by Embury et al. (1977) at Stanford University. After reaching a stage of remission through treatment by chemotherapy, patients were randomized into two groups. The first group received maintenance chemotherapy and the second group did not. The aim of the study was to see if maintenance chemotherapy increased the length of the remission. The data here formed a preliminary analysis which was conducted in October 1974.

Usage

`aml`

Format

This data frame contains the following columns:

time The length of the complete remission (in weeks).

cens An indicator of right censoring. 1 indicates that the patient had a relapse and so `time` is the length of the remission. 0 indicates that the patient had left the study or was still in remission in October 1974, that is the length of remission is right-censored.

group The group into which the patient was randomized. Group 1 received maintenance chemotherapy, group 2 did not.

Note

Package **survival** also has a dataset `aml`. It is the same data with different names and with `group` replaced by a factor `x`.

Source

The data were obtained from

`beaver`*Beaver Body Temperature Data*

Description

The `beaver` data frame has 100 rows and 4 columns. It is a multivariate time series of class `"ts"` and also inherits from class `"data.frame"`.

This data set is part of a long study into body temperature regulation in beavers. Four adult female beavers were live-trapped and had a temperature-sensitive radio transmitter surgically implanted. Readings were taken every 10 minutes. The location of the beaver was also recorded and her activity level was dichotomized by whether she was in the retreat or outside of it since high-intensity activities only occur outside of the retreat.

The data in this data frame are those readings for one of the beavers on a day in autumn.

Usage

```
beaver
```

Format

This data frame contains the following columns:

day The day number. The data includes only data from day 307 and early 308.

time The time of day formatted as hour-minute.

temp The body temperature in degrees Celsius.

activ The dichotomized activity indicator. 1 indicates that the beaver is outside of the retreat and therefore engaged in high-intensity activity.

Source

The data were obtained from

 bigcity

Population of U.S. Cities

Description

The `bigcity` data frame has 49 rows and 2 columns.

The `city` data frame has 10 rows and 2 columns.

The measurements are the population (in 1000's) of 49 U.S. cities in 1920 and 1930. The 49 cities are a random sample taken from the 196 largest cities in 1920. The `city` data frame consists of the first 10 observations in `bigcity`.

Usage

```
bigcity
```

Format

This data frame contains the following columns:

- u** The 1920 population.
- x** The 1930 population.

Source

The data were obtained from

Cochran, W.G. (1977) *Sampling Techniques*. Third edition. John Wiley

 boot

Bootstrap Resampling

Description

Generate R bootstrap replicates of a statistic applied to data. Both parametric and nonparametric resampling are possible. For the nonparametric bootstrap, possible resampling methods are the ordinary bootstrap, the balanced bootstrap, antithetic resampling, and permutation. For nonparametric multi-sample problems stratified resampling is used. This is specified by including a vector of strata in the call to `boot`. Importance resampling weights may be specified.

Usage

```
boot(data, statistic, R, sim="ordinary", stype="i",
      strata=rep(1,n), L=NULL, m=0, weights=NULL,
      ran.gen=function(d, p) d, mle=NULL, simple=FALSE, ...)
```

Arguments

<code>data</code>	The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one multivariate observation.
<code>statistic</code>	A function which when applied to data returns a vector containing the statistic(s) of interest. When <code>sim="parametric"</code> , the first argument to <code>statistic</code> must be the data. For each replicate a simulated dataset returned by <code>ran.gen</code> will be passed. In all other cases <code>statistic</code> must take at least two arguments. The first argument passed will always be the original data. The second will be a vector of indices, frequencies or weights which define the bootstrap sample. Further, if predictions are required, then a third argument is required which would be a vector of the random indices used to generate the bootstrap predictions. Any further arguments can be passed to <code>statistic</code> through the <code>...{}</code> argument.
<code>R</code>	The number of bootstrap replicates. Usually this will be a single positive integer. For importance resampling, some resamples may use one set of weights and others use a different set of weights. In this case <code>R</code> would be a vector of integers where each component gives the number of resamples from each of the rows of weights.
<code>sim</code>	A character string indicating the type of simulation required. Possible values are "ordinary" (the default), "parametric", "balanced", "permutation", or "antithetic". Importance resampling is specified by including importance weights; the type of importance resampling must still be specified but may only be "ordinary" or "balanced" in this case.
<code>stype</code>	A character string indicating what the second argument of <code>statistic</code> represents. Possible values of <code>stype</code> are "i" (indices - the default), "f" (frequencies), or "w" (weights).
<code>strata</code>	An integer vector or factor specifying the strata for multi-sample problems. This may be specified for any simulation, but is ignored when <code>sim</code> is "parametric". When <code>strata</code> is supplied for a nonparametric bootstrap, the simulations are done within the specified strata.
<code>L</code>	Vector of influence values evaluated at the observations. This is used only when <code>sim</code> is "antithetic". If not supplied, they are calculated through a call to <code>empinf</code> . This will use the infinitesimal jackknife provided that <code>stype</code> is "w", otherwise the usual jackknife is used.
<code>m</code>	The number of predictions which are to be made at each bootstrap replicate. This is most useful for (generalized) linear models. This can only be used when <code>sim</code> is "ordinary". <code>m</code> will usually be a single integer but, if there are strata, it may be a vector with length equal to the number of strata, specifying how many of the errors for prediction should come from each strata. The actual predictions should be returned as the final part of the output of <code>statistic</code> , which should also take a vector of indices of the errors to be used for the predictions.
<code>weights</code>	Vector or matrix of importance weights. If a vector then it should have as many elements as there are observations in <code>data</code> . When simulation from more than one set of weights is required, <code>weights</code> should be a matrix where each row of the matrix is one set of importance weights. If <code>weights</code> is a matrix then <code>R</code> must be a vector of length <code>nrow(weights)</code> . This parameter is ignored if <code>sim</code> is not "ordinary" or "balanced".
<code>ran.gen</code>	This function is used only when <code>sim</code> is "parametric" when it describes how random values are to be generated. It should be a function of two arguments.

The first argument should be the observed data and the second argument consists of any other information needed (e.g. parameter estimates). The second argument may be a list, allowing any number of items to be passed to `ran.gen`. The returned value should be a simulated data set of the same form as the observed data which will be passed to `statistic` to get a bootstrap replicate. It is important that the returned value be of the same shape and type as the original dataset. If `ran.gen` is not specified, the default is a function which returns the original data in which case all simulation should be included as part of `statistic`. Use of `sim="parametric"` with a suitable `ran.gen` allows the user to implement any types of nonparametric resampling which are not supported directly.

<code>mle</code>	The second argument to be passed to <code>ran.gen</code> . Typically these will be maximum likelihood estimates of the parameters. For efficiency <code>mle</code> is often a list containing all of the objects needed by <code>ran.gen</code> which can be calculated using the original data set only.
<code>simple</code>	logical, only allowed to be TRUE for <code>sim="ordinary"</code> , <code>stype="i"</code> , <code>n=0</code> (otherwise ignored with a warning). By default a <code>n*R</code> index array is created: this can be large and if <code>simple = TRUE</code> this is avoided by sampling separately for each replication, which is slower but uses less memory.
<code>...</code>	Any other arguments for <code>statistic</code> which are passed unchanged each time it is called. Any such arguments to <code>statistic</code> must follow the arguments which <code>statistic</code> is required to have for the simulation.

Details

The statistic to be bootstrapped can be as simple or complicated as desired as long as its arguments correspond to the dataset and (for a nonparametric bootstrap) a vector of indices, frequencies or weights. `statistic` is treated as a black box by the `boot` function and is not checked to ensure that these conditions are met.

The first order balanced bootstrap is described in Davison, Hinkley and Schechtman (1986). The antithetic bootstrap is described by Hall (1989) and is experimental, particularly when used with strata. The other non-parametric simulation types are the ordinary bootstrap (possibly with unequal probabilities), and permutation which returns random permutations of cases. All of these methods work independently within strata if that argument is supplied.

For the parametric bootstrap it is necessary for the user to specify how the resampling is to be conducted. The best way of accomplishing this is to specify the function `ran.gen` which will return a simulated data set from the observed data set and a set of parameter estimates specified in `mle`.

Value

The returned value is an object of class "boot", containing the following components :

<code>t0</code>	The observed value of <code>statistic</code> applied to <code>data</code> .
<code>t</code>	A matrix with <code>R</code> rows each of which is a bootstrap replicate of <code>statistic</code> .
<code>R</code>	The value of <code>R</code> as passed to <code>boot</code> .
<code>data</code>	The data as passed to <code>boot</code> .
<code>seed</code>	The value of <code>.Random.seed</code> when <code>boot</code> was called.
<code>statistic</code>	The function <code>statistic</code> as passed to <code>boot</code> .
<code>sim</code>	Simulation type used.

stype	Statistic type as passed to <code>boot</code> .
call	The original call to <code>boot</code> .
strata	The strata used. This is the vector passed to <code>boot</code> , if it was supplied or a vector of ones if there were no strata. It is not returned if <code>sim</code> is "parametric".
weights	The importance sampling weights as passed to <code>boot</code> or the empirical distribution function weights if no importance sampling weights were specified. It is omitted if <code>sim</code> is not one of "ordinary" or "balanced".
pred.i	If predictions are required (<code>m</code> >0) this is the matrix of indices at which predictions were calculated as they were passed to <code>statistic</code> . Omitted if <code>m</code> is 0 or <code>sim</code> is not "ordinary".
L	The influence values used when <code>sim</code> is "antithetic". If no such values were specified and <code>stype</code> is not "w" then <code>L</code> is returned as consecutive integers corresponding to the assumption that data is ordered by influence values. This component is omitted when <code>sim</code> is not "antithetic".
ran.gen	The random generator function used if <code>sim</code> is "parametric". This component is omitted for any other value of <code>sim</code> .
mle	The parameter estimates passed to <code>boot</code> when <code>sim</code> is "parametric". It is omitted for all other values of <code>sim</code> .

  remove(".inds", envir=.GlobalEnv)
  c(coef(lm.b), pred.b-(fit.pred+dat$resid[i.pred]))
}

nuke.boot <- boot(nuke.data, nuke.fun, R=999, m=1,
  fit.pred=new.fit, x.pred=new.data)
# The bootstrap prediction error would then be found by
mean(nuke.boot$t[,8]^2)

```

```

# Basic bootstrap prediction limits would be
new.fit=sort(nuke.boot$t[,8])[c(975,25)]

# Finally a parametric bootstrap. For this example we shall look
# at the air-conditioning data. In this example our aim is to test
# the hypothesis that the true value of the index is 1 (i.e. that
# the data come from an exponential distribution) against the
# alternative that the data come from a gamma distribution with
# index not equal to 1.
air.fun <- function(data)
{
  ybar <- mean(data$hours)
  para <- c(log(ybar),mean(log(data$hours)))
  ll <- function(k) {
    if (k <= 0) out <- 1e200 # not NA
    else out <- lgamma(k)-k*(log(k)-1-para[1]+para[2])
    out
  }
  khat <- nlm(ll,ybar^2/var(data$hours))$estimate
  c(ybar, khat)
}

air.rg <- function(data, mle)
# Function to generate random exponential variates. mle will contain
# the mean of the original data
{
  out <- data
  out$hours <- rexp(nrow(out), 1/mle)
  out
}

air.boot <- boot(aircondit, air.fun, R=999, sim="parametric",
  ran.gen=air.rg, mle=mean(aircondit$hours))

# The bootstrap p-value can then be approximated by
sum(abs(air.boot$t[,2]-1) > abs(air.boot$t0[2]-1))/(1+air.boot$R)

```

boot.array

Bootstrap Resampling Arrays

Description

This function takes a bootstrap object calculated by one of the functions `boot`, `censboot`, or `tilt.boot` and returns the frequency (or index) array for the the bootstrap resamples.

Usage

```
boot.array(boot.out, indices=)
```

Arguments

`boot.out` An object of class "boot" returned by one of the generation functions for such an object.

`indices` A logical argument which specifies whether to return the frequency array or the raw index array. The default is `indices=FALSE` unless `boot.out` was created by `tsboot` in which case the default is `indices=TRUE`.

Details

The process by which the original index array was generated is repeated with the same value of `.Random.seed`. If the frequency array is required then `freq.array` is called to convert the index array to a frequency array.

A resampling array can only be returned when such a concept makes sense. In particular it cannot be found for any parametric or model-based resampling schemes. Hence for objects generated by `censboot` the only resampling scheme for which such an array can be found is ordinary case resampling. Similarly if `boot.out$sim` is "parametric" in the case of `boot` or "model" in the case of `tsboot` the array cannot be found. Note also that for post-blackened bootstraps from `tsboot` the indices found will relate to those prior to any post-blackening and so will not be useful.

Frequency arrays are used in many post-bootstrap calculations such as the jackknife-after-bootstrap and finding importance sampling weights. They are also used to find empirical influence values through the regression method.

Value

A matrix with `boot.out$R` rows and `n` columns where `n` is the number of observations in `boot.out$data`. If `indices` is `FALSE` then this will give the frequency of each of the original observations in each bootstrap resample. If `indices` is `TRUE` it will give the indices of the bootstrap resamples in the order in which they would have been passed to the statistic.

Side Effects

This function temporarily resets `.Random.seed` to the value in `boot.out$seed` and then returns it to its original value at the end of the function.

See Also

[boot](#), [censboot](#), [freq.array](#), [tilt.boot](#), [tsboot](#)

Examples

```
# A frequency array for a nonparametric bootstrap
city.boot <- boot(city, corr, R=40, stype="w")
boot.array(city.boot)

perm.cor <- function(d,i)
  cor(d$x,d$u[i])
city.perm <- boot(city, perm.cor, R=40, sim="permutation")
boot.array(city.perm, indices=TRUE)
```

Description

This function generates 5 different types of equi-tailed two-sided nonparametric confidence intervals. These are the first order normal approximation, the basic bootstrap interval, the studentized bootstrap interval, the bootstrap percentile interval, and the adjusted bootstrap percentile (BCa) interval. All or a subset of these intervals can be generated.

Usage

```
boot.ci(boot.out, conf = 0.95, type = "all",
        index = 1:min(2,length(boot.out$t0)), var.t0 = NULL,
        var.t = NULL, t0 = NULL, t = NULL, L = NULL, h = function(t) t,
        hdot = function(t) rep(1,length(t)), hinu = function(t) t, ...)
```

Arguments

boot.out	An object of class "boot" containing the output of a bootstrap calculation.
conf	A scalar or vector containing the confidence level(s) of the required interval(s).
type	A vector of character strings representing the type of intervals required. The value should be any subset of the values c("norm", "basic", "stud", "perc", "bca") or simply "all" which will compute all five types of intervals.
index	This should be a vector of length 1 or 2. The first element of index indicates the position of the variable of interest in boot.out\$t0 and the relevant column in boot.out\$t. The second element indicates the position of the variance of the variable of interest. If both var.t0 and var.t are supplied then the second element of index (if present) is ignored. The default is that the variable of interest is in position 1 and its variance is in position 2 (as long as there are 2 positions in boot.out\$t0).
var.t0	If supplied, a value to be used as an estimate of the variance of the statistic for the normal approximation and studentized intervals. If it is not supplied and length(index) is 2 then var.t0 defaults to boot.out\$t0[index[2]] otherwise var.t0 is undefined. For studentized intervals var.t0 must be defined. For the normal approximation, if var.t0 is undefined it defaults to var(t). If a transformation is supplied through the argument h then var.t0 should be the variance of the untransformed statistic.
var.t	This is a vector (of length boot.out\$R) of variances of the bootstrap replicates of the variable of interest. It is used only for studentized intervals. If it is not supplied and length(index) is 2 then var.t defaults to boot.out\$t[,index[2]], otherwise its value is undefined which will cause an error for studentized intervals. If a transformation is supplied through the argument h then var.t should be the variance of the untransformed bootstrap statistics.

<code>t0</code>	The observed value of the statistic of interest. The default value is <code>boot.out\$t0[index[1]]</code> . Specification of <code>t0</code> and <code>t</code> allows the user to get intervals for a transformed statistic which may not be in the bootstrap output object. See the second example below. An alternative way of achieving this would be to supply the functions <code>h</code> , <code>hdot</code> , and <code>hinv</code> below.
<code>t</code>	The bootstrap replicates of the statistic of interest. It must be a vector of length <code>boot.out\$R</code> . It is an error to supply one of <code>t0</code> or <code>t</code> but not the other. Also if studentized intervals are required and <code>t0</code> and <code>t</code> are supplied then so should be <code>var.t0</code> and <code>var.t</code> . The default value is <code>boot.out\$t[,index]</code> .
<code>L</code>	The empirical influence values of the statistic of interest for the observed data. These are used only for BCa intervals. If a transformation is supplied through the parameter <code>h</code> then <code>L</code> should be the influence values for <code>t</code> ; the values for <code>h(t)</code> are derived from these and <code>hdot</code> within the function. If <code>L</code> is not supplied then the values are calculated using <code>empinf</code> if they are needed.
<code>h</code>	A function defining a transformation. The intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> applied to the resulting intervals. It must be a function of one variable only and for a vector argument, it must return a vector of the same length, i.e. <code>h(c(t1,t2,t3))</code> should return <code>c(h(t1),h(t2),h(t3))</code> . The default is the identity function.
<code>hdot</code>	A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and normal, studentized or BCa intervals are required. The function is used for approximating the variances of <code>h(t0)</code> and <code>h(t)</code> using the delta method, and also for finding the empirical influence values for BCa intervals. Like <code>h</code> it should be able to take a vector argument and return a vector of the same length. The default is the constant function 1.
<code>hinv</code>	A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale.
<code>...</code>	Any extra arguments that <code>boot.out\$statistic</code> is expecting. These arguments are needed only if BCa intervals are required and <code>L</code> is not supplied since in that case <code>L</code> is calculated through a call to <code>empinf</code> which calls <code>boot.out\$statistic</code> .

Details

The formulae on which the calculations are based can be found in Chapter 5 of Davison and Hinkley (1997). Function `boot` must be run prior to running this function to create the object to be passed as `boot.out`.

Variance estimates are required for studentized intervals. The variance of the observed statistic is optional for normal theory intervals. If it is not supplied then the bootstrap estimate of variance is used. The normal intervals also use the bootstrap bias correction.

Interpolation on the normal quantile scale is used when a non-integer order statistic is required. If the order statistic used is the smallest or largest of the `R` values in `boot.out` a warning is generated and such intervals should not be considered reliable.

Value

An object of type "`bootci`" which contains the intervals. It has components

`R` The number of bootstrap replicates on which the intervals were based.

t0	The observed value of the statistic on the same scale as the intervals.
call	The call to <code>boot.ci</code> which generated the object. It will also contain one or more of the following components depending on the value of <code>type</code> used in the call to <code>boot.ci</code> .
normal	A matrix of intervals calculated using the normal approximation. It will have 3 columns, the first being the level and the other two being the upper and lower endpoints of the intervals.
basic	The intervals calculated using the basic bootstrap method.
student	The intervals calculated using the studentized bootstrap method.
percent	The intervals calculated using the bootstrap percentile method.
bca	The intervals calculated using the adjusted bootstrap percentile (BCa) method. These latter four components will be matrices with 5 columns, the first column containing the level, the next two containing the indices of the order statistics used in the calculations and the final two the calculated endpoints themselves.

brambles

*Spatial Location of Bramble Canes***Description**

The brambles data frame has 823 rows and 3 columns.

The location of living bramble canes in a 9m square plot was recorded. We take 9m to be the unit of distance so that the plot can be thought of as a unit square. The bramble canes were also classified by their age.

Usage

```
brambles
```

Format

This data frame contains the following columns:

- x** The x coordinate of the position of the cane in the plot.
- y** The y coordinate of the position of the cane in the plot.
- age** The age classification of the canes; 0 indicates a newly emerged cane, 1 indicates a one year old cane and 2 indicates a two year old cane.

Source

The data were obtained from

Diggle, P.J. (1983) *Statistical Analysis of Spatial Point Patterns*. Academic Press.

breslow

Smoking Deaths Among Doctors

Description

The `breslow` data frame has 10 rows and 5 columns.

In 1961 Doll and Hill sent out a questionnaire to all men on the British Medical Register enquiring about their smoking habits. Almost 70% of such men replied. Death certificates were obtained for medical practitioners and causes of death were assigned on the basis of these certificates. The `breslow` data set contains the person-years of observations and deaths from coronary artery disease accumulated during the first ten years of the study.

Usage

```
breslow
```

Format

This data frame contains the following columns:

age The mid-point of the 10 year age-group for the doctors.

smoke An indicator of whether the doctors smoked (1) or not (0).

n The number of person-years in the category.

y The number of deaths attributed to coronary artery disease.

ns The number of smoker years in the category (`smoke*n`).

Source

The data were obtained from

Breslow, N.E. (1985) Cohort Analysis in Epidemiology. In *A Celebration of Statistics* A.C. Atkinson and S.E. Fienberg (editors), 109–143. Springer-Verlag.

`calcium`*Calcium Uptake Data*

Description

The `calcium` data frame has 27 rows and 2 columns.

Howard Grimes from the Botany Department, North Carolina State University, conducted an experiment for biochemical analysis of intracellular storage and transport of calcium across plasma membrane. Cells were suspended in a solution of radioactive calcium for a certain length of time and then the amount of radioactive calcium that was absorbed by the cells was measured. The experiment was repeated independently with 9 different times of suspension each replicated 3 times.

Usage

```
calcium
```

Format

This data frame contains the following columns:

time The time (in minutes) that the cells were suspended in the solution.

cal The amount of calcium uptake (nmoles/mg).

Source

The data were obtained from

Rawlings, J.O. (1988) *Applied Regression Analysis*. Wadsworth and Brooks/Cole Statistics/Probability Series.

`cane`*Sugar-cane Disease Data*

Description

The `cane` data frame has 180 rows and 5 columns. The data frame represents a randomized block design with 45 varieties of sugar-cane and 4 blocks.

Usage

```
cane
```

Format

This data frame contains the following columns:

- n** The total number of shoots in each plot.
- r** The number of diseased shoots.
- x** The number of pieces of the stems, out of 50, planted in each plot.
- var** A factor indicating the variety of sugar-cane in each plot.
- block** A factor for the blocks.

Details

The aim of the experiment was to classify the varieties into resistant, intermediate and susceptible to a disease called "coal of sugar-cane" (carvão da cana-de-açúcar). This is a disease that is common in sugar-cane plantations in certain areas of Brazil.

For each plot, fifty pieces of sugar-cane stem were put in a solution containing the disease agent and then some were planted in the plot. After a fixed period of time, the total number of shoots and the number of diseased shoots were recorded.

Source

The data were kindly supplied by Dr. C.G.B. Demetrio of Escola Superior de Agricultura, Universidade de São Paulo, Brazil.

capability

Simulated Manufacturing Process Data

Description

The `capability` data frame has 75 rows and 1 column.

The data are simulated successive observations from a process in equilibrium. The process is assumed to have specification limits (5.49, 5.79).

Usage

```
capability
```

Format

This data frame contains the following column:

- y** The simulated measurements.

Source

The data were obtained from

Bissell, A.F. (1990) How reliable is your capability index? *Applied Statistics*, **39**, 331–340.

catsM

Weight Data for Domestic Cats

Description

The `catsM` data frame has 97 rows and 3 columns.

144 adult (over 2kg in weight) cats used for experiments with the drug digitalis had their heart and body weight recorded. 47 of the cats were female and 97 were male. The `catsM` data frame consists of the data for the male cats. The full data are in dataset `cats` in package `MASS`.

Usage

```
cats
```

Format

This data frames contain the following columns:

Sex A factor for the sex of the cat (levels are F and M).

Bwt Body weight in kg.

Hwt Heart weight in g.

Source

The data were obtained from

Fisher, R.A. (1947) The analysis of covariance method for the relation between a part and the whole. *Biometrics*, **3**, 65–68.

`cav`*Position of Muscle Caveolae*

Description

The `cav` data frame has 138 rows and 2 columns.

The data gives the positions of the individual caveolae in a square region with sides of length 500 units. This grid was originally on a 2.65µm square of muscle fibre. The data are those points falling in the lower left hand quarter of the region used for the dataset `caveolae.dat` in the **spatial** package by B.D. Ripley (1994) which is part of the recommended **VR** bundle.

Usage`cav`**Format**

This data frame contains the following columns:

- x** The x coordinate of the caveola's position in the region.
- y** The y coordinate of the caveola's position in the region.

`cd4`*CD4 Counts for HIV-Positive Patients*

Description

The `cd4` data frame has 20 rows and 2 columns.

CD4 cells are carried in the blood as part of the human immune system. One of the effects of the HIV virus is that these cells die. The count of CD4 cells is used in determining the onset of full-blown AIDS in a patient. In this study of the effectiveness of a new anti-viral drug on HIV, 20 HIV-positive patients had their CD4 counts recorded and then were put on a course of treatment with this drug. After using the drug for one year, their CD4 counts were again recorded. The aim of the experiment was to show that patients taking the drug had increased CD4 counts which is not generally seen in HIV-positive patients.

Usage`cd4`

Format

This data frame contains the following columns:

baseline The CD4 counts (in 100's) on admission to the trial.

oneyear The CD4 counts (in 100's) after one year of treatment with the new drug.

Source

The data were obtained from

DiCiccio, T.J. and Efron B. (1996) Bootstrap confidence intervals (with Discussion). *Statistical Science*, **11**, 189–228.

censboot	<i>Bootstrap for Censored Data</i>
----------	------------------------------------

Description

This function applies types of bootstrap resampling which have been suggested to deal with right-censored data. It can also do model-based resampling using a Cox regression model.

Usage

```
censboot(data, statistic, R, F.surv, G.surv, strata=matrix(1,n,2),
          sim="ordinary", cox=NULL, index=c(1, 2), ...)
```

Arguments

<code>data</code>	The data frame or matrix containing the data. It must have at least two columns, one of which contains the times and the other the censoring indicators. It is allowed to have as many other columns as desired (although efficiency is reduced for large numbers of columns) except for <code>sim="weird"</code> when it should only have two columns - the times and censoring indicators. The columns of <code>data</code> referenced by the components of <code>index</code> are taken to be the times and censoring indicators.
<code>statistic</code>	A function which operates on the data frame and returns the required statistic. Its first argument must be the data. Any other arguments that it requires can be passed using the <code>...{}</code> argument. In the case of <code>sim="weird"</code> , the data passed to <code>statistic</code> only contains the times and censoring indicator regardless of the actual number of columns in <code>data</code> . In all other cases the data passed to <code>statistic</code> will be of the same form as the original data. When <code>sim="weird"</code> , the actual number of observations in the resampled data sets may not be the same as the number in <code>data</code> . For this reason, if <code>sim="weird"</code> and <code>strata</code> is supplied, <code>statistic</code> should also take a numeric vector indicating the strata. This allows the statistic to depend on the strata if required.
<code>R</code>	The number of bootstrap replicates.
<code>F.surv</code>	An object returned from a call to <code>survfit</code> giving the survivor function for the data. This is a required argument unless <code>sim="ordinary"</code> or <code>sim="model"</code> and <code>cox</code> is missing.
<code>G.surv</code>	Another object returned from a call to <code>survfit</code> but with the censoring indicators reversed to give the product-limit estimate of the censoring distribution. Note that for consistency the uncensored times should be reduced by a small amount in the call to <code>survfit</code> . This is a required argument whenever <code>sim="cond"</code> or when <code>sim="model"</code> and <code>cox</code> is supplied.
<code>strata</code>	The strata used in the calls to <code>survfit</code> . It can be a vector or a matrix with 2 columns. If it is a vector then it is assumed to be the strata for the survival distribution, and the censoring distribution is assumed to be the same for all observations. If it is a matrix then the first column is the strata for the survival distribution and the second is the strata for the censoring distribution. When <code>sim="weird"</code> only the strata for the survival distribution are used since the censoring times are considered fixed. When <code>sim="ordinary"</code> , only one set of strata is used to stratify the observations, this is taken to be the first column of <code>strata</code> when it is a matrix.
<code>sim</code>	The simulation type. Possible types are <code>"ordinary"</code> (case resampling), <code>"model"</code> (equivalent to <code>"ordinary"</code> if <code>cox</code> is missing, otherwise it is model based resampling), <code>"weird"</code> (the weird bootstrap - this cannot be used if <code>cox</code> is supplied), and <code>"cond"</code> (the conditional bootstrap, in which censoring times are resampled from the conditional censoring distribution).
<code>cox</code>	An object returned from <code>coxph</code> . If it is supplied, then <code>F.surv</code> should have been generated by a call of the form <code>survfit(cox)</code> .
<code>index</code>	A vector of length two giving the positions of the columns in <code>data</code> which correspond to the times and censoring indicators respectively.
<code>...</code>	Any other arguments which are passed to <code>statistic</code> .

Details

The various types of resampling are described in Davison and Hinkley (1997) in sections 3.5 and 7.3. The simplest is case resampling which simply resamples with replacement from the observa-

tions.

The conditional bootstrap simulates failure times from the estimate of the survival distribution. Then, for each observation its simulated censoring time is equal to the observed censoring time if the observation was censored and generated from the estimated censoring distribution conditional on being greater than the observed failure time if the observation was uncensored. If the largest value is censored then it is given a nominal failure time of `Inf` and conversely if it is uncensored it is given a nominal censoring time of `Inf`. This is necessary to allow the largest observation to be in the resamples.

If a Cox regression model is fitted to the data and supplied, then the failure times are generated from the survival distribution using that model. In this case the censoring times can either be simulated from the estimated censoring distribution (`sim="model"`) or from the conditional censoring distribution as in the previous paragraph (`sim="cond"`).

The weird bootstrap holds the censored observations as fixed and also the observed failure times. It then generates the number of events at each failure time using a binomial distribution with mean 1 and denominator the number of failures that could have occurred at that time in the original data set. In our implementation we insist that there is a least one simulated event in each stratum for every bootstrap dataset.

When there are strata involved and `sim` is either `"model"` or `"cond"` the situation becomes more difficult. Since the strata for the survival and censoring distributions are not the same it is possible that for some observations both the simulated failure time and the simulated censoring time are infinite. To see this consider an observation in stratum 1F for the survival distribution and stratum 1G for the censoring distribution. Now if the largest value in stratum 1F is censored it is given a nominal failure time of `Inf`, also if the largest value in stratum 1G is uncensored it is given a nominal censoring time of `Inf` and so both the simulated failure and censoring times could be infinite. When this happens the simulated value is considered to be a failure at the time of the largest observed failure time in the stratum for the survival distribution.

Value

An object of class `"boot"` containing the following components:

<code>t0</code>	The value of <code>statistic</code> when applied to the original data.
<code>t</code>	A matrix of bootstrap replicates of the values of <code>statistic</code> .
<code>R</code>	The number of bootstrap replicates performed.
<code>sim</code>	The simulation type used. This will usually be the input value of <code>sim</code> unless that was <code>"model"</code> but <code>cox</code> was not supplied, in which case it will be <code>"ordinary"</code> .
<code>data</code>	The data used for the bootstrap. This will generally be the input value of <code>data</code> unless <code>sim="weird"</code> , in which case it will just be the columns containing the times and the censoring indicators.
<code>seed</code>	The value of <code>.Random.seed</code> when <code>censboot</code> was called.
<code>statistic</code>	The input value of <code>statistic</code> .
<code>strata</code>	The strata used in the resampling. When <code>sim="ordinary"</code> this will be a vector which stratifies the observations, when <code>sim="weird"</code> it is the strata for the survival distribution and in all other cases it is a matrix containing the strata for the survival distribution and the censoring distribution.
<code>call</code>	The original call to <code>censboot</code> .

```

Description

The `channing` data frame has 462 rows and 5 columns.

Channing House is a retirement centre in Palo Alto, California. These data were collected between the opening of the house in 1964 until July 1, 1975. In that time 97 men and 365 women passed through the centre. For each of these, their age on entry and also on leaving or death was recorded. A large number of the observations were censored mainly due to the resident being alive on July 1, 1975 when the data was collected. Over the time of the study 130 women and 46 men died at Channing House. Differences between the survival of the sexes, taking age into account, was one of the primary concerns of this study.

Usage

```
channing
```

Format

This data frame contains the following columns:

sex A factor for the sex of each resident ("Male" or "Female").

entry The residents age (in months) on entry to the centre

exit The age (in months) of the resident on death, leaving the centre or July 1, 1975 whichever event occurred first.

time The length of time (in months) that the resident spent at Channing House.
(`time=exit-entry`)

cens The indicator of right censoring. 1 indicates that the resident died at Channing House, 0 indicates that they left the house prior to July 1, 1975 or that they were still alive and living in the centre at that date.

Description

The `claridge` data frame has 37 rows and 2 columns.

The data are from an experiment which was designed to look for a relationship between a certain genetic characteristic and handedness. The 37 subjects were women who had a son with mental retardation due to inheriting a defective X-chromosome. For each such mother a genetic measurement of their DNA was made. Larger values of this measurement are known to be linked to the defective gene and it was hypothesized that larger values might also be linked to a progressive shift away from right-handedness. Each woman also filled in a questionnaire regarding which hand they used for various tasks. From these questionnaires a measure of hand preference was found for each mother. The scale of this measure goes from 1, indicating someone who always favours their right hand, to 8, indicating someone who always favours their left hand. Between these two extremes are people who favour one hand for some tasks and the other for other tasks.

Usage

```
claridge
```

Format

This data frame contains the following columns:

dnan The genetic measurement on each woman's DNA.

hand The measure of left-handedness on an integer scale from 1 to 8.

Source

The data were kindly made available by Dr. Gordon S. Claridge from the Department of Experimental Psychology, University of Oxford.

`co.transfer`*Carbon Monoxide Transfer*

Description

The `co.transfer` data frame has 7 rows and 2 columns. Seven smokers with chickenpox had their levels of carbon monoxide transfer measured on entry to hospital and then again after 1 week. The main question being whether one week of hospitalization has changed the carbon monoxide transfer factor.

Usage

```
co.transfer
```

Format

This data frame contains the following columns:

entry Carbon monoxide transfer factor on entry to hospital.

week Carbon monoxide transfer one week after admittance to hospital.

Source

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E (1994) *A Handbook of Small Data Sets*. Chapman and Hall.

`coal`*Dates of Coal Mining Disasters*

Description

The `coal` data frame has 191 rows and 1 columns.

This data frame gives the dates of 191 explosions in coal mines which resulted in 10 or more fatalities. The time span of the data is from March 15, 1851 until March 22 1962.

Usage

```
coal
```

Format

This data frame contains the following column:

date The date of the disaster. The integer part of `date` gives the year. The day is represented as the fraction of the year that had elapsed on that day.

Source

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) *A Handbook of Small Data Sets*, Chapman and Hall.

`control`*Control Variate Calculations*

Description

This function will find control variate estimates from a bootstrap output object. It can either find the adjusted bias estimate using post-simulation balancing or it can estimate the bias, variance, third cumulant and quantiles, using the linear approximation as a control variate.

Usage

```
control(boot.out, L = NULL, distn = NULL, index = 1, t0 = NULL,  
        t = NULL, bias.adj = FALSE, alpha = NULL, ...)
```

Arguments

<code>boot.out</code>	A bootstrap output object returned from <code>boot</code> . The bootstrap replicates must have been generated using the usual nonparametric bootstrap.
<code>L</code>	The empirical influence values for the statistic of interest. If <code>L</code> is not supplied then <code>empinf</code> is called to calculate them from <code>boot.out</code> .
<code>distn</code>	If present this must be the output from <code>smooth.spline</code> giving the distribution function of the linear approximation. This is used only if <code>bias.adj</code> is <code>FALSE</code> . Normally this would be found using a saddlepoint approximation. If it is not supplied in that case then it is calculated by <code>saddle.distn</code> .
<code>index</code>	The index of the variable of interest in the output of <code>boot.out\$statistic</code> .
<code>t0</code>	The observed value of the statistic of interest on the original data set <code>boot.out\$data</code> . This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input value is ignored if <code>t</code> is not also supplied. The default value is <code>boot.out\$t0[index]</code> .
<code>t</code>	The bootstrap replicate values of the statistic of interest. This argument is used only if <code>bias.adj</code> is <code>FALSE</code> . The input is ignored if <code>t0</code> is not supplied also. The default value is <code>boot.out\$t[, index]</code> .
<code>bias.adj</code>	A logical variable which if <code>TRUE</code> specifies that the adjusted bias estimate using post-simulation balance is all that is required. If <code>bias.adj</code> is <code>FALSE</code> (default) then the linear approximation to the statistic is calculated and used as a control variate in estimates of the bias, variance and third cumulant as well as quantiles.
<code>alpha</code>	The alpha levels for the required quantiles if <code>bias.adj</code> is <code>FALSE</code> .
<code>...</code>	Any additional arguments that <code>boot.out\$statistic</code> requires. These are passed unchanged every time <code>boot.out\$statistic</code> is called. <code>boot.out\$statistic</code> is called once if <code>bias.adj</code> is <code>TRUE</code> , otherwise it may be called by <code>empinf</code> for empirical influence calculations if <code>L</code> is not supplied.

Details

If `bias.adj` is `FALSE` then the linear approximation to the statistic is found and evaluated at each bootstrap replicate. Then using the equation $T^* = Tl^* + (T^* - Tl^*)$, moment estimates can be found. For quantile estimation the distribution of the linear approximation to `t` is approximated very accurately by saddlepoint methods, this is then combined with the bootstrap replicates to approximate the bootstrap distribution of `t` and hence to estimate the bootstrap quantiles of `t`.

Value

If `bias.adj` is `TRUE` then the returned value is the adjusted bias estimate.

If `bias.adj` is `FALSE` then the returned value is a list with the following components

<code>L</code>	The empirical influence values used. These are the input values if supplied, and otherwise they are the values calculated by <code>empinf</code> .
<code>tL</code>	The linear approximations to the bootstrap replicates <code>t</code> of the statistic of interest.
<code>bias</code>	The control estimate of bias using the linear approximation to <code>t</code> as a control variate.
<code>var</code>	The control estimate of variance using the linear approximation to <code>t</code> as a control variate.

k3	The control estimate of the third cumulant using the linear approximation to t as a control variate.
quantiles	A matrix with two columns; the first column are the alpha levels used for the quantiles and the second column gives the corresponding control estimates of the quantiles using the linear approximation to t as a control variate.
distn	An output object from <code>smooth.spline</code> describing the saddlepoint approximation to the bootstrap distribution of the linear approximation to t . If <code>distn</code> was supplied on input then this is the same as the input otherwise it is calculated by a call to <code>saddle.distn</code> .

Examples

```
# Use of control variates for the variance of the air-conditioning data
mean.fun <- function(d, i)
{
  m <- mean(d$hours[i])
  n <- nrow(d)
  v <- (n-1)*var(d$hours[i])/n^2
  c(m, v)
}
air.boot <- boot(aircondit, mean.fun, R = 999)
control(air.boot, index = 2, bias.adj = TRUE)
air.cont <- control(air.boot, index = 2)
# Now let us try the variance on the log scale.
air.cont1 <- control(air.boot, t0=log(air.boot$t0[2]),
                   t=log(air.boot$t[,2]))
```

corr

Correlation Coefficient

Description

Calculates the weighted correlation given a data set and a set of weights.

Usage

```
corr(d, w=rep(1, nrow(d))/nrow(d))
```

Arguments

- d** A matrix with two columns corresponding to the two variables whose correlation we wish to calculate.
- w** A vector of weights to be applied to each pair of observations. The default is equal weights for each pair. Normalization takes place within the function so `sum(w)` need not equal 1.

Details

This function finds the correlation coefficient in weighted form. This is often useful in bootstrap methods since it allows for numerical differentiation to get the empirical influence values. It is also necessary to have the statistic in this form to find ABC intervals.

Value

The correlation coefficient between `d[, 1]` and `d[, 2]`.

See Also

[cor](#)

cum3

Calculate Third Order Cumulants

Description

Calculates an estimate of the third cumulant, or skewness, of a vector. Also, if more than one vector is specified, a product-moment of order 3 is estimated.

Usage

```
cum3(a, b=a, c=a, unbiased=TRUE)
```

Arguments

- a** A vector of observations.
- b** Another vector of observations, if not supplied it is set to the value of `a`. If supplied then it must be the same length as `a`.
- c** Another vector of observations, if not supplied it is set to the value of `a`. If supplied then it must be the same length as `a`.
- unbiased** A logical value indicating whether the unbiased estimator should be used.

Details

The unbiased estimator uses a multiplier of $n / ((n-1) * (n-2))$ where n is the sample size, if `unbiased` is `FALSE` then a multiplier of $1/n$ is used. This is multiplied by `sum((a - mean(a)) * (b - mean(b)) * (c - mean(c)))` to give the required estimate.

Value

The required estimate.

cv.glm

*Cross-validation for Generalized Linear Models***Description**

This function calculates the estimated K-fold cross-validation prediction error for generalized linear models.

Usage

```
cv.glm(data, glmfit, cost, K)
```

Arguments

data	A matrix or data frame containing the data. The rows should be cases and the columns correspond to variables, one of which is the response.
glmfit	An object of class "glm" containing the results of a generalized linear model fitted to data.
cost	A function of two vector arguments specifying the cost function for the cross-validation. The first argument to <code>cost</code> should correspond to the observed responses and the second argument should correspond to the predicted or fitted responses from the generalized linear model. <code>cost</code> must return a non-negative scalar value. The default is the average squared error function.
K	The number of groups into which the data should be split to estimate the cross-validation prediction error. The value of <code>K</code> must be such that all groups are of approximately equal size. If the supplied value of <code>K</code> does not satisfy this criterion then it will be set to the closest integer which does and a warning is generated specifying the value of <code>K</code> used. The default is to set <code>K</code> equal to the number of observations in <code>data</code> which gives the usual leave-one-out cross-validation.

Details

The data is divided randomly into `K` groups. For each group the generalized linear model is fit to `data` omitting that group, then the function `cost` is applied to the observed responses in the group that was omitted from the fit and the prediction made by the fitted models for those observations.

When `K` is the number of observations leave-one-out cross-validation is used and all the possible splits of the data are used. When `K` is less than the number of observations the `K` splits to be used are found by randomly partitioning the data into `K` groups of approximately equal size. In this latter case a certain amount of bias is introduced. This can be reduced by using a simple adjustment (see equation 6.48 in Davison and Hinkley, 1997). The second value returned in `delta` is the estimate adjusted by this method.

Value

The returned value is a list with the following components.

call	The original call to <code>cv.glm</code> .
K	The value of <code>K</code> used for the K-fold cross validation.

delta	A vector of length two. The first component is the raw cross-validation estimate of prediction error. The second component is the adjusted cross-validation estimate. The adjustment is designed to compensate for the bias introduced by not using leave-one-out cross-validation.
seed	The value of <code>.Random.seed</code> when <code>cv.glm</code> was called.

Side Effects

The value of `.Random.seed` is updated.

`darwin`*Darwin's Plant Height Differences*

Description

The `darwin` data frame has 15 rows and 1 columns.

Charles Darwin conducted an experiment to examine the superiority of cross-fertilized plants over self-fertilized plants. 15 pairs of plants were used. Each pair consisted of one cross-fertilized plant and one self-fertilized plant which germinated at the same time and grew in the same pot. The plants were measured at a fixed time after planting and the difference in heights between the cross- and self-fertilized plants are recorded in eighths of an inch.

Usage

```
darwin
```

Format

This data frame contains the following column:

y The difference in heights for the pairs of plants (in units of 0.125 inches).

Source

The data were obtained from

Fisher, R.A. (1935) *Design of Experiments*. Oliver and Boyd.

downs.bc

Incidence of Down's Syndrome in British Columbia

Description

The `downs.bc` data frame has 30 rows and 3 columns.

Down's syndrome is a genetic disorder caused by an extra chromosome 21 or a part of chromosome 21 being translocated to another chromosome. The incidence of Down's syndrome is highly dependent on the mother's age and rises sharply after age 30. In the 1960's a large scale study of the effect of maternal age on the incidence of Down's syndrome was conducted at the British Columbia Health Surveillance Registry. These are the data which was collected in that study.

Mothers were classified by age. Most groups correspond to the age in years but the first group comprises all mothers with ages in the range 15-17 and the last is those with ages 46-49. No data for mothers over 50 or below 15 were collected.

Usage

`downs.bc`

Format

This data frame contains the following columns:

age The average age of all mothers in the age category.

m The total number of live births to mothers in the age category.

r The number of cases of Down's syndrome.

Source

The data were obtained from

Geyer, C.J. (1991) Constrained maximum likelihood exemplified by isotonic convex logistic regression. *Journal of the American Statistical Association*, **86**, 717–724.

`ducks`*Behavioral and Plumage Characteristics of Hybrid Ducks*

Description

The `ducks` data frame has 11 rows and 2 columns.

Each row of the data frame represents a male duck who is a second generation cross of mallard and pintail ducks. For 11 such ducks a behavioural and plumage index were calculated. These were measured on scales devised for this experiment which was to examine whether there was any link between which species the ducks resembled physically and which they resembled in behaviour. The scale for the physical appearance ranged from 0 (identical in appearance to a mallard) to 20 (identical to a pintail). The behavioural traits of the ducks were on a scale from 0 to 15 with lower numbers indicating closer to mallard-like in behaviour.

Usage`ducks`**Format**

This data frame contains the following columns:

plumage The index of physical appearance based on the plumage of individual ducks.

behaviour The index of behavioural characteristics of the ducks.

Source

The data were obtained from

Larsen, R.J. and Marx, M.L. (1986) *An Introduction to Mathematical Statistics and its Applications* (Second Edition). Prentice-Hall.

References

Sharpe, R.S., and Johnsgard, P.A. (1966) Inheritance of behavioral characters in F_2 mallard x pintail (*Anas Platyrhynchos L. x Anas Acuta L.*) hybrids. *Behaviour*, **27**, 259-272.

`EEF.profile`*Empirical Likelihoods*

Description

Construct the empirical log likelihood or empirical exponential family log likelihood for a mean.

Usage

```
EEF.profile(y, tmin=min(y) + 0.1, tmax=max(y) - 0.1, n.t=25,
           u=function(y, t) { y-t})
EL.profile(y, tmin = min(y) + 0.1, tmax = max(y) - 0.1, n.t = 25,
          u = function(y, t) y - t)
```

Arguments

<code>y</code>	A vector or matrix of data
<code>tmin</code>	The minimum value of the range over which the likelihood should be computed. This must be larger than <code>min(y)</code> .
<code>tmax</code>	The maximum value of the range over which the likelihood should be computed. This must be smaller than <code>max(y)</code> .
<code>n.t</code>	The number of points between <code>tmin</code> and <code>tmax</code> at which the value of the log-likelihood should be computed.
<code>u</code>	A function of the data and the parameter.

Details

These functions calculate the log likelihood for a mean using either an empirical likelihood or an empirical exponential family likelihood. They are supplied as part of the package `boot` for demonstration purposes with the practicals in chapter 10 of Davison and Hinkley (1997). The functions are not intended for general use and are not supported as part of the `boot` package. For more general and more robust code to calculate empirical likelihoods see Professor A. B. Owen's empirical likelihood home page at the URL <http://www-stat.stanford.edu/~owen/empirical/>.

Value

A matrix with `n.t` rows. The first column contains the values of the parameter used. The second column of the output of `EL.profile` contains the values of the empirical log likelihood. The second and third columns of the output of `EEF.profile` contain two versions of the empirical exponential family log-likelihood. The final column of the output matrix contains the values of the Lagrange multiplier used in the optimization procedure.

empinf

*Empirical Influence Values***Description**

This function calculates the empirical influence values for a statistic applied to a data set. It allows four types of calculation, namely the infinitesimal jackknife (using numerical differentiation), the usual jackknife estimates, the ‘positive’ jackknife estimates and a method which estimates the empirical influence values using regression of bootstrap replicates of the statistic. All methods can be used with one or more samples.

Usage

```
empinf(boot.out = NULL, data = NULL, statistic = NULL,
       type = NULL, stype = NULL, index = 1, t = NULL,
       strata = rep(1, n), eps = 0.001, ...)
```

Arguments

- | | |
|------------------------|--|
| <code>boot.out</code> | A bootstrap object created by the function <code>boot</code> . If <code>type</code> is "reg" then this argument is required. For any of the other types it is an optional argument. If it is included when optional then the values of <code>data</code> , <code>statistic</code> , <code>stype</code> , and <code>strata</code> are taken from the components of <code>boot.out</code> and any values passed to <code>empinf</code> directly are ignored. |
| <code>data</code> | A vector, matrix or data frame containing the data for which empirical influence values are required. It is a required argument if <code>boot.out</code> is not supplied. If <code>boot.out</code> is supplied then <code>data</code> is set to <code>boot.out\$data</code> and any value supplied is ignored. |
| <code>statistic</code> | The statistic for which empirical influence values are required. It must be a function of at least two arguments, the data set and a vector of weights, frequencies or indices. The nature of the second argument is given by the value of <code>stype</code> . Any other arguments that it takes must be supplied to <code>empinf</code> and will be passed to <code>statistic</code> unchanged. This is a required argument if <code>boot.out</code> is not supplied, otherwise its value is taken from <code>boot.out</code> and any value supplied here will be ignored. |
| <code>type</code> | The calculation type to be used for the empirical influence values. Possible values of <code>type</code> are "inf" (infinitesimal jackknife), "jack" (usual jackknife), "pos" (positive jackknife), and "reg" (regression estimation). The default value depends on the other arguments. If <code>t</code> is supplied then the default value of <code>type</code> is "reg" and <code>boot.out</code> should be present so that its frequency array can be found. If <code>t</code> is not supplied then if <code>stype</code> is "w", the default value of <code>type</code> is "inf"; otherwise, if <code>boot.out</code> is present the default is "reg". If none of these conditions apply then the default is "jack". Note that it is an error for <code>type</code> to be "reg" if <code>boot.out</code> is missing or to be "inf" if <code>stype</code> is not "w". |
| <code>stype</code> | A character variable giving the nature of the second argument to <code>statistic</code> . It can take on three values: "w" (weights), "f" (frequencies), or "i" (indices). If <code>boot.out</code> is supplied the value of <code>stype</code> is set to <code>boot.out\$stype</code> and any value supplied here is ignored. Otherwise it is an optional argument which defaults to "w". If <code>type</code> is "inf" then <code>stype</code> MUST be "w". |

index	An integer giving the position of the variable of interest in the output of <code>statistic</code> .
t	A vector of length <code>boot.out\$R</code> which gives the bootstrap replicates of the statistic of interest. <code>t</code> is used only when <code>type</code> is <code>reg</code> and it defaults to <code>boot.out\$t[, index]</code> .
strata	An integer vector or a factor specifying the strata for multi-sample problems. If <code>boot.out</code> is supplied the value of <code>strata</code> is set to <code>boot.out\$strata</code> . Otherwise it is an optional argument which has default corresponding to the single sample situation.
eps	This argument is used only if <code>type</code> is <code>"inf"</code> . In that case the value of epsilon to be used for numerical differentiation will be <code>eps</code> divided by the number of observations in <code>data</code> .
...	Any other arguments that <code>statistic</code> takes. They will be passed unchanged to <code>statistic</code> every time that it is called.

Details

If `type` is `"inf"` then numerical differentiation is used to approximate the empirical influence values. This makes sense only for statistics which are written in weighted form (i.e. `stype` is `"w"`). If `type` is `"jack"` then the usual leave-one-out jackknife estimates of the empirical influence are returned. If `type` is `"pos"` then the positive (include-one-twice) jackknife values are used. If `type` is `"reg"` then a bootstrap object must be supplied. The regression method then works by regressing the bootstrap replicates of `statistic` on the frequency array from which they were derived. The bootstrap frequency array is obtained through a call to `boot.array`. Further details of the methods are given in Section 2.7 of Davison and Hinkley (1997).

Empirical influence values are often used frequently in nonparametric bootstrap applications. For this reason many other functions call `empinf` when they are required. Some examples of their use are for nonparametric delta estimates of variance, BCa intervals and finding linear approximations to statistics for use as control variates. They are also used for antithetic bootstrap resampling.

Value

A vector of the empirical influence values of `statistic` applied to `data`. The values will be in the same order as the observations in `data`.

Warning

All arguments to `empinf` must be passed using the `name = value` convention. If this is not followed then unpredictable errors can occur.

```

envelope

Confidence Envelopes for Curves

Description

This function calculates overall and pointwise confidence envelopes for a curve based on bootstrap replicates of the curve evaluated at a number of fixed points.

Usage

```
envelope(boot.out=NULL, mat=NULL, level=0.95, index=1:ncol(mat))
```

Arguments

<code>boot.out</code>	An object of class "boot" for which <code>boot.out\$t</code> contains the replicates of the curve at a number of fixed points.
<code>mat</code>	A matrix of bootstrap replicates of the values of the curve at a number of fixed points. This is a required argument if <code>boot.out</code> is not supplied and is set to <code>boot.out\$t</code> otherwise.
<code>level</code>	The confidence level of the envelopes required. The default is to find 95% confidence envelopes. It can be a scalar or a vector of length 2. If it is scalar then both the pointwise and the overall envelopes are found at that level. If is a vector then the first element gives the level for the pointwise envelope and the second gives the level for the overall envelope.
<code>index</code>	The numbers of the columns of <code>mat</code> which contain the bootstrap replicates. This can be used to ensure that other statistics which may have been calculated in the bootstrap are not considered as values of the function.

Details

The pointwise envelope is found by simply looking at the quantiles of the replicates at each point. The overall error for that envelope is then calculated using equation (4.17) of Davison and Hinkley (1997). A sequence of pointwise envelopes is then found until one of them has overall error approximately equal to the level required. If no such envelope can be found then the envelope returned will just contain the extreme values of each column of `mat`.

Value

A list with the following components :

<code>point</code>	A matrix with two rows corresponding to the values of the upper and lower pointwise confidence envelope at the same points as the bootstrap replicates were calculated.
<code>overall</code>	A matrix similar to <code>point</code> but containing the envelope which controls the overall error.
<code>k.pt</code>	The quantiles used for the pointwise envelope.
<code>err.pt</code>	A vector with two components, the first gives the pointwise error rate for the pointwise envelope, and the second the overall error rate for that envelope.
<code>k.ov</code>	The quantiles used for the overall envelope.
<code>err.ov</code>	A vector with two components, the first gives the pointwise error rate for the overall envelope, and the second the overall error rate for that envelope.
<code>err.nom</code>	A vector of length 2 giving the nominal error rates for the pointwise and the overall envelopes.

```

exp.tilt

*Exponential Tilting***Description**

This function calculates exponentially tilted multinomial distributions such that the resampling distributions of the linear approximation to a statistic have the required means.

Usage

```
exp.tilt(L, theta=NULL, t0=0, lambda=NULL,
        strata=rep(1, length(L)))
```

Arguments

L	The empirical influence values for the statistic of interest based on the observed data. The length of L should be the same as the size of the original data set. Typically L will be calculated by a call to <code>empinf</code> .
theta	The value at which the tilted distribution is to be centred. This is not required if lambda is supplied but is needed otherwise.
t0	The current value of the statistic. The default is that the statistic equals 0.
lambda	The Lagrange multiplier(s). For each value of lambda a multinomial distribution is found with probabilities proportional to $\exp(\lambda * L)$. In general lambda is not known and so theta would be supplied, and the corresponding value of lambda found. If both lambda and theta are supplied then lambda is ignored and the multipliers for tilting to theta are found.
strata	A vector or factor of the same length as L giving the strata for the observed data and the empirical influence values L.

Details

Exponential tilting involves finding a set of weights for a data set to ensure that the bootstrap distribution of the linear approximation to a statistic of interest has mean `theta`. The weights chosen to achieve this are given by `p[j]` proportional to $\exp(\lambda * L[j] / n)$, where `n` is the number of data points. `lambda` is then chosen to make the mean of the bootstrap distribution, of the linear approximation to the statistic of interest, equal to the the required value `theta`. Thus `lambda` is defined as the solution of a nonlinear equation. The equation is solved by minimizing the Euclidean distance between the left and right hand sides of the equation using the function `nlmin`. If this minimum is not equal to zero then the method fails.

Typically exponential tilting is used to find suitable weights for importance resampling. If a small tail probability or quantile of the distribution of the statistic of interest is required then a more efficient simulation is to centre the resampling distribution close to the point of interest and then use the functions `imp.prob` or `imp.quantile` to estimate the required quantity.

Another method of achieving a similar shifting of the distribution is through the use of `smooth.f`. The function `tilt.boot` uses `exp.tilt` or `smooth.f` to find the weights for a tilted bootstrap.

Value

A list with the following components :

<code>p</code>	The tilted probabilities. There will be <code>m</code> distributions where <code>m</code> is the length of <code>theta</code> (or <code>lambda</code> if supplied). If <code>m</code> is 1 then <code>p</code> is a vector of length(<code>L</code>) probabilities. If <code>m</code> is greater than 1 then <code>p</code> is a matrix with <code>m</code> rows, each of which contain length(<code>L</code>) probabilities. In this case the vector <code>p[i,]</code> is the distribution tilted to <code>theta[i]</code> . <code>p</code> is in the form required by the argument <code>weights</code> of the function <code>boot</code> for importance resampling.
<code>lambda</code>	The Lagrange multiplier used in the equation to determine the tilted probabilities. <code>lambda</code> is a vector of the same length as <code>theta</code> .
<code>theta</code>	The values of <code>theta</code> to which the distributions have been tilted. In general this will be the input value of <code>theta</code> but if <code>lambda</code> was supplied then this is the vector of the corresponding <code>theta</code> values.

```

fir

Counts of Balsam-fir Seedlings

Description

The `fir` data frame has 50 rows and 3 columns.

The number of balsam-fir seedlings in each quadrant of a grid of 50 five foot square quadrants were counted. The grid consisted of 5 rows of 10 quadrants in each row.

Usage

```
fir
```

Format

This data frame contains the following columns:

count The number of seedlings in the quadrant.

row The row number of the quadrant.

col The quadrant number within the row.

`freq.array`*Bootstrap Frequency Arrays*

Description

Take a matrix of indices for nonparametric bootstrap resamples and return the frequencies of the original observations in each resample.

Usage

```
freq.array(i.array)
```

Arguments

`i.array` This will be an matrix of integers between 1 and `n`, where `n` is the number of observations in a data set. The matrix will have `n` columns and `R` rows where `R` is the number of bootstrap resamples. Such matrices are found by `boot` when doing nonparametric bootstraps. They can also be found after a bootstrap has been run through the function `boot.array`.

Value

A matrix of the same dimensions as the input matrix. Each row of the matrix corresponds to a single bootstrap resample. Each column of the matrix corresponds to one of the original observations and specifies its frequency in each bootstrap resample. Thus the first column tells us how often the first observation appeared in each bootstrap resample. Such frequency arrays are often useful for diagnostic purposes such as the jackknife-after-bootstrap plot. They are also necessary for the regression estimates of empirical influence values and for finding importance sampling weights.

`frets`*Head Dimensions in Brothers*

Description

The `frets` data frame has 25 rows and 4 columns.

The data consist of measurements of the length and breadth of the heads of pairs of adult brothers in 25 randomly sampled families. All measurements are expressed in millimetres.

Usage

```
frets
```

Format

This data frame contains the following columns:

- l1** The head length of the eldest son.
- b1** The head breadth of the eldest son.
- l2** The head length of the second son.
- b2** The head breadth of the second son.

Source

The data were obtained from

Frets, G.P. (1921) Heredity of head form in man. *Genetica*, **3**, 193.

 glm.diag

Generalized Linear Model Diagnostics

Description

Calculates jackknife deviance residuals, standardized deviance residuals, standardized Pearson residuals, approximate Cook statistic, leverage and estimated dispersion.

Usage

```
glm.diag(glmfit)
```

Arguments

glmfit glmfit is a glm.object - the result of a call to glm()

Value

Returns a list with the following components

- | | |
|------|--|
| res | The vector of jackknife deviance residuals. |
| rd | The vector of standardized deviance residuals. |
| rp | The vector of standardized Pearson residuals. |
| cook | The vector of approximate Cook statistics. |
| h | The vector of leverages of the observations. |
| sd | The value used to standardize the residuals. This is the the estimate of residual standard deviation in the Gaussian family and is the square root of the estimated shape parameter in the Gamma family. In all other cases it is 1. |

Note

See the help for `glm.diag.plots` for an example of the use of `glm.diag`.

References

Davison, A.C. and Snell, E.J. (1991) Residuals and diagnostics. In *Statistical Theory and Modelling: In Honour of Sir David Cox*. D.V. Hinkley, N. Reid and E.J. Snell (editors), 83–106. Chapman and Hall.

See Also

`glm`, `glm.diag.plots`, `summary.glm`

<code>glm.diag.plots</code>	<i>Diagnostics plots for generalized linear models</i>
-----------------------------	--

Description

Makes plot of jackknife deviance residuals against linear predictor, normal scores plots of standardized deviance residuals, plot of approximate Cook statistics against leverage/(1-leverage), and case plot of Cook statistic.

Usage

```
glm.diag.plots(glmfit, glmdiag=glm.diag(glmfit),
              subset=NULL, iden=FALSE, labels=NULL, ret=FALSE)
```

Arguments

<code>glmfit</code>	<code>glm.object</code> : the result of a call to <code>glm()</code>
<code>glmdiag</code>	Diagnostics of <code>glmfit</code> obtained from a call to <code>glm.diag</code> . If it is not supplied then it is calculated.
<code>subset</code>	Subset of data for which <code>glm</code> fitting performed: should be the same as the <code>subset</code> option used in the call to <code>glm()</code> which generated <code>glmfit</code> . Needed only if the <code>subset=</code> option was used in the call to <code>glm</code> .
<code>iden</code>	A logical argument. If <code>TRUE</code> then, after the plots are drawn, the user will be prompted for an integer between 0 and 4. A positive integer will select a plot and invoke <code>identify()</code> on that plot. After exiting <code>identify()</code> , the user is again prompted, this loop continuing until the user responds to the prompt with 0. If <code>iden</code> is <code>FALSE</code> (default) the user cannot interact with the plots.
<code>labels</code>	A vector of labels for use with <code>identify()</code> if <code>iden</code> is <code>TRUE</code> . If it is not supplied then the labels are derived from <code>glmfit</code> .
<code>ret</code>	A logical argument indicating if <code>glmdiag</code> should be returned. The default is <code>FALSE</code> .

Details

The diagnostics required for the plots are calculated by `glm.diag`. These are then used to produce the four plots on the current graphics device.

The plot on the top left is a plot of the jackknife deviance residuals against the fitted values.

The plot on the top right is a normal QQ plot of the standardized deviance residuals. The dotted line is the expected line if the standardized residuals are normally distributed, i.e. it is the line with intercept 0 and slope 1.

The bottom two panels are plots of the Cook statistics. On the left is a plot of the Cook statistics against the standardized leverages. In general there will be two dotted lines on this plot. The horizontal line is at $8/(n-2p)$ where n is the number of observations and p is the number of parameters estimated. Points above this line may be points with high influence on the model. The vertical line is at $2p/(n-2p)$ and points to the right of this line have high leverage compared to the variance of the raw residual at that point. If all points are below the horizontal line or to the left of the vertical line then the line is not shown.

The final plot again shows the Cook statistic this time plotted against case number enabling us to find which observations are influential.

Use of `iden=T` is encouraged for proper exploration of these four plots as a guide to how well the model fits the data and whether certain observations have an unduly large effect on parameter estimates.

Value

If `ret` is TRUE then the value of `glm.diag` is returned otherwise there is no returned value.

Side Effects

The current device is cleared and four plots are plotted by use of `split.screen(c(2,2))`. If `iden` is TRUE, interactive identification of points is enabled. All screens are closed, but not cleared, on termination of the function.

`gravity`*Acceleration Due to Gravity*

Description

The `gravity` data frame has 81 rows and 2 columns.

The `grav` data set has 26 rows and 2 columns.

Between May 1934 and July 1935, the National Bureau of Standards in Washington D.C. conducted a series of experiments to estimate the acceleration due to gravity, g , at Washington. Each experiment produced a number of replicate estimates of g using the same methodology. Although the basic method remained the same for all experiments, that of the reversible pendulum, there were changes in configuration.

The `gravity` data frame contains the data from all eight experiments. The `grav` data frame contains the data from the experiments 7 and 8. The data are expressed as deviations from 980.000 in centimetres per second squared.

Usage

```
gravity
```

Format

This data frame contains the following columns:

g The deviation of the estimate from 980.000 centimetres per second squared.

series A factor describing from which experiment the estimate was derived.

Source

The data were obtained from

Cressie, N. (1982) Playing safe with misweighted means. *Journal of the American Statistical Association*, **77**, 754–759.

`hirose`*Failure Time of PET Film*

Description

The `hirose` data frame has 44 rows and 3 columns.

PET film is used in electrical insulation. In this accelerated life test the failure times for 44 samples in gas insulated transformers. 4 different voltage levels were used.

Usage

```
hirose
```

Format

This data frame contains the following columns:

volt The voltage (in kV).

time The failure or censoring time in hours.

cens The censoring indicator; 1 means right-censored data.

Source

The data were obtained from

Hirose, H. (1993) Estimation of threshold stress in accelerated life-testing. *IEEE Transactions on Reliability*, **42**, 650–657.

Imp.Estimates

Importance Sampling Estimates

Description

Central moment, tail probability, and quantile estimates for a statistic under importance resampling.

Usage

```
imp.moments(boot.out=NULL, index=1, t=boot.out$t[, index],
            w=NULL, def=TRUE, q=NULL)
imp.prob(boot.out=NULL, index=1, t0=boot.out$t0[index],
         t=boot.out$t[, index], w=NULL, def=TRUE, q=NULL)
imp.quantile(boot.out=NULL, alpha=NULL, index=1,
            t=boot.out$t[, index], w=NULL, def=TRUE, q=NULL)
```

Arguments

<code>boot.out</code>	A object of class "boot" generated by a call to <code>boot</code> or <code>tilt.boot</code> . Use of these functions makes sense only when the bootstrap resampling used unequal weights for the observations. If the importance weights <code>w</code> are not supplied then <code>boot.out</code> is a required argument. It is also required if <code>t</code> is not supplied.
<code>alpha</code>	The alpha levels for the required quantiles. The default is to calculate the 1%, 2.5%, 5%, 10%, 90%, 95%, 97.5% and 99% quantiles.
<code>index</code>	The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This is not used if the argument <code>t</code> is supplied.

<code>t0</code>	The values at which tail probability estimates are required. For each value <code>t0[i]</code> the function will estimate the bootstrap cdf evaluated at <code>t0[i]</code> . If <code>imp.prob</code> is called without the argument <code>t0</code> then the bootstrap cdf evaluated at the observed value of the statistic is found.
<code>t</code>	The bootstrap replicates of a statistic. By default these are taken from the bootstrap output object <code>boot.out</code> but they can be supplied separately if required (e.g. when the statistic of interest is a function of the calculated values in <code>boot.out</code>). Either <code>boot.out</code> or <code>t</code> must be supplied.
<code>w</code>	The importance resampling weights for the bootstrap replicates. If they are not supplied then <code>boot.out</code> must be supplied, in which case the importance weights are calculated by a call to <code>imp.weights</code> .
<code>def</code>	A logical value indicating whether a defensive mixture is to be used for weight calculation. This is used only if <code>w</code> is missing and it is passed unchanged to <code>imp.weights</code> to calculate <code>w</code> .
<code>q</code>	A vector of probabilities specifying the resampling distribution from which any estimates should be found. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations. The estimates depend on this distribution only through the importance weights <code>w</code> so this argument is ignored if <code>w</code> is supplied. If <code>w</code> is missing then <code>q</code> is passed as an argument to <code>imp.weights</code> and used to find <code>w</code> .

Value

A list with the following components :

<code>alpha</code>	The alpha levels used for the quantiles, if <code>imp.quantile</code> is used.
<code>t0</code>	The values at which the tail probabilities are estimated, if <code>imp.prob</code> is used.
<code>raw</code>	The raw importance resampling estimates. For <code>imp.moments</code> this has length 2, the first component being the estimate of the mean and the second being the variance estimate. For <code>imp.prob</code> , <code>raw</code> is of the same length as <code>t0</code> , and for <code>imp.quantile</code> it is of the same length as <code>alpha</code> .
<code>rat</code>	The ratio importance resampling estimates. In this method the weights <code>w</code> are rescaled to have average value one before they are used. The format of this vector is the same as <code>raw</code> .
<code>reg</code>	The regression importance resampling estimates. In this method the weights which are used are derived from a regression of <code>t*w</code> on <code>w</code> . This choice of weights can be shown to minimize the variance of the weights and also the Euclidean distance of the weights from the uniform weights. The format of this vector is the same as <code>raw</code> .

```

imp.weights

Importance Sampling Weights

Description

This function calculates the importance sampling weight required to correct for simulation from a distribution with probabilities p when estimates are required assuming that simulation was from an alternative distribution with probabilities q .

Usage

```
imp.weights(boot.out, def=TRUE, q=NULL)
```

Arguments

- `boot.out` A object of class "boot" generated by `boot` or `tilt.boot`. Typically the bootstrap simulations would have been done using importance resampling and we wish to do our calculations under the assumption of sampling with equal probabilities.
- `def` A logical variable indicating whether the defensive mixture distribution weights should be calculated. This makes sense only in the case where the replicates in `boot.out` were simulated under a number of different distributions. If this is the case then the defensive mixture weights use a mixture of the distributions used in the bootstrap. The alternative is to calculate the weights for each replicate using knowledge of the distribution from which the bootstrap resample was generated.
- `q` A vector of probabilities specifying the resampling distribution from which we require inferences to be made. In general this would correspond to the usual bootstrap resampling distribution which gives equal weight to each of the original observations and this is the default. `q` must have length equal to the number of observations in the `boot.out$data` and all elements of `q` must be positive.

Details

The importance sampling weight for a bootstrap replicate with frequency vector \mathbf{f} is given by $\text{prod}((q/p)^{\mathbf{f}})$. This reweights the replicates so that estimates can be found as if the bootstrap resamples were generated according to the probabilities q even though, in fact, they came from the distribution p .

Value

A vector of importance weights of the same length as `boot.out$t`. These weights can then be used to reweight `boot.out$t` so that estimates can be found as if the simulations were from a distribution with probabilities q .

Note

See the example in the help for `imp.moments` for an example of using `imp.weights`.

`inv.logit`*Inverse Logit Function*

Description

Given a numeric object return the inverse logit of the values.

Usage

```
inv.logit(x)
```

Arguments

`x` A numeric object. Missing values (NAs) are allowed.

Details

The inverse logit is defined by $\exp(x) / (1 + \exp(x))$. Values in `x` of `-Inf` or `Inf` return logits of 0 or 1 respectively. Any NAs in the input will also be NAs in the output.

Value

An object of the same type as `x` containing the inverse logits of the input values.

See Also

`logit`, `plogis` which is the underlying function.

`islay`*Jura Quartzite Azimuths on Islay*

Description

The `islay` data frame has 18 rows and 1 columns.

Measurements were taken of paleocurrent azimuths from the Jura Quartzite on the Scottish island of Islay.

Usage

```
islay
```

Format

This data frame contains the following column:

theta The angle of the azimuth in degrees East of North.

Source

The data were obtained from

Hand, D.J., Daly, F., Lunn, A.D., McConway, K.J. and Ostrowski, E. (1994) *A Handbook of Small Data Sets*, Chapman and Hall.

jack.after.boot *Jackknife-after-Bootstrap Plots*

Description

This function calculates the jackknife influence values from a bootstrap output object and plots the corresponding jackknife-after-bootstrap plot.

Usage

```
jack.after.boot(boot.out, index=1, t=NULL, L=NULL, useJ=TRUE,
               stinf=TRUE, alpha=NULL, main="", ylab=NULL, ...)
```

Arguments

boot.out	An object of class "boot" which would normally be created by a call to <code>boot</code> . It should represent a nonparametric bootstrap. For reliable results <code>boot.out\$R</code> should be reasonably large.
index	The index of the statistic of interest in the output of <code>boot.out\$statistic</code> .
t	A vector of length <code>boot.out\$R</code> giving the bootstrap replicates of the statistic of interest. This is useful if the statistic of interest is a function of the calculated bootstrap output. If it is not supplied then the default is <code>boot.out\$t[,index]</code> .
L	The empirical influence values for the statistic of interest. These are used only if <code>useJ</code> is <code>FALSE</code> . If they are not supplied and are needed, they are calculated by a call to <code>empinf</code> . If <code>L</code> is supplied then it is assumed that they are the infinitesimal jackknife values.
useJ	A logical variable indicating if the jackknife influence values calculated from the bootstrap replicates should be used. If <code>FALSE</code> the empirical influence values are used. The default is <code>TRUE</code> .
stinf	A logical variable indicating whether to standardize the jackknife values before plotting them. If <code>TRUE</code> then the jackknife values used are divided by their standard error.
alpha	The quantiles at which the plots are required. The default is <code>c(0.05, 0.1, 0.16, 0.5, 0.84, 0.9, 0.95)</code> .
main	A character string giving the main title for the plot.

ylab	The label for the Y axis. If the default values of alpha are used and ylab is not supplied then a label indicating which percentiles are plotted is used. If alpha is supplied then the default label will not say which percentiles were used.
...	Any extra arguments required by <code>boot.out\$statistic</code> . These are required only if <code>useJ</code> is <code>FALSE</code> and <code>L</code> is not supplied, in which case they are passed to <code>empinf</code> for use in calculation of the empirical influence values.

Details

The centred jackknife quantiles for each observation are estimated from those bootstrap samples in which the particular observation did not appear. These are then plotted against the influence values. If `useJ` is `TRUE` then the influence values are found in the same way as the difference between the mean of the statistic in the samples excluding the observations and the mean in all samples. If `useJ` is `FALSE` then empirical influence values are calculated by calling `empinf`.

The resulting plots are useful diagnostic tools for looking at the way individual observations affect the bootstrap output.

The plot will consist of a number of horizontal dotted lines which correspond to the quantiles of the centred bootstrap distribution. For each data point the quantiles of the bootstrap distribution calculated by omitting that point are plotted against the (possibly standardized) jackknife values. The observation number is printed below the plots. To make it easier to see the effect of omitting points on quantiles, the plotted quantiles are joined by line segments. These plots provide a useful diagnostic tool in establishing the effect of individual observations on the bootstrap distribution. See the references below for some guidelines on the interpretation of the plots.

Value

There is no returned value but a plot is generated on the current graphics display.

Side Effects

A plot is created on the current graphics device.

```

k3.linear

*Linear Skewness Estimate***Description**

Estimates the skewness of a statistic from its empirical influence values.

Usage

```
k3.linear(L, strata=NULL)
```

Arguments

L	Vector of the empirical influence values of a statistic. These will usually be calculated by a call to <code>empinf</code> .
strata	A numeric vector or factor specifying which observations (and hence which components of L) come from which strata.

Value

The skewness estimate calculated from L.

References

Davison, A. C. and Hinkley, D. V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

See Also

[empinf](#), [linear.approx](#), [var.linear](#)

Examples

```
# To estimate the skewness of the ratio of means for the city data.
ratio <- function(d,w)
  sum(d$x * w)/sum(d$u * w)
k3.linear(empinf(data=city, statistic=ratio))
```

linear.approx

*Linear Approximation of Bootstrap Replicates***Description**

This function takes a bootstrap object and for each bootstrap replicate it calculates the linear approximation to the statistic of interest for that bootstrap sample.

Usage

```
linear.approx(boot.out, L=NULL, index=1, type=NULL, t0=NULL,
             t=NULL, ...)
```

Arguments

boot.out	An object of class "boot" representing a nonparametric bootstrap. It will usually be created by the function <code>boot</code> .
L	A vector containing the empirical influence values for the statistic of interest. If it is not supplied then L is calculated through a call to <code>empinf</code> .
index	The index of the variable of interest within the output of <code>boot.out\$statistic</code> .
type	This gives the type of empirical influence values to be calculated. It is not used if L is supplied. The possible types of empirical influence values are described in the helpfile for <code>empinf</code> .
t0	The observed value of the statistic of interest. The input value is used only if one of t or L is also supplied. The default value is <code>boot.out\$t0[index]</code> . If t0 is supplied but neither t nor L are supplied then t0 is set to <code>boot.out\$t0[index]</code> and a warning is generated.
t	A vector of bootstrap replicates of the statistic of interest. If t0 is missing then t is not used, otherwise it is used to calculate the empirical influence values (if they are not supplied in L).
...	Any extra arguments required by <code>boot.out\$statistic</code> . These are needed if L is not supplied as they are used by <code>empinf</code> to calculate empirical influence values.

Details

The linear approximation to a bootstrap replicate with frequency vector f is given by $t_0 + \sum(L * f) / n$ in the one sample with an easy extension to the stratified case. The frequencies are found by calling `boot.array`.

Value

A vector of length `boot.out$R` with the linear approximations to the statistic of interest for each of the bootstrap samples.

lines.saddle.distn *Add a Saddlepoint Approximation to a Plot*

Description

This function adds a line corresponding to a saddlepoint density or distribution function approximation to the current plot.

Usage

```
## S3 method for class 'saddle.distn':
lines(x, dens = TRUE, h = function(u) u, J = function(u) 1,
      npts = 50, lty = 1, ...)
```

Arguments

x	An object of class "saddle.distn" (see saddle.distn.object representing a saddlepoint approximation to a distribution).
dens	A logical variable indicating whether the saddlepoint density (TRUE; the default) or the saddlepoint distribution function (FALSE) should be plotted.
h	Any transformation of the variable that is required. Its first argument must be the value at which the approximation is being performed and the function must be vectorized.
J	When dens=TRUE this function specifies the Jacobian for any transformation that may be necessary. The first argument of J must the value at which the approximation is being performed and the function must be vectorized. If h is supplied J must also be supplied and both must have the same argument list.
npts	The number of points to be used for the plot. These points will be evenly spaced over the range of points used in finding the saddlepoint approximation.
lty	The line type to be used.
...	Any additional arguments to h and J.

Details

The function uses `smooth.spline` to produce the saddlepoint curve. When `dens=TRUE` the spline is on the log scale and when `dens=FALSE` it is on the probit scale.

Value

`sad.d` is returned invisibly.

Side Effects

A line is added to the current plot.

# The saddlepoint approximation in this case is to the density of
# t-t0 and so t0 must be added for the plot.
lines(exp.sp, h = function(u,t0) u+t0, J = function(u,t0) 1,
      t0 = exp.boot$t0)
```

logit

Logit of Proportions

Description

This function calculates the logit of proportions.

Usage

```
logit(p)
```

Arguments

p A numeric Splus object, all of whose values are in the range [0,1]. Missing values (NAs) are allowed.

Details

If any elements of **p** are outside the unit interval then an error message is generated. Values of **p** equal to 0 or 1 (to within machine precision) will return `-Inf` or `Inf` respectively. Any NAs in the input will also be NAs in the output.

Value

A numeric object of the same type as **p** containing the logits of the input values.

See Also

[inv.logit](#)

 manaus

Average Heights of the Rio Negro river at Manaus

Description

The manaus time series is of class "ts" and has 1080 observations on one variable.

The data values are monthly averages of the daily stages (heights) of the Rio Negro at Manaus. Manaus is 18km upstream from the confluence of the Rio Negro with the Amazon but because of the tiny slope of the water surface and the lower courses of its flatland affluents, they may be regarded as a good approximation of the water level in the Amazon at the confluence. The data here cover 90 years from January 1903 until December 1992.

The Manaus gauge is tied in with an arbitrary bench mark of 100m set in the steps of the Municipal Prefecture; gauge readings are usually referred to sea level, on the basis of a mark on the steps leading to the Parish Church (Matriz), which is assumed to lie at an altitude of 35.874 m according to observations made many years ago under the direction of Samuel Pereira, an engineer in charge of the Manaus Sanitation Committee Whereas such an altitude cannot, by any means, be considered to be a precise datum point, observations have been provisionally referred to it. The measurements are in metres.

Source

The data were kindly made available by Professors H. O'Reilly Sternberg and D. R. Brillinger of the University of California at Berkeley.

 melanoma

Survival from Malignant Melanoma

Description

The melanoma data frame has 205 rows and 7 columns.

The data consist of measurements made on patients with malignant melanoma. Each patient had their tumour removed by surgery at the Department of Plastic Surgery, University Hospital of Odense, Denmark during the period 1962 to 1977. The surgery consisted of complete removal of the tumour together with about 2.5cm of the surrounding skin. Among the measurements taken were the thickness of the tumour and whether it was ulcerated or not. These are thought to be important prognostic variables in that patients with a thick and/or ulcerated tumour have an increased chance of death from melanoma. Patients were followed until the end of 1977.

Usage

melanoma

Format

This data frame contains the following columns:

time Survival time in days since the operation, possibly censored.

status The patients status at the end of the study. 1 indicates that they had died from melanoma, 2 indicates that they were still alive and 3 indicates that they had died from causes unrelated to their melanoma.

sex The patients sex; 1=male, 0=female.

age Age in years at the time of the operation.

year Year of operation.

thickness Tumour thickness in mm.

ulcer Indicator of ulceration; 1=present, 0=absent.

Note

This dataset is not related to the dataset in the **lattice** package with the same name.

motor

Data from a Simulated Motorcycle Accident

Description

The `motor` data frame has 94 rows and 4 columns. The rows are obtained by removing replicate values of `time` from the dataset `mcycle`. Two extra columns are added to allow for strata with a different residual variance in each stratum.

Usage

`motor`

Format

This data frame contains the following columns:

times The time in milliseconds since impact.

accel The recorded head acceleration (in g).

strata A numeric column indicating to which of the three strata (numbered 1, 2 and 3) the observations belong.

v An estimate of the residual variance for the observation. v is constant within the strata but a different estimate is used for each of the three strata.

neuro

Neurophysiological Point Process Data

Description

`neuro` is a matrix containing times of observed firing of a neuron in windows of 250ms either side of the application of a stimulus to a human subject. Each row of the matrix is a replication of the experiment and there were a total of 469 replicates.

Note

There are a lot of missing values in the matrix as different numbers of firings were observed in different replicates. The number of firings observed varied from 2 to 6.

Source

The data were collected and kindly made available by Dr. S.J. Boniface of the Neurophysiology Unit at the Radcliffe Infirmary, Oxford.

References

`nitrofen`*Toxicity of Nitrofen in Aquatic Systems*

Description

The `nitrofen` data frame has 50 rows and 5 columns.

Nitrofen is a herbicide that was used extensively for the control of broad-leaved and grass weeds in cereals and rice. Although it is relatively non-toxic to adult mammals, nitrofen is a significant tetragen and mutagen. It is also acutely toxic and reproductively toxic to cladoceran zooplankton. Nitrofen is no longer in commercial use in the U.S., having been the first pesticide to be withdrawn due to tetrogenic effects.

The data here come from an experiment to measure the reproductive toxicity of nitrofen on a species of zooplankton (*Ceriodaphnia dubia*). 50 animals were randomized into batches of 10 and each batch was put in a solution with a measured concentration of nitrofen. Then the number of live offspring in each of the three broods to each animal was recorded.

Usage

```
nitrofen
```

Format

This data frame contains the following columns:

conc The nitrofen concentration in the solution (mug/litre).

brood1 The number of live offspring in the first brood.

brood2 The number of live offspring in the second brood.

brood3 The number of live offspring in the third brood.

total The total number of live offspring in the first three broods.

Source

The data were obtained from

Bailer, A.J. and Oris, J.T. (1994) Assessing toxicity of pollutants in aquatic systems. In *Case Studies in Biometry*. N. Lange, L. Ryan, L. Billard, D. Brillinger, L. Conquest and J. Greenhouse (editors), 25–40. John Wiley.

nodal

*Nodal Involvement in Prostate Cancer***Description**

The `nodal` data frame has 53 rows and 7 columns.

The treatment strategy for a patient diagnosed with cancer of the prostate depend highly on whether the cancer has spread to the surrounding lymph nodes. It is common to operate on the patient to get samples from the nodes which can then be analysed under a microscope but clearly it would be preferable if an accurate assessment of nodal involvement could be made without surgery.

For a sample of 53 prostate cancer patients, a number of possible predictor variables were measured before surgery. The patients then had surgery to determine nodal involvement. It was required to see if nodal involvement could be accurately predicted from the predictor variables and which ones were most important.

Usage

```
nodal
```

Format

This data frame contains the following columns:

m A column of ones.

r An indicator of nodal involvement.

aged The patients age dichotomized into less than 60 (0) and 60 or over 1.

stage A measurement of the size and position of the tumour observed by palpitation with the fingers via the rectum. A value of 1 indicates a more serious case of the cancer.

grade Another indicator of the seriousness of the cancer, this one is determined by a pathology reading of a biopsy taken by needle before surgery. A value of 1 indicates a more serious case of the cancer.

xray A third measure of the seriousness of the cancer taken from an X-ray reading. A value of 1 indicates a more serious case of the cancer.

acid The level of acid phosphatase in the blood serum.

Source

The data were obtained from

Brown, B.W. (1980) Prediction analysis for binary data. In *Biostatistics Casebook*. R.G. Miller, B. Efron, B.W. Brown and L.E. Moses (editors), 3–18. John Wiley.

References

norm.ci

*Normal Approximation Confidence Intervals***Description**

Using the normal approximation to a statistic, calculate equi-tailed two-sided confidence intervals.

Usage

```
norm.ci(boot.out=NULL, conf=0.95, index=1, var.t0=NULL,
        t0=NULL, t=NULL, L=NULL, h=function(t) t,
        hdot=function(t) 1, hinv=function(t) t)
```

Arguments

<code>boot.out</code>	A bootstrap output object returned from a call to <code>boot</code> . If <code>t0</code> is missing then <code>boot.out</code> is a required argument. It is also required if both <code>var.t0</code> and <code>t</code> are missing.
<code>conf</code>	A scalar or vector containing the confidence level(s) of the required interval(s).
<code>index</code>	The index of the statistic of interest within the output of a call to <code>boot.out\$statistic</code> . It is not used if <code>boot.out</code> is missing, in which case <code>t0</code> must be supplied.
<code>var.t0</code>	The variance of the statistic of interest. If it is not supplied then <code>var(t)</code> is used.
<code>t0</code>	The observed value of the statistic of interest. If it is missing then it is taken from <code>boot.out</code> which is required in that case.
<code>t</code>	Bootstrap replicates of the variable of interest. These are used to estimate the variance of the statistic of interest if <code>var.t0</code> is not supplied. The default value is <code>boot.out\$t[, index]</code> .
<code>L</code>	The empirical influence values for the statistic of interest. These are used to calculate <code>var.t0</code> if neither <code>var.t0</code> nor <code>boot.out</code> are supplied. If a transformation is supplied through <code>h</code> then the influence values must be for the untransformed statistic <code>t0</code> .
<code>h</code>	A function defining a monotonic transformation, the intervals are calculated on the scale of <code>h(t)</code> and the inverse function <code>hinv</code> is applied to the resulting intervals. <code>h</code> must be a function of one variable only and must be vectorized. The default is the identity function.
<code>hdot</code>	A function of one argument returning the derivative of <code>h</code> . It is a required argument if <code>h</code> is supplied and is used for approximating the variance of <code>h(t0)</code> . The default is the constant function 1.
<code>hinv</code>	A function, like <code>h</code> , which returns the inverse of <code>h</code> . It is used to transform the intervals calculated on the scale of <code>h(t)</code> back to the original scale. The default is the identity function. If <code>h</code> is supplied but <code>hinv</code> is not, then the intervals returned will be on the transformed scale.

Details

It is assumed that the statistic of interest has an approximately normal distribution with variance `var.t0` and so a confidence interval of length $2 * qnorm((1+conf)/2) * sqrt(var.t0)$ is found. If `boot.out` or `t` are supplied then the interval is bias-corrected using the bootstrap bias estimate, and so the interval would be centred at $2 * t0 - mean(t)$. Otherwise the interval is centred at `t0`.

Value

If `length(conf)` is 1 then a vector containing the confidence level and the endpoints of the interval is returned. Otherwise, the returned value is a matrix where each row corresponds to a different confidence level.

Note

This function is primarily designed to be called by `boot.ci` to calculate the normal approximation after a bootstrap but it can also be used without doing any bootstrap calculations as long as `t0` and `var.t0` can be supplied. See the examples below.

```

Description

The `nuclear` data frame has 32 rows and 11 columns.

The data relate to the construction of 32 light water reactor (LWR) plants constructed in the U.S.A in the late 1960's and early 1970's. The data was collected with the aim of predicting the cost of construction of further LWR plants. 6 of the power plants had partial turnkey guarantees and it is possible that, for these plants, some manufacturers' subsidies may be hidden in the quoted capital costs.

Usage

```
nuclear
```

Format

This data frame contains the following columns:

cost The capital cost of construction in millions of dollars adjusted to 1976 base.

date The date on which the construction permit was issued. The data are measured in years since January 1 1990 to the nearest month.

t1 The time between application for and issue of the construction permit.

t2 The time between issue of operating license and construction permit.

cap The net capacity of the power plant (MWe).

pr A binary variable where 1 indicates the prior existence of a LWR plant at the same site.

ne A binary variable where 1 indicates that the plant was constructed in the north-east region of the U.S.A.

ct A binary variable where 1 indicates the use of a cooling tower in the plant.

bw A binary variable where 1 indicates that the nuclear steam supply system was manufactured by Babcock-Wilcox.

cum.n The cumulative number of power plants constructed by each architect-engineer.

pt A binary variable where 1 indicates those plants with partial turnkey guarantees.

Source

paulsen

Neurotransmission in Guinea Pig Brains

Description

The `paulsen` data frame has 346 rows and 1 columns.

Sections were prepared from the brain of adult guinea pigs. Spontaneous currents that flowed into individual brain cells were then recorded and the peak amplitude of each current measured. The aim of the experiment was to see if the current flow was quantal in nature (i.e. that it is not a single burst but instead is built up of many smaller bursts of current). If the current was indeed quantal then it would be expected that the distribution of the current amplitude would be multimodal with modes at regular intervals. The modes would be expected to decrease in magnitude for higher current amplitudes.

Usage

```
paulsen
```

Format

This data frame contains the following column:

y The current flowing into individual brain cells. The currents are measured in pico-amperes.

Source

The data were kindly made available by Dr. O. Paulsen from the Department of Pharmacology at the University of Oxford.

Paulsen, O. and Heggelund, P. (1994) The quantal size at retinogeniculate synapses determined from spontaneous and evoked EPSCs in guinea-pig thalamic slices. *Journal of Physiology*, **480**, 505–511.

plot.boot

Plots of the Output of a Bootstrap Simulation

Description

This takes a bootstrap object and produces plots for the bootstrap replicates of the variable of interest.

Usage

```
## S3 method for class 'boot':
plot(x, index=1, t0=NULL, t=NULL, jack=FALSE, qdist="norm",
      nclass=NULL, df, ...)
```

Arguments

x	An object of class "boot" returned from one of the bootstrap generation functions.
index	The index of the variable of interest within the output of <code>boot.out</code> . This is ignored if <code>t</code> and <code>t0</code> are supplied.
t0	The original value of the statistic. This defaults to <code>boot.out\$t0[index]</code> unless <code>t</code> is supplied when it defaults to <code>NULL</code> . In that case no vertical line is drawn on the histogram.
t	The bootstrap replicates of the statistic. Usually this will take on its default value of <code>boot.out\$t[,index]</code> , however it may be useful sometimes to supply a different set of values which are a function of <code>boot.out\$t</code> .
jack	A logical value indicating whether a jackknife-after-bootstrap plot is required. The default is not to produce such a plot.
qdist	The distribution against which the Q-Q plot should be drawn. At present "norm" (normal distribution - the default) and "chisq" (chi-squared distribution) are the only possible values.
nclass	An integer giving the number of classes to be used in the bootstrap histogram. The default is the integer between 10 and 100 closest to <code>ceiling(length(t)/25)</code> .
df	If <code>qdist</code> is "chisq" then this is the degrees of freedom for the chi-squared distribution to be used. It is a required argument in that case.
...	When <code>jack</code> is <code>TRUE</code> additional parameters to <code>jack.after.boot</code> can be supplied. See the help file for <code>jack.after.boot</code> for details of the possible parameters.

Details

This function will generally produce two side-by-side plots. The left plot will be a histogram of the bootstrap replicates. Usually the breaks of the histogram will be chosen so that `t0` is at a breakpoint and all intervals are of equal length. A vertical dotted line indicates the position of `t0`. This cannot be done if `t` is supplied but `t0` is not and so, in that case, the breakpoints are computed by `hist` using the `nclass` argument and no vertical line is drawn.

The second plot is a Q-Q plot of the bootstrap replicates. The order statistics of the replicates can be plotted against normal or chi-squared quantiles. In either case the expected line is also plotted. For the normal, this will have intercept `mean(t)` and slope `sqrt(var(t))` while for the chi-squared it has intercept 0 and slope 1.

If `jack` is `TRUE` a third plot is produced beneath these two. That plot is the jackknife-after-bootstrap plot. This plot may only be requested when nonparametric simulation has been used. See `jack.after.boot` for further details of this plot.

Value

`boot.out` is returned invisibly.

Side Effects

All screens are closed and cleared and a number of plots are produced on the current graphics device. Screens are closed but not cleared at termination of this function.

poisons

Animal Survival Times

Description

The `poisons` data frame has 48 rows and 3 columns.

The data form a 3x4 factorial experiment, the factors being three poisons and four treatments. Each combination of the two factors was used for four animals, the allocation to animals having been completely randomized.

Usage

```
poisons
```

Format

This data frame contains the following columns:

time The survival time of the animal in units of 10 hours.

poison A factor with levels 1, 2 and 3 giving the type of poison used.

treat A factor with levels A, B, C and D giving the treatment.

Source

The data were obtained from

Box, G.E.P. and Cox, D.R. (1964) An analysis of transformations (with Discussion). *Journal of the Royal Statistical Society, B*, **26**, 211–252.

polar

Pole Positions of New Caledonian Laterites

Description

The `polar` data frame has 50 rows and 2 columns.

The data are the pole positions from a paleomagnetic study of New Caledonian laterites.

Usage

```
polar
```

Format

This data frame contains the following columns:

lat The latitude (in degrees) of the pole position. Note that all latitudes are negative as the axis is taken to be in the lower hemisphere.

long The longitude (in degrees) of the pole position.

Source

The data were obtained from

Fisher, N.I., Lewis, T. and Embleton, B.J.J. (1987) *Statistical Analysis of Spherical Data*. Cambridge University Press.

print.boot

Print a Summary of a Bootstrap Object

Description

This is a method for the function `print` for objects of the class `"boot"`.

Usage

```
## S3 method for class 'boot':
print(x, digits = getOption("digits"),
      index = 1:ncol(boot.out$t), ...)
```

Arguments

x	A bootstrap output object of class "boot" generated by one of the bootstrap functions.
digits	The number of digits to be printed in the summary statistics.
index	Indices indicating for which elements of the bootstrap output summary statistics are required.
...	further arguments passed to or from other methods.

Details

For each statistic calculated in the bootstrap the original value and the bootstrap estimates of its bias and standard error are printed. If `boot.out$t0` is missing (such as when it was created by a call to `tsboot` with `orig.t=FALSE`) the bootstrap mean and standard error are printed. If resampling was done using importance resampling weights, then the bootstrap estimates are reweighted as if uniform resampling had been done. The ratio importance sampling estimates are used and if there were a number of distributions then defensive mixture distributions are used. In this case an extra column with the mean of the observed bootstrap statistics is also printed.

Value

The bootstrap object is returned invisibly.

See Also

```
print.bootci
```

Print Bootstrap Confidence Intervals

Description

This is a method for the function `print()` to print objects of the class "bootci".

Usage

```
## S3 method for class 'bootci':
print(x, hinv = NULL, ...)
```

Arguments

x	The output from a call to <code>boot.ci</code> .
hinv	A transformation to be made to the interval end-points before they are printed.
...	further arguments passed to or from other methods.

Details

This function prints out the results from `boot.ci` in a "nice" format. It also notes whether the scale of the intervals is the original scale of the input to `boot.ci` or a different scale and whether the calculations were done on a transformed scale. It also looks at the order statistics that were used in calculating the intervals. If the smallest or largest values were used then it prints a message

```
Warning : Intervals used Extreme Quantiles
```

Such intervals should be considered very unstable and not relied upon for inferences. Even if the extreme values are not used, it is possible that the intervals are unstable if they used quantiles close to the extreme values. The function alerts the user to intervals which use the upper or lower 10 order statistics with the message

```
Some intervals may be unstable
```

Value

The object `ci.out` is returned invisibly.

See Also

[boot.ci](#)

`print.saddle.distn` *Print Quantiles of Saddlepoint Approximations*

Description

This is a method for the function `print()` to print objects of class `"saddle.distn"`.

Usage

```
## S3 method for class 'saddle.distn':
print(x, ...)
```

Arguments

`x` An object of class `"saddle.distn"` created by a call to `saddle.distn`.
`...` further arguments passed to or from other methods.

Details

The quantiles of the saddlepoint approximation to the distribution are printed along with the original call and some other useful information.

Value

The input is returned invisibly.

See Also

[lines.saddle.distn](#), [saddle.distn](#)

print.simplex *Print Solution to Linear Programming Problem*

Description

This is a method for the function `print()` to print objects of class "simplex".

Usage

```
## S3 method for class 'simplex':  
print(x, ...)
```

Arguments

`x` An object of class "simplex" created by calling the function `simplex` to solve a linear programming problem.

`...` further arguments passed to or from other methods.

Details

The coefficients of the objective function are printed. If a solution to the linear programming problem was found then the solution and the optimal value of the objective function are printed. If a feasible solution was found but the maximum number of iterations was exceeded then the last feasible solution and the objective function value at that point are printed. If no feasible solution could be found then a message stating that is printed.

Value

`x` is returned silently.

See Also

[simplex](#)

remission *Cancer Remission and Cell Activity*

Description

The `remission` data frame has 27 rows and 3 columns.

Usage

```
remission
```

Format

This data frame contains the following columns:

- LI** A measure of cell activity.
- m** The number of patients in each group (all values are actually 1 here).
- r** The number of patients (out of m) who went into remission.

Source

The data were obtained from

Freeman, D.H. (1987) *Applied Categorical Data Analysis*. Marcel Dekker.

References

Davison, A.C. and Hinkley, D.V. (1997) *Bootstrap Methods and Their Application*. Cambridge University Press.

saddle

Saddlepoint Approximations for Bootstrap Statistics

Description

This function calculates a saddlepoint approximation to the distribution of a linear combination of \mathbf{W} at a particular point u , where \mathbf{W} is a vector of random variables. The distribution of \mathbf{W} may be multinomial (default), Poisson or binary. Other distributions are possible also if the adjusted cumulant generating function and its second derivative are given. Conditional saddlepoint approximations to the distribution of one linear combination given the values of other linear combinations of \mathbf{W} can be calculated for \mathbf{W} having binary or Poisson distributions.

Usage

```
saddle(A=NULL, u=NULL, wdist="m", type="simp", d=NULL, dl=1,
       init=rep(0.1, d), mu=rep(0.5, n), LR=FALSE, strata=NULL,
       K.adj=NULL, K2=NULL)
```

Arguments

- | | |
|-------|---|
| A | A vector or matrix of known coefficients of the linear combinations of \mathbf{W} . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored. |
| u | The value at which it is desired to calculate the saddlepoint approximation to the distribution of the linear combination of \mathbf{W} . It is a required argument unless <code>K.adj</code> and <code>K2</code> are supplied, in which case it is ignored. |
| wdist | The distribution of \mathbf{W} . This can be one of "m" (multinomial), "p" (Poisson), "b" (binary) or "o" (other). If <code>K.adj</code> and <code>K2</code> are given <code>wdist</code> is set to "o". |
| type | The type of saddlepoint approximation. Possible types are "simp" for simple saddlepoint and "cond" for the conditional saddlepoint. When <code>wdist</code> is "o" or "m", <code>type</code> is automatically set to "simp", which is the only type of saddlepoint currently implemented for those distributions. |

d	This specifies the dimension of the whole statistic. This argument is required only when <code>wdist="o"</code> and defaults to 1 if not supplied in that case. For other distributions it is set to <code>ncol(A)</code> .
d1	When <code>type</code> is "cond" this is the dimension of the statistic of interest which must be less than <code>length(u)</code> . Then the saddlepoint approximation to the conditional distribution of the first <code>d1</code> linear combinations given the values of the remaining combinations is found. Conditional distribution function approximations can only be found if the value of <code>d1</code> is 1.
init	Used if <code>wdist</code> is either "m" or "o", this gives initial values to <code>nlmin</code> which is used to solve the saddlepoint equation.
mu	The values of the parameters of the distribution of W when <code>wdist</code> is "m", "p" or "b". <code>mu</code> must be of the same length as W (i.e. <code>nrow(A)</code>). The default is that all values of <code>mu</code> are equal and so the elements of W are identically distributed.
LR	If TRUE then the Lugananni-Rice approximation to the cdf is used, otherwise the approximation used is based on Barndorff-Nielsen's r^* .
strata	The strata for stratified data.
K.adj	The adjusted cumulant generating function used when <code>wdist</code> is "o". This is a function of a single parameter, <code>zeta</code> , which calculates $K(zeta) - u \cdot zeta$, where $K(zeta)$ is the cumulant generating function of W .
K2	This is a function of a single parameter <code>zeta</code> which returns the matrix of second derivatives of $K(zeta)$ for use when <code>wdist</code> is "o". If <code>K.adj</code> is given then this must be given also. It is called only once with the calculated solution to the saddlepoint equation being passed as the argument. This argument is ignored if <code>K.adj</code> is not supplied.

Details

If `wdist` is "o" or "m", the saddlepoint equations are solved using `nlmin` to minimize `K.adj` with respect to its parameter `zeta`. For the Poisson and binary cases, a generalized linear model is fitted such that the parameter estimates solve the saddlepoint equations. The response variable 'y' for the `glm` must satisfy the equation $t(A) \cdot y = u(t())$ ($t()$ being the transpose function). Such a vector can be found as a feasible solution to a linear programming problem. This is done by a call to `simplex`. The covariate matrix for the `glm` is given by `A`.

Value

A list consisting of the following components

<code>spa</code>	The saddlepoint approximations. The first value is the density approximation and the second value is the distribution function approximation.
<code>zeta.hat</code>	The solution to the saddlepoint equation. For the conditional saddlepoint this is the solution to the saddlepoint equation for the numerator.
<code>zeta2.hat</code>	If <code>type</code> is "cond" this is the solution to the saddlepoint equation for the denominator. This component is not returned for any other value of <code>type</code> .

```
# To evaluate the bootstrap distribution of the mean failure time of
# air-conditioning equipment at 80 hours
saddle(A=aircondit$hours/12, u=80)

# Alternatively this can be done using a conditional poisson
saddle(A=cbind(aircondit$hours/12,1), u=c(80,12), wdist="p", type="cond")

# To use the Lugananni-Rice approximation to this
saddle(A=cbind(aircondit$hours/12,1), u=c(80,12), wdist="p", type="cond",
      LR = TRUE)

# Example 9.16 of Davison and Hinkley (1997) calculates saddlepoint
# approximations to the distribution of the ratio statistic for the
# city data. Since the statistic is not in itself a linear combination
# of random Variables, its distribution cannot be found directly.
# Instead the statistic is expressed as the solution to a linear
# estimating equation and hence its distribution can be found. We
# get the saddlepoint approximation to the pdf and cdf evaluated at
# t=1.25 as follows.
jacobian <- function(dat,t,zeta)
{
  p <- exp(zeta*(dat$x-t*dat$u))
  abs(sum(dat$u*p)/sum(p))
}
city.sp1 <- saddle(A=city$x-1.25*city$u, u=0)
city.sp1$spa[1] <- jacobian(city, 1.25, city.sp1$zeta.hat) * city.sp1$spa[1]
city.sp1
```

saddle.distn

Saddlepoint Distribution Approximations for Bootstrap Statistics

Description

Approximate an entire distribution using saddlepoint methods. This function can calculate simple and conditional saddlepoint distribution approximations for a univariate quantity of interest. For the simple saddlepoint the quantity of interest is a linear combination of \mathbf{W} where \mathbf{W} is a vector of random variables. For the conditional saddlepoint we require the distribution of one linear combination given the values of any number of other linear combinations. The distribution of \mathbf{W} must be one of multinomial, Poisson or binary. The primary use of this function is to calculate quantiles of bootstrap distributions using saddlepoint approximations. Such quantiles are required by the function `control` to approximate the distribution of the linear approximation to a statistic.

Usage

```
saddle.distn(A, u=NULL, alpha=NULL, wdist="m",
             type="simp", npts=20, t=NULL, t0=NULL,
             init=rep(0.1, d), mu=rep(0.5, n), LR=FALSE,
             strata=NULL, ...)
```

Arguments

A	This is a matrix of known coefficients or a function which returns such a matrix. If a function then its first argument must be the point t at which a saddlepoint is required. The most common reason for A being a function would be if the statistic is not itself a linear combination of the \mathbf{W} but is the solution to a linear estimating equation.
u	If A is a function then u must also be a function returning a vector with length equal to the number of columns of the matrix returned by A. Usually all components other than the first will be constants as the other components are the values of the conditioning variables. If A is a matrix with more than one column (such as when <code>wdist="cond"</code>) then u should be a vector with length one less than <code>ncol(A)</code> . In this case u specifies the values of the conditioning variables. If A is a matrix with one column or a vector then u is not used.
alpha	The alpha levels for the quantiles of the distribution which should be returned. By default the 0.1, 0.5, 1, 2.5, 5, 10, 20, 50, 80, 90, 95, 97.5, 99, 99.5 and 99.9 percentiles are calculated.
wdist	The distribution of \mathbf{W} . Possible values are "m" (multinomial), "p" (Poisson), or "b" (binary).
type	The type of saddlepoint to be used. Possible values are "simp" (simple saddlepoint) and "cond" (conditional). If <code>wdist</code> is "m", <code>type</code> is set to "simp".
npts	The number of points at which the saddlepoint approximation should be calculated and then used to fit the spline.
t	A vector of points at which the saddlepoint approximations are calculated. These points should extend beyond the extreme quantiles required but still be in the possible range of the bootstrap distribution. The observed value of the statistic should not be included in t as the distribution function approximation breaks down at that point. The points should, however cover the entire effective range of the distribution including close to the centre. If t is supplied then <code>npts</code> is set to <code>length(t)</code> . When t is not supplied, the function attempts to find the effective range of the distribution and then selects points to cover this range.
t0	If t is not supplied then a vector of length 2 should be passed as <code>t0</code> . The first component of <code>t0</code> should be the centre of the distribution and the second should be an estimate of spread (such as a standard error). These two are then used to find the effective range of the distribution. The range finding mechanism does rely on an accurate estimate of location in <code>t0[1]</code> .
init	When <code>wdist</code> is "m", this vector should contain the initial values to be passed to <code>n1min</code> when it is called to solve the saddlepoint equations.
mu	The vector of parameter values for the distribution. The default is that the components of \mathbf{W} are identically distributed.
LR	A logical flag. When <code>LR</code> is <code>TRUE</code> the Lugananni-Rice cdf approximations are calculated and used to fit the spline. Otherwise the cdf approximations used are based on Barndorff-Nielsen's r^* .

strata	A vector giving the strata when the rows of A relate to stratified data. This is used only when wdist is "m".
...	When A and u are functions any additional arguments are passed unchanged each time one of them is called.

Details

The range at which the saddlepoint is used is such that the cdf approximation at the endpoints is more extreme than required by the extreme values of `alpha`. The lower endpoint is found by evaluating the saddlepoint at the points `t0[1]-2*t0[2]`, `t0[1]-4*t0[2]`, `t0[1]-8*t0[2]` etc. until a point is found with a cdf approximation less than `min(alpha)/10`, then a bisection method is used to find the endpoint which has cdf approximation in the range `(min(alpha)/1000, min(alpha)/10)`. Then a number of, equally spaced, points are chosen between the lower endpoint and `t0[1]` until a total of `npts/2` approximations have been made. The remaining `npts/2` points are chosen to the right of `t0[1]` in a similar manner. Any points which are very close to the centre of the distribution are then omitted as the cdf approximations are not reliable at the centre. A smoothing spline is then fitted to the probit of the saddlepoint distribution function approximations at the remaining points and the required quantiles are predicted from the spline.

Sometimes the function will terminate with the message "Unable to find range". There are two main reasons why this may occur. One is that the distribution is too discrete and/or the required quantiles too extreme, this can cause the function to be unable to find a point within the allowable range which is beyond the extreme quantiles. Another possibility is that the value of `t0[2]` is too small and so too many steps are required to find the range. The first problem cannot be solved except by asking for less extreme quantiles, although for very discrete distributions the approximations may not be very good. In the second case using a larger value of `t0[2]` will usually solve the problem.

Value

The returned value is an object of class "saddle.distn". See the help file for [saddle.distn.object](#) for a description of such an object.

saddle.distn.object

Saddlepoint Distribution Approximation Objects

Description

Class of objects that result from calculating saddlepoint distribution approximations by a call to `saddle.distn`.

Generation

This class of objects is returned from calls to the function `saddle.distn`.

Methods

The class "saddle.distn" has methods for the functions `lines` and `print`.

Structure

Objects of class "saddle.distn" are implemented as a list with the following components.

quantiles A matrix with 2 columns. The first column contains the probabilities α and the second column contains the estimated quantiles of the distribution at those probabilities derived from the spline.

points A matrix of evaluations of the saddlepoint approximation. The first column contains the values of t which were used, the second and third contain the density and cdf approximations at those points and the rest of the columns contain the solutions to the saddlepoint equations. When `type` is "simp", there is only one of those. When `type` is "cond" there are $2 * d - 1$ where d is the

number of columns in A or the output of $A(t, \dots \{\})$. The first d of these correspond to the numerator and the remainder correspond to the denominator.

distn An object of class `smooth.spline`. This corresponds to the spline fitted to the saddlepoint cdf approximations in points in order to approximate the entire distribution. For the structure of the object see `smooth.spline`.

call The original call to `saddle.distn` which generated the object.

LR A logical variable indicating whether the Lugananni-Rice approximations were used.

salinity

Water Salinity and River Discharge

Description

The `salinity` data frame has 28 rows and 4 columns.

Biweekly averages of the water salinity and river discharge in Pamlico Sound, North Carolina were recorded between the years 1972 and 1977. The data in this set consists only of those measurements in March, April and May.

Usage

```
salinity
```

Format

This data frame contains the following columns:

sal The average salinity of the water over two weeks.

lag The average salinity of the water lagged two weeks. Since only spring is used, the value of `lag` is not always equal to the previous value of `sal`.

trend A factor indicating in which of the 6 biweekly periods between March and May, the observations were taken. The levels of the factor are from 0 to 5 with 0 being the first two weeks in March.

dis The amount of river discharge during the two weeks for which `sal` is the average salinity.

simplex

*Simplex Method for Linear Programming Problems***Description**

This function will optimize the linear function $a\%*\%x$ subject to the constraints $A1\%*\%x \leq b1$, $A2\%*\%x \geq b2$, $A3\%*\%x = b3$ and $x \geq 0$. Either maximization or minimization is possible but the default is minimization.

Usage

```
simplex(a, A1 = NULL, b1 = NULL, A2 = NULL, b2 = NULL, A3 = NULL,
       b3 = NULL, maxi = FALSE, n.iter = n + 2 * m, eps = 1e-10)
```

Arguments

a	A vector of length n which gives the coefficients of the objective function.
A1	An m1 by n matrix of coefficients for the "<=" type of constraints.
b1	A vector of length m1 giving the right hand side of the "<=" constraints. This argument is required if A1 is given and ignored otherwise. All values in b1 must be non-negative.
A2	An m2 by n matrix of coefficients for the ">=" type of constraints.
b2	A vector of length m2 giving the right hand side of the ">=" constraints. This argument is required if A2 is given and ignored otherwise. All values in b2 must be non-negative. Note that the constraints $x \geq 0$ are included automatically and so should not be repeated here.
A3	An m3 by n matrix of coefficients for the equality constraints.
b3	A vector of length m3 giving the right hand side of equality constraints. This argument is required if A3 is given and ignored otherwise. All values in b3 must be non-negative.
maxi	A logical flag which specifies minimization if FALSE (default) and maximization otherwise. If maxi is TRUE then the maximization problem is recast as a minimization problem by changing the objective function coefficients to their negatives.
n.iter	The maximum number of iterations to be conducted in each phase of the simplex method. The default is $n+2*(m1+m2+m3)$.
eps	The floating point tolerance to be used in tests of equality.

Details

The method employed by this function is the two phase tableau simplex method. If there are ">=" or equality constraints an initial feasible solution is not easy to find. To find a feasible solution an artificial variable is introduced into each ">=" or equality constraint and an auxiliary objective function is defined as the sum of these artificial variables. If a feasible solution to the set of constraints exists then the auxiliary objective will be minimized when all of the artificial variables are 0. These are then discarded and the original problem solved starting at the solution to the auxiliary problem. If the only constraints are of the "<=" form, the origin is a feasible solution and so the first stage can be omitted.

Value

An object of class "simplex": see [simplex.object](#).

Note

The method employed here is suitable only for relatively small systems. Also if possible the number of constraints should be reduced to a minimum in order to speed up the execution time which is approximately proportional to the cube of the number of constraints. In particular if there are any constraints of the form $x[i] \geq b2[i]$ they should be omitted by setting $x[i] = x[i] - b2[i]$, changing all the constraints and the objective function accordingly and then transforming back after the solution has been found.

simplex(a = enj, A1 = fat, b1 = 13800, A2 = rbind(vitx, vity, vitz),
      b2 = c(600, 300, 550), maxi = TRUE)
```

simplex.object

Linear Programming Solution Objects

Description

Class of objects that result from solving a linear programming problem using `simplex`.

Generation

This class of objects is returned from calls to the function `simplex`.

Methods

The class "saddle.distn" has a method for the function `print`.

Structure

Objects of class "simplex" are implemented as a list with the following components.

- soln The values of x which optimize the objective function under the specified constraints provided those constraints are jointly feasible.
- solved This indicates whether the problem was solved. A value of -1 indicates that no feasible solution could be found. A value of 0 that the maximum number of iterations was reached without termination of the second stage. This may indicate an unbounded function or simply that more iterations are needed. A value of 1 indicates that an optimal solution has been found.
- value The value of the objective function at `soln`.
- val.aux This is `NULL` if a feasible solution is found. Otherwise it is a positive value giving the value of the auxiliary objective function when it was minimized.
- obj The original coefficients of the objective function.
 - a The objective function coefficients re-expressed such that the basic variables have coefficient zero.
- a.aux This is `NULL` if a feasible solution is found. Otherwise it is the re-expressed auxiliary objective function at the termination of the first phase of the simplex method.
 - A The final constraint matrix which is expressed in terms of the non-basic variables. If a feasible solution is found then this will have dimensions $m_1+m_2+m_3$ by $n+m_1+m_2$, where the final m_1+m_2 columns correspond to slack and surplus variables. If no feasible solution is found there will be an additional $m_1+m_2+m_3$ columns for the artificial variables introduced to solve the first phase of the problem.
- basic The indices of the basic (non-zero) variables in the solution. Indices between $n+1$ and $n+m_1$ correspond to slack variables, those between $n+m_1+1$ and $n+m_2$ correspond to surplus variables and those greater than $n+m_2$ are artificial variables. Indices greater than $n+m_2$ should occur only if `solved` is -1 as the artificial variables are discarded in the second stage of the simplex method.
- slack The final values of the m_1 slack variables which arise when the " \leq " constraints are re-expressed as the equalities $A_1 * x + \text{slack} = b_1$.
- surplus The final values of the m_2 surplus variables which arise when the " \leq " constraints are re-expressed as the equalities $A_2 * x - \text{surplus} = b_2$.
- artificial This is `NULL` if a feasible solution can be found. If no solution can be found then this contains the values of the $m_1+m_2+m_3$ artificial variables which minimize their sum subject to the original constraints. A feasible solution exists only if all of the artificial variables can be made 0 simultaneously.

smooth.f

*Smooth Distributions on Data Points***Description**

This function uses the method of frequency smoothing to find a distribution on a data set which has a required value, `theta`, of the statistic of interest. The method results in distributions which vary smoothly with `theta`.

Usage

```
smooth.f(theta, boot.out, index=1, t=boot.out$t[, index], width=0.5)
```

Arguments

<code>theta</code>	The required value for the statistic of interest. If <code>theta</code> is a vector, a separate distribution will be found for each element of <code>theta</code> .
<code>boot.out</code>	A bootstrap output object returned by a call to <code>boot</code> .
<code>index</code>	The index of the variable of interest in the output of <code>boot.out\$statistic</code> . This argument is ignored if <code>t</code> is supplied. <code>index</code> must be a scalar.
<code>t</code>	The bootstrap values of the statistic of interest. This must be a vector of length <code>boot.out\$R</code> and the values must be in the same order as the bootstrap replicates in <code>boot.out</code> .
<code>width</code>	The standardized width for the kernel smoothing. The smoothing uses a value of <code>width*s</code> for epsilon, where <code>s</code> is the bootstrap estimate of the standard error of the statistic of interest. <code>width</code> should take a value in the range (0.2, 1) to produce a reasonable smoothed distribution. If <code>width</code> is too large then the distribution becomes closer to uniform.

Details

The new distributional weights are found by applying a normal kernel smoother to the observed values of `t` weighted by the observed frequencies in the bootstrap simulation. The resulting distribution may not have parameter value exactly equal to the required value `theta` but it will typically have a value which is close to `theta`. The details of how this method works can be found in Davison, Hinkley and Worton (1995) and Section 3.9.2 of Davison and Hinkley (1997).

Value

If `length(theta)` is 1 then a vector with the same length as the data set `boot.out$data` is returned. The value in position `i` is the probability to be given to the data point in position `i` so that the distribution has parameter value approximately equal to `theta`. If `length(theta)` is bigger than 1 then the returned value is a matrix with `length(theta)` rows each of which corresponds to a distribution with the parameter value approximately equal to the corresponding value of `theta`.

Examples

```
# Example 9.8 of Davison and Hinkley (1997) requires tilting the resampling
# distribution of the studentized statistic to be centred at the observed
# value of the test statistic 1.84. In the book exponential tilting was used
# but it is also possible to use smooth.f.
grav1 <- gravity[as.numeric(gravity[,2])>=7,]
grav.fun <- function(dat, w, orig)
{
  strata <- tapply(dat[, 2], as.numeric(dat[, 2]))
  d <- dat[, 1]
  ns <- tabulate(strata)
  w <- w/tapply(w, strata, sum)[strata]
  mns <- tapply(d * w, strata, sum)
  mn2 <- tapply(d * d * w, strata, sum)
  s2hat <- sum((mn2 - mns^2)/ns)
  c(mns[2]-mns[1], s2hat, (mns[2]-mns[1]-orig)/sqrt(s2hat))
}
grav.z0 <- grav.fun(grav1, rep(1,26), 0)
grav.boot <- boot(grav1, grav.fun, R=499, stype="w",
  strata=grav1[,2], orig=grav.z0[1])
grav.sm <- smooth.f(grav.z0[3], grav.boot, index=3)

# Now we can run another bootstrap using these weights
grav.boot2 <- boot(grav1, grav.fun, R=499, stype="w",
  strata=grav1[,2], orig=grav.z0[1],
  weights=grav.sm)

# Estimated p-values can be found from these as follows
mean(grav.boot$t[,3] >= grav.z0[3])
imp.prob(grav.boot2, t0=-grav.z0[3], t=-grav.boot2$t[,3])

# Note that for the importance sampling probability we must
# multiply everything by -1 to ensure that we find the correct
# probability. Raw resampling is not reliable for probabilities
# greater than 0.5. Thus
1-imp.prob(grav.boot2, index=3, t0=grav.z0[3])$raw
# can give very strange results (negative probabilities).
```

Description

sunspot is a time series and contains 289 observations.

The Zurich sunspot numbers have been analyzed in almost all books on time series analysis as well as numerous papers. The data set, usually attributed to Rudolf Wolf, consists of means of daily relative numbers of sunspot sightings. The relative number for a day is given by $k(f+10g)$ where g is the number of sunspot groups observed, f is the total number of spots within the groups and k is a scaling factor relating the observer and telescope to a baseline. The relative numbers are then averaged to give an annual figure. See Insenman (1983) for a discussion of the relative numbers. The figures are for the years 1700-1988.

survival

Survival of Rats after Radiation Doses

Description

The survival data frame has 14 rows and 2 columns.

The data measured the survival percentages of batches of rats who were given varying doses of radiation. At each of 6 doses there were two or three replications of the experiment.

Usage

survival

Format

This data frame contains the following columns:

dose The dose of radiation administered (rads).

surv The survival rate of the batches expressed as a percentage.

Source

The data were obtained from

 tau

Tau Particle Decay Modes

Description

The tau data frame has 60 rows and 2 columns.

The tau particle is a heavy electron-like particle discovered in the 1970's by Martin Perl at the Stanford Linear Accelerator Center. Soon after its production the tau particle decays into various collections of more stable particles. About 86% of the time the decay involves just one charged particle. This rate has been measured independently 13 times.

The one-charged-particle event is made up of four major modes of decay as well as a collection of other events. The four main types of decay are denoted rho, pi, e and mu. These rates have been measured independently 6, 7, 14 and 19 times respectively. Due to physical constraints each experiment can only estimate the composite one-charged-particle decay rate or the rate of one of the major modes of decay.

Each experiment consists of a major research project involving many years work. One of the goals of the experiments was to estimate the rate of decay due to events other than the four main modes of decay. These are uncertain events and so cannot themselves be observed directly.

Usage

tau

Format

This data frame contains the following columns:

rate The decay rate expressed as a percentage.

decay The type of decay measured in the experiment. It is a factor with levels 1, rho, pi, e and mu.

tilt.boot

*Non-parametric Tilted Bootstrap***Description**

This function will run an initial bootstrap with equal resampling probabilities (if required) and will use the output of the initial run to find resampling probabilities which put the value of the statistic at required values. It then runs an importance resampling bootstrap using the calculated probabilities as the resampling distribution.

Usage

```
tilt.boot(data, statistic, R, sim="ordinary", stype="i",
          strata=rep(1, n), L=NULL, theta=NULL,
          alpha=c(0.025, 0.975), tilt=TRUE, width=0.5,
          index=1, ...)
```

Arguments

data	The data as a vector, matrix or data frame. If it is a matrix or data frame then each row is considered as one (multivariate) observation.
statistic	A function which when applied to data returns a vector containing the statistic(s) of interest. It must take at least two arguments. The first argument will always be data and the second should be a vector of indices, weights or frequencies describing the bootstrap sample. Any other arguments must be supplied to tilt.boot and will be passed unchanged to statistic each time it is called.
R	The number of bootstrap replicates required. This will generally be a vector, the first value stating how many uniform bootstrap simulations are to be performed at the initial stage. The remaining values of R are the number of simulations to be performed resampling from each reweighted distribution. The first value of R must always be present, a value of 0 implying that no uniform resampling is to be carried out. Thus length(R) should always equal 1+length(theta).
sim	This is a character string indicating the type of bootstrap simulation required. There are only two possible values that this can take: "ordinary" and "balanced". If other simulation types are required for the initial un-weighted bootstrap then it will be necessary to run boot, calculate the weights appropriately, and run boot again using the calculated weights.
stype	A character string indicating the type of second argument expected by statistic. The possible values that stype can take are "i" (indices), "w" (weights) and "f" (frequencies).
strata	An integer vector or factor representing the strata for multi-sample problems.
L	The empirical influence values for the statistic of interest. They are used only for exponential tilting when tilt is TRUE. If tilt is TRUE and they are not supplied then tilt.boot uses empinf to calculate them.
theta	The required parameter value(s) for the tilted distribution(s). There should be one value of theta for each of the non-uniform distributions. If R[1] is 0 theta is a required argument. Otherwise theta values can be estimated from the initial uniform bootstrap and the values in alpha.

alpha	The alpha level to which tilting is required. This parameter is ignored if <code>R[1]</code> is 0 or if <code>theta</code> is supplied, otherwise it is used to find the values of <code>theta</code> as quantiles of the initial uniform bootstrap. In this case <code>R[1]</code> should be large enough that $\min(c(\text{alpha}, 1-\text{alpha})) * R[1] > 5$, if this is not the case then a warning is generated to the effect that the <code>theta</code> are extreme values and so the tilted output may be unreliable.
tilt	A logical variable which if <code>TRUE</code> (the default) indicates that exponential tilting should be used, otherwise local frequency smoothing (<code>smooth.f</code>) is used. If <code>tilt</code> is <code>FALSE</code> then <code>R[1]</code> must be positive. In fact in this case the value of <code>R[1]</code> should be fairly large (in the region of 500 or more).
width	This argument is used only if <code>tilt</code> is <code>FALSE</code> , in which case it is passed unchanged to <code>smooth.f</code> as the standardized bandwidth for the smoothing operation. The value should generally be in the range (0.2, 1). See <code>smooth.f</code> for more details.
index	The index of the statistic of interest in the output from <code>statistic</code> . By default the first element of the output of <code>statistic</code> is used.
...	Any additional arguments required by <code>statistic</code> . These are passed unchanged to <code>statistic</code> each time it is called.

Value

An object of class "boot" with the following components

t0	The observed value of the statistic on the original data.
t	The values of the bootstrap replicates of the statistic. There will be <code>sum(R)</code> of these, the first <code>R[1]</code> corresponding to the uniform bootstrap and the remainder to the tilted bootstrap(s).
R	The input vector of the number of bootstrap replicates.
data	The original data as supplied.
statistic	The <code>statistic</code> function as supplied.
sim	The simulation type used in the bootstrap(s), it can either be "ordinary" or "balanced".
stype	The type of statistic supplied, it is the same as the input value <code>stype</code> .
call	A copy of the original call to <code>tilt.boot</code> .
strata	The strata as supplied.
weights	The matrix of weights used. If <code>R[1]</code> is greater than 0 then the first row will be the uniform weights and each subsequent row the tilted weights. If <code>R[1]</code> equals 0 then the uniform weights are omitted and only the tilted weights are output.
theta	The values of <code>theta</code> used for the tilted distributions. These are either the input values or the values derived from the uniform bootstrap and <code>alpha</code> .

 tsboot

Bootstrapping of Time Series

Description

Generate R bootstrap replicates of a statistic applied to a time series. The replicate time series can be generated using fixed or random block lengths or can be model based replicates.

Usage

```
tsboot(tseries, statistic, R, l=NULL, sim="model", endcorr=TRUE,
       n.sim=NROW(tseries), orig.t=TRUE, ran.gen,
       ran.args=NULL, norm=TRUE, ...)
```

Arguments

<code>tseries</code>	A univariate or multivariate time series.
<code>statistic</code>	A function which when applied to <code>tseries</code> returns a vector containing the statistic(s) of interest. Each time <code>statistic</code> is called it is passed a time series of length <code>n.sim</code> which is of the same class as the original <code>tseries</code> . Any other arguments which <code>statistic</code> takes must remain constant for each bootstrap replicate and should be supplied through the <code>...</code> argument to <code>tsboot</code> .
<code>R</code>	A positive integer giving the number of bootstrap replicates required.
<code>sim</code>	The type of simulation required to generate the replicate time series. The possible input values are "model" (model based resampling), "fixed" (block resampling with fixed block lengths of <code>l</code>), "geom" (block resampling with block lengths having a geometric distribution with mean <code>l</code>) or "scramble" (phase scrambling).
<code>l</code>	If <code>sim</code> is "fixed" then <code>l</code> is the fixed block length used in generating the replicate time series. If <code>sim</code> is "geom" then <code>l</code> is the mean of the geometric distribution used to generate the block lengths. <code>l</code> should be a positive integer less than the length of <code>tseries</code> . This argument is not required when <code>sim</code> is "model" but it is required for all other simulation types.
<code>endcorr</code>	A logical variable indicating whether end corrections are to be applied when <code>sim</code> is "fixed". When <code>sim</code> is "geom", <code>endcorr</code> is automatically set to TRUE; <code>endcorr</code> is not used when <code>sim</code> is "model" or "scramble".
<code>n.sim</code>	The length of the simulated time series. Typically this will be equal to the length of the original time series but there are situations when it will be larger. One obvious situation is if prediction is required. Another situation in which <code>n.sim</code> is larger than the original length is if <code>tseries</code> is a residual time series from fitting some model to the original time series. In this case, <code>n.sim</code> would usually be the length of the original time series.
<code>orig.t</code>	A logical variable which indicates whether <code>statistic</code> should be applied to <code>tseries</code> itself as well as the bootstrap replicate series. If <code>statistic</code> is expecting a longer time series than <code>tseries</code> or if applying <code>statistic</code> to <code>tseries</code> will not yield any useful information then <code>orig.t</code> should be set to FALSE.
<code>ran.gen</code>	This is a function of three arguments. The first argument is a time series. If <code>sim</code> is code "model" then it will always be <code>tseries</code> that is passed. For other simulation types it is the result of selecting <code>n.sim</code> observations from <code>tseries</code> by some scheme and converting the result back into a time series of the same form as <code>tseries</code> (although of length <code>n.sim</code>). The second argument to <code>ran.gen</code> is always the value <code>n.sim</code> , and the third argument is <code>ran.args</code> , which is used to supply any other objects needed by <code>ran.gen</code> . If <code>sim</code> is "model" then the generation of the replicate time series will be done in <code>ran.gen</code> (for example through use of <code>arima.sim</code>). For the other simulation types <code>ran.gen</code> is used for 'post-blackening'. The default is that the function simply returns the time series passed to it.
<code>ran.args</code>	This will be supplied to <code>ran.gen</code> each time it is called. If <code>ran.gen</code> needs any extra arguments then they should be supplied as components of <code>ran.args</code> . Multiple arguments may be passed by making <code>ran.args</code> a list. If <code>ran.args</code> is NULL then it should not be used within <code>ran.gen</code> but note that <code>ran.gen</code> must still have its third argument.

norm	A logical argument indicating whether normal margins should be used for phase scrambling. If <code>norm</code> is <code>FALSE</code> then margins corresponding to the exact empirical margins are used.
...	Any extra arguments to <code>statistic</code> may be supplied here.

Details

If `sim` is "fixed" then each replicate time series is found by taking blocks of length `l`, from the original time series and putting them end-to-end until a new series of length `n.sim` is created. When `sim` is "geom" a similar approach is taken except that now the block lengths are generated from a geometric distribution with mean 1. Post-blackening can be carried out on these replicate time series by including the function `ran.gen` in the call to `tsboot` and having `tseries` as a time series of residuals.

Model based resampling is very similar to the parametric bootstrap and all simulation must be in one of the user specified functions. This avoids the complicated problem of choosing the block length but relies on an accurate model choice being made.

Phase scrambling is described in Section 8.2.4 of Davison and Hinkley (1997). The types of statistic for which this method produces reasonable results is very limited and the other methods seem to do better in most situations. Other types of resampling in the frequency domain can be accomplished using the function `boot` with the argument `sim="parametric"`.

Value

An object of class "boot" with the following components.

<code>t0</code>	If <code>orig.t</code> is <code>TRUE</code> then <code>t0</code> is the result of <code>statistic(tseries, ...)</code> otherwise it is <code>NULL</code> .
<code>t</code>	The results of applying <code>statistic</code> to the replicate time series.
<code>R</code>	The value of <code>R</code> as supplied to <code>tsboot</code> .
<code>tseries</code>	The original time series.
<code>statistic</code>	The function <code>statistic</code> as supplied.
<code>sim</code>	The simulation type used in generating the replicates.
<code>endcorr</code>	The value of <code>endcorr</code> used. The value is meaningful only when <code>sim</code> is "fixed"; it is ignored for model based simulation or phase scrambling and is always set to <code>TRUE</code> if <code>sim</code> is "geom".
<code>n.sim</code>	The value of <code>n.sim</code> used.
<code>l</code>	The value of <code>l</code> used for block based resampling. This will be <code>NULL</code> if block based resampling was not used.
<code>ran.gen</code>	The <code>ran.gen</code> function used for generating the series or for "post-blackening".
<code>ran.args</code>	The extra arguments passed to <code>ran.gen</code> .
<code>call</code>	The original call to <code>tsboot</code> .

Examples

```
lynx.fun <- function(tsb)
{   ar.fit <- ar(tsb, order.max=25)
    c(ar.fit$order, mean(tsb), tsb)
}

# the stationary bootstrap with mean block length 20
lynx.1 <- tsboot(log(lynx), lynx.fun, R=99, l=20, sim="geom")

# the fixed block bootstrap with length 20
lynx.2 <- tsboot(log(lynx), lynx.fun, R=99, l=20, sim="fixed")

# Now for model based resampling we need the original model
# Note that for all of the bootstraps which use the residuals as their
# data, we set orig.t to FALSE since the function applied to the residual
# time series will be meaningless.
lynx.ar <- ar(log(lynx))
lynx.model <- list(order=c(lynx.ar$order,0,0),ar=lynx.ar$ar)
lynx.res <- lynx.ar$resid[!is.na(lynx.ar$resid)]
lynx.res <- lynx.res - mean(lynx.res)

lynx.sim <- function(res,n.sim, ran.args) {
# random generation of replicate series using arima.sim
  rgl <- function(n, res)
    sample(res, n, replace=TRUE)
  ts.orig <- ran.args$ts
  ts.mod <- ran.args$model
  mean(ts.orig)+ts(arima.sim(model=ts.mod, n=n.sim,
    rand.gen=rgl, res=as.vector(res)))
}

lynx.3 <- tsboot(lynx.res, lynx.fun, R=99, sim="model", n.sim=114,
  orig.t=FALSE, ran.gen=lynx.sim,
  ran.args=list(ts=log(lynx), model=lynx.model))

# For "post-blackening" we need to define another function
lynx.black <- function(res, n.sim, ran.args)
{   ts.orig <- ran.args$ts
    ts.mod <- ran.args$model
    mean(ts.orig) + ts(arima.sim(model=ts.mod,n=n.sim,innov=res))
}

# Now we can run apply the two types of block resampling again but this
# time applying post-blackening.
lynx.1b <- tsboot(lynx.res, lynx.fun, R=99, l=20, sim="fixed",
  n.sim=114, orig.t=FALSE, ran.gen=lynx.black,

  ran.args=list(ts=log(lynx), model=lynx.model))
```

```
# To compare the observed order of the bootstrap replicates we
# proceed as follows.
table(lynx.1$t[,1])
table(lynx.1b$t[,1])
table(lynx.2$t[,1])
table(lynx.2b$t[,1])
table(lynx.3$t[,1])
# Notice that the post-blackened and model-based bootstraps preserve
# the true order of the model (11) in many more cases than the others.
```

tuna

Tuna Sighting Data

Description

The `tuna` data frame has 64 rows and 1 column.

The data come from an aerial line transect survey of Southern Bluefin Tuna in the Great Australian Bight. An aircraft with two spotters on board flies randomly allocated line transects. Each school of tuna sighted is counted and its perpendicular distance from the transect measured. The survey was conducted in summer when tuna tend to stay on the surface.

Usage

```
tuna
```

Format

This data frame contains the following column:

- y** The perpendicular distance, in miles, from the transect for 64 independent sightings of tuna schools.

Source

The data were obtained from

Chen, S.X. (1996) Empirical likelihood confidence intervals for nonparametric density estimation. *Biometrika*, **83**, 329–341.

References

`urine`*Urine Analysis Data*

Description

The `urine` data frame has 79 rows and 7 columns.

79 urine specimens were analyzed in an effort to determine if certain physical characteristics of the urine might be related to the formation of calcium oxalate crystals.

Usage

```
urine
```

Format

This data frame contains the following columns:

r Indicator of the presence of calcium oxalate crystals.

gravity The specific gravity of the urine.

ph The pH reading of the urine.

osmo The osmolarity of the urine. Osmolarity is proportional to the concentration of molecules in solution.

cond The conductivity of the urine. Conductivity is proportional to the concentration of charged ions in solution.

urea The urea concentration in millimoles per litre.

calc The calcium concentration in millimoles per litre.

Source

The data were obtained from

`var.linear` *Linear Variance Estimate*

Description

Estimates the variance of a statistic from its empirical influence values.

Usage

```
var.linear(L, strata=NULL)
```

Arguments

`L` Vector of the empirical influence values of a statistic. These will usually be calculated by a call to `empinf`.

`strata` A numeric vector or factor specifying which observations (and hence empirical influence values) come from which strata.

Value

The variance estimate calculated from `L`.

Examples

```
# To estimate the variance of the ratio of means for the city data.
ratio <- function(d,w)
  sum(d$x * w) / sum(d$u * w)
var.linear(empinf(data=city, statistic=ratio))
```

`wool` *Australian Relative Wool Prices*

Description

`wool` is a time series of class "ts" and contains 309 observations.

Each week that the market is open the Australian Wool Corporation set a floor price which determines their policy on intervention and is therefore a reflection of the overall price of wool for the week in question. Actual prices paid can vary considerably about the floor price. The series here is the log of the ratio between the price for fine grade wool and the floor price, each market week between July 1976 and Jun 1984.

Chapter 13

The `class` package

`batchSOM`

Self-Organizing Maps: Batch Algorithm

Description

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

Usage

```
batchSOM(data, grid = somgrid(), radii, init)
```

Arguments

<code>data</code>	a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
<code>grid</code>	A grid for the representatives: see <code>somgrid</code> .
<code>radii</code>	the radii of the neighbourhood to be used for each pass: one pass is run for each element of <code>radii</code> .
<code>init</code>	the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .

Details

The batch SOM algorithm of Kohonen(1995, section 3.14) is used.

Value

an object of class "SOM" with components

<code>grid</code>	the grid, an object of class "somgrid".
<code>codes</code>	a matrix of representatives.

     as.character(crabs.grp))
```

condense

Condense training set for k-NN classifier

Description

Condense training set for k-NN classifier

Usage

```
condense(train, class, store, trace = TRUE)
```

Arguments

train	matrix for training set
class	vector of classifications for test set
store	initial store set. Default one randomly chosen element of the set.
trace	logical. Trace iterations?

Details

The store set is used to 1-NN classify the rest, and misclassified patterns are added to the store set. The whole set is checked until no additions occur.

Value

index vector of cases to be retained (the final store set).

Examples

```
data(iris3)
train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
keep <- condense(train, cl)
knn(train[keep, , drop=FALSE], test, cl[keep])
keep2 <- reduce.nn(train, keep, cl)
knn(train[keep2, , drop=FALSE], test, cl[keep2])
```

knn

k-Nearest Neighbour Classification

Description

k-nearest neighbour classification for test set from training set. For each row of the test set, the k nearest (in Euclidean distance) training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the kth nearest vector, all candidates are included in the vote.

Usage

```
knn(train, test, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

Arguments

train	matrix or data frame of training set cases.
test	matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
cl	factor of true classifications of training set
k	number of neighbours considered.
l	minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than k-1 dissenting votes are allowed, even if k is increased by ties.)
prob	If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .
use.all	controls handling of ties. If true, all distances equal to the kth largest are included. If false, a random selection of distances equal to the kth is chosen to use exactly k neighbours.

Value

factor of classifications of test set. `doubt` will be returned as NA.

References

Ripley, B. D. (1996) *Pattern Recognition and Neural Networks*. Cambridge.
 Venables, W. N. and Ripley, B. D. (2002) *Modern Applied Statistics with S*. Fourth edition. Springer.

train <- rbind(iris3[1:25,,1], iris3[1:25,,2], iris3[1:25,,3])
test <- rbind(iris3[26:50,,1], iris3[26:50,,2], iris3[26:50,,3])
cl <- factor(c(rep("s",25), rep("c",25), rep("v",25)))
knn(train, test, cl, k = 3, prob=TRUE)
attributes(.Last.value)
```

knn.cv

k-Nearest Neighbour Cross-Validatory Classification

Description

k-nearest neighbour cross-validatory classification from training set.

Usage

```
knn.cv(train, cl, k = 1, l = 0, prob = FALSE, use.all = TRUE)
```

Arguments

<code>train</code>	matrix or data frame of training set cases.
<code>cl</code>	factor of true classifications of training set
<code>k</code>	number of neighbours considered.
<code>l</code>	minimum vote for definite decision, otherwise <code>doubt</code> . (More precisely, less than $k-1$ dissenting votes are allowed, even if k is increased by ties.)
<code>prob</code>	If this is true, the proportion of the votes for the winning class are returned as attribute <code>prob</code> .
<code>use.all</code>	controls handling of ties. If true, all distances equal to the k th largest are included. If false, a random selection of distances equal to the k th is chosen to use exactly k neighbours.

Details

This uses leave-one-out cross validation. For each row of the training set `train`, the k nearest (in Euclidean distance) other training set vectors are found, and the classification is decided by majority vote, with ties broken at random. If there are ties for the k th nearest vector, all candidates are included in the vote.

Value

factor of classifications of training set. `doubt` will be returned as NA.

attributes(.Last.value)
```

`knn1`*1-nearest neighbour classification*

Description

Nearest neighbour classification for test set from training set. For each row of the test set, the nearest (by Euclidean distance) training set vector is found, and its classification used. If there is more than one nearest, a majority vote is used with ties broken at random.

Usage

```
knn1(train, test, cl)
```

Arguments

<code>train</code>	matrix or data frame of training set cases.
<code>test</code>	matrix or data frame of test set cases. A vector will be interpreted as a row vector for a single case.
<code>cl</code>	factor of true classification of training set.

Value

factor of classifications of test set.

lvq1

*Learning Vector Quantization I***Description**

Moves examples in a codebook to better represent the training set.

Usage

```
lvq1(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03)
```

Arguments

x	a matrix or data frame of examples
cl	a vector or factor of classifications for the examples
codebk	a codebook
niter	number of iterations
alpha	constant for training

Details

Selects `niter` examples at random with replacement, and adjusts the nearest example in the codebook for each.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

References

```

Description

Moves examples in a codebook to better represent the training set.

Usage

```
lvq2(x, cl, codebk, niter = 100 * nrow(codebk$x), alpha = 0.03,  
      win = 0.3)
```

Arguments

x	a matrix or data frame of examples
cl	a vector or factor of classifications for the examples
codebk	a codebook
niter	number of iterations
alpha	constant for training
win	a tolerance for the closeness of the two nearest vectors.

Details

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook if one is correct and the other incorrect.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

*Learning Vector Quantization 3***Description**

Moves examples in a codebook to better represent the training set.

Usage

```
lvq3(x, c1, codebk, niter = 100*nrow(codebk$x), alpha = 0.03,
     win = 0.3, epsilon = 0.1)
```

Arguments

x	a matrix or data frame of examples
c1	a vector or factor of classifications for the examples
codebk	a codebook
niter	number of iterations
alpha	constant for training
win	a tolerance for the closeness of the two nearest vectors.
epsilon	proportion of move for correct vectors

Details

Selects `niter` examples at random with replacement, and adjusts the nearest two examples in the codebook for each.

Value

A codebook, represented as a list with components `x` and `c1` giving the examples and classes.

lvqinit

*Initialize a LVQ Codebook***Description**

Construct an initial codebook for LVQ methods.

Usage

```
lvqinit(x, cl, size, prior, k = 5)
```

Arguments

x	a matrix or data frame of training examples, n by p.
cl	the classifications for the training examples. A vector or factor of length n.
size	the size of the codebook. Defaults to $\min(\text{round}(0.4 \cdot \text{ng} \cdot (\text{ng} - 1 + p/2)), 0), n)$ where ng is the number of classes.
prior	Probabilities to represent classes in the codebook. Default proportions in the training set.
k	k used for k-NN test of correct classification. Default is 5.

Details

Selects `size` examples from the training set without replacement with proportions proportional to the prior or the original proportions.

Value

A codebook, represented as a list with components `x` and `cl` giving the examples and classes.

lvqtest

Classify Test Set from LVQ Codebook

Description

Classify a test set by 1-NN from a specified LVQ codebook.

Usage

```
lvqtest(codebk, test)
```

Arguments

codebk	codebook object returned by other LVQ software
test	matrix of test examples

Details

uses 1-NN to classify each test example against the codebook.

Value

factor of classification for each row of x

References

Description

Multiedit for k-NN classifier

Usage

```
multiedit(x, class, k = 1, V = 3, I = 5, trace = TRUE)
```

Arguments

<code>x</code>	matrix of training set.
<code>class</code>	vector of classification of training set.
<code>k</code>	number of neighbours used in k-NN.
<code>V</code>	divide training set into V parts.
<code>I</code>	number of null passes before quitting.
<code>trace</code>	logical for statistics at each pass.

Value

index vector of cases to be retained.

`reduce.nn`*Reduce Training Set for a k-NN Classifier*

Description

Reduce training set for a k-NN classifier. Used after `condense`.

Usage

```
reduce.nn(train, ind, class)
```

Arguments

<code>train</code>	matrix for training set
<code>ind</code>	Initial list of members of the training set (from <code>condense</code>).
<code>class</code>	vector of classifications for test set

Details

All the members of the training set are tried in random order. Any which when dropped do not cause any members of the training set to be wrongly classified are dropped.

Value

index vector of cases to be retained.

SOM

*Self-Organizing Maps: Online Algorithm***Description**

Kohonen's Self-Organizing Maps are a crude form of multidimensional scaling.

Usage

```
SOM(data, grid = somgrid(), rlen = 10000, alpha, radii, init)
```

Arguments

<code>data</code>	a matrix or data frame of observations, scaled so that Euclidean distance is appropriate.
<code>grid</code>	A grid for the representatives: see somgrid .
<code>rlen</code>	the number of updates: used only in the defaults for <code>alpha</code> and <code>radii</code> .
<code>alpha</code>	the amount of change: one update is done for each element of <code>alpha</code> . Default is to decline linearly from 0.05 to 0 over <code>rlen</code> updates.
<code>radii</code>	the radii of the neighbourhood to be used for each update: must be the same length as <code>alpha</code> . Default is to decline linearly from 4 to 1 over <code>rlen</code> updates.
<code>init</code>	the initial representatives. If missing, chosen (without replacement) randomly from <code>data</code> .

Details

`alpha` and `radii` can also be lists, in which case each component is used in turn, allowing two or more phase training.

Value

an object of class "SOM" with components

<code>grid</code>	the grid, an object of class "somgrid".
<code>codes</code>	a matrix of representatives.

plot(crabs.som2)

```

somgrid

*Plot SOM Fits***Description**

Plotting functions for SOM results.

Usage

```

somgrid(xdim = 8, ydim = 6, topo = c("rectangular", "hexagonal"))

## S3 method for class 'somgrid':
plot(x, type = "p", ...)

## S3 method for class 'SOM':
plot(x, ...)

```

Arguments

xdim, ydim	dimensions of the grid
topo	the topology of the grid.
x	an object inheriting from class "somgrid" or "SOM".
type, ...	graphical parameters.

Details

The class "somgrid" records the coordinates of the grid to be used for (batch or on-line) SOM: this has a plot method.

The plot method for class "SOM" plots a *stars* plot of the representative at each grid point.

Value

For somgrid, an object of class "somgrid", a list with components

pts	a two-column matrix giving locations for the grid points.
xdim, ydim, topo	as in the arguments to somgrid.

Chapter 14

The `cluster` package

`agnes`

Agglomerative Nesting (Hierarchical Clustering)

Description

Computes agglomerative hierarchical clustering of the dataset.

Usage

```
agnes(x, diss = inherits(x, "dist"), metric = "euclidean",
      stand = FALSE, method = "average", par.method,
      keep.diss = n < 100, keep.data = !diss)
```

Arguments

<code>x</code>	<p>data matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code>. Also a vector with length $n*(n-1)/2$ is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.</p>
<code>diss</code>	<p>logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> is assumed to be a dissimilarity matrix. If FALSE, then <code>x</code> is treated as a matrix of observations by variables.</p>
<code>metric</code>	<p>character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.</p>
<code>stand</code>	<p>logical flag: if TRUE, then the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable</p>

(column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If x is already a dissimilarity matrix, then this argument will be ignored.

`method` character string defining the clustering method. The six methods implemented are "average" ([unweighted pair-]group average method, UPGMA), "single" (single linkage), "complete" (complete linkage), "ward" (Ward's method), "weighted" (weighted average linkage) and its generalization "flexible" which uses (a constant version of) the Lance-Williams formula and the `par.method` argument. Default is "average".

`par.method` if `method == "flexible"`, numeric vector of length 1, 3, or 4, see in the details section.

`keep.diss`, `keep.data` logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to `FALSE` can give much smaller results and hence even save memory allocation *time*.

Details

`agnes` is fully described in chapter 5 of Kaufman and Rousseeuw (1990). Compared to other agglomerative clustering methods such as `hclust`, `agnes` has the following features: (a) it yields the agglomerative coefficient (see `agnes.object`) which measures the amount of clustering structure found; and (b) apart from the usual tree it also provides the banner, a novel graphical display (see `plot.agnes`).

The `agnes`-algorithm constructs a hierarchy of clusterings.

At first, each observation is a small cluster by itself. Clusters are merged until only one large cluster remains which contains all the observations. At each stage the two *nearest* clusters are combined to form one larger cluster.

For `method="average"`, the distance between two clusters is the average of the dissimilarities between the points in one cluster and the points in the other cluster.

In `method="single"`, we use the smallest dissimilarity between a point in the first cluster and a point in the second cluster (nearest neighbor method).

When `method="complete"`, we use the largest dissimilarity between a point in the first cluster and a point in the second cluster (furthest neighbor method).

The `method = "flexible"` allows (and requires) more details: The Lance-Williams formula specifies how dissimilarities are computed when clusters are agglomerated (equation (32) in K.&R., p.237). If clusters C_1 and C_2 are agglomerated into a new cluster, the dissimilarity between their union and another cluster Q is given by

$$D(C_1 \cup C_2, Q) = \alpha_1 * D(C_1, Q) + \alpha_2 * D(C_2, Q) + \beta * D(C_1, C_2) + \gamma * |D(C_1, Q) - D(C_2, Q)|,$$

where the four coefficients $(\alpha_1, \alpha_2, \beta, \gamma)$ are specified by the vector `par.method`:

If `par.method` is of length 1, say $= \alpha$, `par.method` is extended to give the "Flexible Strategy" (K. & R., p.236 f) with Lance-Williams coefficients $(\alpha_1 = \alpha_2 = \alpha, \beta = 1 - 2\alpha, \gamma = 0)$.

If of length 3, $\gamma = 0$ is used.

Care and expertise is probably needed when using `method = "flexible"` particularly for the case when `par.method` is specified of longer length than one. The *weighted average* (`method="weighted"`) is the same as `method="flexible"`, `par.method = 0.5`.

Value

an object of class "agnes" representing the clustering. See `agnes.object` for details.

BACKGROUND

Cluster analysis divides a dataset into groups (clusters) of observations that are similar to each other.

Hierarchical methods like `agnes`, `diana`, and `mona` construct a hierarchy of clusterings, with the number of clusters ranging from one to the number of observations.

Partitioning methods like `pam`, `clara`, and `fanny` require that the number of clusters be given by the user.

plot(agnS)
par(op)

data(agriculture)
## Plot similar to Figure 7 in ref
## Not run: plot(agnes(agriculture), ask = TRUE)
```

Description

The objects of class "agnes" represent an agglomerative hierarchical clustering of a dataset.

Value

A legitimate `agnes` object is a list with the following components:

<code>order</code>	a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
<code>order.lab</code>	a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
<code>height</code>	a vector with the distances between merging clusters at the successive stages.
<code>ac</code>	the agglomerative coefficient, measuring the clustering structure of the dataset. For each observation i , denote by $m(i)$ its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The <code>ac</code> is the average of all $1 - m(i)$. It can also be seen as the average width (or the percentage filled) of the banner plot. Because <code>ac</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
<code>merge</code>	an $(n-1)$ by 2 matrix, where n is the number of observations. Row i of <code>merge</code> describes the merging of clusters at step i of the clustering. If a number j in the row is negative, then the single observation $ j $ is merged at this stage. If j is positive, then the merger is with the cluster formed at stage j of the algorithm.
<code>diss</code>	an object of class "dissimilarity" (see dissimilarity.object), representing the total dissimilarity matrix of the dataset.
<code>data</code>	a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.

GENERATION

This class of objects is returned from [agnes](#).

METHODS

The "agnes" class has methods for the following generic functions: `print`, `summary`, `plot`.

INHERITANCE

The class "agnes" inherits from "twins". Therefore, the generic functions [pltree](#) and [as.hclust](#) are available for agnes objects. After applying `as.hclust()`, all *its* methods are available, of course.

`agriculture`*European Union Agricultural Workforces*

Description

Gross National Product (GNP) per capita and percentage of the population working in agriculture for each country belonging to the European Union in 1993.

Usage

```
data(agriculture)
```

Format

A data frame with 12 observations on 2 variables:

```
 [,1] x numeric per capita GNP
 [,2] y numeric percentage in agriculture
```

The row names of the data frame indicate the countries.

Details

The data seem to show two clusters, the “more agricultural” one consisting of Greece, Portugal, Spain, and Ireland.

animals

Attributes of Animals

Description

This data set considers 6 binary attributes for 20 animals.

Usage

```
data(animals)
```

Format

A data frame with 20 observations on 6 variables:

[, 1]	war	warm-blooded
[, 2]	fly	can fly
[, 3]	ver	vertebrate
[, 4]	end	endangered
[, 5]	gro	live in groups
[, 6]	hai	have hair

All variables are encoded as 1 = 'no', 2 = 'yes'.

Details

This dataset is useful for illustrating monothetic (only a single variable is used for each split) hierarchical clustering.

 bannerplot

Plot Banner (of Hierarchical Clustering)

Description

Draws a “banner”, i.e. basically a horizontal [barplot](#) visualizing the (agglomerative or divisive) hierarchical clustering or an other binary dendrogram structure.

Usage

```
bannerplot(x, w = rev(x$height), fromLeft = TRUE,
           main=NULL, sub=NULL, xlab = "Height", adj = 0,
           col = c(2, 0), border = 0, axes = TRUE, frame.plot = axes,
           rev.xax = !fromLeft, xax.pretty = TRUE,
           labels = NULL, nmax.lab = 35, max.strlen = 5,
           yax.do = axes && length(x$order) <= nmax.lab,
           yaxRight = fromLeft, yax.mar = 2.4 + max.strlen/2.5, ...)
```

Arguments

<code>x</code>	a list with components <code>order</code> , <code>order.lab</code> and <code>height</code> when <code>w</code> , the next argument is not specified.
<code>w</code>	non-negative numeric vector of bar widths.
<code>fromLeft</code>	logical, indicating if the banner is from the left or not.
<code>main, sub</code>	main and sub titles, see title .
<code>xlab</code>	x axis label (with ‘correct’ default e.g. for <code>plot.agnes</code>).
<code>adj</code>	passed to title (<code>main, sub</code>) for string adjustment.
<code>col</code>	vector of length 2, for two horizontal segments.
<code>border</code>	color for bar border; now defaults to background (no border).
<code>axes</code>	logical indicating if axes (and labels) should be drawn at all.
<code>frame.plot</code>	logical indicating the banner should be framed; mainly used when <code>border = 0</code> (as per default).
<code>rev.xax</code>	logical indicating if the x axis should be reversed (as in <code>plot.diana</code>).
<code>xax.pretty</code>	logical or integer indicating if pretty() should be used for the x axis. <code>xax.pretty = FALSE</code> is mainly for back compatibility.
<code>labels</code>	labels to use on y-axis; the default is constructed from <code>x</code> .
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in banner plot labeling.
<code>yax.do</code>	logical indicating if a y axis and banner labels should be drawn.
<code>yaxRight</code>	logical indicating if the y axis is on the right or left.

`y.mar` positive number specifying the margin width to use when banners are labeled (along a y-axis). The default adapts to the string width and optimally would also depend on the font.

`...` graphical parameters (see [par](#)) may also be supplied as arguments to this function.

Note

This is mainly a utility called from [plot.agnes](#), [plot.diana](#) and [plot.mona](#).

Author(s)

Martin Maechler (from original code of Kaufman and Rousseeuw).

Examples

```
data(agriculture)
bannerplot(agnes(agriculture), main = "Bannerplot")
```

chorSub

Subset of C-horizon of Kola Data

Description

This is a small rounded subset of the C-horizon data [chorizon](#) from package **mvoutlier**.

Usage

```
data(chorSub)
```

Format

A data frame with 61 observations on 10 variables. The variables contain scaled concentrations of chemical elements.

Details

This data set was produced from [chorizon](#) via these statements:

```
data(chorizon, package = "mvoutlier")
chorSub <- round(100*scale(chorizon[,101:110]))[190:250,]
storage.mode(chorSub) <- "integer"
colnames(chorSub) <- gsub("_.*", "", colnames(chorSub))
```

Source

Kola Project (1993-1998)

See Also

[chorizon](#) in package **mvoutlier** and other Kola data in the same package.

Examples

```
data(chorSub)
summary(chorSub)
pairs(chorSub, gap= .1)# some outliers
```

Description

Computes a "clara" object, a list representing a clustering of the data into k clusters.

Usage

```
clara(x, k, metric = "euclidean", stand = FALSE, samples = 5,
      sampsize = min(n, 40 + 2 * k), trace = 0, medoids.x = TRUE,
      keep.data = medoids.x, rngR = FALSE)
```

Arguments

- `x` data matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
- `k` integer, the number of clusters. It is required that $0 < k < n$ where n is the number of observations (i.e., $n = \text{nrow}(x)$).
- `metric` character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.
- `stand` logical, indicating if the measurements in `x` are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.
- `samples` integer, number of samples to be drawn from the dataset.
- `sampsize` integer, number of observations in each sample. `sampsize` should be higher than the number of clusters (k) and at most the number of observations ($n = \text{nrow}(x)$).
- `trace` integer indicating a *trace level* for diagnostic output during the algorithm.
- `medoids.x` logical indicating if the medoids should be returned, identically to some rows of the input data `x`. If `FALSE`, `keep.data` must be false as well, and the medoid indices, i.e., row numbers of the medoids will still be returned (`i.med` component), and the algorithm saves space by needing one copy less of `x`.
- `keep.data` logical indicating if the (*scaled* if `stand` is true) data should be kept in the result. Setting this to `FALSE` saves memory (and hence time), but disables `clusplot()`ing of the result. Use `medoids.x = FALSE` to save even more memory.
- `rngR` logical indicating if R's random number generator should be used instead of the primitive `clara()`-builtin one. If true, this also means that each call to `clara()` returns a different result – though only slightly different in good situations.

Details

`clara` is fully described in chapter 3 of Kaufman and Rousseeuw (1990). Compared to other partitioning methods such as `pam`, it can deal with much larger datasets. Internally, this is achieved by considering sub-datasets of fixed size (`sampsize`) such that the time and storage requirements become linear in n rather than quadratic.

Each sub-dataset is partitioned into k clusters using the same algorithm as in `pam`.

Once k representative objects have been selected from the sub-dataset, each observation of the entire dataset is assigned to the nearest medoid.

The sum of the dissimilarities of the observations to their closest medoid is used as a measure of the quality of the clustering. The sub-dataset for which the sum is minimal, is retained. A further analysis is carried out on the final partition.

Each sub-dataset is forced to contain the medoids obtained from the best sub-dataset until then. Randomly drawn observations are added to this set until `sampsize` has been reached.

Value

an object of class "clara" representing the clustering. See `clara.object` for details.

Note

By default, the random sampling is implemented with a *very* simple scheme (with period $2^{16} = 65536$) inside the Fortran code, independently of R's random number generation, and as a matter of fact, deterministically. Alternatively, we recommend setting `rngR = TRUE` which uses R's random number generators. Then, `clara()` results are made reproducible typically by using `set.seed()` before calling `clara`.

The storage requirement of `clara` computation (for small k) is about $O(n \times p) + O(j^2)$ where $j = \text{sampsize}$, and $(n, p) = \text{dim}(x)$. The CPU computing time (again assuming small k) is about $O(n \times p \times j^2 \times N)$, where $N = \text{samples}$.

For "small" datasets, the function `pam` can be used directly. What can be considered *small*, is really a function of available computing power, both memory (RAM) and speed. Originally (1990), "small" meant less than 100 observations; in 1997, the authors said "*small (say with fewer than 200 observations)*"; as of 2006, you can use `pam` with several thousand observations.

Author(s)

Kaufman and Rousseeuw (see `agnes`), originally. All arguments from `trace` on, and most R documentation and all tests by Martin Maechler.

See Also

`agnes` for background and references; `clara.object`, `pam`, `partition.object`, `plot.partition`.

Examples

```
## generate 500 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(200,0,8), rnorm(200,0,8)),
           cbind(rnorm(300,50,8), rnorm(300,50,8)))
clarax <- clara(x, 2)
clarax
clarax$clusinfo
plot(clarax)
```

```

## `xclara' is an artificial data set with 3 clusters of 1000 bivariate
## objects each.
data(xclara)
(clx3 <- clara(xclara, 3))
## Plot similar to Figure 5 in Struyf et al (1996)
## Not run: plot(clx3, ask = TRUE)

## Try 100 times *different* random samples -- for reliability:
nSim <- 100
nCl <- 3 # = no.classes
set.seed(421) # (reproducibility)
cl <- matrix(NA, nrow(xclara), nSim)
for(i in 1:nSim)
  cl[,i] <- clara(xclara, nCl, medoids.x = FALSE, rngR = TRUE)$cluster
tcl <- apply(cl, 1, tabulate, nbins = nCl)
## those that are not always in same cluster (5 out of 3000 for this seed):
(iDoubt <- which(apply(tcl, 2, function(n) all(n < nSim))))
if(length(iDoubt)) { # (not for all seeds)
  tabD <- tcl[,iDoubt, drop=FALSE]
  dimnames(tabD) <- list(cluster = paste(1:nCl), obs = format(iDoubt))
  t(tabD) # how many times in which clusters
}

```

clara.object

Clustering Large Applications (CLARA) Object

Description

The objects of class "clara" represent a partitioning of a large dataset into clusters and are typically returned from [clara](#).

Value

A legitimate clara object is a list with the following components:

sample	labels or case numbers of the observations in the best sample, that is, the sample used by the clara algorithm for the final partition.
medoids	the medoids or representative objects of the clusters. It is a matrix with in each row the coordinates of one medoid. Possibly NULL, namely when the object resulted from clara(*, medoids.x=FALSE). Use the following i.med in that case.
i.med	the <i>indices</i> of the medoids above: medoids <- x[i.med,] where x is the original data matrix in clara(x,*).
clustering	the clustering vector, see partition.object .
objective	the objective function for the final clustering of the entire dataset.
clusinfo	matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid. The last column is the maximal dissimilarity between the observations in the

	cluster and the cluster's medoid, divided by the minimal dissimilarity between the cluster's medoid and the medoid of any other cluster. If this ratio is small, the cluster is well-separated from the other clusters.
diss	dissimilarity (maybe NULL), see partition.object .
silinfo	list with silhouette width information for the best sample, see partition.object .
call	generating call, see partition.object .
data	matrix, possibly standardized, or NULL, see partition.object .

Methods, Inheritance

The "clara" class has methods for the following generic functions: `print`, `summary`.

The class "clara" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a clara object.

[clara](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

clusplot

Cluster Plot - Generic Function

Description

Draws a 2-dimensional "clusplot" on the current graphics device. This is a generic function with a default and `partition` method.

Usage

```
clusplot(x, ...)
```

Arguments

x	an R object.
...	additional arguments for methods . Graphical parameters (see par) may also be supplied as arguments to this function.

Side Effects

a 2-dimensional clusplot is created on the current graphics device.

See Also

(for references and examples) [clusplot.default](#), [clusplot.partition](#), [partition.object](#), [pam](#), [fanny](#), [clara](#).

clusplot.default *Bivariate Cluster Plot (clusplot) Default Method*

Description

Creates a bivariate plot visualizing a partition (clustering) of the data. All observation are represented by points in the plot, using principal components or multidimensional scaling. Around each cluster an ellipse is drawn.

Usage

```
## Default S3 method:
clusplot(x, clus, diss = FALSE, cor = TRUE, stand = FALSE,
         lines = 2, shade = FALSE, color = FALSE,
         labels= 0, plotchar = TRUE,
         col.p = "dark green", col.txt = col.p,
         col.clus = if(color) c(2, 4, 6, 3) else 5,
         span = TRUE, xlim = NULL, ylim = NULL,
         main = paste("CLUSPLOT(", deparse(substitute(x)), ")"),
         sub = paste("These two components explain",
                    round(100 * var.dec, digits = 2), "% of the point variability."),
         verbose = getOption("verbose"),
         ...)
```

Arguments

<code>x</code>	matrix or data frame, or dissimilarity matrix, depending on the value of the <code>diss</code> argument. In case of a matrix (alike), each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed. They are replaced by the median of the corresponding variable. When some variables or some observations contain only missing values, the function stops with a warning message. In case of a dissimilarity matrix, <code>x</code> is the output of <code>daisy</code> or <code>dist</code> or a symmetric matrix. Also, a vector of length $n * (n - 1) / 2$ is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.
<code>clus</code>	a vector of length n representing a clustering of <code>x</code> . For each observation the vector lists the number or name of the cluster to which it has been assigned. <code>clus</code> is often the clustering component of the output of <code>pam</code> , <code>fanny</code> or <code>clara</code> .
<code>diss</code>	logical indicating if <code>x</code> will be considered as a dissimilarity matrix or a matrix of observations by variables (see <code>x</code> argument above).
<code>cor</code>	logical flag, only used when working with a data matrix (<code>diss = FALSE</code>). If TRUE, then the variables are scaled to unit variance.
<code>stand</code>	logical flag: if true, then the representations of the n observations in the 2-dimensional plot are standardized.
<code>lines</code>	integer out of 0, 1, 2, used to obtain an idea of the distances between ellipses. The distance between two ellipses E1 and E2 is measured along the line connecting the centers $m1$ and $m2$ of the two ellipses.

In case E1 and E2 overlap on the line through $m1$ and $m2$, no line is drawn. Otherwise, the result depends on the value of `lines`: If

lines = 0, no distance lines will appear on the plot;
lines = 1, the line segment between $m1$ and $m2$ is drawn;
lines = 2, a line segment between the boundaries of E1 and E2 is drawn (along the line connecting $m1$ and $m2$).

shade	logical flag: if TRUE, then the ellipses are shaded in relation to their density. The density is the number of points in the cluster divided by the area of the ellipse.
color	logical flag: if TRUE, then the ellipses are colored with respect to their density. With increasing density, the colors are light blue, light green, red and purple. To see these colors on the graphics device, an appropriate color scheme should be selected (we recommend a white background).
labels	integer code, currently one of 0,1,2,3,4 and 5. If labels= 0 , no labels are placed in the plot; labels= 1 , points and ellipses can be identified in the plot (see <code>identify</code>); labels= 2 , all points and ellipses are labelled in the plot; labels= 3 , only the points are labelled in the plot; labels= 4 , only the ellipses are labelled in the plot. labels= 5 , the ellipses are labelled in the plot, and points can be identified. The levels of the vector <code>clus</code> are taken as labels for the clusters. The labels of the points are the rownames of <code>x</code> if <code>x</code> is matrix like. Otherwise (<code>diss = TRUE</code>), <code>x</code> is a vector, point labels can be attached to <code>x</code> as a "Labels" attribute (<code>attr(x, "Labels")</code>), as is done for the output of <code>daisy</code> . A possible <code>names</code> attribute of <code>clus</code> will not be taken into account.
plotchar	logical flag: if TRUE, then the plotting symbols differ for points belonging to different clusters.
span	logical flag: if TRUE, then each cluster is represented by the ellipse with smallest area containing all its points. (This is a special case of the minimum volume ellipsoid.) If FALSE, the ellipse is based on the mean and covariance matrix of the same points. While this is faster to compute, it often yields a much larger ellipse. There are also some special cases: When a cluster consists of only one point, a tiny circle is drawn around it. When the points of a cluster fall on a straight line, <code>span=FALSE</code> draws a narrow ellipse around it and <code>span=TRUE</code> gives the exact line segment.
col.p	color code(s) used for the observation points.
col.txt	color code(s) used for the labels (if <code>labels >= 2</code>).
col.clus	color code for the ellipses (and their labels); only one if <code>color</code> is false (as per default).
xlim, ylim	numeric vectors of length 2, giving the x- and y- ranges as in <code>plot.default</code> .
main	main title for the plot; by default, one is constructed.
sub	sub title for the plot; by default, one is constructed.
verbose	a logical indicating, if there should be extra diagnostic output; mainly for 'debugging'.
...	Further graphical parameters may also be supplied, see <code>par</code> .

Details

clusplot uses the functions `princomp` and `cmdscale`. These functions are data reduction techniques. They will represent the data in a bivariate plot. Ellipses are then drawn to indicate the clusters. The further layout of the plot is determined by the optional arguments.

Value

An invisible list with components:

Distances	When <code>lines</code> is 1 or 2 we obtain a k by k matrix (k is the number of clusters). The element in <code>[i, j]</code> is the distance between ellipse i and ellipse j. If <code>lines = 0</code> , then the value of this component is NA.
Shading	A vector of length k (where k is the number of clusters), containing the amount of shading per cluster. Let y be a vector where element i is the ratio between the number of points in cluster i and the area of ellipse i. When the cluster i is a line segment, <code>y[i]</code> and the density of the cluster are set to NA. Let z be the sum of all the elements of y without the NAs. Then we put <code>shading = y/z * 37 + 3</code> .

Side Effects

a visual display of the clustering is plotted on the current graphics device.

Note

When we have 4 or fewer clusters, then the `color=TRUE` gives every cluster a different color. When there are more than 4 clusters, clusplot uses the function `pam` to cluster the densities into 4 groups such that ellipses with nearly the same density get the same color. `col.clus` specifies the colors used.

The `col.p` and `col.txt` arguments, added for R, are recycled to have length the number of observations. If `col.p` has more than one value, using `color = TRUE` can be confusing because of a mix of point and ellipse colors.

clusplot.partition *Bivariate Clusplot of a Partitioning Object*

Description

Clusplot (Clustering Plot) method for an object of class partition.

Usage

```
## S3 method for class 'partition':
clusplot(x, main = NULL, dist = NULL, ...)
```

Arguments

x	an object of class "partition", e.g. created by the functions pam , clara , or fanny .
main	title for the plot; when NULL (by default), a title is constructed, using x\$call.

- `dist` when `x` does not have a `diss` nor a data component, e.g., for `pam(dist(*), keep.diss=FALSE)`, `dist` must specify the dissimilarity for the `clusplot`.
- `...` all optional arguments available for the `clusplot.default` function (except for the `diss` one) may also be supplied to this function. Graphical parameters (see `par`) may also be supplied as arguments to this function.

Details

This `clusplot.partition()` method relies on `clusplot.default`.

If the clustering algorithms `pam`, `fanny` and `clara` are applied to a data matrix of observations-by-variables then a `clusplot` of the resulting clustering can always be drawn. When the data matrix contains missing values and the clustering is performed with `pam` or `fanny`, the dissimilarity matrix will be given as input to `clusplot`. When the clustering algorithm `clara` is applied to a data matrix with NAs then `clusplot` will replace the missing values as described in `clusplot.default`, because a dissimilarity matrix is not available.

Value

An invisible list with components

- `Distances` When option `lines` is 1 or 2 we obtain a `k` by `k` matrix (`k` is the number of clusters). The element at row `j` and column `s` is the distance between ellipse `j` and ellipse `s`. If `lines=0`, then the value of this component is NA.
- `Shading` A vector of length `k` (where `k` is the number of clusters), containing the amount of shading per cluster. Let `y` be a vector where element `i` is the ratio between the number of objects in cluster `i` and the area of ellipse `i`. When the cluster `i` is a line segment, `y[i]` and the density of the cluster are set to NA. Let `z` be the sum of all the elements of `y` without the NAs. Then we put `shading = y/z * 37 + 3`.

See Also

`clusplot.default` for references; `partition.object`, `pam`, `pam.object`, `clara`, `clara.object`, `fanny`, `fanny.object`, `par`.

Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
clusplot(pam(x, 2))
## add noise, and try again :
x4 <- cbind(x, rnorm(25), rnorm(25))
clusplot(pam(x4, 2))
```

coef.hclust *Agglomerative Coefficient for 'hclust' Objects*

Description

Computes the “agglomerative coefficient”, measuring the clustering structure of the dataset.

For each observation i , denote by $m(i)$ its dissimilarity to the first cluster it is merged with, divided by the dissimilarity of the merger in the final step of the algorithm. The agglomerative coefficient is the average of all $1 - m(i)$. It can also be seen as the average width (or the percentage filled) of the banner plot.

Because it grows with the number of observations, this measure should not be used to compare datasets of very different sizes.

Usage

```
coef.hclust(object, ...)
## S3 method for class 'hclust':
coef(object, ...)
## S3 method for class 'twins':
coef(object, ...)
```

Arguments

object	an object of class "hclust" or "twins", i.e., typically the result of <code>hclust(.)</code> , <code>agnes(.)</code> , or <code>diana(.)</code> . Since <code>coef.hclust</code> only uses <code>object\$heights</code> , and <code>object\$merge</code> , <code>object</code> can be any list-like object with appropriate <code>merge</code> and <code>heights</code> components.
...	currently unused potential further arguments

Value

a number specifying the *agglomerative* (or *divisive* for `diana` objects) coefficient as defined by Kaufman and Rousseeuw, see `agnes.object` \$ `ac` or `diana.object` \$ `dc`.

Examples

```
data(agriculture)
aa <- agnes(agriculture)
coef(aa) # really just extracts aa$ac
coef(as.hclust(aa)) # recomputes
```

daisy

*Dissimilarity Matrix Calculation***Description**

Compute all the pairwise dissimilarities (distances) between observations in the data set. The original variables may be of mixed types.

Usage

```
daisy(x, metric = c("euclidean", "manhattan", "gower"),
      stand = FALSE, type = list())
```

Arguments

- | | |
|--------|---|
| x | numeric matrix or data frame. Dissimilarities will be computed between the rows of x. Columns of mode <code>numeric</code> (i.e. all columns when x is a matrix) will be recognized as interval scaled variables, columns of class <code>factor</code> will be recognized as nominal variables, and columns of class <code>ordered</code> will be recognized as ordinal variables. Other variable types should be specified with the <code>type</code> argument. Missing values (NAs) are allowed. |
| metric | character string specifying the metric to be used. The currently available options are "euclidean" (the default), "manhattan" and "gower".
Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences.
"Gower's distance" is chosen by metric "gower" or automatically if some columns of x are not numeric. Also known as Gower's coefficient (1971), expressed as a dissimilarity, this implies that a particular standardisation will be applied to each variable, and the "distance" between two units is the sum of all the variable-specific distances, see the details section. |
| stand | logical flag: if TRUE, then the measurements in x are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation.
If not all columns of x are numeric, stand will be ignored and Gower's standardization (based on the range) will be applied in any case, see argument <code>metric</code> , above, and the details section. |
| type | list for specifying some (or all) of the types of the variables (columns) in x. The list may contain the following components: "ordratio" (ratio scaled variables to be treated as ordinal variables), "logratio" (ratio scaled variables that must be logarithmically transformed), "asymm" (asymmetric binary) and "symm" (symmetric binary variables). Each component's value is a vector, containing the names or the numbers of the corresponding columns of x. Variables not mentioned in the <code>type</code> list are interpreted as usual (see argument x). |

Details

daisy is fully described in chapter 1 of Kaufman and Rousseeuw (1990). Compared to [dist](#) whose input must be numeric variables, the main feature of daisy is its ability to handle other

variable types as well (e.g. nominal, ordinal, (a)symmetric binary) even when different types occur in the same data set.

The handling of nominal, ordinal, and (a)symmetric binary data is achieved by using the general dissimilarity coefficient of Gower (1971). If `x` contains any columns of these data-types, both arguments `metric` and `stand` will be ignored and Gower's coefficient will be used as the metric. This can also be activated for purely numeric data by `metric = "gower"`. With that, each variable (column) is first standardized by dividing each entry by the range of the corresponding variable.

Note that setting the type to `symm` (symmetric binary) gives the same dissimilarities as using `nominal` (which is chosen for non-ordered factors) only when no missing values are present, and more efficiently.

Note that `daisy` now gives a warning when 2-valued numerical variables don't have an explicit `type` specified, because the reference authors recommend to consider using `asymm`.

In the `daisy` algorithm, missing values in a row of `x` are not included in the dissimilarities involving that row. There are two main cases,

1. If all variables are interval scaled, the metric is "euclidean", and `ng` is the number of columns in which neither row `i` and `j` have NAs, then the dissimilarity `d(i,j)` returned is $\sqrt{\text{ncol}(x)/ng}$ times the Euclidean distance between the two vectors of length `ng` shortened to exclude NAs. The rule is similar for the "manhattan" metric, except that the coefficient is $\text{ncol}(x)/ng$. If `ng` is zero, the dissimilarity is NA.

2. When some variables have a type other than interval scaled, the dissimilarity between two rows is the weighted sum of the contributions of each variable.

The weight becomes zero when that variable is missing in either or both rows, or when the variable is asymmetric binary and both values are zero. In all other situations, the weight of the variable is 1.

The contribution of a nominal or binary variable to the total dissimilarity is 0 if both values are different, 1 otherwise. The contribution of other variables is the absolute difference of both values, divided by the total range of that variable. Ordinal variables are first converted to ranks.

If `nok` is the number of nonzero weights, the dissimilarity is multiplied by the factor $1/nok$ and thus ranges between 0 and 1. If `nok = 0`, the dissimilarity is set to NA.

Value

an object of class "dissimilarity" containing the dissimilarities among the rows of `x`. This is typically the input for the functions `pam`, `fanny`, `agnes` or `diana`. For more details, see [dissimilarity.object](#).

Background

Dissimilarities are used as inputs to cluster analysis and multidimensional scaling. The choice of metric may have a large impact.

## this failed earlier:
summary(df13 <- daisy(flower,
                     type = list(asymm = c("V1", "V3"), symm= 2,
                                ordratio= 7, logratio= 8)))
```

diana

Divisive ANAlysis Clustering

Description

Computes a divisive hierarchical clustering of the dataset returning an object of class `diana`.

Usage

```
diana(x, diss = inherits(x, "dist"), metric = "euclidean", stand = FALSE,
      keep.diss = n < 100, keep.data = !diss)
```

Arguments

<code>x</code>	<p>data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.</p> <p>In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) <i>are</i> allowed.</p> <p>In case of a dissimilarity matrix, <code>x</code> is typically the output of daisy or dist. Also a vector of length $n*(n-1)/2$ is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed.</p>
<code>diss</code>	<p>logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables.</p>

<code>metric</code>	character string specifying the metric to be used for calculating dissimilarities between observations. The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.
<code>stand</code>	logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable's mean value and dividing by the variable's mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored.
<code>keep.diss, keep.data</code>	logicals indicating if the dissimilarities and/or input data <code>x</code> should be kept in the result. Setting these to <code>FALSE</code> can give much smaller results and hence even save memory allocation <i>time</i> .

Details

`diana` is fully described in chapter 6 of Kaufman and Rousseeuw (1990). It is probably unique in computing a divisive hierarchy, whereas most other software for hierarchical clustering is agglomerative. Moreover, `diana` provides (a) the divisive coefficient (see `diana.object`) which measures the amount of clustering structure found; and (b) the banner, a novel graphical display (see `plot.diana`).

The `diana`-algorithm constructs a hierarchy of clusterings, starting with one large cluster containing all n observations. Clusters are divided until each cluster contains only a single observation.

At each stage, the cluster with the largest diameter is selected. (The diameter of a cluster is the largest dissimilarity between any two of its observations.)

To divide the selected cluster, the algorithm first looks for its most disparate observation (i.e., which has the largest average dissimilarity to the other observations of the selected cluster). This observation initiates the "splinter group". In subsequent steps, the algorithm reassigns observations that are closer to the "splinter group" than to the "old party". The result is a division of the selected cluster into two new clusters.

Value

an object of class "diana" representing the clustering; this class has methods for the following generic functions: `print`, `summary`, `plot`.

Further, the class "diana" inherits from "twins". Therefore, the generic function `pltree` can be used on a `diana` object, and an `as.hclust` method is available.

A legitimate `diana` object is a list with the following components:

<code>order</code>	a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
<code>order.lab</code>	a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
<code>height</code>	a vector with the diameters of the clusters prior to splitting.
<code>dc</code>	the divisive coefficient, measuring the clustering structure of the dataset. For each observation i , denote by $d(i)$ the diameter of the last cluster to which it belongs (before being split off as a single observation), divided by the diameter of the whole dataset. The <code>dc</code> is the average of all $1 - d(i)$. It can also be

	seen as the average width (or the percentage filled) of the banner plot. Because <code>dc</code> grows with the number of observations, this measure should not be used to compare datasets of very different sizes.
<code>merge</code>	an (n-1) by 2 matrix, where n is the number of observations. Row <i>i</i> of <code>merge</code> describes the split at step n-i of the clustering. If a number <i>j</i> in row <i>r</i> is negative, then the single observation $ j $ is split off at stage n-r. If <i>j</i> is positive, then the cluster that will be splitted at stage n-j (described by row <i>j</i>), is split off at stage n-r.
<code>diss</code>	an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset.
<code>data</code>	a matrix containing the original or standardized measurements, depending on the <code>stand</code> option of the function <code>agnes</code> . If a dissimilarity matrix was given as input structure, then this component is not available.

See Also

`agnes` also for background and references; `cutree` (and `as.hclust`) for grouping extraction; `daisy`, `dist`, `plot.diana`, `twins.object`.

Examples

```
data(votes.repub)
dv <- diana(votes.repub, metric = "manhattan", stand = TRUE)
print(dv)
plot(dv)

## Cut into 2 groups:
dv2 <- cutree(as.hclust(dv), k = 2)
table(dv2) # 8 and 42 group members
rownames(votes.repub)[dv2 == 1]

## For two groups, does the metric matter ?
dv0 <- diana(votes.repub, stand = TRUE) # default: Euclidean
dv.2 <- cutree(as.hclust(dv0), k = 2)
table(dv2 == dv.2) ## identical group assignments

data(agriculture)
## Plot similar to Figure 8 in ref
## Not run: plot(diana(agriculture), ask = TRUE)
```

dissimilarity.object

Dissimilarity Matrix Object

Description

Objects of class "dissimilarity" representing the dissimilarity matrix of a dataset.

Value

The dissimilarity matrix is symmetric, and hence its lower triangle (column wise) is represented as a vector to save storage space. If the object, is called `do`, and `n` the number of observations, i.e., `n <- attr(do, "Size")`, then for $i < j \leq n$, the dissimilarity between (row) i and j is `do[n*(i-1) - i*(i-1)/2 + j-i]`. The length of the vector is $n*(n-1)/2$, i.e., of order n^2 .

"dissimilarity" objects also inherit from class `dist` and can use `dist` methods, in particular, `as.matrix`, such that d_{ij} from above is just `as.matrix(do)[i, j]`.

The object has the following attributes:

<code>Size</code>	the number of observations in the dataset.
<code>Metric</code>	the metric used for calculating the dissimilarities. Possible values are "euclidean", "manhattan", "mixed" (if variables of different types were present in the dataset), and "unspecified".
<code>Labels</code>	optionally, contains the labels, if any, of the observations of the dataset.
<code>NA.message</code>	optionally, if a dissimilarity could not be computed, because of too many missing values for some observations of the dataset.
<code>Types</code>	when a mixed metric was used, the types for each variable as one-letter codes (as in the book, e.g. p.54): <ul style="list-style-type: none"> A Asymmetric binary S Symmetric binary N Nominal (factor) O Ordinal (ordered factor) I Interval scaled (numeric) T raTio to be log transformed (positive numeric) .

GENERATION

`daisy` returns this class of objects. Also the functions `pam`, `clara`, `fanny`, `agnes`, and `diana` return a `dissimilarity` object, as one component of their return objects.

METHODS

The "dissimilarity" class has methods for the following generic functions: `print`, `summary`.

See Also

`daisy`, `dist`, `pam`, `clara`, `fanny`, `agnes`, `diana`.

ellipsoidhull

*Compute the Ellipsoid Hull or Spanning Ellipsoid of a Point Set***Description**

Compute the “ellipsoid hull” or “spanning ellipsoid”, i.e. the ellipsoid of minimal volume (‘area’ in 2D) such that all given points lie just inside or on the boundary of the ellipsoid.

Usage

```
ellipsoidhull(x, tol=0.01, maxit=5000,
             ret.wt = FALSE, ret.sqdist = FALSE, ret.pr = FALSE)
## S3 method for class 'ellipsoid':
print(x, digits = max(1, getOption("digits") - 2), ...)
```

Arguments

`x` the n p -dimensional points as numeric $n \times p$ matrix.

`tol` convergence tolerance for Titterington’s algorithm. Setting this to much smaller values may drastically increase the number of iterations needed, and you may want to increase `maxit` as well.

`maxit` integer giving the maximal number of iteration steps for the algorithm.

`ret.wt`, `ret.sqdist`, `ret.pr` logicals indicating if additional information should be returned, `ret.wt` specifying the *weights*, `ret.sqdist` the *squared distances* and `ret.pr` the final **probabilities** in the algorithms.

`digits`, ... the usual arguments to `print` methods.

Details

The “spanning ellipsoid” algorithm is said to stem from Titterington(1976), in Pison et al(1999) who use it for `clusplot.default`.

The problem can be seen as a special case of the “Min.Vol.” ellipsoid of which a more flexible and general implementation is `cov.mve` in the MASS package.

Value

an object of class "ellipsoid", basically a `list` with several components, comprising at least

`cov` $p \times p$ covariance matrix description the ellipsoid.

`loc` p -dimensional location of the ellipsoid center.

`d2` average squared radius. Further, $d2 = t^2$, where t is “the value of a t-statistic on the ellipse boundary” (from `ellipse` in the **ellipse** package), and hence, more usefully, $d2 = qchisq(alpha, df = p)$, where `alpha` is the confidence level for p -variate normally distributed data with location and covariance `loc` and `cov` to lie inside the ellipsoid.

`wt` the vector of weights iff `ret.wt` was true.

`sqdist` the vector of squared distances iff `ret.sqdist` was true.

`prob` the vector of algorithm probabilities iff `ret.pr` was true.

<code>it</code>	number of iterations used.
<code>tol, maxit</code>	just the input argument, see above.
<code>eps</code>	the achieved tolerance which is the maximal squared radius minus p .
<code>ierr</code>	error code as from the algorithm; 0 means <i>ok</i> .
<code>conv</code>	logical indicating if the converged. This is defined as <code>it < maxit && ierr == 0</code> .

Author(s)

Martin Maechler did the present class implementation; Rousseeuw et al did the underlying code.

`predict.ellipsoid` which is also the `predict` method for `ellipsoid` objects. `volume.ellipsoid` for an example of ‘manual’ `ellipsoid` object construction; further `ellipse` from package `ellipse` and `ellipsePoints` from package `sfsmisc`. `chull` for the convex hull, `clusplot` which makes use of this; `cov.mve`.

Examples

```
x <- rnorm(100)
xy <- unname(cbind(x, rnorm(100) + 2*x + 10))
exy <- ellipsoidhull(xy)
exy # >> calling print.ellipsoid()

plot(xy)
lines(predict(exy))
points(rbind(exy$loc), col = "red", cex = 3, pch = 13)

exy <- ellipsoidhull(xy, tol = 1e-7, ret.wt = TRUE, ret.sq = TRUE)
str(exy) # had small `tol`, hence many iterations
(ii <- which(zapsmall(exy $ wt) > 1e-6)) # only about 4 to 6 points
round(exy$wt[ii], 3); sum(exy$wt[ii]) # sum to 1
```

Description

Computes a fuzzy clustering of the data into k clusters.

Usage

```
fanny(x, k, diss = inherits(x, "dist"), memb.exp = 2,
      metric = c("euclidean", "manhattan", "SqEuclidean"),
      stand = FALSE, iniMem.p = NULL, cluster.only = FALSE,
      keep.diss = !diss && !cluster.only && n < 100,
      keep.data = !diss && !cluster.only,
      maxit = 500, tol = 1e-15, trace.lev = 0)
```

Arguments

- x** data matrix or data frame, or dissimilarity matrix, depending on the value of the `diss` argument.
- In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed.
- In case of a dissimilarity matrix, `x` is typically the output of `daisy` or `dist`. Also a vector of length $n*(n-1)/2$ is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are not allowed.
- k** integer giving the desired number of clusters. It is required that $0 < k < n/2$ where n is the number of observations.
- diss** logical flag: if TRUE (default for `dist` or `dissimilarity` objects), then `x` is assumed to be a dissimilarity matrix. If FALSE, then `x` is treated as a matrix of observations by variables.
- memb.exp** number r strictly larger than 1 specifying the *membership exponent* used in the fit criterion; see the ‘Details’ below. Default: 2 which used to be hardwired inside FANNY.
- metric** character string specifying the metric to be used for calculating dissimilarities between observations. Options are "euclidean" (default), "manhattan", and "SqEuclidean". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences, and "SqEuclidean", the *squared* euclidean distances are sum-of-squares of differences. Using this last option is equivalent (but somewhat slower) to computing so called “fuzzy C-means”.
- If `x` is already a dissimilarity matrix, then this argument will be ignored.
- stand** logical; if true, the measurements in `x` are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If `x` is already a dissimilarity matrix, then this argument will be ignored.
- iniMem.p** numeric $n \times k$ matrix or NULL (by default); can be used to specify a starting membership matrix, i.e., a matrix of non-negative numbers, each row summing to one.
- cluster.only** logical; if true, no silhouette information will be computed and returned, see details.
- keep.diss, keep.data** logicals indicating if the dissimilarities and/or input data `x` should be kept in the result. Setting these to FALSE can give smaller results and hence also save memory allocation *time*.

<code>maxit, tol</code>	maximal number of iterations and default tolerance for convergence (relative convergence of the fit criterion) for the FANNY algorithm. The defaults <code>maxit = 500</code> and <code>tol = 1e-15</code> used to be hardwired inside the algorithm.
<code>trace.lev</code>	integer specifying a trace level for printing diagnostics during the C-internal algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

In a fuzzy clustering, each observation is “spread out” over the various clusters. Denote by u_{iv} the membership of observation i to cluster v .

The memberships are nonnegative, and for a fixed observation i they sum to 1. The particular method `fanny` stems from chapter 4 of Kaufman and Rousseeuw (1990) (see the references in `daisy`) and has been extended by Martin Maechler to allow user specified `memb.exp`, `iniMem.p`, `maxit`, `tol`, etc.

Fanny aims to minimize the objective function

$$\sum_{v=1}^k \frac{\sum_{i=1}^n \sum_{j=1}^n u_{iv}^r u_{jv}^r d(i, j)}{2 \sum_{j=1}^n u_{jv}^r}$$

where n is the number of observations, k is the number of clusters, r is the membership exponent `memb.exp` and $d(i, j)$ is the dissimilarity between observations i and j .

Note that $r \rightarrow 1$ gives increasingly crisper clusterings whereas $r \rightarrow \infty$ leads to complete fuzzyness. K&R(1990), p.191 note that values too close to 1 can lead to slow convergence. Further note that even the default, $r = 2$ can lead to complete fuzzyness, i.e., memberships $u_{iv} \equiv 1/k$. In that case a warning is signalled and the user is advised to chose a smaller `memb.exp (= r)`.

Compared to other fuzzy clustering methods, `fanny` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust to the spherical cluster assumption; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`).

Value

an object of class "fanny" representing the clustering. See `fanny.object` for details.

See Also

`agnes` for background and references; `fanny.object`, `partition.object`, `plot.partition`, `daisy`, `dist`.

Examples

```
## generate 10+15 objects in two clusters, plus 3 objects lying
## between those clusters.
x <- rbind(cbind(rnorm(10, 0, 0.5), rnorm(10, 0, 0.5)),
          cbind(rnorm(15, 5, 0.5), rnorm(15, 5, 0.5)),
          cbind(rnorm( 3, 3.2, 0.5), rnorm( 3, 3.2, 0.5)))
fannyx <- fanny(x, 2)
## Note that observations 26:28 are "fuzzy" (closer to # 2):
fannyx
summary(fannyx)
plot(fannyx)

(fan.x.15 <- fanny(x, 2, memb.exp = 1.5)) # 'crispier' for obs. 26:28
```

```
(fanny(x, 2, memb.exp = 3))           # more fuzzy in general

data(ruspini)
f4 <- fanny(ruspini, 4)
stopifnot(rle(f4$clustering)$lengths == c(20,23,17,15))
plot(f4, which = 1)
## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))
```

fanny.object

*Fuzzy Analysis (FANNY) Object***Description**

The objects of class "fanny" represent a fuzzy clustering of a dataset.

Value

A legitimate fanny object is a list with the following components:

membership	matrix containing the memberships for each pair consisting of an observation and a cluster.
memb.exp	the membership exponent used in the fitting criterion.
coeff	Dunn's partition coefficient $F(k)$ of the clustering, where k is the number of clusters. $F(k)$ is the sum of all <i>squared</i> membership coefficients, divided by the number of observations. Its value is between $1/k$ and 1. The normalized form of the coefficient is also given. It is defined as $(F(k) - 1/k)/(1 - 1/k)$, and ranges between 0 and 1. A low value of Dunn's coefficient indicates a very fuzzy clustering, whereas a value close to 1 indicates a near-crisp clustering.
clustering	the clustering vector of the nearest crisp clustering, see partition.object .
k.crisp	integer ($\leq k$) giving the number of <i>crisp</i> clusters; can be less than k , where it's recommended to decrease <code>memb.exp</code> .
objective	named vector containing the minimal value of the objective function reached by the FANNY algorithm and the relative convergence tolerance <code>tol</code> used.
convergence	named vector with <code>iterations</code> , the number of iterations needed and <code>converged</code> indicating if the algorithm converged (in <code>maxit</code> iterations within convergence tolerance <code>tol</code>).
diss	an object of class "dissimilarity", see partition.object .
call	generating call, see partition.object .
silinfo	list with silhouette information of the nearest crisp clustering, see partition.object .
data	matrix, possibly standardized, or NULL, see partition.object .

GENERATION

These objects are returned from [fanny](#).

METHODS

The "fanny" class has methods for the following generic functions: `print`, `summary`.

INHERITANCE

The class "fanny" inherits from "partition". Therefore, the generic functions `plot` and `clusplot` can be used on a fanny object.

See Also

`fanny`, `print.fanny`, `dissimilarity.object`, `partition.object`,
`plot.partition`.

flower

Flower Characteristics

Description

8 characteristics for 18 popular flowers.

Usage

```
data(flower)
```

Format

A data frame with 18 observations on 8 variables:

```
[ , "V1"] factor winters
[ , "V2"] factor shadow
[ , "V3"] factor tubers
[ , "V4"] factor color
[ , "V5"] ordered soil
[ , "V6"] ordered preference
[ , "V7"] numeric height
[ , "V8"] numeric distance
```

V1 winters, is binary and indicates whether the plant may be left in the garden when it freezes.

V2 shadow, is binary and shows whether the plant needs to stand in the shadow.

V3 tubers, is asymmetric binary and distinguishes between plants with tubers and plants that grow in any other way.

V4 color, is nominal and specifies the flower's color (1 = white, 2 = yellow, 3 = pink, 4 = red, 5 = blue).

V5 soil, is ordinal and indicates whether the plant grows in dry (1), normal (2), or wet (3) soil.

V6 preference, is ordinal and gives someone's preference ranking going from 1 to 18.

V7 height, is interval scaled, the plant's height in centimeters.

V8 distance, is interval scaled, the distance in centimeters that should be left between the plants.

## Example 2 in ref
daisy(flower, type = list(asymm = 3))
daisy(flower, type = list(asymm = c(1, 3), ordratio = 7))
```

lower.to.upper.tri.inds

Permute Indices for Triangular Matrices

Description

Compute index vectors for extracting or reordering of lower or upper triangular matrices that are stored as contiguous vectors.

Usage

```
lower.to.upper.tri.inds(n)
upper.to.lower.tri.inds(n)
```

Arguments

n integer larger than 1.

Value

integer vector containing a permutation of $1:N$ where $N = n(n-1)/2$.

Note

these functions are mainly for internal use in the cluster package, and may not remain available (unless we see a good reason).

See Also

[upper.tri](#), [lower.tri](#) with a related purpose.

Examples

```

m5 <- matrix(NA, 5, 5)
m <- m5; m[lower.tri(m)] <- upper.to.lower.tri.inds(5); m
m <- m5; m[upper.tri(m)] <- lower.to.upper.tri.inds(5); m

stopifnot(lower.to.upper.tri.inds(2) == 1,
           lower.to.upper.tri.inds(3) == 1:3,
           upper.to.lower.tri.inds(3) == 1:3,
           sort(upper.to.lower.tri.inds(5)) == 1:10,
           sort(lower.to.upper.tri.inds(6)) == 1:15)

```

mona

*MONothetic Analysis Clustering of Binary Variables***Description**

Returns a list representing a divisive hierarchical clustering of a dataset with binary variables only.

Usage

```
mona(x)
```

Arguments

x data matrix or data frame in which each row corresponds to an observation, and each column corresponds to a variable. All variables must be binary. A limited number of missing values (NAs) is allowed. Every observation must have at least one value different from NA. No variable should have half of its values missing. There must be at least one variable which has no missing values. A variable with all its non-missing values identical, is not allowed.

Details

`mona` is fully described in chapter 7 of Kaufman and Rousseeuw (1990). It is "monothetic" in the sense that each division is based on a single (well-chosen) variable, whereas most other hierarchical methods (including `agnes` and `diana`) are "polythetic", i.e. they use all variables together.

The `mona`-algorithm constructs a hierarchy of clusterings, starting with one large cluster. Clusters are divided until all observations in the same cluster have identical values for all variables.

At each stage, all clusters are divided according to the values of one variable. A cluster is divided into one cluster with all observations having value 1 for that variable, and another cluster with all observations having value 0 for that variable.

The variable used for splitting a cluster is the variable with the maximal total association to the other variables, according to the observations in the cluster to be splitted. The association between variables f and g is given by $a(f,g)*d(f,g) - b(f,g)*c(f,g)$, where $a(f,g)$, $b(f,g)$, $c(f,g)$, and $d(f,g)$ are the numbers in the contingency table of f and g . [That is, $a(f,g)$ (resp. $d(f,g)$) is the number of observations for which f and g both have value 0 (resp. value 1); $b(f,g)$ (resp. $c(f,g)$) is the number of observations for which f has value 0 (resp. 1) and g has value 1 (resp. 0).] The total association of a variable f is the sum of its associations to all variables.

This algorithm does not work with missing values, therefore the data are revised, e.g. all missing values are filled in. To do this, the same measure of association between variables is used as in the algorithm. When variable f has missing values, the variable g with the largest absolute association

to `f` is looked up. When the association between `f` and `g` is positive, any missing value of `f` is replaced by the value of `g` for the same observation. If the association between `f` and `g` is negative, then any missing value of `f` is replaced by the value of `1-g` for the same observation.

Value

an object of class "mona" representing the clustering. See `mona.object` for details.

See Also

`agnes` for background and references; `mona.object`, `plot.mona`.

Examples

```
data(animals)
ma <- mona(animals)
ma
## Plot similar to Figure 10 in Struyf et al (1996)
plot(ma)
```

`mona.object`

Monothetic Analysis (MONA) Object

Description

The objects of class "mona" represent the divisive hierarchical clustering of a dataset with only binary variables (measurements). This class of objects is returned from `mona`.

Value

A legitimate `mona` object is a list with the following components:

<code>data</code>	matrix with the same dimensions as the original data matrix, but with factors coded as 0 and 1, and all missing values replaced.
<code>order</code>	a vector giving a permutation of the original observations to allow for plotting, in the sense that the branches of a clustering tree will not cross.
<code>order.lab</code>	a vector similar to <code>order</code> , but containing observation labels instead of observation numbers. This component is only available if the original observations were labelled.
<code>variable</code>	vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the variables used to separate the observations of <code>order</code> .
<code>step</code>	vector of length <code>n-1</code> where <code>n</code> is the number of observations, specifying the separation steps at which the observations of <code>order</code> are separated.

METHODS

The "mona" class has methods for the following generic functions: `print`, `summary`, `plot`.

See Also

`mona` for examples etc, `plot.mona`.

pam

*Partitioning Around Medoids***Description**

Partitioning (clustering) of the data into k clusters “around medoids”, a more robust version of K-means.

Usage

```
pam(x, k, diss = inherits(x, "dist"), metric = "euclidean",
    medoids = NULL, stand = FALSE, cluster.only = FALSE,
    do.swap = TRUE,
    keep.diss = !diss && !cluster.only && n < 100,
    keep.data = !diss && !cluster.only, trace.lev = 0)
```

Arguments

- | | |
|--------------|--|
| x | data matrix or data frame, or dissimilarity matrix or object, depending on the value of the <code>diss</code> argument.

In case of a matrix or data frame, each row corresponds to an observation, and each column corresponds to a variable. All variables must be numeric. Missing values (NAs) are allowed—as long as every pair of observations has at least one case not missing.

In case of a dissimilarity matrix, <code>x</code> is typically the output of <code>daisy</code> or <code>dist</code> . Also a vector of length $n*(n-1)/2$ is allowed (where n is the number of observations), and will be interpreted in the same way as the output of the above-mentioned functions. Missing values (NAs) are <i>not</i> allowed. |
| k | positive integer specifying the number of clusters, less than the number of observations. |
| diss | logical flag: if TRUE (default for <code>dist</code> or <code>dissimilarity</code> objects), then <code>x</code> will be considered as a dissimilarity matrix. If FALSE, then <code>x</code> will be considered as a matrix of observations by variables. |
| metric | character string specifying the metric to be used for calculating dissimilarities between observations.

The currently available options are "euclidean" and "manhattan". Euclidean distances are root sum-of-squares of differences, and manhattan distances are the sum of absolute differences. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored. |
| medoids | NULL (default) or length- k vector of integer indices (in $1:n$) specifying initial medoids instead of using the ‘ <i>build</i> ’ algorithm. |
| stand | logical; if true, the measurements in <code>x</code> are standardized before calculating the dissimilarities. Measurements are standardized for each variable (column), by subtracting the variable’s mean value and dividing by the variable’s mean absolute deviation. If <code>x</code> is already a dissimilarity matrix, then this argument will be ignored. |
| cluster.only | logical; if true, only the clustering will be computed and returned, see details. |

<code>do.swap</code>	logical indicating if the swap phase should happen. The default, <code>TRUE</code> , correspond to the original algorithm. On the other hand, the swap phase is much more computer intensive than the build one for large n , so can be skipped by <code>do.swap = FALSE</code> .
<code>keep.diss, keep.data</code>	logicals indicating if the dissimilarities and/or input data x should be kept in the result. Setting these to <code>FALSE</code> can give much smaller results and hence even save memory allocation <i>time</i> .
<code>trace.lev</code>	integer specifying a trace level for printing diagnostics during the build and swap phase of the algorithm. Default 0 does not print anything; higher values print increasingly more.

Details

`pam` is fully described in chapter 2 of Kaufman and Rousseeuw (1990). Compared to the `k-means` approach in `kmeans`, the function `pam` has the following features: (a) it also accepts a dissimilarity matrix; (b) it is more robust because it minimizes a sum of dissimilarities instead of a sum of squared euclidean distances; (c) it provides a novel graphical display, the silhouette plot (see `plot.partition`) (d) it allows to select the number of clusters using `mean(silhouette(pr))` on the result `pr <- pam(..)`, or directly its component `pr$silinfo$avg.width`, see also [pam.object](#).

When `cluster.only` is true, the result is simply a (possibly named) integer vector specifying the clustering, i.e.,

`pam(x, k, cluster.only=TRUE)` is the same as
`pam(x, k)$clustering` but computed more efficiently.

The `pam`-algorithm is based on the search for k representative objects or medoids among the observations of the dataset. These observations should represent the structure of the data. After finding a set of k medoids, k clusters are constructed by assigning each observation to the nearest medoid. The goal is to find k representative objects which minimize the sum of the dissimilarities of the observations to their closest representative object.

By default, when `medoids` are not specified, the algorithm first looks for a good initial set of medoids (this is called the **build** phase). Then it finds a local minimum for the objective function, that is, a solution such that there is no single switch of an observation with a medoid that will decrease the objective (this is called the **swap** phase).

When the `medoids` are specified, their order does *not* matter; in general, the algorithms have been designed to not depend on the order of the observations.

Value

an object of class "pam" representing the clustering. See [?pam.object](#) for details.

Note

For large datasets, `pam` may need too much memory or too much computation time since both are $O(n^2)$. Then, `clara()` is preferable, see its documentation.

See Also

[agnes](#) for background and references; [pam.object](#), [clara](#), [daisy](#), [partition.object](#), [plot.partition](#), [dist](#).

Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
pamx <- pam(x, 2)
pamx
summary(pamx)
plot(pamx)
## use obs. 1 & 16 as starting medoids -- same result (typically)
(p2m <- pam(x, 2, medoids = c(1,16)))

p3m <- pam(x, 3, trace = 2)
## rather stupid initial medoids:
(p3m. <- pam(x, 3, medoids = 3:1, trace = 1))

pam(daisy(x, metric = "manhattan"), 2, diss = TRUE)

data(ruspini)
## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)
```

pam.object

*Partitioning Around Medoids (PAM) Object***Description**

The objects of class "pam" represent a partitioning of a dataset into clusters.

Value

A legitimate pam object is a list with the following components:

medoids	the medoids or representative objects of the clusters. If a dissimilarity matrix was given as input to pam, then a vector of numbers or labels of observations is given, else medoids is a matrix with in each row the coordinates of one medoid.
id.med	integer vector of <i>indices</i> giving the medoid observation numbers.
clustering	the clustering vector, see partition.object .
objective	the objective function after the first and second step of the pam algorithm.
isolation	vector with length equal to the number of clusters, specifying which clusters are isolated clusters (L- or L*-clusters) and which clusters are not isolated. A cluster is an L*-cluster iff its diameter is smaller than its separation. A cluster is an L-cluster iff for each observation <i>i</i> the maximal dissimilarity between <i>i</i> and any other observation of the cluster is smaller than the minimal dissimilarity between <i>i</i> and any observation of another cluster. Clearly each L*-cluster is also an L-cluster.
clusinfo	matrix, each row gives numerical information for one cluster. These are the cardinality of the cluster (number of observations), the maximal and average dissimilarity between the observations in the cluster and the cluster's medoid,

the diameter of the cluster (maximal dissimilarity between two observations of the cluster), and the separation of the cluster (minimal dissimilarity between an observation of the cluster and an observation of another cluster).

silinfo list with silhouette width information, see [partition.object](#).
 diss dissimilarity (maybe NULL), see [partition.object](#).
 call generating call, see [partition.object](#).
 data (possibly standardized) see [partition.object](#).

GENERATION

These objects are returned from [pam](#).

METHODS

The "pam" class has methods for the following generic functions: print, summary.

INHERITANCE

The class "pam" inherits from "partition". Therefore, the generic functions plot and clusplot can be used on a pam object.

See Also

[pam](#), [dissimilarity.object](#), [partition.object](#), [plot.partition](#).

Examples

```
## Use the silhouette widths for assessing the best number of clusters,
## following a one-dimensional example from Christian Hennig :
##
x <- c(rnorm(50), rnorm(50,mean=5), rnorm(30,mean=15))
asw <- numeric(20)
## Note that "k=1" won't work!
for (k in 2:20)
  asw[k] <- pam(x, k) $ silinfo $ avg.width
k.best <- which.max(asw)
cat("silhouette-optimal number of clusters:", k.best, "\n")

plot(1:20, asw, type="h", main = "pam() clustering assessment",
     xlab="k (# clusters)", ylab = "average silhouette width")
axis(1, k.best, paste("best",k.best,sep="\n"), col = "red", col.axis = "red")
```

partition.object *Partitioning Object*

Description

The objects of class "partition" represent a partitioning of a dataset into clusters.

Value

a "partition" object is a list with the following (and typically more) components:

clustering	the clustering vector. An integer vector of length n , the number of observations, giving for each observation the number ('id') of the cluster to which it belongs.
call	the matched <code>call</code> generating the object.
silinfo	a list with all <i>silhouette</i> information, only available when the number of clusters is non-trivial, i.e., $1 < k < n$ and then has the following components, see <code>silhouette</code> <p>widths an ($n \times 3$) matrix, as returned by <code>silhouette()</code>, with for each observation i the cluster to which i belongs, as well as the neighbor cluster of i (the cluster, not containing i, for which the average dissimilarity between its observations and i is minimal), and the silhouette width $s(i)$ of the observation.</p> <p>clus.avg.widths the average silhouette width per cluster.</p> <p>avg.width the average silhouette width for the dataset, i.e., simply the average of $s(i)$ over all observations i.</p> <p>This information is also needed to construct a <i>silhouette plot</i> of the clustering, see <code>plot.partition</code>.</p> <p>Note that <code>avg.width</code> can be maximized over different clusterings (e.g. with varying number of clusters) to choose an <i>optimal</i> clustering.</p>
objective	value of criterion maximized during the partitioning algorithm, may more than one entry for different stages.
diss	an object of class "dissimilarity", representing the total dissimilarity matrix of the dataset (or relevant subset, e.g. for <code>clara</code>).
data	a matrix containing the original or standardized data. This might be missing to save memory or when a dissimilarity matrix was given as input structure to the clustering method.

GENERATION

These objects are returned from `pam`, `clara` or `fanny`.

METHODS

The "partition" class has a method for the following generic functions: `plot`, `clusplot`.

INHERITANCE

The following classes inherit from class "partition": "pam", "clara" and "fanny".

See `pam.object`, `clara.object` and `fanny.object` for details.

See Also

`pam`, `clara`, `fanny`.

 plantTraits

Plant Species Traits Data

Description

This dataset constitutes a description of 136 plant species according to biological attributes (morphological or reproductive)

Usage

```
data(plantTraits)
```

Format

A data frame with 136 observations on the following 31 variables.

pdias Diaspore mass (mg)

longindex Seed bank longevity

durflow Flowering duration

height Plant height, an ordered factor with levels 1 < 2 < ... < 8.

begflow Time of first flowering, an ordered factor with levels 1 < 2 < 3 < 4 < 5 < 6 < 7 < 8 < 9

mycor Mycorrhizas, an ordered factor with levels 0never < 1 sometimes < 2always

vegaer aerial vegetative propagation, an ordered factor with levels 0never < 1 present but limited < 2important.

vegsout underground vegetative propagation, an ordered factor with 3 levels identical to vegaer above.

autopoll selfing pollination, an ordered factor with levels 0never < 1rare < 2 often < the rule3

insects insect pollination, an ordered factor with 5 levels 0 < ... < 4.

wind wind pollination, an ordered factor with 5 levels 0 < ... < 4.

lign a binary factor with levels 0 : 1, indicating if plant is woody.

piq a binary factor indicating if plant is thorny.

ros a binary factor indicating if plant is rosette.

semiros semi-rosette plant, a binary factor (0: no; 1: yes).

leafy leafy plant, a binary factor.

suman summer annual, a binary factor.

winan winter annual, a binary factor.

monocarp monocarpic perennial, a binary factor.

polycarp polycarpic perennial, a binary factor.

seasaes seasonal aestival leaves, a binary factor.

seashiv seasonal hibernal leaves, a binary factor.

seasver seasonal vernal leaves, a binary factor.

everalw leaves always evergreen, a binary factor.

everparti leaves partially evergreen, a binary factor.

elaio fruits with an elaiosome (dispersed by ants), a binary factor.

endozoo endozoochorous fruits, a binary factor.
epizoo epizoochorous fruits, a binary factor.
aquat aquatic dispersal fruits, a binary factor.
windgl wind dispersed fruits, a binary factor.
unsp unspecialized mechanism of seed dispersal, a binary factor.

Details

Most of factor attributes are not disjunctive. For example, a plant can be usually pollinated by insects but sometimes self-pollination can occurred.

Examples

```
data(plantTraits)

## Calculation of a dissimilarity matrix
library(cluster)
dai.b <- daisy(plantTraits,
              type = list(ordratio = 4:11, symm = 12:13, asymm = 14:31))

## Hierarchical classification
agn.trts <- agnes(dai.b, method="ward")
plot(agn.trts, which.plots = 2, cex= 0.6)
plot(agn.trts, which.plots = 1)
cutree6 <- cutree(agn.trts, k=6)
cutree6

## Principal Coordinate Analysis
cmds dai.b <- cmdscale(dai.b, k=6)
plot(cmdsdai.b[, 1:2], asp = 1, col = cutree6)
```

plot.agnes

Plots of an Agglomerative Hierarchical Clustering

Description

Creates plots for visualizing an agnes object.

Usage

```
## S3 method for class 'agnes':
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
     sub = paste("Agglomerative Coefficient = ", round(x$ac, digits = 2)),
     adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

Arguments

<code>x</code>	an object of class "agnes", typically created by <code>agnes(.)</code> .
<code>ask</code>	logical; if true and <code>which.plots</code> is NULL, <code>plot.agnes</code> operates in interactive mode, via <code>menu</code> .
<code>which.plots</code>	integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or "clustering tree".
<code>main, sub</code>	main and sub title for the plot, with convenient defaults. See documentation for these arguments in <code>plot.default</code> .
<code>adj</code>	for label adjustment in <code>bannerplot()</code> .
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in banner plot labeling.
<code>xax.pretty</code>	logical or integer indicating if <code>pretty(*, n = xax.pretty)</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.
<code>...</code>	graphical parameters (see <code>par</code>) may also be supplied and are passed to <code>bannerplot()</code> or <code>pltree()</code> , respectively.

Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.agnes` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 5 of Kaufman and Rousseeuw (1990). The banner plots distances at which observations and clusters are merged. The observations are listed in the order found by the `agnes` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. Two branches come together at the distance between the two clusters being merged.

For more customization of the plots, rather call `bannerplot` and `pltree` directly with corresponding arguments, e.g., `xlab` or `ylab`.

Side Effects

Appropriate plots are produced on the current graphics device. This can be one or both of the following choices:

Banner

Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

Examples

```
## Can also pass `labels` to pltree() and bannerplot():
data(iris)
cS <- as.character(Sp <- iris$Species)
cS[Sp == "setosa"] <- "S"
cS[Sp == "versicolor"] <- "V"
cS[Sp == "virginica"] <- "G"
ai <- agnes(iris[, 1:4])
plot(ai, labels = cS, nmax = 150) # bannerplot labels are mess
```

plot.diana

Plots of a Divisive Hierarchical Clustering

Description

Creates plots for visualizing a diana object.

Usage

```
## S3 method for class 'diana':
plot(x, ask = FALSE, which.plots = NULL, main = NULL,
      sub = paste("Divisive Coefficient = ", round(x$dc, digits = 2)),
      adj = 0, nmax.lab = 35, max.strlen = 5, xax.pretty = TRUE, ...)
```

Arguments

- | | |
|-------------|---|
| x | an object of class "diana", typically created by diana(.) . |
| ask | logical; if true and which.plots is NULL, plot.diana operates in interactive mode, via menu . |
| which.plots | integer vector or NULL (default), the latter producing both plots. Otherwise, which.plots must contain integers of 1 for a <i>banner</i> plot or 2 for a dendrogram or “clustering tree”. |
| main, sub | main and sub title for the plot, each with a convenient default. See documentation for these arguments in plot.default . |
| adj | for label adjustment in bannerplot(.) . |

nmax.lab	integer indicating the number of labels which is considered too large for single-name labelling the banner plot.
max.strlen	positive integer giving the length to which strings are truncated in banner plot labeling.
xax.pretty	logical or integer indicating if <code>pretty(*, n = xax.pretty)</code> should be used for the x axis. <code>xax.pretty = FALSE</code> is for back compatibility.
...	graphical parameters (see <code>par</code>) may also be supplied and are passed to <code>bannerplot()</code> or <code>pltree()</code> , respectively.

Details

When `ask = TRUE`, rather than producing each plot sequentially, `plot.diana` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted one must set `par(ask= TRUE)` before invoking the plot command.

The banner displays the hierarchy of clusters, and is equivalent to a tree. See Rousseeuw (1986) or chapter 6 of Kaufman and Rousseeuw (1990). The banner plots the diameter of each cluster being splitted. The observations are listed in the order found by the `diana` algorithm, and the numbers in the `height` vector are represented as bars between the observations.

The leaves of the clustering tree are the original observations. A branch splits up at the diameter of the cluster being splitted.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Banner
Clustering tree

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

References

see those in `plot.agnes`.

See Also

`diana`, `diana.object`, `twins.object`, `par`.

Examples

```
example(diana)# -> dv <- diana(...)

plot(dv, which = 1, nmax.lab = 100)

## wider labels :
op <- par(mar = par("mar") + c(0, 2, 0, 0))
plot(dv, which = 1, nmax.lab = 100, max.strlen = 12)
par(op)
```

plot.mona

Banner of Monothetic Divisive Hierarchical Clusterings

Description

Creates the banner of a `mona` object.

Usage

```
## S3 method for class 'mona':
plot(x, main = paste("Banner of ", deparse(x$call)),
      sub = NULL, xlab = "Separation step",
      col = c(2,0), axes = TRUE, adj = 0,
      nmax.lab = 35, max.strlen = 5, ...)
```

Arguments

<code>x</code>	an object of class "mona", typically created by <code>mona(.)</code> .
<code>main, sub</code>	main and sub titles for the plot, with convenient defaults. See documentation in plot.default .
<code>xlab</code>	x axis label, see title .
<code>col, adj</code>	graphical parameters passed to <code>bannerplot()</code> .
<code>axes</code>	logical, indicating if (labeled) axes should be drawn.
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for labeling.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in labeling.
<code>...</code>	further graphical arguments are passed to <code>bannerplot()</code> and <code>text</code> .

Details

Plots the separation step at which clusters are splitted. The observations are given in the order found by the `mona` algorithm, the numbers in the `step` vector are represented as bars between the observations.

When a long bar is drawn between two observations, those observations have the same value for each variable. See chapter 7 of Kaufman and Rousseeuw (1990).

Side Effects

A banner is plotted on the current graphics device.

Note

In the banner plot, observation labels are only printed when the number of observations is limited less than `nmax.lab` (35, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

References

see those in [plot.agnes](#).

plot.partition	<i>Plot of a Partition of the Data Set</i>
----------------	--

Description

Creates plots for visualizing a `partition` object.

Usage

```
## S3 method for class 'partition':
plot(x, ask = FALSE, which.plots = NULL,
     nmax.lab = 40, max.strlen = 5, data = x$data, dist = NULL,
     cor = TRUE, stand = FALSE, lines = 2,
     shade = FALSE, color = FALSE, labels = 0, plotchar = TRUE,
     span = TRUE, xlim = NULL, ylim = NULL, main = NULL, ...)
```

Arguments

<code>x</code>	an object of class "partition", typically created by the functions pam , clara , or fanny .
<code>ask</code>	logical; if true and <code>which.plots</code> is NULL, <code>plot.partition</code> operates in interactive mode, via menu .
<code>which.plots</code>	integer vector or NULL (default), the latter producing both plots. Otherwise, <code>which.plots</code> must contain integers of 1 for a <i>clusplot</i> or 2 for <i>silhouette</i> .
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in silhouette plot labeling.
<code>data</code>	numeric matrix with the scaled data; per default taken from the partition object <code>x</code> , but can be specified explicitly.
<code>dist</code>	when <code>x</code> does not have a <code>diss</code> component as for pam (*, <code>keep.diss=FALSE</code>), <code>dist</code> must be the dissimilarity if a <i>clusplot</i> is desired.
<code>cor</code> , <code>stand</code> , <code>lines</code> , <code>shade</code> , <code>color</code> , <code>labels</code> , <code>plotchar</code> , <code>span</code> , <code>xlim</code> , <code>ylim</code> , <code>main</code> , ...	All optional arguments available for the clusplot.default function (except for the <code>diss</code> one) and graphical parameters (see par) may also be supplied as arguments to this function.

Details

When `ask= TRUE`, rather than producing each plot sequentially, `plot.partition` displays a menu listing all the plots that can be produced. If the menu is not desired but a pause between plots is still wanted, call `par(ask= TRUE)` before invoking the plot command.

The *clusplot* of a cluster partition consists of a two-dimensional representation of the observations, in which the clusters are indicated by ellipses (see [clusplot.partition](#) for more details).

The *silhouette plot* of a nonhierarchical clustering is fully described in Rousseeuw (1987) and in chapter 2 of Kaufman and Rousseeuw (1990). For each observation i , a bar is drawn, representing its silhouette width $s(i)$, see [silhouette](#) for details. Observations are grouped per cluster, starting with cluster 1 at the top. Observations with a large $s(i)$ (almost 1) are very well clustered, a small $s(i)$ (around 0) means that the observation lies between two clusters, and observations with a negative $s(i)$ are probably placed in the wrong cluster.

A clustering can be performed for several values of k (the number of clusters). Finally, choose the value of k with the largest overall average silhouette width.

Side Effects

An appropriate plot is produced on the current graphics device. This can be one or both of the following choices:

Clusplot
Silhouette plot

Note

In the silhouette plot, observation labels are only printed when the number of observations is less than `nmax.lab` (40, by default), for readability. Moreover, observation labels are truncated to maximally `max.strlen` (5) characters.

For more flexibility, use `plot(silhouette(x), ...)`, see [plot.silhouette](#).

[partition.object](#), [clusplot.partition](#), [clusplot.default](#), [pam](#),
[pam.object](#), [clara](#), [clara.object](#), [fanny](#), [fanny.object](#), [par](#).

Examples

```
## generate 25 objects, divided into 2 clusters.
x <- rbind(cbind(rnorm(10,0,0.5), rnorm(10,0,0.5)),
           cbind(rnorm(15,5,0.5), rnorm(15,5,0.5)))
plot(pam(x, 2))

## Save space not keeping data in clus.object, and still clusplot() it:
data(xclara)
cx <- clara(xclara, 3, keep.data = FALSE)
cx$data # is NULL
plot(cx, data = xclara)
```

 pltree

Clustering Trees - Generic Function

Description

Generic function drawing a clustering tree (“dendrogram”) on the current graphics device. There is a `twins` method, see [pltree.twins](#) for usage and examples.

Usage

```
pltree(x, ...)
```

Arguments

`x` an R object (for which a `pltree` method is defined).

`...` methods may have additional arguments. Graphical parameters (see [par](#)) may also be supplied as arguments to this function.

See Also

[pltree.twins](#), [twins.object](#).

 pltree.twins

Clustering Tree of a Hierarchical Clustering

Description

Draws a clustering tree (dendrogram) of a `twins` object, i.e., hierarchical clustering, typically resulting from [agnes\(\)](#) or [diana\(\)](#).

Usage

```
## S3 method for class 'twins':
pltree(x, main = paste("Dendrogram of ", deparse(x$call)),
       labels = NULL, ylab = "Height", ...)
```

Arguments

`x` an object of class "twins", typically created by either [agnes\(\)](#) or [diana\(\)](#).

`main` main title with a sensible default.

`labels` labels to use; the default is constructed from `x`.

`ylab` label for y-axis.

`...` graphical parameters (see [par](#)) may also be supplied as arguments to this function.

Details

Creates a plot of a clustering tree given a `twins` object. The leaves of the tree are the original observations. In case of an agglomerative clustering, two branches come together at the distance between the two clusters being merged. For a divisive clustering, a branch splits up at the diameter of the cluster being splitted.

Note that currently the method function simply calls `plot(as.hclust(x), ...)`, which dispatches to `plot.hclust(...)`. If more flexible plots are needed, consider `xx <- as.dendrogram(as.dendrogram(x))` and plotting `xx`, see `plot.dendrogram`.

Value

a NULL value is returned.

See Also

`agnes`, `agnes.object`, `diana`, `diana.object`, `hclust`, `par`, `plot.agnes`, `plot.diana`.

Examples

```
data(votes.repub)
agn <- agnes(votes.repub)
pltree(agn)

dagn <- as.dendrogram(as.hclust(agn))
dagn2 <- as.dendrogram(as.hclust(agn), hang = 0.2)
op <- par(mar = par("mar") + c(0,0,0, 2)) # more space to the right
plot(dagn2, horiz = TRUE)
plot(dagn, horiz = TRUE, center = TRUE,
      nodePar = list(lab.cex = 0.6, lab.col = "forest green", pch = NA),
      main = deparse(agn$call))
par(op)
```

pluton

Isotopic Composition Plutonium Batches

Description

The `pluton` data frame has 45 rows and 4 columns, containing percentages of isotopic composition of 45 Plutonium batches.

Usage

```
data(pluton)
```

Format

This data frame contains the following columns:

Pu238 the percentages of ^{238}Pu , always less than 2 percent.

Pu239 the percentages of ^{239}Pu , typically between 60 and 80 percent (from neutron capture of Uranium, ^{238}U).

Pu240 percentage of the plutonium 240 isotope.

Pu241 percentage of the plutonium 241 isotope.

Details

Note that the percentage of plutonium 242 can be computed from the other four percentages, see the examples.

In the reference below it is explained why it is very desirable to combine these plutonium patches in three groups of similar size.

Source

Available as 'pluton.dat' from the archive currently <http://www.agoras.ua.ac.be/datasets/clusplot-examples.tar.gz>.

References

Rousseeuw, P.J. and Kaufman, L and Trauwaert, E. (1996) Fuzzy clustering using scatter matrices, *Computational Statistics and Data Analysis* **23**(1), 135–151.

Examples

```
data(pluton)

hist(apply(pluton,1,sum), col = "gray") # between 94% and 100%
pu5 <- pluton
pu5$Pu242 <- 100 - apply(pluton,1,sum) # the remaining isotope.
pairs(pu5)
```

predict.ellipsoid *Predict Method for Ellipsoid Objects*

Description

Compute points on the ellipsoid boundary, mostly for drawing.

Usage

```
predict.ellipsoid(object, n.out=201, ...)
## S3 method for class 'ellipsoid':
predict(object, n.out=201, ...)
ellipsoidPoints(A, d2, loc, n.half = 201)
```

Arguments

object	an object of class <code>ellipsoid</code> , typically from <code>ellipsoidhull()</code> ; alternatively any list-like object with proper components, see details below.
n.out, n.half	half the number of points to create.
A, d2, loc	arguments of the auxiliary <code>ellipsoidPoints</code> , see below.
...	passed to and from methods.

Details

Note `ellipsoidPoints` is the workhorse function of `predict.ellipsoid` a standalone function and method for `ellipsoid` objects, see [ellipsoidhull](#). The class of `object` is not checked; it must solely have valid components `loc` (length p), the $p \times p$ matrix `cov` (corresponding to A) and `d2` for the center, the shape (“covariance”) matrix and the squared average radius (or distance) or `qchisq(*, p)` quantile.

Value

a numeric matrix of dimension $2 * n.out$ times p .

See Also

[ellipsoidhull](#), [volume.ellipsoid](#).

Examples

```
## see also example(ellipsoidhull)

## Robust vs. L.S. covariance matrix
set.seed(143)
x <- rt(200, df=3)
y <- 3*x + rt(200, df=2)
plot(x,y, main="non-normal data (N=200)")
mtext("with classical and robust cov.matrix ellipsoids")
X <- cbind(x,y)
C.ls <- cov(X) ; m.ls <- colMeans(X)
d2.99 <- qchisq(0.99, df = 2)
lines(ellipsoidPoints(C.ls, d2.99, loc=m.ls), col="green")
if(require(MASS)) {
  Cxy <- cov.rob(cbind(x,y))
  lines(ellipsoidPoints(Cxy$cov, d2 = d2.99, loc=Cxy$center), col="red")
}# MASS
```

print.agnes

Print Method for AGNES Objects

Description

Prints the call, agglomerative coefficient, ordering of objects and distances between merging clusters (‘Height’) of an `agnes` object.

This is a method for the generic `print()` function for objects inheriting from class `agnes`, see [agnes.object](#).

Usage

```
## S3 method for class 'agnes':
print(x, ...)
```

Arguments

`x` an `agnes` object.
`...` potential further arguments (required by generic).

See Also

[summary.agnes](#) producing more output; [agnes](#), [agnes.object](#), [print](#), [print.default](#).

print.clara *Print Method for CLARA Objects*

Description

Prints the best sample, medoids, clustering vector and objective function of clara object.

This is a method for the function `print()` for objects inheriting from class `clara`.

Usage

```
## S3 method for class 'clara':  
print(x, ...)
```

Arguments

`x` a clara object.
`...` potential further arguments (require by generic).

See Also

[summary.clara](#) producing more output; [clara](#), [clara.object](#), [print](#), [print.default](#).

print.diana *Print Method for DIANA Objects*

Description

Prints the ordering of objects, diameters of splitted clusters, and divisive coefficient of a diana object.

This is a method for the function `print()` for objects inheriting from class `diana`.

Usage

```
## S3 method for class 'diana':  
print(x, ...)
```

Arguments

`x` a diana object.
`...` potential further arguments (require by generic).

See Also

[diana](#), [diana.object](#), [print](#), [print.default](#).

```
print.dissimilarity
```

Print and Summary Methods for Dissimilarity Objects

Description

Print or summarize the distances and the attributes of a dissimilarity object.

These are methods for the functions `print()` and `summary()` for dissimilarity objects. See `print`, `print.default`, or `summary` for the general behavior of these.

Usage

```
## S3 method for class 'dissimilarity':
print(x, diag = NULL, upper = NULL,
      digits = getOption("digits"), justify = "none", right = TRUE, ...)
## S3 method for class 'dissimilarity':
summary(object,
        digits = max(3, getOption("digits") - 2), ...)
## S3 method for class 'summary.dissimilarity':
print(x, ...)
```

Arguments

`x`, `object` a dissimilarity object or a `summary.dissimilarity` one for `print.summary.dissimilarity()`.

`digits` the number of digits to use, see `print.default`.

`diag`, `upper`, `justify`, `right` optional arguments specifying how the triangular dissimilarity matrix is printed; see `print.dist`.

`...` potential further arguments (require by generic).

See Also

[daisy](#), [dissimilarity.object](#), [print](#), [print.default](#), [print.dist](#).

Examples

```
## See example(daisy)

sd <- summary(daisy(matrix(rnorm(100), 20, 5)))
sd # -> print.summary.dissimilarity(.)
str(sd)
```

`print.fanny`*Print and Summary Methods for FANNY Objects*

Description

Prints the objective function, membership coefficients and clustering vector of `fanny` object.

This is a method for the function `print()` for objects inheriting from class `fanny`.

Usage

```
## S3 method for class 'fanny':
print(x, digits = getOption("digits"), ...)
## S3 method for class 'fanny':
summary(object, ...)
## S3 method for class 'summary.fanny':
print(x, digits = getOption("digits"), ...)
```

Arguments

<code>x</code> , object	a <code>fanny</code> object.
<code>digits</code>	number of significant digits for printing, see <code>print.default</code> .
<code>...</code>	potential further arguments (required by generic).

See Also

`fanny`, `fanny.object`, `print`, `print.default`.

`print.mona`*Print Method for MONA Objects*

Description

Prints the ordering of objects, separation steps, and used variables of a `mona` object.

This is a method for the function `print()` for objects inheriting from class `mona`.

Usage

```
## S3 method for class 'mona':
print(x, ...)
```

Arguments

<code>x</code>	a <code>mona</code> object.
<code>...</code>	potential further arguments (require by generic).

See Also

`mona`, `mona.object`, `print`, `print.default`.

`print.pam`*Print Method for PAM Objects*

Description

Prints the medoids, clustering vector and objective function of pam object.

This is a method for the function `print()` for objects inheriting from class `pam`.

Usage

```
## S3 method for class 'pam':  
print(x, ...)
```

Arguments

`x` a pam object.
`...` potential further arguments (require by generic).

See Also

`pam`, `pam.object`, `print`, `print.default`.

`ruspini`*Ruspini Data*

Description

The Ruspini data set, consisting of 75 points in four groups that is popular for illustrating clustering techniques.

Usage

```
data(ruspini)
```

Format

A data frame with 75 observations on 2 variables giving the x and y coordinates of the points, respectively.

Source

E. H. Ruspini (1970): Numerical methods for fuzzy clustering. *Inform. Sci.*, **2**, 319–350.

References

Anja Struyf, Mia Hubert & Peter J. Rousseeuw (1996): Clustering in an Object-Oriented Environment. *Journal of Statistical Software*, **1**. <http://www.stat.ucla.edu/journals/jss/>

Examples

```

data(ruspini)

## Plot similar to Figure 4 in Stryuf et al (1996)
## Not run: plot(pam(ruspini, 4), ask = TRUE)

## Plot similar to Figure 6 in Stryuf et al (1996)
plot(fanny(ruspini, 5))

```

silhouette

*Compute or Extract Silhouette Information from Clustering***Description**

Compute silhouette information according to a given clustering in k clusters.

Usage

```

silhouette(x, ...)
## Default S3 method:
silhouette(x, dist, dmatrix, ...)
## S3 method for class 'partition':
silhouette(x, ...)
## S3 method for class 'clara':
silhouette(x, full = FALSE, ...)

sortSilhouette(object, ...)
## S3 method for class 'silhouette':
summary(object, FUN = mean, ...)
## S3 method for class 'silhouette':
plot(x, nmax.lab = 40, max.strlen = 5,
      main = NULL, sub = NULL, xlab = expression("Silhouette width "* s[i]),
      col = "gray", do.col.sort = length(col) > 1, border = 0,
      cex.names = par("cex.axis"), do.n.k = TRUE, do.clus.stat = TRUE, ...)

```

Arguments

<code>x</code>	an object of appropriate class; for the default method an integer vector with k different integer cluster codes or a list with such an <code>x\$clustering</code> component. Note that silhouette statistics are only defined if $2 \leq k \leq n - 1$.
<code>dist</code>	a dissimilarity object inheriting from class <code>dist</code> or coercible to one. If not specified, <code>dmatrix</code> must be.
<code>dmatrix</code>	a symmetric dissimilarity matrix ($n \times n$), specified instead of <code>dist</code> , which can be more efficient.
<code>full</code>	logical specifying if a <i>full</i> silhouette should be computed for <code>clara</code> object. Note that this requires $O(n^2)$ memory, since the full dissimilarity (see <code>daisy</code>) is needed internally.
<code>object</code>	an object of class <code>silhouette</code> .
<code>...</code>	further arguments passed to and from methods.

<code>FUN</code>	function used to summarize silhouette widths.
<code>nmax.lab</code>	integer indicating the number of labels which is considered too large for single-name labeling the silhouette plot.
<code>max.strlen</code>	positive integer giving the length to which strings are truncated in silhouette plot labeling.
<code>main, sub, xlab</code>	arguments to <code>title</code> ; have a sensible non-NULL default here.
<code>col, border, cex.names</code>	arguments passed <code>barplot()</code> ; note that the default used to be <code>col = heat.colors(n)</code> , <code>border = par("fg")</code> instead. <code>col</code> can also be a color vector of length k for clusterwise coloring, see also <code>do.col.sort</code> :
<code>do.col.sort</code>	logical indicating if the colors <code>col</code> should be sorted “along” the silhouette; this is useful for casewise or clusterwise coloring.
<code>do.n.k</code>	logical indicating if n and k “title text” should be written.
<code>do.clus.stat</code>	logical indicating if cluster size and averages should be written right to the silhouettes.

Details

For each observation i , the *silhouette width* $s(i)$ is defined as follows:

Put $a(i)$ = average dissimilarity between i and all other points of the cluster to which i belongs (if i is the *only* observation in its cluster, $s(i) := 0$ without further calculations). For all *other* clusters C , put $d(i, C)$ = average dissimilarity of i to all observations of C . The smallest of these $d(i, C)$ is $b(i) := \min_C d(i, C)$, and can be seen as the dissimilarity between i and its “neighbor” cluster, i.e., the nearest one to which it does *not* belong. Finally,

$$s(i) := \frac{b(i) - a(i)}{\max(a(i), b(i))}.$$

`silhouette.default()` is now based on C code donated by Romain Francois (the R version being still available as `cluster::silhouette.default.R`).

Observations with a large $s(i)$ (almost 1) are very well clustered, a small $s(i)$ (around 0) means that the observation lies between two clusters, and observations with a negative $s(i)$ are probably placed in the wrong cluster.

Value

`silhouette()` returns an object, `sil`, of class `silhouette` which is an $[n \times 3]$ matrix with attributes. For each observation i , `sil[i,]` contains the cluster to which i belongs as well as the neighbor cluster of i (the cluster, not containing i , for which the average dissimilarity between its observations and i is minimal), and the silhouette width $s(i)$ of the observation. The `colnames` correspondingly are `c("cluster", "neighbor", "sil_width")`.

`summary(sil)` returns an object of class `summary.silhouette`, a list with components

`si.summary` numerical [summary](#) of the individual silhouette widths $s(i)$.

`clus.avg.widths`

numeric (rank 1) array of clusterwise *means* of silhouette widths where `mean = FUN` is used.

`avg.width` the total mean `FUN(s)` where s are the individual silhouette widths.

clus.sizes [table](#) of the k cluster sizes.
 call if available, the call creating `sil`.
 Ordered logical identical to `attr(sil, "Ordered")`, see below.

`sortSilhouette(sil)` orders the rows of `sil` as in the silhouette plot, by cluster (increasingly) and decreasing silhouette width $s(i)$.
`attr(sil, "Ordered")` is a logical indicating if `sil` is ordered as by `sortSilhouette()`. In that case, `rownames(sil)` will contain case labels or numbers, and
`attr(sil, "iOrd")` the ordering index vector.

Note

While `silhouette()` is *intrinsic* to the [partition](#) clusterings, and hence has a (trivial) method for these, it is straightforward to get silhouettes from hierarchical clusterings from `silhouette.default()` with `cutree()` and distance as input.

By default, for `clara()` partitions, the silhouette is just for the best random *subset* used. Use `full = TRUE` to compute (and later possibly plot) the full silhouette.

Examples

```
data(ruspini)
pr4 <- pam(ruspini, 4)
str(si <- silhouette(pr4))
(ssi <- summary(si))
plot(si) # silhouette plot
plot(si, col = c("red", "green", "blue", "purple")) # with cluster-wise coloring

si2 <- silhouette(pr4$clustering, dist(ruspini, "canberra"))
summary(si2) # has small values: "canberra"'s fault
plot(si2, nmax= 80, cex.names=0.6)

op <- par(mfrow= c(3,2), oma= c(0,0, 3, 0),
          mgp= c(1.6, .8, 0), mar= .1+c(4,2,2,2))
for(k in 2:6)
  plot(silhouette(pam(ruspini, k=k)), main = paste("k = ",k), do.n.k=FALSE)
mtext("PAM(Ruspini) as in Kaufman & Rousseeuw, p.101",
      outer = TRUE, font = par("font.main"), cex = par("cex.main"))
par(op)

## clara(): standard silhouette is just for the best random subset
data(xclara)
set.seed(7)
str(xclk <- xclara[sample(nrow(xclara), size = 1000) ,])
```

```

cl3 <- clara(xclk, 3)
plot(silhouette(cl3)) # only of the "best" subset of 46
## The full silhouette: internally needs large (36 MB) dist object:
sf <- silhouette(cl3, full = TRUE) ## this is the same as
s.full <- silhouette(cl3$clustering, daisy(xclk))
if(paste(R.version$major, R.version$minor, sep=".") >= "2.3.0")
  stopifnot(all.equal(sf, s.full, check.attributes = FALSE, tol = 0))
## color dependent on original "3 groups of each 1000":
plot(sf, col = 2+ as.integer(names(cl3$clustering) ) %% 1000,
      main = "plot(silhouette(clara(.), full = TRUE))")

## Silhouette for a hierarchical clustering:
ar <- agnes(ruspini)
si3 <- silhouette(cutree(ar, k = 5), # k = 4 gave the same as pam() above
                 daisy(ruspini))
plot(si3, nmax = 80, cex.names = 0.5)
## 2 groups: Agnes() wasn't too good:
si4 <- silhouette(cutree(ar, k = 2), daisy(ruspini))
plot(si4, nmax = 80, cex.names = 0.5)

```

sizeDiss

*Sample Size of Dissimilarity Like Object***Description**

Returns the number of observations (*sample size*) corresponding to a dissimilarity like object, or equivalently, the number of rows or columns of a matrix when only the lower or upper triangular part (without diagonal) is given.

It is nothing else but the inverse function of $f(n) = n(n - 1)/2$.

Usage

```
sizeDiss(d)
```

Arguments

`d` any R object with length (typically) $n(n - 1)/2$.

Value

a number; n if length(`d`) == $n(n-1)/2$, NA otherwise.

See Also

[dissimilarity.object](#) and also [as.dist](#) for class dissimilarity and dist objects which have a `Size` attribute.

Examples

```

sizeDiss(1:10) # 5, since 10 == 5 * (5 - 1) / 2
sizeDiss(1:9) # NA

n <- 1:100
stopifnot(n == sapply( n*(n-1)/2, function(n) sizeDiss(logical(n))))

```

summary.agnes	<i>Summary Method for 'agnes' Objects</i>
---------------	---

Description

Returns (and prints) a summary list for an `agnes` object. Printing gives more output than the corresponding `print.agnes` method.

Usage

```
## S3 method for class 'agnes':
summary(object, ...)
## S3 method for class 'summary.agnes':
print(x, ...)
```

Arguments

`x, object` a `agnes` object.
`...` potential further arguments (require by generic).

See Also

`agnes`, `agnes.object`.

Examples

```
data(agriculture)
summary(agnes(agriculture))
```

summary.clara	<i>Summary Method for 'clara' Objects</i>
---------------	---

Description

Returns (and prints) a summary list for a `clara` object. Printing gives more output than the corresponding `print.clara` method.

Usage

```
## S3 method for class 'clara':
summary(object, ...)
## S3 method for class 'summary.clara':
print(x, ...)
```

Arguments

`x, object` a `clara` object.
`...` potential further arguments (require by generic).

See Also

[clara.object](#)

Examples

```
## generate 2000 objects, divided into 5 clusters.
set.seed(47)
x <- rbind(cbind(rnorm(400, 0, 4), rnorm(400, 0, 4)),
           cbind(rnorm(400, 10, 8), rnorm(400, 40, 6)),
           cbind(rnorm(400, 30, 4), rnorm(400, 0, 4)),
           cbind(rnorm(400, 40, 4), rnorm(400, 20, 2)),
           cbind(rnorm(400, 50, 4), rnorm(400, 50, 4))
)
clx5 <- clara(x, 5)
## Mis`classification' table:
table(rep(1:5, rep(400, 5)), clx5$clust) # -> 1 "error"
summary(clx5)

## Graphically:
par(mfrow = c(3, 1), mgp = c(1.5, 0.6, 0), mar = par("mar") - c(0, 0, 2, 0))
plot(x, col = rep(2:6, rep(400, 5)))
plot(clx5)
```

summary.diana

Summary Method for 'diana' Objects

Description

Returns (and prints) a summary list for a diana object.

Usage

```
## S3 method for class 'diana':
summary(object, ...)
## S3 method for class 'summary.diana':
print(x, ...)
```

Arguments

`x, object` a [diana](#) object.
`...` potential further arguments (require by generic).

See Also

[diana](#), [diana.object](#).

`summary.mona`*Summary Method for 'mona' Objects*

Description

Returns (and prints) a summary list for a mona object.

Usage

```
## S3 method for class 'mona':  
summary(object, ...)  
## S3 method for class 'summary.mona':  
print(x, ...)
```

Arguments

`x, object` a [mona](#) object.
`...` potential further arguments (require by generic).

See Also

[mona](#), [mona.object](#).

`summary.pam`*Summary Method for PAM Objects*

Description

Summarize a [pam](#) object and return an object of class `summary.pam`. There's a [print](#) method for the latter.

Usage

```
## S3 method for class 'pam':  
summary(object, ...)  
## S3 method for class 'summary.pam':  
print(x, ...)
```

Arguments

`x, object` a [pam](#) object.
`...` potential further arguments (require by generic).

See Also

[pam](#), [pam.object](#).

`twins.object` *Hierarchical Clustering Object*

Description

The objects of class "twins" represent an agglomerative or divisive (polythetic) hierarchical clustering of a dataset.

Value

See [agnes.object](#) and [diana.object](#) for details.

GENERATION

This class of objects is returned from `agnes` or `diana`.

METHODS

The "twins" class has a method for the following generic function: `pltree`.

INHERITANCE

The following classes inherit from class "twins": "agnes" and "diana".

See Also

[agnes,diana](#).

`volume.ellipsoid` *Compute the Volume of Planar Object*

Description

Compute the volume of a planar object. This is a generic function and a method for `ellipsoid` objects.

Usage

```
## S3 method for class 'ellipsoid':  
volume(object)
```

Arguments

`object` an R object the volume of which is wanted; for the `ellipsoid` method, an object of that class (see [ellipsoidhull](#) or the example below).

Value

a number, the volume of the given object.

See Also

`ellipsoidhull` for spanning ellipsoid computation.

Examples

```
## example(ellipsoidhull) # which defines `ellipsoid' object <namefoo>
myEl <- structure(list(cov = rbind(c(3,1),1:2), loc = c(0,0), d2 = 10),
                  class = "ellipsoid")
volume(myEl) # i.e. "area" here (d = 2)
myEl # also mentions the "volume"
```

votes.repub

Votes for Republican Candidate in Presidential Elections

Description

A data frame with the percents of votes given to the republican candidate in presidential elections from 1856 to 1976. Rows represent the 50 states, and columns the 31 elections.

Usage

```
data(votes.repub)
```

Source

S. Peterson (1973): *A Statistical History of the American Presidential Elections*. New York: Frederick Ungar Publishing Co.

Data from 1964 to 1976 is from R. M. Scammon, *American Votes 12*, Congressional Quarterly.

xclara

Bivariate Data Set with 3 Clusters

Description

An artificial data set consisting of 3000 points in 3 well-separated clusters of size 1000 each.

Usage

```
data(xclara)
```

Format

A data frame with 3000 observations on 2 numeric variables giving the x and y coordinates of the points, respectively.

Source

Sample data set accompanying the reference below, obtained from <http://www.stat.ucla.edu/journals/jss/v01/i04/data/>.

References

Anja Struyf, Mia Hubert & Peter J. Rousseeuw (1996): Clustering in an Object-Oriented Environment. *Journal of Statistical Software*, **1**. <http://www.stat.ucla.edu/journals/jss/>

Chapter 15

The codetools package

checkUsage

Check R Code for Possible Problems

Description

Check R code for possible problems.

Usage

```
checkUsage(fun, name = "<anonymous>", report = cat, all = FALSE,
           suppressLocal = FALSE, suppressParamAssigns = !all,
           suppressParamUnused = !all, suppressFundefMismatch = FALSE,
           suppressLocalUnused = FALSE, suppressNoLocalFun = !all,
           skipWith = FALSE, suppressUndefined = dfltSuppressUndefined)
checkUsageEnv(env, ...)
checkUsagePackage(pack, ...)
```

Arguments

fun	closure.
name	character; name of closure.
env	environment containing closures to check.
pack	character naming package to check.
...	options to be passed to checkUsage.
report	function to use to report possible problems.
all	logical; report all possible problems if TRUE.
suppressLocal	suppress all local variable warnings.
suppressParamAssigns	suppress warnings about assignments to formal parameters.
suppressParamUnused	suppress warnings about unused formal parameters.

```

suppressFundefMismatch
    suppress warnings about multiple local function definitions with different formal
    argument lists
suppressLocalUnused
    suppress warnings about unused local variables
suppressNoLocalFun
    suppress warnings about using local variables as functions with no apparent
    local function definition
skipWith      logical; if true, do not examine code portion of with expressions.
suppressUndefined
    suppress warnings about undefined global functions and variables.

```

Details

`checkUsage` checks a single R closure. Options control which possible problems to report. The default settings are moderately verbose. A first pass might use `suppressLocal=TRUE` to suppress all information related to local variable usage. The `suppressXYZ` values can either be scalar logicals or character vectors; then they are character vectors they only suppress problem reports for the variables with names in the vector.

`checkUsageEnv` and `checkUsagePackage` are convenience functions that apply `checkUsage` to all closures in an environment or a package. `checkUsagePackage` requires that the package be loaded. If the package has a name space then the internal name space frame is checked.

Author(s)

Luke Tierney

Examples

```

checkUsage(checkUsage)
checkUsagePackage("codetools", all=TRUE)
## Not run: checkUsagePackage("base", suppressLocal=TRUE)

```

codetools

Low Level Code Analysis Tools for R

Description

These functions provide some tools for analysing R code. Mainly indented to support the other tools in this package and byte code compilation.

Usage

```

collectLocals(e, collect)
collectUsage(fun, name = "<anonymous>", ...)
constantFold(e, env = NULL, fail = NULL)
findFuncLocals(formals, body)
findLocals(e, envir = .BaseEnv)
findLocalsList(elist, envir = .BaseEnv)
flattenAssignment(e)

```

```
getAssignedVar(e)
isConstantValue(v, w)
makeCodeWalker(..., handler, call, leaf)
makeLocalsCollector(..., leaf, handler, isLocal, exit, collect)
makeUsageCollector(fun, ..., name, enterLocal, enterGlobal, enterInternal,
                   startCollectLocals, finishCollectLocals, warn,
                   signal)
walkCode(e, w = makeCodeWalker())
```

Arguments

<code>e</code>	R expression.
<code>elist</code>	list of R expressions.
<code>v</code>	R object.
<code>fun</code>	closure.
<code>formals</code>	formal arguments of a closure.
<code>body</code>	body of a closure.
<code>name</code>	character.
<code>env</code>	character.
<code>envir</code>	environment.
<code>w</code>	code walker.
<code>...</code>	extra elements for code walker.
<code>collect</code>	function.
<code>fail</code>	function.
<code>handler</code>	function.
<code>call</code>	function.
<code>leaf</code>	function.
<code>isLocal</code>	function.
<code>exit</code>	function.
<code>enterLocal</code>	function.
<code>enterGlobal</code>	function.
<code>enterInternal</code>	function.
<code>startCollectLocals</code>	function.
<code>finishCollectLocals</code>	function.
<code>warn</code>	function.
<code>signal</code>	function.

Author(s)

Luke Tierney

findGlobals *Find Global Functions and Variables Used by a Closure*

Description

Finds global functions and variables used by a closure.

Usage

```
findGlobals(fun, merge = TRUE)
```

Arguments

fun	closure.
merge	logical

Details

The result is an approximation. R semantics only allow variables that might be local to be identified (and event that assumes no use of `assign` and `rm`).

Value

Character vector if `merge` is true; otherwise, a list with functions and variables components.

Author(s)

Luke Tierney

Examples

```
findGlobals(findGlobals)
findGlobals(findGlobals, merge = FALSE)
```

showTree *Print Lisp-Style Representation of R Expression*

Description

Prints a Lisp-style representation of R expression. This can be useful for understanding how some things are parsed.

Usage

```
showTree(e, write = cat)
```

Arguments

e	R expression.
write	function of one argument to write the result.

Author(s)

Luke Tierney

Examples

```
showTree(quote(-3))  
showTree(quote("x"<-1))  
showTree(quote("f"(x)))
```

Chapter 16

The foreign package

lookup.xport

Lookup Information on a SAS XPORT Format Library

Description

Scans a file as a SAS XPORT format library and returns a list containing information about the SAS library.

Usage

```
lookup.xport (file)
```

Arguments

`file` character variable with the name of the file to read. The file must be in SAS XPORT format.

Value

A list with one component for each dataset in the XPORT format library.

Author(s)

Saikat DebRoy

References

SAS Technical Support document TS-140: “The Record Layout of a Data Set in SAS Transport (XPORT) Format” available as <http://ftp.sas.com/techsup/download/technote/ts140.html>.

See Also

Examples

```
## Not run:  
lookup.xport("transport")  
## End(Not run)
```

read.arff *Read Data from ARFF Files*

Description

Reads data from Weka Attribute-Relation File Format (ARFF) files.

Usage

```
read.arff(file)
```

Arguments

file a character string with the name of the ARFF file to read from, or a [connection](#) which will be opened if necessary, and if so closed at the end of the function call.

Value

A data frame containing the data from the ARFF file.

References

Attribute-Relation File Format <http://www.cs.waikato.ac.nz/~ml/weka/arff.html>

See Also

[write.arff](#)

read.dbf *Read a DBF File*

Description

The function reads a DBF file into a data frame, converting character fields to factors, and trying to respect NULL fields.

Usage

```
read.dbf(file, as.is = FALSE)
```

Arguments

file name of input file
as.is should character vectors not be converted to factors?

Details

DBF is the extension used for files written for the 'XBASE' family of database languages, 'covering the dBase, Clipper, FoxPro, and their Windows equivalents Visual dBase, Visual Objects, and Visual FoxPro, plus some older products' (<http://www.clicketyclick.dk/databases/xbase/format/>). Most of these follow the file structure used by Ashton-Tate's dBase II, III or 4 (later owned by Borland).

`read.dbf` is based on C code from <http://shapelib.maptools.org/> which implements the 'XBASE' specification. It can convert fields of type "L" (logical), "N" and "F" (numeric and float) and "D" (dates): all other field types are read as-is as character vectors. A numeric field are read as an R integer vector if it is encoded to have no decimals, otherwise as a numeric vector. However, if the numbers are too large to fit into an integer vector, it is changed to numeric. Note that is possible to read integers that cannot be represented exactly even as doubles: this sometimes occurs if IDs are incorrectly coded as numeric.

Value

A data frame of data from the DBF file; note that the field names are adjusted to use in R using `make.names` (`unique=TRUE`).

There is an attribute "data_type" giving the single-character dBase types for each field.

Author(s)

Nicholas Lewin-Koh and Roger Bivand; shapelib by Frank Warmerdam

References

<http://shapelib.maptools.org/>.

```
x <- read.dbf(system.file("files/sids.dbf", package="foreign"))[1]
str(x)
summary(x)
```

read.dta

Read Stata Binary Files

Description

Reads a file in Stata version 5–10 binary format into a data frame.

Usage

```
read.dta(file, convert.dates = TRUE, convert.factors = TRUE,
         missing.type = FALSE,
         convert.underscore = FALSE, warn.missing.labels = TRUE)
```

Arguments

<code>file</code>	a filename as a character string.
<code>convert.dates</code>	Convert Stata dates to Date class?
<code>convert.factors</code>	Use Stata value labels to create factors? (version 6.0 or later).
<code>missing.type</code>	For version 8 or later, store information about different types of missing data?
<code>convert.underscore</code>	Convert "_" in Stata variable names to "." in R names?
<code>warn.missing.labels</code>	Warn if a variable is specified with value labels and those value labels are not present in the file.

Details

The variables in the Stata data set become the columns of the data frame. Missing values are correctly handled. The data label, variable labels, and timestamp are stored as attributes of the data frame. Nothing is done with variable characteristics.

By default Stata dates (`%d` and `%td` formats) are converted to R's `Date` class and variables with Stata value labels are converted to factors. Ordinarily, `read.dta` will not convert a variable to a factor unless a label is present for every level. Use `convert.factors = NA` to override this. In any case the value label and format information is stored as attributes on the returned data frame.

Stata 8.0 introduced a system of 27 different missing data values. If `missing.type` is `TRUE` a separate list is created with the same variable names as the loaded data. For string variables the list value is `NULL`. For other variables the value is `NA` where the observation is not missing and 0–26 when the observation is missing. This is attached as the "missing" attribute of the returned value.

Value

a data frame with attributes. These will include "datalabel", "time.stamp", "formats", "types", "val.labels", "var.labels" and "version" and may include "label.table". Possible versions are 5, 6, 7, -7 (Stata 7SE, 'format-111'), 8 (Stata 8 and 9, 'format-113') and 10 (Stata 10, 'format-114').

The value labels in attribute "val.labels" name a table for each variable, or are an empty string. The tables are elements of the named list attribute "label.table": each is an integer vector with names,

read.epiinfo *Read Epi Info Data Files*

Description

Reads data files in the .REC format used by Epi Info versions 6 and earlier and by EpiData. Epi Info is a public domain database and statistics package produced by the US Centers for Disease Control and EpiData is a freely available data entry and validation system.

Usage

```
read.epiinfo(file, read.deleted = FALSE, guess.broken.dates = FALSE,
             thisyear = NULL, lower.case.names = FALSE)
```

Arguments

`file` A filename, URL, or connection.

`read.deleted` Deleted records are read if TRUE, omitted if FALSE or replaced with NA if NA.

`guess.broken.dates` Attempt to convert dates with 0 or 2 digit year information (see Details below).

`thisyear` A 4-digit year to use for dates with no year. Defaults to the current year.

`lower.case.names` Convert variable names to lowercase?

Details

Epi Info allows dates to be specified with no year or with a 2 or 4 digits. Dates with four-digit years are always converted to Date class. With the `guess.broken.dates` option the function will attempt to convert two-digit years using the operating system's default method (see [Date](#)) and will use the current year or the `thisyear` argument for dates with no year information.

If `read.deleted` is TRUE the "deleted" attribute of the data frame indicates the deleted records.

Value

A data frame.

Note

Epi Info 2000, the current version, uses the Microsoft Access file format to store data. This may be readable with the RODBC or RDCOM packages.

read.mtp

Read a Minitab Portable Worksheet

Description

Return a list with the data stored in a file as a Minitab Portable Worksheet.

Usage

```
read.mtp(file)
```

Arguments

`file` character variable with the name of the file to read. The file must be in Minitab Portable Worksheet format.

Value

A list with one component for each column, matrix, or constant stored in the Minitab worksheet.

Author(s)

Douglas M. Bates

References

<http://www.minitab.com/>

Examples

```
## Not run:  
read.mtp("ex1-10.mtp")  
## End(Not run)
```

read.octave	<i>Read Octave Text Data Files</i>
-------------	------------------------------------

Description

Read a file in Octave text data format into a list.

Usage

```
read.octave(file)
```

Arguments

file a character string with the name of the file to read.

Details

This function is used to read in files in Octave text data format, as created by `save -ascii` in Octave. It knows about most of the common types of variables, including the standard atomic (real and complex scalars, matrices, and N -d arrays, strings, ranges, and boolean scalars and matrices) and recursive (structs, cells, and lists) ones, but has no guarantee to read all types. If a type is not recognized, a warning indicating the unknown type is issued, it is attempted to skip the unknown entry, and `NULL` is used as its value. Note that this will give incorrect results, and maybe even errors, in the case of unknown recursive data types.

As Octave can read MATLAB binary files, one can make the contents of such files available to R by using Octave's load and save (as text) facilities as an intermediary step.

Value

A list with one named component for each variable in the file.

Author(s)

Stephen Eglen (stephen@gnu.org) and Kurt Hornik

References

<http://www.octave.org/>

read.spss	<i>Read an SPSS Data File</i>
-----------	-------------------------------

Description

`read.spss` reads a file stored by the SPSS `save` or `export` commands.

Usage

```
read.spss(file, use.value.labels = TRUE, to.data.frame = FALSE,  
          max.value.labels = Inf, trim.factor.names = FALSE,  
          trim_values = TRUE, reencode = NA, use.missings = to.data.frame)
```

Arguments

<code>file</code>	Character string: the name of the file to read.
<code>use.value.labels</code>	Convert variables with value labels into R factors with those levels?
<code>to.data.frame</code>	return a data frame?
<code>max.value.labels</code>	Only variables with value labels and at most this many unique values will be converted to factors if <code>use.value.labels = TRUE</code> .
<code>trim.factor.names</code>	Logical: trim trailing spaces from factor levels?
<code>trim_values</code>	logical: should values and value labels have trailing spaces ignored when matching for <code>use.value.labels = TRUE</code> ?
<code>reencode</code>	logical: should character strings be re-encoded to the current locale. The default, <code>NA</code> , means to do so in a UTF-8 locale, only. Alternatively character, specifying an encoding to assume.
<code>use.missings</code>	logical: should information on user-defined missing values be used to set the corresponding values to <code>NA</code> ?

Details

This uses modified code from the PSPP project (<http://www.gnu.org/software/pspp/>) for reading the SPSS formats.

Occasionally in SPSS value labels will be added to some values of a continuous variable (eg to distinguish different types of missing data), and you will not want these variables converted to factors. By setting `max.val.labels` you can specify that variables with a large number of distinct values are not converted to factors even if they have value labels. In addition, variables will not be converted to factors if there are non-missing values that have no value label. The value labels are then returned in the `"value.labels"` attribute of the variable.

If SPSS variable labels are present, they are returned as the `"variable.labels"` attribute of the answer.

Fixed length strings (including value labels) are padded on the right with spaces by SPSS, and so are read that way by R. The default argument `trim_values=TRUE` causes trailing spaces to be ignored when matching to value labels, as examples have been seen where the strings and the value labels had different amounts of padding. See the examples for `sub` for ways to remove trailing spaces in character data.

Value

A list (or data frame) with one component for each variable in the saved data set.

If what looks like a Windows codepage was recorded in the SPSS file, it is attached (as a number) as attribute `"codepage"` to the result.

There may be attributes `"label.table"` and `"variable.labels"`. Attribute `"label.table"` is a named list of value labels with one element per variable, either `NULL` or a names character vector. Attribute `"variable.labels"` is a named character vector with names the short variable names and elements the long names.

If there are user-defined missing values, there will be a attribute `"Missings"`. This is a named list with one list element per variable. Each element has an element `type`, a length-one character vector giving the type of missingness, and may also have an element `value` with the values

corresponding to missingness. This is a complex subject (where the R and C source code for `read.spss` is the main documentation), but the simplest cases are types "one", "two" and "three" with a corresponding number of (real or string) values whose labels can be found from the "label.table" attribute. Other possibilities are a finite or semi-infinite range, possibly plus a single value. See also http://www.gnu.org/software/pspp/manual/html_node/Missing-Observations.html#Missing-Observations.

Note

If SPSS value labels are converted to factors the underlying numerical codes will not in general be the same as the SPSS numerical values, since the numerical codes in R are always 1,2,3,...

You may see warnings about the file encoding for SPSS `save` files: it is possible such files contain non-ASCII character data which need re-encoding. The most common occurrence is Windows codepage 1252, a superset of Latin-1. The encoding is recorded (as an integer) in attribute "codepage" of the result if it looks like a Windows codepage. Automatic re-encoding is done only in UTF-8 locales: see argument `reencode`.

Author(s)

Saikat DebRoy and the R Core team

Examples

```
## Not run:
read.spss("datafile")
## don't convert value labels to factor levels
read.spss("datafile", use.value.labels = FALSE)
## convert value labels to factors for variables with at most
## ten distinct values.
read.spss("datafile", max.val.labels = 10)
## End(Not run)
```

read.ssd

Obtain a Data Frame from a SAS Permanent Dataset, via read.xport

Description

Generates a SAS program to convert the `ssd` contents to SAS transport format and then uses `read.xport` to obtain a dataframe.

Usage

```
read.ssd(libname, sectionnames,
         tmpXport=tempfile(), tmpProgLoc=tempfile(), sascmd="sas")
```

Arguments

`libname` character string defining the SAS library (usually a directory reference)

`sectionnames` character vector giving member names. These are files in the `libname` directory. They will usually have a `.ssd0x` or `.sas7bdat` extension, which should be omitted.

tmpXport	character string: location where temporary xport format archive should reside – defaults to a randomly named file in the session temporary directory, which will be removed.
tmpProgLoc	character string: location where temporary conversion SAS program should reside – defaults to a randomly named file in session temporary directory, which will be removed on successful operation.
sascmd	character string giving full path to SAS executable.

Details

Creates a SAS program and runs it.

Error handling is primitive.

Value

A data frame if all goes well, or NULL with warnings and some enduring side effects (log file for auditing)

Note

This requires SAS to be available. If you have a SAS dataset without access to SAS you will need another product to convert it to a format such as `.csv`, for example ‘Stat/Transfer’ or ‘DBMS/Copy’ or the ‘SAS System Viewer’ (Windows only).

         sascmd = file.path(sashome, "sas.exe"))
## End(Not run)
```

read.systat *Obtain a Data Frame from a Systat File*

Description

read.systat reads a rectangular data file stored by the Systat `SAVE` command as (legacy) `*.sys` or more recently `*.syd` files.

Usage

```
read.systat(file, to.data.frame = TRUE)
```

Arguments

`file` character variable with the name of the file to read
`to.data.frame` return a data frame (otherwise a list)

Details

The function only reads those Systat files that are rectangular data files (`mtype = 1`), and warns when files have non-standard variable name codings. The files tested were produced on MS-DOS and Windows: files for the Mac version of Systat have a completely different format.

The C code was originally written for an add-on module for Systat described in Bivand (1992 paper). Variable names retain the trailing dollar in the list returned when `to.data.frame` is `FALSE`, and in that case character variables are returned as is and filled up to 12 characters with blanks on the right. The original function was limited to reading Systat files with up to 256 variables (a Systat limitation); it will now read up to 8192 variables.

If there is a user comment in the header this is returned as attribute `"comment"`. Such comments are always a multiple of 72 characters (with a maximum of 720 chars returned), normally padded with trailing spaces.

Value

A data frame (or list) with one component for each variable in the saved data set.

Author(s)

Roger Bivand

References

Examples

```
summary(iris)
iris.s <- read.systat(system.file("files/Iris.syd", package="foreign")[1])
str(iris.s)
summary(iris.s)
```

`read.xport`*Read a SAS XPORT Format Library*

Description

Reads a file as a SAS XPORT format library and returns a list of data.frames.

Usage

```
read.xport(file)
```

Arguments

`file` character variable with the name of the file to read. The file must be in SAS XPORT format.

Value

If there is a more than one dataset in the XPORT format library, a named list of data frames, otherwise a data frame. The columns of the data frames will be either numeric (corresponding to numeric in SAS) or factor (corresponding to character in SAS). All SAS numeric missing values (including special missing values represented by `._.`, `.A` to `.Z` by SAS) are mapped to R `NA`.

Trailing blanks are removed from character columns before conversion to a factor. Some sources claim that character missing values in SAS are represented by `' '` or `" "`: these are not treated as R missing values.

read.xport("transport")
## End(Not run)
```

S3 read functions *Read an S3 Binary or data.dump File*

Description

Reads binary data files or `data.dump` files that were produced in S version 3.

Usage

```
data.restore(file, print = FALSE, verbose = FALSE, env = .GlobalEnv)
read.S(file)
```

Arguments

<code>file</code>	the filename of the S-PLUS <code>data.dump</code> or binary file.
<code>print</code>	whether to print the name of each object as read from the file.
<code>verbose</code>	whether to print the name of every subitem within each object.
<code>env</code>	environment within which to create the restored object(s).

Details

`read.S` can read the binary files produced in some older versions of S-PLUS on either Windows (versions 3.x, 4.x, 2000) or Unix (version 3.x with 4 byte integers). It automatically detects whether the file was produced on a big- or little-endian machine and adapts itself accordingly.

`data.restore` can read a similar range of files produced by `data.dump` and for newer versions of S-PLUS, those from `data.dump(..., oldStyle=TRUE)`.

Not all S3 objects can be handled in the current version. The most frequently encountered exceptions are functions and expressions; you will also have trouble with objects that contain model formulas. In particular, comments will be lost from function bodies, and the argument lists of functions will often be changed.

Value

for `read.S`, an R version of the S3 object.

for `data.restore`, the name of the file.

Author(s)

Duncan Murdoch

Examples

```
## Not run:
read.S(file.path("_Data", "myobj"))
data.restore("dumpdata", print = TRUE)
## End(Not run)
```

write.arff	<i>Write Data into ARFF Files</i>
------------	-----------------------------------

Description

Writes data into Weka Attribute-Relation File Format (ARFF) files.

Usage

```
write.arff(x, file, eol = "\n")
```

Arguments

x	the data to be written, preferably a matrix or data frame. If not, coercion to a data frame is attempted.
file	either a character string naming a file, or a connection. "" indicates output to the standard output connection.
eol	the character(s) to print at the end of each line (row).

References

Attribute-Relation File Format <http://www.cs.waikato.ac.nz/~ml/weka/arff.html>

See Also

[read.arff](#)

Examples

```
write.arff(iris, file = "")
```

write.dbf	<i>Write a DBF File</i>
-----------	-------------------------

Description

The function tries to write a data frame to a DBF file.

Usage

```
write.dbf(dataframe, file, factor2char = TRUE, max_nchar = 254)
```

Arguments

dataframe	a data frame object.
file	a file name to be written to.
factor2char	logical, default TRUE, convert factor columns to character: otherwise they are written as the internal integer codes.
max_nchar	The maximum number of characters allowed in a character field. Strings which exceed this will be truncated with a warning. See Details.

Details

Dots in column names are replaced by underlines in the DBF file, and names are truncated to 11 characters.

Only vector columns of classes "logical", "numeric", "integer", "character", "factor" and "Date" can be written. Other columns should be converted to one of these.

Maximum precision (number of digits including minus sign and decimal sign) for numeric is 19 - scale (digits after the decimal sign) which is calculated internally based on the number of digits before the decimal sign.

The original DBASE format limited character fields to 254 bytes. It is said that Clipper and FoxPro can read up to 32K, and it is possible to write a reader that could accept up to 65535 bytes. (The documentation suggests that only ASCII characters can be assumed to be supported.) Readers expecting the older standard (which includes Excel 2003, Access 2003 and OpenOffice 2.0) will truncate the field to the maximum width modulo 256, so increase `max_nchar` only if you are sure the intended reader supports wider character fields.

Value

Invisible NULL.

Note

Other applications have varying abilities to read the data types used here. Microsoft Access reads "numeric", "integer", "character" and "Date" fields, including recognizing missing values, but not "logical" (read as 0, -1). Microsoft Excel understood all possible types but did not interpret missing values in character fields correctly (showing them as character nuls).

in2 <- read.dbf(try2)
str(in2)
unlink(c(try1, try2))
```

write.dta

*Write Files in Stata Binary Format***Description**

Writes the data frame to file in the Stata binary format. Does not write matrix variables.

Usage

```
write.dta(dataframe, file, version = 7L,
          convert.dates = TRUE, tz = "GMT",
          convert.factors = c("labels", "string", "numeric", "codes"))
```

Arguments

dataframe	a data frame.
file	character string giving filename.
version	integer: Stata version: 6, 7, 8 and 10 are supported, and 9 is mapped to 8.
convert.dates	Convert Date and POSIXt objects to Stata dates?
tz	timezone for date conversion
convert.factors	how to handle factors

Details

The major differences between Stata versions is that 7.0 and later allows 32-character variable names (5 and 6 were restricted to 8-character name). The `abbreviate` function is used to trim long variables to the permitted length. A warning is given if this is needed and it is an error for the abbreviated names not to be unique.

The columns in the data frame become variables in the Stata data set. Missing values are correctly handled. Optionally, R date/time objects (POSIXt classes) are converted into the Stata format. This loses information – Stata dates are in days since 1960-1-1. POSIXct objects can be written without conversion but will not be understood as dates by Stata; POSIXlt objects cannot be written without conversion.

There are four options for handling factors. The default is to use Stata value labels for the factor levels. With `convert.factors="string"`, the factor levels are written as strings. With `convert.factors="numeric"` the numeric values of the levels are written, or NA if they cannot be coerced to numeric. Finally, `convert.factors="codes"` writes the underlying integer codes of the factors. This last used to be the only available method and is provided largely for backwards compatibility.

For Stata 8 or later use the default `version=7` – the only advantage of Stata 8 format is that it can represent multiple different missing value types, and R doesn't have them. Stata 10 allows longer format lists, but R does not make use of them.

Note that the Stata formats are documented to be use ASCII strings – R does not enforce this, but use of non-ASCII character strings will not be portable as the encoding is not recorded.

Stata uses some large numerical values to represent missing values. This function does not currently check, and hence integers greater than 2147483620 and doubles greater than 8.988e+307 may be misinterpreted by Stata.

Value

NULL

Author(s)

Thomas Lumley

References

write.dta(swiss, swissfile <- tempfile())
read.dta(swissfile)
```

write.foreign *Write Text Files and Code to Read Them*

Description

This function exports simple data frames to other statistical packages by writing the data as free-format text and writing a separate file of instructions for the other package to read the data.

Usage

```
write.foreign(df, datafile, codefile,
              package = c("SPSS", "Stata", "SAS"), ...)
```

Arguments

df	A data frame
datafile	Name of file for data output
codefile	Name of file for code output
package	Name of package
...	Other arguments for the individual writeForeign functions

Details

The work for this function is done by `foreign::writeForeignStata`, `foreign::writeForeignSAS` and `foreign::writeForeignSPSS`. To add support for another package, eg `Systat`, create a function `writeForeignSystat` with the same first three arguments as `write.foreign`. This will be called from `write.foreign` when `package="Systat"`.

Numeric variables and factors are supported for all packages: dates and times (`Date`, `dates`, `date`, and `POSIXt` classes) are also supported for SAS and characters are supported for SPSS.

For `package="SAS"` there are optional arguments `dataname="rdata"` taking a string that will be the SAS data set name and `validvarname` taking either `"V6"` or `"V7"`.

Value

None

Author(s)

Thomas Lumley and Stephen Weigand

Examples

```
## Not run:
datafile<-tempfile()
codefile<-tempfile()
write.foreign(esoph,datafile,codefile,package="SPSS")
file.show(datafile)
file.show(codefile)
unlink(datafile)
unlink(codefile)
## End(Not run)
```

Chapter 17

The lattice package

`axis.default` *Default axis annotation utilities*

Description

Lattice functions provide control over how the plot axes are annotated through a common interface. There are two levels of control. The `xscale.components` and `yscale.components` arguments can be functions that determine tick mark locations and labels given a packet. For more direct control, the `axis` argument can be a function that actually draws the axes. The functions documented here are the defaults for these arguments. They can additionally be used as components of user written replacements.

Usage

```
xscale.components.default(lim,
                          packet.number = 0,
                          packet.list = NULL,
                          top = TRUE,
                          ...)
yscale.components.default(lim,
                          packet.number = 0,
                          packet.list = NULL,
                          right = TRUE,
                          ...)
axis.default(side = c("top", "bottom", "left", "right"),
            scales, components, as.table,
            labels = c("default", "yes", "no"),
            ticks = c("default", "yes", "no"),
            ...)
```

Arguments

`lim` the range of the data in that packet (data subset corresponding to a combination of levels of the conditioning variable). The range is not necessarily numeric; e.g. for factors, they could be character vectors representing levels, and for the

various date-time representations, they could be vectors of length 2 with the corresponding class.

<code>packet.number</code>	which packet (counted according to the packet order, described in <code>print.trellis</code>) is being processed. In cases where all panels have the same limits, this function is called only once (rather than once for each packet), in which case this argument will have the value 0.
<code>packet.list</code>	list, as long as the number of packets, giving all the actual packets. Specifically, each component is the list of arguments given to the panel function when and if that packet is drawn in a panel. (This has not yet been implemented.)
<code>top, right</code>	the value of the <code>top</code> and <code>right</code> components of the result, as appropriate. See below for interpretation.
<code>side</code>	on which side the axis is to be drawn. The usual partial matching rules apply.
<code>scales</code>	the appropriate component of the <code>scales</code> argument supplied to the high level function, suitably standardized.
<code>components</code>	list, similar to those produced by <code>xscale.components.default</code> and <code>yscale.components.default</code> .
<code>as.table</code>	the <code>as.table</code> argument in the high level function.
<code>labels</code>	whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.
<code>ticks</code>	whether labels are to be drawn. By default, the rules determined by <code>scales</code> are used.
<code>...</code>	many other arguments may be supplied, and are passed on to other internal functions.

Details

These functions are part of a new API introduced in lattice 0.14 to provide the user more control over how axis annotation is done. While the API has been designed in anticipation of use that was previously unsupported, the implementation has initially focused on reproducing existing capabilities, rather than test new features. At the time of writing, several features are unimplemented. If you require them, please contact the maintainer.

Value

`xscale.components.default` and `yscale.components.default` return a list of the form suitable as the `components` argument of `axis.default`. Valid components in the return value of `xscale.components.default` are:

`this-is-escaped-codenormal-bracket50bracket-normal`

A numeric limit for the box.

`this-is-escaped-codenormal-bracket53bracket-normal`

A list with two elements, `ticks` and `labels`. `ticks` must be a list with components `at` and `tck` which give the location and lengths of tick marks. `tck` can be a vector, and will be recycled to be as long as `at`. `labels` must be a list with components `at`, `labels`, and `check.overlap`. `at` and `labels` give the location and labels of the tick labels; this is usually the same as the location of the ticks, but is not required to be so. `check.overlap` is a logical flag indicating whether overlapping of labels should be avoided by omitting some of the labels while rendering.

```
this-is-escaped-codenormal-bracket70bracket-normal
```

This can be a logical flag; if TRUE, top is treated as being the same as bottom; if FALSE, axis annotation for the top axis is omitted. Alternatively, top can be a list like bottom.

Valid components in the return value of `yscale.components.default` are `left` and `right`. Their interpretations are analogous to (respectively) the `bottom` and `top` components described above.

```

 banking

Banking

Description

Calculates banking slope

Usage

```
banking(dx, dy)
```

Arguments

`dx`, `dy` vector of consecutive x, y differences.

Details

banking is the banking function used when `aspect = "xy"` in high level Trellis functions. It is usually not very meaningful except with `xyplot`. It considers the absolute slopes (based on `dx` and `dy`) and returns a value which when adjusted by the panel scale limits will make the median of the above absolute slopes correspond to a 45 degree line.

This function was inspired by the discussion of banking in the documentation for Trellis Graphics available at Bell Labs' website (see [Lattice](#)), but is most likely identical to an algorithm described by Cleveland et al (see below). It is not clear (to the author) whether this is the algorithm used in S-PLUS. Alternative banking rules, implemented as a similar function, can be used as a drop-in replacement by suitably modifying `lattice.options("banking")`.

```

barchart.table *table methods for barchart and dotplot*

Description

Contingency tables are often displayed using barcharts and dotplots. These methods are provided for convenience and operate directly on tables. Arrays and matrices are simply coerced to be a table.

Usage

```
## S3 method for class 'table':
barchart(x, data, groups = TRUE,
         origin = 0, stack = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array':
barchart(x, data, ...)

## S3 method for class 'matrix':
barchart(x, data, ...)
```

```
## S3 method for class 'table':
dotplot(x, data, groups = TRUE, ..., horizontal = TRUE)

## S3 method for class 'array':
dotplot(x, data, ...)

## S3 method for class 'matrix':
dotplot(x, data, ...)
```

Arguments

<code>x</code>	a table, array or matrix object.
<code>data</code>	should not be specified. If specified, will be ignored with a warning.
<code>groups</code>	logical, whether to use the last dimension as the grouping variable in the display.
<code>origin, stack</code>	arguments to <code>panel.barchart</code> controlling the display. The defaults for the table method are different.
<code>horizontal</code>	logical, indicating whether the plot should be horizontal (with the categorical variable on the y-axis) or vertical.
<code>...</code>	other arguments, passed to the underlying formula method.

Details

The first dimension is used as the variable on the vertical axis. The last dimension is optionally used as a grouping variable (to produce stacked barcharts by default). All other dimensions are used as conditioning variables. The order of these variables cannot be altered (except by permuting the original argument using `t` or `aperm`). For more flexibility, use the formula method after converting the table to a data frame using the relevant `as.data.frame` method.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

barley

Yield data from a Minnesota barley trial

Description

Total yield in bushels per acre for 10 varieties at 6 sites in each of two years.

Usage

barley

Format

A data frame with 120 observations on the following 4 variables.

yield Yield (averaged across three blocks) in bushels/acre.

variety Factor with levels "Svansota", "No. 462", "Manchuria", "No. 475", "Velvet", "Peatland", "Glabron", "No. 457", "Wisconsin No. 38", "Trebi".

year Factor with levels 1932, 1931

site Factor with 6 levels: "Grand Rapids", "Duluth", "University Farm", "Morris", "Crookston", "Waseca"

Details

These data are yields in bushels per acre, of 10 varieties of barley grown in 1/40 acre plots at University Farm, St. Paul, and at the five branch experiment stations located at Waseca, Morris, Crookston, Grand Rapids, and Duluth (all in Minnesota). The varieties were grown in three randomized blocks at each of the six stations during 1931 and 1932, different land being used each year of the test.

Immer et al. (1934) present the data for each Year*Site*Variety*Block. The data here is the average yield across the three blocks.

Immer et al. (1934) refer (once) to the experiment as being conducted in 1930 and 1931, then later refer to it (repeatedly) as being conducted in 1931 and 1932. Later authors have continued the confusion.

Cleveland (1993) suggests that the data for the Morris site may have had the years switched.

Author(s)

Documentation contributed by Kevin Wright.

        aspect=0.5, layout = c(1,6), ylab=NULL)
```

cloud

3d Scatter Plot and Wireframe Surface Plot

Description

Generic functions to draw 3d scatter plots and surfaces. The "formula" methods do most of the actual work.

Usage

```
cloud(x, data, ...)
wireframe(x, data, ...)

## S3 method for class 'formula':
cloud(x,
      data,
      allow.multiple = is.null(groups) || outer,
      outer = FALSE,
      auto.key = FALSE,
      aspect = c(1,1),
      panel.aspect = 1,
      panel = lattice.getOption("panel.cloud"),
      prepanel = NULL,
      scales = list(),
      strip = TRUE,
      groups = NULL,
      xlab,
      ylab,
      zlab,
      xlim = if (is.factor(x)) levels(x) else range(x, finite = TRUE),
      ylim = if (is.factor(y)) levels(y) else range(y, finite = TRUE),
      zlim = if (is.factor(z)) levels(z) else range(z, finite = TRUE),
      at,
      drape = FALSE,
      pretty = FALSE,
      drop.unused.levels,
      ...,
      lattice.options = NULL,
```

```

default.scales =
list(distance = c(1, 1, 1),
      arrows = TRUE,
      axs = axs.default),
colorkey,
col.regions,
alpha.regions,
cuts = 70,
subset = TRUE,
axs.default = "r")

## S3 method for class 'formula':
wireframe(x,
          data,
          panel = lattice.getOption("panel.wireframe"),
          ...)

## S3 method for class 'matrix':
cloud(x, data = NULL, type = "h",
      zlab = deparse(substitute(x)), aspect, ...,
      xlim, ylim, row.values, column.values)

## S3 method for class 'table':
cloud(x, data = NULL, groups = FALSE,
      zlab = deparse(substitute(x)),
      type = "h", ...)

## S3 method for class 'matrix':
wireframe(x, data = NULL,
          zlab = deparse(substitute(x)), aspect, ...,
          xlim, ylim, row.values, column.values)

```

Arguments

- x** The object on which method dispatch is carried out.
- For the "formula" methods, a formula of the form $z \sim x * y | g1 * g2 * \dots$, where z is a numeric response, and x, y are numeric values. $g1, g2, \dots$, if present, are conditioning variables used for conditioning, and must be either factors or shingles. In the case of `wireframe`, calculations are based on the assumption that the x and y values are evaluated on a rectangular grid defined by their unique values. The grid points need not be equally spaced.
- For `wireframe`, x, y and z may also be matrices (of the same dimension), in which case they are taken to represent a 3-D surface parametrized on a 2-D grid (e.g., a sphere). Conditioning is not possible with this feature. See details below.
- Missing values are allowed, either as NA values in the z vector, or missing rows in the data frame (note however that in that case the X and Y grids will be determined only by the available values). For a grouped display (producing multiple surfaces), missing rows are not allowed, but NA-s in z are.
- Both `wireframe` and `cloud` have methods for `matrix` objects, in which case x provides the z vector described above, while its rows and columns are interpreted as the x and y vectors respectively. This is similar to the form used

	in persp.
data	for the "formula" methods, an optional data frame in which variables in the formula (as well as <code>groups</code> and <code>subset</code> , if any) are to be evaluated. <code>data</code> should not be specified except when using the "formula" method.
row.values, column.values	Optional vectors of values that define the grid when <code>x</code> is a matrix. <code>row.values</code> and <code>column.values</code> must have the same lengths as <code>nrow(x)</code> and <code>ncol(x)</code> respectively. By default, row and column numbers.
allow.multiple, outer, auto.key, prepanel, strip, groups, xlab, xlim, ylab, ylim	These arguments are documented in the help page for <code>xyplot</code> . For the <code>cloud.table</code> method, <code>groups</code> must be a logical indicating whether the last dimension should be used as a grouping variable as opposed to a conditioning variable. This is only relevant if the table has more than 2 dimensions.
type	type of display in <code>cloud</code> (see <code>panel.3dscatter</code> for details). Defaults to "h" for the <code>matrix</code> method.
aspect, panel.aspect	unlike other high level functions, <code>aspect</code> is taken to be a numeric vector of length 2, giving the relative aspects of the y-size/x-size and z-size/x-size of the enclosing cube. The usual role of the <code>aspect</code> argument in determining the aspect ratio of the panel (see <code>xyplot</code> for details) is played by <code>panel.aspect</code> , except that it can only be a numeric value. For the <code>matrix</code> methods, the default y/x aspect is <code>ncol(x) / nrow(x)</code> and the z/x aspect is the smaller of the y/x aspect and 1.
panel	panel function used to create the display. See <code>panel.cloud</code> for (non-trivial) details.
scales	a list describing the scales. As with other high level functions (see <code>xyplot</code> for details), this list can contain parameters in name=value form. It can also contain components with the special names <code>x</code> , <code>y</code> and <code>z</code> , which can be similar lists with axis-specific values overriding the ones specified in <code>scales</code> . The most common use for this argument is to set <code>arrows=FALSE</code> , which causes tick marks and labels to be used instead of arrows being drawn (the default). Both can be suppressed by <code>draw=FALSE</code> . Another special component is <code>distance</code> , which specifies the relative distance of the axis label from the bounding box. If specified as a component of <code>scales</code> (as opposed to one of <code>scales\$z</code> etc), this can be (and is recycled if not) a vector of length 3, specifying distances for the x, y and z labels respectively. Other components that work in the <code>scales</code> argument of <code>xyplot</code> etc. should also work here (as long as they make sense), including explicit specification of tick mark locations and labels. (Not everything is implemented yet, but if you find something that should work but does not, feel free to bug the maintainer.) Note, however, that for these functions <code>scales</code> cannot contain information that is specific to particular panels. If you really need that, consider using the <code>scales.3d</code> argument of <code>panel.cloud</code> .
axs.default	Unlike 2-D display functions, <code>cloud</code> does not expand the bounding box to slightly beyond the range of the data, even though it should. This is primarily because this is the natural behaviour in <code>wireframe</code> , which uses the same code. <code>axs.default</code> is intended to provide a different default for <code>cloud</code> . However, this feature has not yet been implemented.
zlab	Specifies a label describing the z variable in ways similar to <code>xlab</code> and <code>ylab</code> (i.e. "grob", character string, expression or list) in other high level functions.

	Additionally, if <code>zlab</code> (and <code>xlab</code> and <code>ylab</code>) is a list, it can contain a component called <code>rot</code> , controlling the rotation for the label
<code>zlim</code>	limits for the z-axis. Similar to <code>xlim</code> and <code>ylim</code> in other high level functions
<code>drape</code>	logical, whether the wireframe is to be draped in color. If <code>TRUE</code> , the height of a facet is used to determine its color in a manner similar to the coloring scheme used in <code>levelplot</code> . Otherwise, the background color is used to color the facets. This argument is ignored if <code>shade = TRUE</code> (see <code>panel.3dwire</code>).
<code>at</code> , <code>col.regions</code> , <code>alpha.regions</code>	these arguments are analogous to those in <code>levelplot</code> . if <code>drape=TRUE</code> , <code>at</code> gives the vector of cutpoints where the colors change, and <code>col.regions</code> the vector of colors to be used in that case. <code>alpha.regions</code> determines the alpha-transparency on supporting devices. These are passed down to the panel function, and also used in the colorkey if appropriate. The default for <code>col.regions</code> and <code>alpha.regions</code> is derived from the Trellis setting "regions"
<code>cuts</code>	if <code>at</code> is unspecified, the approximate number of cutpoints if <code>drape=TRUE</code>
<code>pretty</code>	whether automatic choice of cutpoints should be prettified
<code>colorkey</code>	logical indicating whether a color key should be drawn alongside, or a list describing such a key. See <code>levelplot</code> for details.
<code>...</code>	Any number of other arguments can be specified, and are passed to the panel function. In particular, the arguments <code>distance</code> , <code>perspective</code> , <code>screen</code> and <code>R.mat</code> are very important in determining the 3-D display. The argument <code>shade</code> can be useful for <code>wireframe</code> calls, and controls shading of the rendered surface. These arguments are described in detail in the help page for <code>panel.cloud</code> . Additionally, an argument called <code>zoom</code> may be specified, which should be a numeric scalar to be interpreted as a scale factor by which the projection is magnified. This can be useful to get the variable names into the plot. This argument is actually only used by the default <code>prepanel</code> function.

Details

These functions produce three dimensional plots in each panel (as long as the default panel functions are used). The orientation is obtained as follows: the data are scaled to fall within a bounding box that is contained in the $[-0.5, 0.5]$ cube (even smaller for non-default values of `aspect`). The viewing direction is given by a sequence of rotations specified by the `screen` argument, starting from the positive Z-axis. The viewing point (camera) is located at a distance of $1/\text{distance}$ from the origin. If `perspective=FALSE`, `distance` is set to 0 (i.e., the viewing point is at an infinite distance).

`cloud` draws a 3-D Scatter Plot, while `wireframe` draws a 3-D surface (usually evaluated on a grid). Multiple surfaces can be drawn by `wireframe` using the `groups` argument (although this is of limited use because the display is incorrect when the surfaces intersect). Specifying `groups` with `cloud` results in a `panel.superpose`-like effect (via `panel.3dscatter`).

`wireframe` can optionally render the surface as being illuminated by a light source (no shadows though). Details can be found in the help page for `panel.3dwire`. Note that although arguments controlling these are actually arguments for the panel function, they can be supplied to `cloud` and `wireframe` directly.

For single panel plots, `wireframe` can also plot parametrized 3-D surfaces (i.e., functions of the form $f(u,v) = (x(u,v), y(u,v), z(u,v))$, where values of (u,v) lie on a rectangle. The simplest example of this sort of surface is a sphere parametrized by latitude and longitude. This can be achieved

by calling `wireframe` with a formula x of the form $z \sim x * y$, where x , y and z are all matrices of the same dimension, representing the values of $x(u,v)$, $y(u,v)$ and $z(u,v)$ evaluated on a discrete rectangular grid (the actual values of (u,v) are irrelevant).

When this feature is used, the heights used to calculate drupe colors or shading colors are no longer the z values, but the distances of (x, y, z) from the origin.

Note that this feature does not work with `groups`, `subscripts`, `subset`, etc. Conditioning variables are also not supported in this case.

The algorithm for identifying which edges of the bounding box are ‘behind’ the points doesn’t work in some extreme situations. Also, `panel.cloud` tries to figure out the optimal location of the arrows and axis labels automatically, but can fail on occasion (especially when the view is from ‘below’ the data). This can be manually controlled by the `scpos` argument in `panel.cloud`.

These and all other high level Trellis functions have several other arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Note

There is a known problem with grouped `wireframe` displays when the (x, y) coordinates represented in the data do not represent the full evaluation grid. The problem occurs whether the grouping is specified through the `groups` argument or through the formula interface, and currently causes memory access violations. Depending on the circumstances, this is manifested either as a meaningless plot or a crash. To work around the problem, it should be enough to have a row in the data frame for each grid point, with an NA response (z) in rows that were previously missing.

  ylab="Ozone (cube root ppb)")
})

```

ethanol

*Engine exhaust fumes from burning ethanol***Description**

Ethanol fuel was burned in a single-cylinder engine. For various settings of the engine compression and equivalence ratio, the emissions of nitrogen oxides were recorded.

Usage

ethanol

Format

A data frame with 88 observations on the following 3 variables.

NOx Concentration of nitrogen oxides (NO and NO₂) in micrograms/J.

C Compression ratio of the engine.

E Equivalence ratio—a measure of the richness of the air and ethanol fuel mixture.

Author(s)

Documentation contributed by Kevin Wright.

            ...,
            lattice.options = NULL,
            default.scales = list(),
            subscripts,
            subset)
## S3 method for class 'numeric':
densityplot(x, data = NULL, xlab, ...)

do.breaks(endpoints, nint)

```

Arguments

- x** The object on which method dispatch is carried out.
 For the `formula` method, a formula of the form `~ x | g1 * g2 * ...` indicates that histograms or Kernel Density estimates of `x` should be produced conditioned on the levels of the (optional) variables `g1`, `g2`, `...`. `x` can be numeric (or factor for histogram), and each of `g1`, `g2`, `...` must be either factors or shingles.
 As a special case, the right hand side of the formula can contain more than one variable separated by a `+` sign. What happens in this case is described in details in the documentation for `xyplot`. Note that in either form, all the variables involved in the formula have to have same length.
 For the `numeric` and `factor` methods, `x` replaces the `x` vector described above. Conditioning is not allowed in these cases.
- data** For the `formula` method, an optional data frame in which variables are to be

	evaluated. Ignored with a warning in other cases.
type	Character string indicating type of histogram to be drawn. "percent" and "count" give relative frequency and frequency histograms, and can be misleading when breakpoints are not equally spaced. "density" produces a density scale histogram. type defaults to "percent", except when the breakpoints are unequally spaced or breaks = NULL, when it defaults to "density".
nint	Number of bins. Applies only when breaks is unspecified or NULL in the call. Not applicable when the variable being plotted is a factor.
endpoints	vector of length 2 indicating the range of x-values that is to be covered by the histogram. This applies only when breaks is unspecified and the variable being plotted is not a factor. In do.breaks, this specifies the interval that is to be divided up.
breaks	usually a numeric vector of length (number of bins + 1) defining the breakpoints of the bins. Note that when breakpoints are not equally spaced, the only value of type that makes sense is density. When unspecified, the default is to use $\text{breaks} = \text{seq_len}(1 + \text{nlevels}(x)) - 0.5$ when x is a factor, and $\text{breaks} = \text{do.breaks}(\text{endpoints}, \text{nint})$ otherwise. Breakpoints calculated in such a manner are used in all panels. Other values of breaks are possible, in which case they affect the display in each panel differently. A special value of breaks is NULL, in which case the number of bins is determined by nint and then breakpoints are chosen according to the value of equal.widths. Other valid values of breaks are those of the breaks argument in hist. This allows specification of breaks as an integer giving the number of bins (similar to nint), as a character string denoting a method, and as a function.
equal.widths	logical, relevant only when breaks=NULL. If TRUE, equally spaced bins will be selected, otherwise, approximately equal area bins will be selected (this would mean that the breakpoints will not be equally spaced).
n	number of points at which density is to be evaluated
panel	The function that uses the packet (subset of display variables) corresponding to a panel to create a display. Default panel functions are documented separately, and often have arguments that can be used to customize its display in various ways. Such arguments can usually be directly supplied to the high level function.
allow.multiple, outer, auto.key, aspect, prepanel, scales, strip, groups, xlab,	See xyplot
weights	numeric vector of weights for the density calculations, evaluated in the non-standard manner used for groups and terms in the formula, if any. If this is specified, it is subsetted using subscripts inside the panel function to match it to the corresponding x values. At the time of writing, weights do not work in conjunction with an extended formula specification (this is not too hard to fix, so just bug the maintainer if you need this feature).
bw, adjust, kernel, window, width, give.Rkern, from, to, cut, na.rm	arguments to density , passed on as appropriate
...	Further arguments. See corresponding entry in xyplot for non-trivial details.

Details

`histogram` draws Conditional Histograms, while `densityplot` draws Conditional Kernel Density Plots. The density estimate in `densityplot` is actually calculated using the function `density`, and all arguments accepted by it can be passed (as `...`) in the call to `densityplot` to control the output. See documentation of `density` for details. (Note: The default value of the argument `n` of `density` is changed to 50.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

`do.breaks` is an utility function that calculates breakpoints given an interval and the number of pieces to break it into.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Note

The form of the arguments accepted by the default panel function `panel.histogram` is different from that in S-PLUS. Whereas S-PLUS calculates the heights inside `histogram` and passes only the breakpoints and the heights to the panel function, here the original variable `x` is passed along with the breakpoints. This allows plots as in the second example below.

            xlab = "Height (inches)", bw = 5)
```

interaction *Functions to Interact with Lattice Plots*

Description

The classic Trellis paradigm is to plot the whole object at once, without the possibility of interacting with it afterwards. However, by keeping track of the grid viewports where the panels and strips are drawn, it is possible to go back to them afterwards and enhance them one panel at a time. These functions provide convenient interfaces to help in this. Note that these are still experimental and the exact details may change in future.

Usage

```
panel.identify(x, y = NULL,
              subscripts = seq_along(x),
              labels = subscripts,
              n = length(x), offset = 0.5,
              threshold = 18, ## in points, roughly 0.25 inches
              panel.args = trellis.panelArgs(),
              ...)
panel.identify.qqmath(x, distribution, groups, subscripts, labels,
                    panel.args = trellis.panelArgs(),
                    ...)
panel.identify.cloud(x, y, z, subscripts,
                   perspective, distance,
                   xlim, ylim, zlim,
                   screen, R.mat, aspect, scales.3d,
                   ...,
                   panel.3d.identify,
                   n = length(subscripts),
                   offset = 0.5,
                   threshold = 18,
                   labels = subscripts,
                   panel.args = trellis.panelArgs())
panel.link.splom(threshold = 18, verbose = getOption("verbose"), ...)
panel.brush.splom(threshold = 18, verbose = getOption("verbose"), ...)

trellis.vpname(name = c("position", "split", "split.location", "toplevel",
                       "figure", "panel", "strip", "strip.left", "legend",
                       "main", "sub", "xlab", "ylab", "page"),
              column, row,
              side = c("left", "top", "right", "bottom", "inside"),
              clip.off = FALSE, prefix)
trellis.grobname(name, prefix)
trellis.focus(name, column, row, side, clip.off,
             highlight = interactive(), ...,
             guess = TRUE, verbose = getOption("verbose"))
trellis.switchFocus(name, side, clip.off, highlight, ...)
```

```
trellis.unfocus()
trellis.panelArgs(x, packet.number)
```

Arguments

- `x, y, z` variables defining the contents of the panel. In the case of `trellis.panelArgs`, a "trellis" object.
- `n` the number of points to identify by default (overridden by a right click)
- `subscripts` an optional vector of integer indices associated with each point. See details below.
- `labels` an optional vector of labels associated with each point. Defaults to `subscripts`
- `distribution, groups` typical panel arguments of `panel.qqmath`. These will usually be obtained from `panel.args`
- `offset` the labels are printed either below, above, to the left or to the right of the identified point, depending on the relative location of the mouse click. The `offset` specifies (in "char" units) how far from the identified point the labels should be printed.
- `threshold` threshold in grid's "points" units. Points further than these from the mouse click position are not considered
- `panel.args` list that contains components names `x` (and usually `y`), to be used if `x` is missing. Typically, when called after `trellis.focus`, this would appropriately be the arguments passed to that panel.
- `perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, scales.3d` arguments as passed to `panel.cloud`. These are required to recompute the relevant three-dimensional projections in `panel.identify.cloud`.
- `panel.3d.identify` the function that is responsible for the actual interaction once the data rescaling and rotation computations have been done. By default, an internal function similar to `panel.identify` is used.
- `name` character string indicating which viewport or grob we are looking for. Although these do not necessarily provide access to all viewports and grobs created by a lattice plot, they cover most that users might find interesting.
- `trellis.vpname` and `trellis.focus` deal with viewport names only, and only accept the values explicitly listed above. `trellis.grobname` is meant to create names for grobs, and can currently accept any value.
- If `name`, as well as `column` and `row` is missing in a call to `trellis.focus`, the user can click inside a panel (or an associated strip) to focus on that panel. Note however that this assumes equal width and height for each panel, and may not work when this is not true.
- When `name` is "panel", "strip", or "strip.left", `column` and `row` must also be specified. When `name` is "legend", `side` must also be specified.
- `column, row` integers, indicating position of the panel or strip that should be assigned focus in the Trellis layout. Rows are usually calculated from the bottom up, unless the plot was created with `as.table=TRUE`
- `guess` logical. If TRUE, and the display has only one panel, that panel will be automatically selected by a call to `trellis.focus`.

<code>side</code>	character string, relevant only for legends (i.e., when <code>name="legend"</code>), indicating their position. Partial specification is allowed, as long as it is unambiguous.
<code>clip.off</code>	logical, whether clipping should be off, relevant when <code>name</code> is "panel" or "strip". This is necessary if axes are to be drawn outside the panel or strip. Note that setting <code>clip.off=FALSE</code> does not necessarily mean that clipping is on; that is determined by conditions in effect during printing.
<code>prefix</code>	character string acting as a prefix, meant to distinguish otherwise equivalent viewports in different plots. This only becomes relevant when a particular page is occupied by more than one plot. Defaults to the value appropriate for the last "trellis" object printed, as determined by the <code>prefix</code> argument in <code>print.trellis</code> . Users should not usually need to supply a value for this argument (see note below), however, if supplied explicitly, this has to be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently " : ")
<code>highlight</code>	logical, whether the viewport being assigned focus should be highlighted. For <code>trellis.focus</code> , the default is <code>TRUE</code> in interactive mode, and <code>trellis.switchFocus</code> by default preserves the setting currently active.
<code>packet.number</code>	integer, which panel to get data from. See <code>packet.number</code> for details on how this is calculated
<code>verbose</code>	whether details will be printed
<code>...</code>	For <code>panel.identify.qqmath</code> , extra parameters are passed on to <code>panel.identify</code> . For <code>panel.identify</code> , extra arguments are treated as graphical parameters and are used for labelling. For <code>trellis.focus</code> and <code>trellis.switchFocus</code> , these are used (in combination with <code>lattice.options</code>) for highlighting the chosen viewport if so requested. Graphical parameters can be supplied for <code>panel.link.splom</code> .

Details

`panel.identify` is similar to `identify`. When called, it waits for the user to identify points (in the panel being drawn) via mouse clicks. Clicks other than left-clicks terminate the procedure. Although it is possible to call it as part of the panel function, it is more typical to use it to identify points after plotting the whole object, in which case a call to `trellis.focus` first is necessary.

`panel.link.splom` is meant for use with `splom`, and requires a panel to be chosen using `trellis.focus` before it is called. Clicking on a point causes that and the corresponding projections in other pairwise scatter plots to be highlighted. `panel.brush.splom` is a (misnamed) alias for `panel.link.splom`, retained for back-compatibility.

`panel.identify.qqmath` is a specialized wrapper meant for use with the display produced by `qqmath`. `panel.identify.cloud` is a specialized wrapper meant for use with the display produced by `cloud`. It would be unusual to call them except in a context where default panel function arguments are available through `trellis.panelArgs` (see below).

One way in which `panel.identify` etc. are different from `identify` is in how it uses the `subscripts` argument. In general, when one identifies points in a panel, one wants to identify the origin in the data frame used to produce the plot, and not within that particular panel. This information is available to the panel function, but only in certain situations. One way to ensure that `subscripts` is available is to specify `subscripts = TRUE` in the high level call such as `xyplot`. If `subscripts` is not explicitly specified in the call to `panel.identify`,

but is available in `panel.args`, then those values will be used. Otherwise, they default to `seq_along(x)`. In either case, the final return value will be the subscripts that were marked.

The process of printing (plotting) a Trellis object builds up a grid layout with named viewports which can then be accessed to modify the plot further. While full flexibility can only be obtained by using grid functions directly, a few lattice functions are available for the more common tasks.

`trellis.focus` can be used to move to a particular panel or strip, identified by its position in the array of panels. It can also be used to focus on the viewport corresponding to one of the labels or a legend, though such usage would be less useful. The exact viewport is determined by the name along with the other arguments, not all of which are relevant for all names. Note that when more than one object is plotted on a page, `trellis.focus` will always go to the plot that was created last. For more flexibility, use grid functions directly (see note below).

After a successful call to `trellis.focus`, the desired viewport (typically panel or strip area) will be made the 'current' viewport (plotting area), which can then be enhanced by calls to standard lattice panel functions as well as grid functions.

It is quite common to have the layout of panels chosen when a "trellis" object is drawn, and not before then. Information on the layout (specifically, how many rows and columns, and which packet belongs in which position in this layout) is retained for the last "trellis" object plotted, and is available through `trellis.currentLayout`.

`trellis.unfocus` unsets the focus, and makes the top level viewport the current viewport.

`trellis.switchFocus` is a convenience function to switch from one viewport to another, while preserving the current `row` and `column`. Although the rows and columns only make sense for panels and strips, they would be preserved even when the user switches to some other viewport (where row/column is irrelevant) and then switches back.

Once a panel or strip is in focus, `trellis.panelArgs` can be used to retrieve the arguments that were available to the panel function at that position. In this case, it can be called without arguments as

```
trellis.panelArgs()
```

This usage is also allowed when a "trellis" object is being printed, e.g. inside the panel functions or the axis function (but not inside the prepanel function). `trellis.panelArgs` can also retrieve the panel arguments from any "trellis" object. Note that for this usage, one needs to specify the `packet.number` (as described under the `panel` entry in [xyplot](#)) and not the position in the layout, because a layout determines the panel only **after** the object has been printed.

It is usually not necessary to call `trellis.vpname` and `trellis.grobname` directly. However, they can be useful in generating appropriate names in a portable way when using grid functions to interact with the plots directly, as described in the note below.

Value

`panel.identify` returns an integer vector containing the subscripts of the identified points (see details above). The equivalent of `identify` with `pos=TRUE` is not yet implemented, but can be considered for addition if requested.

`trellis.panelArgs` returns a named list of arguments that were available to the panel function for the chosen panel.

`trellis.vpname` and `trellis.grobname` return character strings.

`trellis.focus` has a meaningful return value only if it has been used to focus on a panel interactively, in which case the return value is a list with components `col` and `row` giving the column and row positions respectively of the chosen panel, unless the choice was cancelled (by a right click), in which case the return value is `NULL`. If click was outside a panel, both `col` and `row` are set to 0.

Note

The viewports created by lattice is accessible to the user only up to a certain extent, as described above. In particular, `trellis.focus` can only be used to manipulate the last plot drawn. For full flexibility, use appropriate functions from the grid package directly. For example, `current.vpTree` can be used to inspect the current viewport tree and `seekViewport` or `downViewport` can be used to navigate to these viewports. For such usage, `trellis.vpname` and `trellis.grobname` (with a non-default `prefix` argument) provides a portable way to access the appropriate viewports and grobs by name.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org). Felix Andrews provided initial implementations of `panel.identify.qqmath` and support for focusing on panels interactively.

Description

Implementation of Trellis Graphics in R

Details

Trellis Graphics is a framework for data visualization developed at the Bell Labs by Rick Becker, Bill Cleveland et al, extending ideas presented in Bill Cleveland's 1993 book *Visualizing Data*.

Lattice is best thought of as an implementation of Trellis Graphics for R. It is built upon the Grid graphics engine and requires the `grid` add-on package. It is not (readily) compatible with traditional R graphics tools. The public interface is based on the implementation in S-PLUS, but features several extensions, in addition to incompatibilities introduced through the use of `grid`. To the extent possible, care has been taken to ensure that existing Trellis code written for S-PLUS works unchanged (or with minimal change) in Lattice. If you are having problems porting S-PLUS code, read the entry for `panel` in the documentation for `xyplot`. Most high level Trellis functions in S-PLUS are implemented, with the exception of `piechart`.

Type `help(package = lattice)` to see a list of (public) Lattice graphics functions for which further documentation is available. The ‘See Also’ section below has list of specific areas of possible interest and pointers to the help pages with respective details. Apart from the documentation accompanying this package, several documents outlining the use of Trellis graphics are available from Bell Lab’s website; these might provide a holistic introduction to the Trellis paradigm. A book on lattice is also available as part of Springer’s ‘Use R’ series.

The example section below shows how to bring up a brief history of changes to the lattice package, which provides a summary of new features.

Note

High level Lattice functions (like `xyplot`) are different from conventional R graphics functions because they don’t actually draw anything. Instead, they return an object of class "trellis" which has to be then `printed` or `plotted` to create the actual plot. This is normally done automatically, but not when the high level functions are called inside another function (most often `source`) or other contexts where automatic printing is suppressed (e.g. `for` or `while` loops). In such situations, an explicit call to `print` or `plot` is required.

Lattice plots are highly customizable via user-modifiable settings. However, these are completely unrelated to base graphics settings; in particular, changing `par()` settings usually have no effect on lattice plots.

See Also

The Lattice user interface primarily consists of several ‘high level’ generic functions (listed below), each designed to create a particular type of statistical display by default. While each function does different things, they share several common features, reflected in several common arguments that affect the resulting displays in similar ways. These arguments are extensively (sometimes only) documented in the help page for `xyplot`. This includes a discussion of *conditioning* and control of the Trellis layout.

Lattice employs an extensive system of user-controllable parameters to determine the look and feel of the displays it produces. To learn how to use and customise the Graphical parameters used by the Lattice functions, see `trellis.par.set`. For other settings, see `lattice.options`. The default graphical settings are different for different graphical devices. To learn how to initialise new devices with the desired settings or change the settings of the current device, see `trellis.device`.

To learn about sophisticated (non-default) printing capabilities, see `print.trellis`. See `update.trellis` to learn about manipulating a "trellis" object. Tools to augment

lattice plots after they are drawn (including `locator`-like functionality) is described in the `trellis.focus` help page.

The following is a list of ‘high level’ functions in the Lattice package with a brief description of what they do. In all cases, the actual display is produced by the so-called `panel` function, which has a suitable default, but can be substituted by an user defined function to create custom displays. The user will most often be interested in the default panel functions, which have a separate help page, linked to from the help pages of the corresponding high level function. Although documented separately, arguments to these panel functions can be supplied directly to the high level functions, which will forward the arguments as appropriate.

Univariate:

`barchart` bar plots

`bwplot` box and whisker plots

`densityplot` kernel density plots

`dotplot` dot plots

`histogram` histograms

`qqmath` quantile plots against mathematical distributions

`stripplot` 1-dimensional scatterplot

Bivariate:

`qq` q-q plot for comparing two distributions

`xypplot` scatter plot (and possibly a lot more)

Trivariate:

`levelplot` level plots (similar to image plots in R)

`contourplot` contour plots

`cloud` 3-D scatter plots

`wireframe` 3-D surfaces (similar to persp plots in R)

Hypervariate:

`splom` scatterplot matrix

`parallel` parallel coordinate plots

Miscellaneous:

`rfs` residual and fitted value plot (also see `oneway`)

`tmd` Tukey Mean-Difference plot

Additionally, there are several panel functions that do little by themselves, but can be useful components of custom panel functions. These are documented in `panel.functions`. Lattice also has a collection of convenience functions that correspond to the base graphics primitives `lines`, `points`, etc. They are implemented using Grid graphics, but try to be as close to the base versions as possible in terms of their argument list. These functions have imaginative names like `llines` or `panel.lines` and are often useful when writing (or porting from S-PLUS code) nontrivial panel functions.

Examples

```
## Not run:
RShowDoc("NEWS", package = "lattice")
## End(Not run)
```

lattice.options *Low-level Options Controlling Behaviour of Lattice*

Description

Functions to handle settings used by lattice. Their main purpose is to make code maintenance easier, and users normally should not need to use these functions. However, fine control at this level maybe useful in certain cases.

Usage

```
lattice.options(...)  
lattice.getOption(name)
```

Arguments

name	character giving the name of a setting
...	new options can be defined, or existing ones modified, using one or more arguments of the form <code>name = value</code> or by passing a list of such tagged values. Existing values can be retrieved by supplying the names (as character strings) of the components as unnamed arguments.

Details

These functions are modeled on `options` and `getOption`, and behave similarly for the most part. The components currently used are not documented here, but are fairly self-explanatory.

Value

`lattice.getOption` returns the value of a single component, whereas `lattice.options` always returns a list with one or more named components. When changing the values of components, the old values of the modified components are returned by `lattice.options`. If called without any arguments, the full list is returned.

[options](#), [trellis.device](#), [trellis.par.get](#), [Lattice](#)

Examples

```
str(lattice.options())  
lattice.getOption("save.object")
```

latticeParseFormula

Parse Trellis formula

Description

this function is used by high level Lattice functions like `xyplot` to parse the formula argument and evaluate various components of the data.

Usage

```
latticeParseFormula(model, data, dimension = 2,
                    subset = TRUE, groups = NULL,
                    multiple, outer,
                    subscripts,
                    drop)
```

Arguments

model	the model/formula to be parsed. This can be in either of two possible forms, one for 2d and one for 3d formulas, determined by the <code>dimension</code> argument. The 2d formulas are of the form $y \sim x g_1 * \dots * g_n$, and the 3d formulas are of the form $z \sim x * y g_1 * \dots * g_n$. In the first form, y may be omitted. The conditioning variables g_1, \dots, g_n can be omitted in either case.
data	the environment/dataset where the variables in the formula are evaluated.
dimension	dimension of the model, see above
subset	index for choosing a subset of the data frame
groups	the grouping variable, if present
multiple, outer	logicals, determining how a '+' in the y and x components of the formula are processed. See <code>xyplot</code> for details
subscripts	logical, whether subscripts are to be calculated
drop	logical or list, similar to the <code>drop.unused.levels</code> argument in <code>xyplot</code> , indicating whether unused levels of conditioning factors and data variables that are factors are to be dropped.

Value

returns a list with several components, including `left`, `right`, `left.name`, `right.name`, `condition` for 2-D, and `left`, `right.x`, `right.y`, `left.name`, `right.x.name`, `right.y.name`, `condition` for 3-D. Other possible components are `groups`, `subscr`

            labels = TRUE,
            contour = TRUE,
            pretty = TRUE,
```

```

        region = FALSE,
        ...)

## S3 method for class 'table':
levelplot(x, data = NULL, aspect = "iso", ...,
          xlim, ylim, row.values, column.values)

## S3 method for class 'table':
contourplot(x, data = NULL, aspect = "iso", ...,
            xlim, ylim, row.values, column.values)

## S3 method for class 'matrix':
levelplot(x, data = NULL, xlab, ylab, ...)

## S3 method for class 'matrix':
contourplot(x, data = NULL, xlab, ylab, ...)

## S3 method for class 'array':
levelplot(x, data = NULL, ...)

## S3 method for class 'array':
contourplot(x, data = NULL, ...)

```

Arguments

<code>x</code>	<p>for the formula method, a formula of the form $z \sim x * y \mid g1 * g2 * \dots$, where z is a numeric response, and x, y are numeric values evaluated on a rectangular grid. $g1, g2, \dots$ are optional conditional variables, and must be either factors or shingles if present.</p> <p>Calculations are based on the assumption that all x and y values are evaluated on a grid (defined by their unique values). The function will not return an error if this is not true, but the display might not be meaningful. However, the x and y values need not be equally spaced.</p> <p>Both <code>levelplot</code> and <code>wireframe</code> have methods for <code>matrix</code>, <code>array</code>, and <code>table</code> objects, in which case x provides the z vector described above, while its rows and columns are interpreted as the x and y vectors respectively. This is similar to the form used in <code>filled.contour</code> and <code>image</code>. For higher-dimensional arrays and tables, further dimensions are used as conditioning variables. Note that the dimnames may be duplicated; this is handled by calling <code>make.unique</code> to make the names unique (although the original labels are used for the x- and y-axes).</p>
<code>data</code>	For the formula methods, an optional data frame in which variables in the formula (as well as <code>groups</code> and <code>subset</code> , if any) are to be evaluated. Usually ignored with a warning in other cases.
<code>row.values, column.values</code>	Optional vectors of values that define the grid when x is a matrix. <code>row.values</code> and <code>column.values</code> must have the same lengths as <code>nrow(x)</code> and <code>ncol(x)</code> respectively. By default, row and column numbers.
<code>panel</code>	panel function used to create the display, as described in xyplot
<code>aspect</code>	For the matrix methods, the default aspect ratio is chosen to make each cell square. The usual default is <code>aspect="fill"</code> , as described in xyplot .

at	numeric vector giving breaks along the range of z. Contours (if any) will be drawn at these heights, and the regions in between would be colored using <code>col.regions</code> .
<code>col.regions</code>	color vector to be used if <code>regions</code> is TRUE. The general idea is that this should be a color vector of moderately large length (longer than the number of regions. By default this is 100). It is expected that this vector would be gradually varying in color (so that nearby colors would be similar). When the colors are actually chosen, they are chosen to be equally spaced along this vector. When there are more regions than <code>col.regions</code> , the colors are recycled.
<code>alpha.regions</code>	numeric, specifying alpha transparency (works only on some devices)
colorkey	logical specifying whether a color key is to be drawn alongside the plot, or a list describing the color key. The list may contain the following components: space: location of the colorkey, can be one of "left", "right", "top" and "bottom". Defaults to "right". x, y: location, currently unused col: vector of colors at: numeric vector specifying where the colors change. must be of length 1 more than the col vector. labels: a character vector for labelling the at values, or more commonly, a list describing characteristics of the labels. This list may include components <code>labels</code> , <code>at</code> , <code>cex</code> , <code>col</code> , <code>rot</code> , <code>font</code> , <code>fontface</code> and <code>fontfamily</code> . tick.number: approximate number of ticks. corner: interacts with x, y; unimplemented width: width of the key height: length of key w.r.t side of plot.
contour	logical, whether to draw contour lines.
cuts	number of levels the range of z would be divided into
labels	typically a logical indicating whether contour lines should be labelled, but other possibilities for more sophisticated control exists. Details are documented in the help page for panel.levelplot , to which this argument is passed on unchanged. That help page also documents the <code>label.style</code> argument, which affects how the labels are rendered.
pretty	logical, whether to use pretty cut locations and labels
region	logical, whether regions between contour lines should be filled
<code>allow.multiple</code> , <code>outer</code> , <code>prepanel</code> , <code>scales</code> , <code>strip</code> , <code>groups</code> , <code>xlab</code> , <code>xlim</code> , <code>ylab</code> , <code>ylim</code> ,	these arguments are described in the help page for xyplot .
...	other arguments. Some are processed by <code>levelplot</code> or <code>contourplot</code> , and those unrecognized are passed on to the panel function.

Details

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Other useful arguments are mentioned in the help page for the default panel function [panel.levelplot](#) (these are formally arguments to the panel function, but can be specified in the high level calls directly).

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

 l`lines`
Replacements of traditional graphics functions

Description

These functions are intended to replace common low level traditional graphics functions, primarily for use in panel functions. The originals can not be used (at least not easily) because lattice panel functions need to use grid graphics. Low level drawing functions in grid can be used directly as well, and is often more flexible. These functions are provided for convenience and portability.

Usage

```

lplot.xy(xy, type, pch, lty, col, cex, lwd,
         font, fontfamily, fontface,
         col.line, col.symbol, alpha, fill,
         origin = 0, ...)

llines(x, ...)
lpoints(x, ...)
ltext(x, ...)

## Default S3 method:
llines(x, y = NULL, type = "l",
       col, alpha, lty, lwd, ...)
## Default S3 method:
lpoints(x, y = NULL, type = "p", col, pch, alpha, fill,
        font, fontfamily, fontface, cex, ...)
## Default S3 method:
ltext(x, y = NULL, labels = seq_along(x),
      col, alpha, cex, srt = 0,
      lineheight, font, fontfamily, fontface,
      adj = c(0.5, 0.5), pos = NULL, offset = 0.5, ...)

lsegments(x0, y0, x1, y1, x2, y2,
          col, alpha, lty, lwd, ...)
lrect(xleft, ybottom, xright, ytop,
      x = (xleft + xright) / 2,
      y = (ybottom + ytop) / 2,
      width = xright - xleft,
      height = ytop - ybottom,
      col = "transparent",
      border = "black",
      lty = 1, lwd = 1, alpha = 1,
      just = "center",
      hjust = NULL, vjust = NULL,
      ...)
larrows(x0 = NULL, y0 = NULL, x1, y1, x2 = NULL, y2 = NULL,
        angle = 30, code = 2, length = 0.25, unit = "inches",
        ends = switch(code, "first", "last", "both"),
        type = "open",
        col = add.line$col,

```

```

        alpha = add.line$alpha,
        lty = add.line$lty,
        lwd = add.line$lwd,
        fill = NULL, ...)
lpolygon(x, y = NULL,
         border = "black", col = "transparent",
         font, fontface, ...)

panel.lines(...)
panel.points(...)
panel.segments(...)
panel.text(...)
panel.rect(...)
panel.arrows(...)
panel.polygon(...)

```

Arguments

`x`, `y`, `x0`, `y0`, `x1`, `y1`, `x2`, `y2`, `xy`
 locations. `x2` and `y2` are available for for S compatibility.

`length`, `unit` determines extent of arrow head. `length` specifies the length in terms of `unit`, which can be any valid grid unit as long as it doesn't need a data argument. `unit` defaults to inches, which is the only option in the base version of the function, [arrows](#).

`angle`, `code`, `type`, `labels`, `srt`, `adj`, `pos`, `offset`
 arguments controlling behaviour. See respective base functions for details. For `larrows` and `panel.larrows`, `type` is either "open" or "closed", indicating the type of arrowhead.

`ends` serves the same function as `code`, using descriptive names rather than integer codes. If specified, this overrides `code`

`col`, `alpha`, `lty`, `lwd`, `fill`, `pch`, `cex`, `lineheight`, `font`, `fontfamily`, `fontface`, `co`
 graphical parameters. `fill` applies to points when `pch` is in 21:25 and specifies the fill color, similar to the `bg` argument in the base graphics function [points](#). For devices that support alpha-transparency, a numeric argument `alpha` between 0 and 1 can controls transparency. Be careful with this, since for devices that do not support alpha-transparency, nothing will be drawn at all if this is set to anything other than 0. `font` and `fontface` are included in `lpolygon` only to ensure that they are not passed down (as [gpar](#) doesn't like them).

`origin` for `type="h"` or `type="H"`, the value to which lines drop down.

`xleft`, `ybottom`, `xright`, `yttop`
 see [rect](#)

`width`, `height`, `just`, `hjust`, `vjust`
 finer control over rectangles, see [grid.rect](#)

... extra arguments, passed on to lower level functions as appropriate.

Details

These functions are meant to be grid replacements of the corresponding base R graphics functions, to allow existing Trellis code to be used with minimal modification. The functions `panel.*` are essentially identical to the `l*` versions, are recommended for use in new code (as opposed to ported code) as they have more readable names.

See the documentation of the base functions for usage. Not all arguments are always supported. All these correspond to the default methods only.

Note

There is a new `type="H"` option wherever appropriate, which is similar to `type="h"`, but with horizontal lines.

`lset`*Interface to modify Trellis Settings - Deprecated*

Description

A (hopefully) simpler alternative to `trellis.par.get/set`. This is deprecated, and the same functionality is now available with `trellis.par.set`

Usage

```
lset(theme = col.whitebg())
```

Arguments

`theme` a list describing how to change the settings of the current active device. Valid components are those in the list returned by `trellis.par.get()`. Each component must itself be a list, with one or more of the appropriate components (need not have all components). Changes are made to the settings for the currently active device only.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

`make.groups`*Grouped data from multiple vectors*

Description

Combines two or more vectors, possibly of different lengths, producing a data frame with a second column indicating which of these vectors that row came from. This is mostly useful for getting data into a form suitable for use in high level Lattice functions.

Usage

```
make.groups(...)
```

Arguments

... one or more vectors of the same type (coercion is attempted if not), or one or more data frames with similar columns, with possibly differing number of rows.

Value

When all the input arguments are vectors, a data frame with two columns

```
this-is-escaped-codenormal-bracket9bracket-normal  
all the vectors supplied, concatenated
```

```
this-is-escaped-codenormal-bracket12bracket-normal  
factor indicating which vector the corresponding data value came from
```

When all the input arguments are data frames, the result of `rbind` applied to them, along with an additional `which` column as described above.

  make.groups(uniform = runif(200),  
             exponential = rexp(175),  
             lognormal = rlnorm(150),  
             normal = rnorm(125))  
qqmath(~ data | which, sim.dat, scales = list(y = "free"))
```

`melanoma`*Melanoma skin cancer incidence*

Description

These data from the Connecticut Tumor Registry present age-adjusted numbers of melanoma skin-cancer incidences per 100,000 people in Connecticut for the years from 1936 to 1972.

Usage

```
melanoma
```

Format

A data frame with 37 observations on the following 2 variables.

year Years 1936 to 1972.

incidence Rate of melanoma cancer per 100,000 population.

Note

This dataset is not related to the `melanoma` dataset in the `boot` package with the same name.

The S-PLUS 6.2 help for the melanoma data says that the incidence rate is per *million*, but this is not consistent with data found at the National Cancer Institute (<http://www.nci.nih.gov>).

Author(s)

Documentation contributed by Kevin Wright.

Examples

```
# Time-series plot. Figure 3.64 from Cleveland.
xyplot(incidence ~ year,
  data = melanoma,
  aspect = "xy",
  panel = function(x, y)
    panel.xyplot(x, y, type="o", pch = 16),
  ylim = c(0, 6),
  xlab = "Year",
  ylab = "Incidence")
```

oneway	<i>Fit One-way Model</i>
--------	--------------------------

Description

Fits a One-way model to univariate data grouped by a factor, the result often being displayed using `rfs`

Usage

```
oneway(formula, data, location=mean, spread=function(x) sqrt(var(x)))
```

Arguments

<code>formula</code>	formula of the form $y \sim x$ where y is the numeric response and x is the grouping factor
<code>data</code>	data frame in which the model is to be evaluated
<code>location</code>	function or numeric giving the location statistic to be used for centering the observations, e.g. <code>median</code> , 0 (to avoid centering).
<code>spread</code>	function or numeric giving the spread statistic to be used for scaling the observations, e.g. <code>sd</code> , 1 (to avoid scaling).

Value

A list with components

<code>location</code>	vector of locations for each group.
<code>spread</code>	vector of spreads for each group.
<code>fitted.values</code>	vector of locations for each observation.
<code>residuals</code>	residuals ($y - \text{fitted.values}$).
<code>scaled.residuals</code>	residuals scaled by spread for their group

`packet.panel.default`*Associating Packets with Panels*

Description

When a "trellis" object is plotted, panels are always drawn in an order such that columns vary the fastest, then rows and then pages. An optional function can be specified that determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. The function documented here implements the default behaviour, which is to match panel order with packet order, determined by varying the first conditioning variable the fastest, then the second, and so on. This matching is performed after any reordering and/or permutation of the conditioning variables.

Usage

```
packet.panel.default(layout, condlevels, page, row, column,  
                    skip, all.pages.skip = TRUE)
```

Arguments

<code>layout</code>	the <code>layout</code> argument in high level functions, suitably standardized.
<code>condlevels</code>	a list of levels of conditioning variables, after relevant permutations and/or re-ordering of levels
<code>page, row, column</code>	the location of the panel in the coordinate system of pages, rows and columns.
<code>skip</code>	the <code>skip</code> argument in high level functions
<code>all.pages.skip</code>	whether <code>skip</code> should be replicated over all pages. If <code>FALSE</code> , <code>skip</code> will be replicated to be only as long as the number of positions on a page, and that template will be used for all pages.

Value

A suitable combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable. Specifically, if the return value is `p`, then the `i`-th conditioning variable will have level `condlevels[[i]][p[i]]`.

Examples

```

packet.panel.page <- function(n)
{
  ## returns a function that when used as the 'packet.panel'
  ## argument in print.trellis plots page number 'n' only
  function(layout, page, ...) {
    stopifnot(layout[3] == 1)
    packet.panel.default(layout = layout, page = n, ...)
  }
}

data(mtcars)
HP <- equal.count(mtcars$hp, 6)
p <-
  xyplot(mpg ~ disp | HP * factor(cyl),
         mtcars, layout = c(0, 6, 1))

print(p, packet.panel = packet.panel.page(1))
print(p, packet.panel = packet.panel.page(2))

```

panel.axis

Panel Function for Drawing Axis Ticks and Labels

Description

panel.axis is the function used by lattice to draw axes. It is typically not used by users, except those wishing to create advanced annotation. Keep in mind issues of clipping when trying to use it as part of the panel function. current.panel.limits can be used to retrieve a panel's x and y limits.

Usage

```

panel.axis(side = c("bottom", "left", "top", "right"),
          at,
          labels = TRUE,
          draw.labels = TRUE,
          check.overlap = FALSE,
          outside = FALSE,
          ticks = TRUE,
          half = !outside,
          which.half,
          tck = as.numeric(ticks),
          rot = if (is.logical(labels)) 0 else c(90, 0),
          text.col, text.alpha, text.cex, text.font,
          text.fontfamily, text.fontface,
          line.col, line.lty, line.lwd, line.alpha)

current.panel.limits(unit = "native")

```

Arguments

<code>side</code>	character string indicating which side axes are to be drawn on. Partial specification is allowed.
<code>at</code>	location of labels
<code>labels</code>	the labels to go along with <code>at</code> . The labels can be a character vector or a vector of expressions. Alternatively, this can be a logical. If TRUE, the labels are derived from <code>at</code> , otherwise, labels are empty.
<code>draw.labels</code>	logical indicating whether labels are to be drawn
<code>check.overlap</code>	logical, whether to check for overlapping of labels. This also has the effect of removing <code>at</code> values that are ‘too close’ to the limits.
<code>outside</code>	logical, whether to the labels draw outside the panel or inside. Note that <code>outside=TRUE</code> will only have a visible effect if clipping is disabled for the viewport (<code>panel</code>).
<code>ticks</code>	logical, whether to draw the tickmarks
<code>half</code>	logical, whether only half of scales will be drawn for each side
<code>which.half</code>	character string, one of "lower" and "upper". Indicates which half is to be used for tick locations if <code>half=TRUE</code> . Defaults to whatever is suitable for splom
<code>tck</code>	numeric scalar, multiplier for tick length. Can be negative.
<code>rot</code>	rotation angles for labels in degrees. Can be a vector of length 2 for x- and y-axes respectively
<code>text.col</code> , <code>text.alpha</code> , <code>text.cex</code> , <code>text.font</code> , <code>text.fontfamily</code> , <code>text.fontface</code> , <code>line.</code>	graphical parameters
<code>unit</code>	which grid unit the values should be in

Details

`panel.axis` can draw axis tick marks inside or outside a panel (more precisely, a grid viewport). It honours the (native) axis scales. Used in [panel.pairs](#) for [splom](#), as well as for all the usual axis drawing by the print method for "trellis" objects. It can also be used to enhance plots ‘after the fact’ by adding axes.

Value

`current.panel.limits` returns a list with components `xlim` and `ylim`, which are both numeric vectors of length 2, giving the scales of the current panel (viewport). The values correspond to the unit system specified by `unit`, by default "native".

panel.barchart *Default Panel Function for barchart*

Description

Default panel function for barchart.

Usage

```
panel.barchart(x, y, box.ratio = 1, box.width,
              horizontal = TRUE,
              origin = NULL, reference = TRUE,
              stack = FALSE,
              groups = NULL,
              col = if (is.null(groups)) plot.polygon$col
                    else superpose.polygon$col,
              border = if (is.null(groups)) plot.polygon$border
                    else superpose.polygon$border,
              lty = if (is.null(groups)) plot.polygon$lty
                    else superpose.polygon$lty,
              lwd = if (is.null(groups)) plot.polygon$lwd
                    else superpose.polygon$lwd,
              ...)
```

Arguments

x	Extent of Bars. By default, bars start at left of panel, unless <code>origin</code> is specified, in which case they start there
y	Horizontal location of bars, possibly factor
box.ratio	ratio of bar width to inter-bar space
box.width	thickness of bars in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.
horizontal	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.
origin	the origin for the bars. For grouped displays with <code>stack = TRUE</code> , this argument is ignored and the origin set to 0. Otherwise, defaults to <code>NULL</code> , in which case bars start at the left (or bottom) end of a panel. This choice is somewhat unfortunate, as it can be misleading, but is the default for historical reasons. For tabular (or similar) data, <code>origin = 0</code> is usually more appropriate; if not, one should reconsider the use of a bar chart in the first place (dot plots are often a good alternative).
reference	logical, whether a reference line is to be drawn at the origin
stack	logical, relevant when <code>groups</code> is non-null. If <code>FALSE</code> (the default), bars for different values of the grouping variable are drawn side by side, otherwise they are stacked.
groups	optional grouping variable

```
col, border, lty, lwd
```

Graphical parameters for the bars. By default, the trellis parameter `plot.polygon` is used if there is no grouping variable, otherwise `superpose.polygon` is used. `col` gives the fill color, `border` the border color, and `lty` and `lwd` the line type and width of the borders.

```
...
```

extra arguments will be accepted but ignored

Details

A barchart is drawn in the panel. Note that most arguments controlling the display can be supplied to the high-level `barchart` call directly.

panel.bwplot

Default Panel Function for bwplot

Description

This is the default panel function for `bwplot`.

Usage

```
panel.bwplot(x, y, box.ratio = 1,
             box.width = box.ratio / (1 + box.ratio),
             horizontal = TRUE,
             pch, col, alpha, cex,
             font, fontfamily, fontface,
             fill, varwidth = FALSE,
             notch = FALSE, notch.frac = 0.5,
             ...,
             levels.fos,
             stats = boxplot.stats,
             coef = 1.5,
             do.out = TRUE)
```

Arguments

<code>x, y</code>	numeric vector or factor. Boxplots drawn for each unique value of <code>y</code> (<code>x</code>) if <code>horizontal</code> is <code>TRUE</code> (<code>FALSE</code>)
<code>box.ratio</code>	ratio of box thickness to inter box space
<code>box.width</code>	thickness of box in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.

horizontal	logical. If FALSE, the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of bwplot for a fuller explanation.
pch, col, alpha, cex, font, fontfamily, fontface	graphical parameters controlling the dot. pch=" " is treated specially, by replacing the dot with a line (similar to boxplot)
fill	color to fill the boxplot
varwidth	logical. If TRUE, widths of boxplots are proportional to the number of points used in creating it.
notch	if notch is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is ‘strong evidence’ that the two medians differ (Chambers et al., 1983, p. 62). See boxplot.stats for the calculations used.
notch.frac	numeric in (0,1). When notch=TRUE, the fraction of the box width that the notches should use.
stats	a function, defaulting to boxplot.stats , that accepts a numeric vector and returns a list similar to the return value of boxplot.stats . The function must accept arguments coef and do.out even if they do not use them (a ... argument is good enough). This function is used to determine the box and whisker plot.
coef, do.out	passed to stats
levels.fos	numeric values corresponding to positions of the factor or shingle variable. For internal use.
...	further arguments, ignored.

Details

Creates Box and Whisker plot of x for every level of y (or the other way round if horizontal=FALSE). By default, the actual boxplot statistics are calculated using [boxplot.stats](#). Note that most arguments controlling the display can be supplied to the high-level [bwplot](#) call directly.

Although the graphical parameters for the dot representing the median can be controlled by optional arguments, many others can not. These parameters are obtained from the relevant settings parameters ("box.rectangle" for the box, "box.umbrella" for the whiskers and "plot.symbol" for the outliers).

       notch = TRUE, pch = "|")

```

panel.cloud

Default Panel Function for cloud

Description

These are default panel functions controlling cloud and wireframe displays.

Usage

```

panel.cloud(x, y, subscripts, z,
           groups = NULL,
           perspective = TRUE,
           distance = if (perspective) 0.2 else 0,
           xlim, ylim, zlim,
           panel.3d.cloud = "panel.3dscatter",
           panel.3d.wireframe = "panel.3dwire",
           screen = list(z = 40, x = -60),
           R.mat = diag(4), aspect = c(1, 1),
           par.box = NULL,
           xlab, ylab, zlab,
           xlab.default, ylab.default, zlab.default,
           scales.3d,
           proportion = 0.6,
           wireframe = FALSE,
           scpos,
           ...,
           at)

panel.wireframe(...)

              groups, type = "p",
              xlim.scaled, ylim.scaled, zlim.scaled,
              zero.scaled,
              col, col.point, col.line,
              lty, lwd, cex, pch,
              cross, ..., subscripts)
panel.3dwire(x, y, z, rot.mat = diag(4), distance,
            shade = FALSE,
            shade.colors.palette = trellis.par.get("shade.colors")$palette,
            light.source = c(0, 0, 1000),
            xlim.scaled,
            ylim.scaled,
            zlim.scaled,
            col = if (shade) "transparent" else "black",

```

```

lty = 1, lwd = 1,
alpha,
col.groups = superpose.polygon$col,
polynum = 100,
...,
drape = FALSE,
at,
col.regions = regions$col,
alpha.regions = regions$alpha)

```

Arguments

- `x`, `y`, `z` numeric (or possibly factors) vectors representing the data to be displayed. The interpretation depends on the context. For `panel.cloud` these are essentially the same as the data passed to the high level plot (except if `formula` was a matrix, the appropriate `x` and `y` vectors are generated). By the time they are passed to `panel.3dscatter` and `panel.3dwire`, they have been appropriately subsetted (using `subscripts`) and scaled (to lie inside a bounding box, usually the [-0.5, 0.5] cube). Further, for `panel.3dwire`, `x` and `y` are shorter than `z` and represent the sorted locations defining a rectangular grid. Also in this case, `z` may be a matrix if the display is grouped, with each column representing one surface. In `panel.cloud` (called from `wireframe`) and `panel.3dwire`, `x`, `y` and `z` could also be matrices (of the same dimension) when they represent a 3-D surface parametrized on a 2-D grid.
- `subscripts` index specifying which points to draw. The same `x`, `y` and `z` values (representing the whole data) are passed to `panel.cloud` for each panel. `subscripts` specifies the subset of rows to be used for the particular panel.
- `groups` specification of a grouping variable, passed down from the high level functions.
- `perspective` logical, whether to plot a perspective view. Setting this to `FALSE` is equivalent to setting `distance` to 0
- `distance` numeric, between 0 and 1, controls amount of perspective. The distance of the viewing point from the origin (in the transformed coordinate system) is $1 / \text{distance}$. This is described in a little more detail in the documentation for `cloud`
- `screen` A list determining the sequence of rotations to be applied to the data before being plotted. The initial position starts with the viewing point along the positive `z`-axis, and the `x` and `y` axes in the usual position. Each component of the list should be named one of "x", "y" or "z" (repetitions are allowed), with their values indicating the amount of rotation about that axis in degrees.
- `R.mat` initial rotation matrix in homogeneous coordinates, to be applied to the data before `screen` rotates the view further.
- `par.box` graphical parameters for box, namely, `col`, `lty` and `lwd`. By default obtained from the parameter `box.3d`
- `xlim`, `ylim`, `zlim` limits for the respective axes. As with other lattice functions, these could each be a numeric 2-vector or a character vector indicating levels of a factor.
- `panel.3d.cloud`, `panel.3d.wireframe` functions that draw the data-driven part of the plot (as opposed to the bounding box and scales) in `cloud` and `wireframe`. This function is called after the 'back' of the bounding box is drawn, but before the 'front' is drawn.

Any user-defined custom display would probably want to change these functions. The intention is to pass as much information to this function as might be useful (not all of which are used by the defaults). In particular, these functions can expect arguments called `xlim`, `ylim`, `zlim` which give the bounding box ranges in the original data scale and `xlim.scaled`, `ylim.scaled`, `zlim.scaled` which give the bounding box ranges in the transformed scale. More arguments can be considered on request.

<code>aspect</code>	aspect as in <code>cloud</code>
<code>xlab</code> , <code>ylab</code> , <code>zlab</code>	Labels, have to be lists. Typically the user will not manipulate these, but instead control this via arguments to <code>cloud</code> directly.
<code>xlab.default</code>	for internal use
<code>ylab.default</code>	for internal use
<code>zlab.default</code>	for internal use
<code>scales.3d</code>	list defining the scales
<code>proportion</code>	numeric scalar, gives the length of arrows as a proportion of the sides
<code>scpos</code>	A list with three components <code>x</code> , <code>y</code> and <code>z</code> (each a scalar integer), describing which of the 12 sides of the cube the scales should be drawn. The defaults should be OK. Valid values are <code>x</code> : 1, 3, 9, 11; <code>y</code> : 8, 5, 7, 6 and <code>z</code> : 4, 2, 10, 12. (See comments in the source code of <code>panel.cloud</code> to see the details of this enumeration.)
<code>wireframe</code>	logical, indicating whether this is a wireframe plot
<code>drape</code>	logical, whether the facets will be colored by height, in a manner similar to <code>levelplot</code> . This is ignored if <code>shade=TRUE</code> .
<code>at</code> , <code>col.regions</code> , <code>alpha.regions</code>	deals with specification of colors when <code>drape = TRUE</code> in <code>wireframe</code> . <code>at</code> can be a numeric vector, <code>col.regions</code> a vector of colors, and <code>alpha.regions</code> a numeric scalar controlling transparency. The resulting behaviour is similar to <code>levelplot</code> , <code>at</code> giving the breakpoints along the <code>z</code> -axis where colors change, and the other two determining the colors of the facets that fall in between.
<code>rot.mat</code>	4x4 transformation matrix in homogeneous coordinates. This gives the rotation matrix combining the <code>screen</code> and <code>R.mat</code> arguments to <code>panel.cloud</code>
<code>type</code>	character vector, specifying type of cloud plot. Can include one or more of "p", "l", "h" or "b". "p" and "l" mean 'points' and 'lines' respectively, and "b" means 'both'. "h" stands for 'histogram', and causes a line to be drawn from each point to the X-Y plane (i.e., the plane representing $z = 0$), or the lower (or upper) bounding box face, whichever is closer.
<code>xlim.scaled</code> , <code>ylim.scaled</code> , <code>zlim.scaled</code>	axis limits (after being scaled to the bounding box)
<code>zero.scaled</code>	<code>z</code> -axis location (after being scaled to the bounding box) of the X-Y plane in the original data scale, to which lines will be dropped (if within range) from each point when <code>type = "h"</code>
<code>cross</code>	logical, defaults to <code>TRUE</code> if <code>pch = "+"</code> . <code>panel.3dscatter</code> can represent each point by a 3d 'cross' of sorts (it's much easier to understand looking at an example than from a description). This is different from the usual <code>pch</code> argument, and reflects the depth of the points and the orientation of the axes. This argument indicates whether this feature will be used.

This is useful for two reasons. It can be set to `FALSE` to use "+" as the plotting character in the regular sense. It can also be used to force this feature in grouped displays.

<code>shade</code>	logical, indicating whether the surface is to be colored using an illumination model with a single light source
<code>shade.colors.palette</code>	a function (or the name of one) that is supposed to calculate the color of a facet when shading is being used. Three pieces of information are available to the function: first, the cosine of the angle between the incident light ray and the normal to the surface (representing foreshortening); second, the cosine of half the angle between the reflected ray and the viewing direction (useful for non-Lambertian surfaces); and third, the scaled (average) height of that particular facet with respect to the total plot z-axis limits. All three numbers should be between 0 and 1. The <code>shade.colors.palette</code> function should return a valid color. The default function is obtained from the trellis settings.
<code>light.source</code>	a 3-vector representing (in cartesian coordinates) the light source. This is relative to the viewing point being (0, 0, 1/distance) (along the positive z-axis), keeping in mind that all observations are bounded within the [-0.5, 0.5] cube
<code>polynum</code>	quadrilateral faces are drawn in batches of <code>polynum</code> at a time. Drawing too few at a time increases the total number of calls to the underlying <code>grid.polygon</code> function, which affects speed. Trying to draw too many at once may be unnecessarily memory intensive. This argument controls the trade-off.
<code>col.groups</code>	colors for different groups
<code>col</code> , <code>col.point</code> , <code>col.line</code> , <code>lty</code> , <code>lwd</code> , <code>cex</code> , <code>pch</code> , <code>alpha</code>	graphical parameters
<code>...</code>	other parameters, passed down when appropriate

Details

These functions together are responsible for the content drawn inside each panel in `cloud` and `wireframe`. `panel.wireframe` is a wrapper to `panel.cloud`, which does the actual work. `panel.cloud` is responsible for drawing the content that does not depend on the data, namely, the bounding box, the arrows/scales, etc. At some point, depending on whether `wireframe` is `TRUE`, it calls either `panel.3d.wireframe` or `panel.3d.cloud`, which draws the data-driven part of the plot.

The arguments accepted by these two functions are different, since they have essentially different purposes. For `cloud`, the data is unstructured, and `x`, `y` and `z` are all passed to the `panel.3d.cloud` function. For `wireframe`, on the other hand, `x` and `y` are increasing vectors with unique values, defining a rectangular grid. `z` must be a matrix with `length(x) * length(y)` rows, and as many columns as the number of groups.

`panel.3dscatter` is the default `panel.3d.cloud` function. It has a `type` argument similar to `panel.xyplot`, and supports grouped displays. It tries to honour depth ordering, i.e., points and lines closer to the camera are drawn later, overplotting more distant ones. (Of course there is no absolute ordering for line segments, so an ad hoc ordering is used. There is no hidden point removal.)

`panel.3dwire` is the default `panel.3d.wireframe` function. It calculates polygons corresponding to the facets one by one, but waits till it has collected information about `polynum` facets, and draws them all at once. This avoids the overhead of drawing `grid.polygon` repeatedly,

speeding up the rendering considerably. If `shade = TRUE`, these attempt to color the surface as being illuminated from a light source at `light.source`. `palette.shade` is a simple function that provides the default shading colors

Multiple surfaces are drawn if `groups` is non-null in the call to `wireframe`, however, the algorithm is not sophisticated enough to render intersecting surfaces correctly.

panel.densityplot *Default Panel Function for densityplot*

Description

This is the default panel function for `densityplot`.

Usage

```
panel.densityplot(x, darg, plot.points = "jitter", ref = FALSE,
                 groups = NULL, weights = NULL,
                 jitter.amount, type, ...)
```

Arguments

<code>x</code>	data points for which density is to be estimated
<code>darg</code>	list of arguments to be passed to the <code>density</code> function. Typically, this should be a list with zero or more of the following components : <code>bw</code> , <code>adjust</code> , <code>kernel</code> , <code>window</code> , <code>width</code> , <code>give.Rkern</code> , <code>n</code> , <code>from</code> , <code>to</code> , <code>cut</code> , <code>na.rm</code> (see density for details)
<code>plot.points</code>	logical specifying whether or not the data points should be plotted along with the estimated density. Alternatively, a character string specifying how the points should be plotted. Meaningful values are <code>"rug"</code> , in which case panel.rug is used to plot a ‘rug’, and <code>"jitter"</code> , in which case the points are jittered vertically to better distinguish overlapping points.
<code>ref</code>	logical, whether to draw x-axis
<code>groups</code>	an optional grouping variable. If present, panel.superpose will be used instead to display each subgroup
<code>weights</code>	numeric vector of weights for the density calculations. If this is specified, the <code>...</code> part must also include a <code>subscripts</code> argument that matches the weights to <code>x</code> .
<code>jitter.amount</code>	when <code>plot.points="jitter"</code> , the value to use as the <code>amount</code> argument to jitter .

`type` type argument used to plot points, if requested. This is not expected to be useful, it is available mostly to protect a `type` argument, if specified, from affecting the density curve.

`...` extra graphical parameters. Note that additional arguments to `panel.rug` cannot be passed on through `panel.densityplot`.

`densityplot`, `jitter`

panel.dotplot

Default Panel Function for dotplot

Description

Default panel function for dotplot.

Usage

```
panel.dotplot(x, y, horizontal = TRUE,
              pch, col, lty, lwd,
              col.line, levels.fos,
              groups = NULL,
              ...)
```

Arguments

`x, y` variables to be plotted in the panel. Typically `y` is the ‘factor’

`horizontal` logical. If `FALSE`, the plot is ‘transposed’ in the sense that the behaviours of `x` and `y` are switched. `x` is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of `bwplot` for a fuller explanation.

`pch, col, lty, lwd, col.line` graphical parameters

`levels.fos` locations where reference lines will be drawn

`groups` grouping variable (affects graphical parameters)

`...` extra parameters, passed to `panel.xyplot` which is responsible for drawing the foreground points (`panel.dotplot` only draws the background reference lines).

Details

Creates (possibly grouped) Dotplot of `x` against `y` or vice versa

panel.functions *Useful Panel Functions*

Description

These are predefined panel functions available in lattice for use in constructing new panel functions (usually on-the-fly).

Usage

```

panel.abline(a = NULL, b = 0,
             h = NULL, v = NULL,
             reg = NULL, coef = NULL,
             col, col.line, lty, lwd, alpha, type,
             ...,
             reference = FALSE)
panel.refline(...)

panel.curve(expr, from, to, n = 101,
           curve.type = "l",
           col, lty, lwd, type,
           ...)

panel.rug(x = NULL, y = NULL,
         regular = TRUE,
         start = if (regular) 0 else 0.97,
         end = if (regular) 0.03 else 1,
         x.units = rep("npc", 2),
         y.units = rep("npc", 2),
         col, lty, lwd, alpha,
         ...)

panel.average(x, y, fun = mean, horizontal = TRUE,
             lwd, lty, col, col.line, type,
             ...)

panel.linejoin(x, y, fun = mean, horizontal = TRUE,
             lwd, lty, col, col.line, type,
             ...)

panel.fill(col, border, ...)
panel.grid(h=3, v=3, col, col.line, lty, lwd, ...)
panel.lmline(x, y, ...)
panel.loess(x, y, span = 2/3, degree = 1,
           family = c("symmetric", "gaussian"),
           evaluation = 50,
           lwd, lty, col, col.line, type,
           horizontal = FALSE,
           ...)

panel.mathdensity(dmath = dnorm, args = list(mean=0, sd=1),
                 n = 50, col, col.line, lwd, lty, type,
                 ...)

```

Arguments

<code>x, y</code>	variables defining the contents of the panel
<code>a, b</code>	Coefficients of the line to be added by <code>panel.abline</code> . <code>a</code> can be a vector of length 2, representing the coefficients of the line to be added, in which case <code>b</code> should be missing. <code>a</code> can also be an appropriate ‘regression’ object, i.e., an object which has a <code>coef</code> method that returns a length 2 numeric vector. The corresponding line will be plotted. The <code>reg</code> argument will override <code>a</code> if specified.
<code>coef</code>	Coefficients of the line to be added as a length 2 vector
<code>reg</code>	A regression object. The corresponding fitted line will be drawn
<code>h, v</code>	For <code>panel.abline</code> , these are numeric vectors giving locations respectively of horizontal and vertical lines to be added to the plot, in native coordinates. For <code>panel.grid</code> , these usually specify the number of horizontal and vertical reference lines to be added to the plot. Alternatively, they can be negative numbers. <code>h=-1</code> and <code>v=-1</code> are intended to make the grids aligned with the axis labels. This doesn’t always work; all that actually happens is that the locations are chosen using <code>pretty</code> , which is also how the label positions are chosen in the most common cases (but not for factor or date-time variables, for instance). <code>h</code> and <code>v</code> can be negative numbers other than <code>-1</code> , in which case <code>-h</code> and <code>-v</code> (as appropriate) is supplied as the <code>n</code> argument to <code>pretty</code> .
<code>reference</code>	logical indicating whether the default graphical parameters for <code>panel.abline</code> should be taken from the “reference.line” parameter settings. The default is to take them from the “add.line” settings. The <code>panel.refline</code> function is a wrapper around <code>panel.abline</code> that calls it with <code>reference=TRUE</code> .
<code>expr</code>	expression as a function of <code>x</code> or a function to plot as a curve
<code>n</code>	the number of points to use for drawing the curve
<code>regular</code>	logical indicating whether the ‘rug’ is to be drawn on the regular side (left / bottom) or not (right / top)
<code>start, end</code>	endpoints of rug segments, in normalized parent coordinates (between 0 and 1). Defaults depend on value of <code>regular</code> , and cover 3% of the panel width and height
<code>x.units, y.units</code>	character vector, replicated to be of length two. Specifies the (grid) units associated with <code>start</code> and <code>end</code> above. <code>x.units</code> and <code>y.units</code> are for the rug on the x-axis and y-axis respectively (and thus are associated with <code>start</code> and <code>end</code> values on the y and x scales respectively).
<code>from, to</code>	optional lower and upper x-limits of curve. If missing, limits of current panel are used
<code>curve.type</code>	type of curve (“p” for points, etc), passed to <code>llines</code>
<code>col, col.line, lty, lwd, border</code>	graphical parameters
<code>type</code>	passed on to <code>panel.points</code> by <code>panel.average</code> , but is usually ignored by the other panel functions documented here. In such cases, the argument is present only to make sure an explicitly specified <code>type</code> argument (perhaps meant for another function) doesn’t affect the display.
<code>span, degree, family, evaluation</code>	arguments to <code>loess.smooth</code> , for which <code>panel.loess</code> is essentially a wrapper.

<code>fun</code>	the function that will be applied to the subset of $x(y)$ determined by the unique values of $y(x)$
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of x and y are switched. x is now the ‘factor’. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.
<code>dmath</code>	A vectorized function that produces density values given a numeric vector named x , e.g., <code>dnorm</code>
<code>args</code>	list giving additional arguments to be passed to <code>dmath</code>
<code>...</code>	graphical parameters can be supplied. see function definition for details. Color can usually be specified by <code>col</code> , <code>col.line</code> and <code>col.symbol</code> , the last two overriding the first for lines and points respectively.

Details

`panel.abline` adds a line of the form $y=a+bx$ or vertical and/or horizontal lines. Graphical parameters are obtained from the “add.line” settings by default. `panel.refline` is similar, but uses the “reference.line” settings for the defaults.

`panel.grid` draws a reference grid.

`panel.curve` adds a curve, similar to what `curve` does with `add = TRUE`. Graphical parameters for the line are obtained from the `add.line` setting.

`panel.average` treats one of x and y as a factor (according to the value of `horizontal`), calculates `fun` applied to the subsets of the other variable determined by each unique value of the factor, and joins them by a line. Can be used in conjunction with `panel.xyplot` and more commonly with `panel.superpose` to produce interaction plots. See `xyplot` documentation for an example. `panel.linejoin` is an alias for `panel.average` retained for back-compatibility and may go away in future.

`panel.mathdensity` plots a (usually theoretical) probability density function. This can be useful in conjunction with `histogram` and `densityplot` to visually estimate goodness of fit (note, however, that `qqmath` is more suitable for this).

`panel.rug` adds a *rug* representation of the (marginal) data to the panel, much like `rug`.

`panel.lmline(x, y)` is equivalent to `panel.abline(lm(y~x))`.

`panel.histogram` *Default Panel Function for histogram*

Description

This is the default panel function for `histogram`.

Usage

```
panel.histogram(x,
                breaks,
                equal.widths = TRUE,
                type = "density",
                nint = round(log2(length(x)) + 1),
                alpha, col, border, lty, lwd,
                ...)
```

Arguments

x	The data points for which the histogram is to be drawn
breaks	The breakpoints for the histogram
equal.widths	logical used when breaks==NULL
type	Type of histogram, possible values being "percent", "density" and "count"
nint	Number of bins for the histogram
alpha, col, border, lty, lwd	graphical parameters for bars; defaults are obtained from the plot.polygon settings.
...	other arguments, passed to <code>hist</code> when deemed appropriate

[histogram](#)

panel.levelplot *Default Panel Function for levelplot*

Description

This is the default panel function for levelplot.

Usage

```
panel.levelplot(x, y, z,
                subscripts,
                at = pretty(z),
                shrink,
                labels = NULL,
                label.style = c("mixed", "flat", "align"),
                contour = FALSE,
                region = TRUE,
                col = add.line$col,
                lty = add.line$lty,
```

```

        lwd = add.line$lwd,
        ...,
        col.regions = regions$col,
        alpha.regions = regions$alpha)
panel.contourplot(...)

```

Arguments

<code>x, y, z</code>	variables defining the plot
<code>subscripts</code>	integer vector indicating what subset of <code>x, y</code> and <code>z</code> to draw
<code>at</code>	numeric vector specifying breakpoints for change in colors
<code>shrink</code>	either a numeric vector of length 2 (meant to work as both <code>x</code> and <code>y</code> components), or a list with components <code>x</code> and <code>y</code> which are numeric vectors of length 2. This allows the rectangles to be scaled proportional to the <code>z</code> -value. The specification can be made separately for widths (<code>x</code>) and heights (<code>y</code>). The elements of the length 2 numeric vector gives the minimum and maximum proportion of shrinkage (corresponding to min and max of <code>z</code>).
<code>labels</code>	either a logical scalar indicating whether the labels are to be drawn, or a character or expression vector giving the labels associated with the <code>at</code> values. Alternatively, <code>labels</code> can be a list with the following components: labels: a character or expression vector giving the labels. This can be omitted, in which case the defaults will be used. col, cex, alpha: graphical parameters for label texts fontfamily, fontface, font: font used for the labels
<code>label.style</code>	controls how label positions and rotation are determined. A value of "flat" causes the label to be positioned where the contour is flattest, and the label is not rotated. A value of "align" causes the label to be drawn as far from the boundaries as possible, and the label is rotated to align with the contour at that point. The default is to mix these approaches, preferring the flattest location unless it is too close to the boundaries.
<code>contour</code>	logical, specifying whether contour lines should be drawn
<code>region</code>	logical, specifying whether inter-contour regions should be filled with the appropriate color
<code>col, lty, lwd</code>	graphical parameters for contour lines
<code>...</code>	extra parameters
<code>col.regions</code>	a vector of colors used if <code>region=TRUE</code> . Usually a subset of the colors are used, the exact number being one more than the length of <code>at</code> . These are chosen to be roughly equally spaced along <code>col.regions</code> . In the unusual case when <code>col.regions</code> is not longer than <code>at</code> , it is repeated to be as long as necessary.
<code>alpha.regions</code>	numeric scalar controlling transparency of facets

Details

The same function is used for both `levelplot` and `contourplot` (which differ only in default values of some arguments). `panel.contourplot` is a simple wrapper to `panel.levelplot`.

When `contour=TRUE`, the `contourLines` function is used to calculate the contour lines.

panel.number

Accessing Auxiliary Information During Plotting

Description

Control over lattice plots are provided through a collection of user specifiable functions that perform various tasks during the plotting. Not all information is available to all functions. The functions documented here attempt to provide a consistent interface to access relevant information from within these user specified functions, namely those specified as the `panel`, `strip` and `axis` functions.

Usage

```
current.row()
current.column()
panel.number()
packet.number()
which.packet()

trellis.currentLayout(which = c("packet", "panel"))
```

Arguments

`which` whether return value (a matrix) should contain panel numbers or packet numbers, which are usually, but not necessarily, the same (see below for details).

Value

`trellis.currentLayout` returns a matrix with as many rows and columns as in the layout of panels in the current plot. Entries in the matrix are integer indices indicating which packet (or panel; see below) occupies that position, with 0 indicating the absence of a panel. `current.row` and `current.column` return integer indices specifying which row and column in the layout are currently active. `panel.number` returns an integer counting which panel is being drawn (starting from 1 for the first panel, a.k.a. the panel order). `packet.number` gives the packet number according to the packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. `which.packet` returns the combination of levels of the conditioning variables in the form of a numeric vector as long as the number of conditioning variables, with each element an integer indexing the levels of the corresponding variable.

Note

The availability of these functions make redundant some features available in earlier versions of lattice, namely optional arguments called `panel.number` and `packet.number` that were made available to `panel` and `strip`. If you have written such functions, it should be enough to replace instances of `panel.number` and `packet.number` by the corresponding function calls. You should also remove `panel.number` and `packet.number` from the argument list of your function to avoid a warning.

If these accessor functions are not enough for your needs, feel free to contact the maintainer and ask for more.

panel.pairs

Default Superpanel Function for splom

Description

This is the default superpanel function for `splom`.

Usage

```
panel.pairs(z,
            panel = lattice.getOption("panel.splom"),
            lower.panel = panel,
            upper.panel = panel,
            diag.panel = "diag.panel.splom",
            as.matrix = FALSE,
            groups = NULL,
            panel.subscripts,
            subscripts,
            pscales = 5,
            prepanel.limits = function(x) if (is.factor(x)) levels(x) else
            extend.limits(range(as.numeric(x), finite = TRUE)),

            varname.col, varname.cex, varname.font,
            varname.fontfamily, varname.fontface,
            axis.text.col, axis.text.cex, axis.text.font,
            axis.text.fontfamily, axis.text.fontface,
            axis.line.col, axis.line.lty, axis.line.lwd,
            axis.line.alpha, axis.line.tck,
            ...)
diag.panel.splom(x = NULL,
                 varname = NULL, limits, at = NULL, lab = NULL,
                 draw = TRUE,
```

```

varname.col, varname.cex,
varname.lineheight, varname.font,
varname.fontfamily, varname.fontface,
axis.text.col, axis.text.alpha,
axis.text.cex, axis.text.font,
axis.text.fontfamily, axis.text.fontface,
axis.line.col, axis.line.alpha,
axis.line.lty, axis.line.lwd,
axis.line.tck,
...)
```

Arguments

<code>z</code>	The data frame used for the plot.
<code>panel</code> , <code>lower.panel</code> , <code>upper.panel</code>	The panel function used to display each pair of variables. If specified, <code>lower.panel</code> and <code>upper.panel</code> are used for panels below and above the diagonal respectively.
<code>diag.panel</code>	The panel function used for the diagonals. See arguments to <code>diag.panel.splom</code> to know what arguments this function is passed when called.
<code>as.matrix</code>	logical. If TRUE, the layout of the panels will have origin on the top left instead of bottom left (similar to <code>pairs</code>). This is in essence the same functionality as provided by <code>as.table</code> for the panel layout
<code>groups</code>	Grouping variable, if any
<code>panel.subscripts</code>	logical specifying whether the panel function accepts an argument named <code>subscripts</code> .
<code>subscripts</code>	The indices of the rows of <code>z</code> that are to be displayed in this (super)panel.
<code>pscales</code>	Controls axis labels, passed down from <code>splom</code> . If <code>pscales</code> is a single number, it indicates the approximate number of equally-spaced ticks that should appear on each axis. If <code>pscales</code> is a list, it should have one component for each column in <code>z</code> , each of which itself a list with the following valid components: <code>at</code> : a numeric vector specifying tick locations <code>labels</code> : character vector labels to go with <code>at</code> <code>limits</code> : numeric 2-vector specifying axis limits (should be made more flexible at some point to handle factors) These are specifications on a per-variable basis, and used on all four sides in the diagonal cells used for labelling. Factor variables are labelled with the factor names. Use <code>pscales=0</code> to suppress the axes entirely.
<code>prepanel.limits</code>	The 'regular' high level lattice plots such as <code>xyplot</code> use the <code>prepanel</code> function for deciding on axis limits from data. This function serves a similar function, and works on a per-variable basis, by calculating the limits, which can be overridden by the corresponding <code>limits</code> component in the <code>pscales</code> list.
<code>x</code>	data vector corresponding to that row / column (which will be the same for diagonal 'panels').
<code>varname</code>	(scalar) character string or expression that is to be written centred within the panel

<code>limits</code>	numeric of length 2, or, vector of characters, specifying the scale for that panel (used to calculate tick locations when missing)
<code>at</code>	locations of tick marks
<code>lab</code>	optional labels for tick marks
<code>draw</code>	logical, specifying whether to draw the tick marks and labels. If FALSE, only variable names are written
<code>varname.col</code> , <code>varname.cex</code> , <code>varname.lineheight</code> , <code>varname.font</code> , <code>varname.fontfamily</code> ,	graphical parameters for the variable name in each diagonal panel
<code>axis.text.col</code> , <code>axis.text.cex</code> , <code>axis.text.font</code> , <code>axis.text.fontfamily</code> , <code>axis.text.f</code>	graphical parameters for axis tick marks and labels
<code>axis.line.tck</code>	length of tick marks in diagonal panels
<code>...</code>	extra arguments passed on to <code>panel</code> , <code>lower.panel</code> , <code>upper.panel</code> and <code>diag.panel</code> from <code>panel.pairs</code> . Currently ignored by <code>diag.panel.splom</code> .

Details

`panel.pairs` is the function that is actually passed in as the `panel` function in a trellis object produced by `splom` (taking the `panel` function as its argument).

Note that the axis labeling does not support date-time classes at present.

`panel.parallel` *Default Panel Function for parallel*

Description

This is the default panel function for `parallel`.

Usage

```
panel.parallel(x, y, z, subscripts,
              groups = NULL,
              col, lwd, lty, alpha,
              common.scale = FALSE,
              lower,
              upper,
              ...,
              horizontal.axis = TRUE)
```

Arguments

<code>x, y</code>	dummy variables, ignored.
<code>z</code>	The data frame used for the plot. Each column will be coerced to numeric before being plotted, and an error will be issued if this fails.
<code>subscripts</code>	The indices of the rows of <code>z</code> that are to be displayed in this panel.
<code>groups</code>	An optional grouping variable. If specified, different groups are distinguished by use of different graphical parameters (i.e., rows of <code>z</code> in the same group share parameters).
<code>col, lwd, lty, alpha</code>	graphical parameters (defaults to the settings for <code>superpose.line</code>). If <code>groups</code> is non-null, these parameters used one for each group. Otherwise, they are recycled and used to distinguish between rows of the data frame <code>z</code> .
<code>common.scale</code>	logical, whether a common scale should be used columns of <code>z</code> . Defaults to <code>FALSE</code> , in which case the horizontal range for each column is different (as determined by <code>lower</code> and <code>upper</code>).
<code>lower, upper</code>	numeric vectors replicated to be as long as the number of columns in <code>z</code> . Determines the lower and upper bounds to be used for scaling the corresponding columns of <code>z</code> after coercing them to numeric. Defaults to the minimum and maximum of each column. Alternatively, these could be functions (to be applied on each column) that return a scalar.
<code>...</code>	other arguments (ignored)
<code>horizontal.axis</code>	logical indicating whether the parallel axes should be laid out horizontally (<code>TRUE</code>) or vertically (<code>FALSE</code>).

Details

Produces parallel coordinate plots, which are easier to understand from an example than through a verbal description. See example for [parallel](#)

`panel.qqmath`*Default Panel and Prepanel Function for qqmath*

Description

This is the default panel function for `qqmath`.

Usage

```
panel.qqmath(x, f.value = NULL,  
             distribution = qnorm,  
             qtype = 7,  
             groups = NULL, ...)
```

Arguments

<code>x</code>	vector (typically numeric, coerced if not) of data values to be used in the panel.
<code>f.value</code> , <code>distribution</code>	Defines how quantiles are calculated. See qqmath for details.
<code>qtype</code>	The type argument to be used in quantile
<code>groups</code>	An optional grouping variable. Within each panel, one Q-Q plot is produced for every level of this grouping variable, differentiated by different graphical parameters.
<code>...</code>	further arguments, often graphical parameters.

Details

Creates a Q-Q plot of the data and the theoretical distribution given by `distribution`. Note that most of the arguments controlling the display can be supplied directly to the high-level `qqmath` call.

panel.qqmathline *Useful panel function with qqmath*

Description

Useful panel function with qqmath. Draws a line passing through the points (usually) determined by the .25 and .75 quantiles of the sample and the theoretical distribution.

Usage

```
panel.qqmathline(x, y = x,  
                 distribution = qnorm,  
                 p = c(0.25, 0.75),  
                 qtype = 7,  
                 groups = NULL,  
                 ...)
```

Arguments

x	The original sample, possibly reduced to a fewer number of quantiles, as determined by the <code>f.value</code> argument to <code>qqmath</code>
y	an alias for <code>x</code> for backwards compatibility
distribution	quantile function for reference theoretical distribution.
p	numeric vector of length two, representing probabilities. Corresponding quantile pairs define the line drawn.
qtype	the type of quantile computation used in quantile
groups	optional grouping variable. If non-null, a line will be drawn for each group.
...	other arguments.

panel.stripplot *Default Panel Function for stripplot*

Description

This is the default panel function for `stripplot`. Also see `panel.superpose`

Usage

```
panel.stripplot(x, y, jitter.data = FALSE,  
               factor = 0.5, amount = NULL,  
               horizontal = TRUE, groups = NULL,  
               ...)
```

Arguments

<code>x, y</code>	coordinates of points to be plotted
<code>jitter.data</code>	whether points should be jittered to avoid overplotting. The actual jittering is performed inside <code>panel.xyplot</code> , using its <code>jitter.x</code> or <code>jitter.y</code> argument (depending on the value of <code>horizontal</code>).
<code>factor, amount</code>	amount of jittering, see <code>jitter</code>
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is 'transposed' in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the 'factor'. Interpretation of other arguments change accordingly. See documentation of <code>bwplot</code> for a fuller explanation.
<code>groups</code>	optional grouping variable
<code>...</code>	additional arguments, passed on to <code>panel.xyplot</code>

Details

Creates stripplot (one dimensional scatterplot) of `x` for each level of `y` (or vice versa, depending on the value of `horizontal`)

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org)

`stripplot`, `jitter`

`panel.superpose` *Panel Function for Display Marked by groups*

Description

These are panel functions for Trellis displays useful when a grouping variable is specified for use within panels. The `x` (and `y` where appropriate) variables are plotted with different graphical parameters for each distinct value of the grouping variable.

Usage

```
panel.superpose(x, y = NULL, subscripts, groups,
               panel.groups = "panel.xyplot",
               col, col.line, col.symbol,
               pch, cex, fill, font,
               fontface, fontfamily,
               lty, lwd, alpha,
               type = "p",
               ...,
               distribute.type = FALSE)
panel.superpose.2(..., distribute.type = TRUE)
```

Arguments

- `x, y` coordinates of the points to be displayed
- `panel.groups` the panel function to be used for each group of points. Defaults to `panel.xyplot` (behaviour in S).
To be able to distinguish between different levels of the originating group inside `panel.groups`, it will be supplied a special argument called `group.number` which will hold the numeric code corresponding to the current level of groups. No special care needs to be taken when writing a `panel.groups` function if this feature is not used.
- `subscripts` subscripts giving indices in original data frame
- `groups` a grouping variable. Different graphical parameters will be used to plot the subsets of observations given by each distinct value of `groups`. The default graphical parameters are obtained from `superpose.symbol` and `superpose.line` using `trellis.par.get` wherever appropriate
- `type` usually a character vector specifying what should be drawn for each group, passed on to the `panel.groups` function, which must know what to do with it. By default, this is `panel.xyplot`, whose help page describes the admissible values.
The functions `panel.superpose` and `panel.superpose.2` differ only in the default value of `distribute.type`, which controls the way the `type` argument is interpreted. If `distribute.type = FALSE`, then the interpretation is the same as for `panel.xyplot` for each of the unique groups. In other words, if `type` is a vector, all the individual components are honoured concurrently. If `distribute.type = TRUE`, `type` is replicated to be as long as the number of unique values in `groups`, and one component used for the points corresponding to the each different group. Even in this case, it is possible to request multiple types per group, specifying `type` as a list, each component being the desired `type` vector for the corresponding group.
If `distribute.type = FALSE`, any occurrence of "g" in `type` causes a grid to be drawn, and all such occurrences are removed before `type` is passed on to `panel.groups`.
- `col, col.line, col.symbol, pch, cex, fill, font, fontface, fontfamily, lty, lwd,`
graphical parameters, replicated to be as long as the number of groups. These are eventually passed down to `panel.groups`, but as scalars rather than vectors. When `panel.groups` is called for the *i*-th level of `groups`, the corresponding element of each graphical parameter is passed to it.
- `...` Extra arguments. Passed down to `panel.superpose` from `panel.superpose.2`, and to `panel.groups` from `panel.superpose`.
- `distribute.type`
logical controlling interpretation of the `type` argument.

Details

`panel.superpose` and `panel.superpose.2` differ essentially in how `type` is interpreted by default. The default behaviour in `panel.superpose` is the opposite of that in S, which is the same as that of `panel.superpose.2`.

panel.violin

Panel Function to create Violin Plots

Description

This is a panel function that can create a violin plot. It is typically used in a high-level call to `bwplot`.

Usage

```
panel.violin(x, y, box.ratio = 1, box.width,
             horizontal = TRUE,
             alpha, border, lty, lwd, col,
             varwidth = FALSE,
             bw, adjust, kernel, window,
             width, n = 50, from, to, cut,
             na.rm, ...)
```

Arguments

<code>x, y</code>	numeric vector or factor. Violin plots are drawn for each unique value of <code>y</code> (<code>x</code>) if <code>horizontal</code> is <code>TRUE</code> (<code>FALSE</code>)
<code>box.ratio</code>	ratio of the thickness of each violin and inter violin space
<code>box.width</code>	thickness of the violins in absolute units; overrides <code>box.ratio</code> . Useful for specifying thickness when the categorical variable is not a factor, as use of <code>box.ratio</code> alone cannot achieve a thickness greater than 1.
<code>horizontal</code>	logical. If <code>FALSE</code> , the plot is ‘transposed’ in the sense that the behaviours of <code>x</code> and <code>y</code> are switched. <code>x</code> is now the ‘factor’. See documentation of bwplot for a fuller explanation.
<code>alpha, border, lty, lwd, col</code>	graphical parameters controlling the violin. Defaults are taken from the “ <code>plot.polygon</code> ” settings.
<code>varwidth</code>	logical. If <code>FALSE</code> , the densities are scaled separately for each group, so that the maximum value of the density reaches the limit of the allocated space for each violin (as determined by <code>box.ratio</code>). If <code>TRUE</code> , densities across violins will have comparable scale.
<code>bw, adjust, kernel, window, width, n, from, to, cut, na.rm</code>	arguments to density , passed on as appropriate
<code>...</code>	arguments passed on to <code>density</code> .

Details

Creates Violin plot of x for every level of y . Note that most arguments controlling the display can be supplied to the high-level (typically `bwplot`) call directly.

[bwplot](#), [density](#)

Examples

```
bwplot(voice.part ~ height, singer,
       panel = function(..., box.ratio) {
         panel.violin(..., col = "transparent",
                     varwidth = FALSE, box.ratio = box.ratio)
         panel.bwplot(..., fill = NULL, box.ratio = .1)
       } )
```

panel.xyplot

Default Panel Function for xyplot

Description

This is the default panel function for `xyplot`. Also see `panel.superpose`. The default panel functions for `splom` and `qq` are essentially the same function.

Usage

```
panel.xyplot(x, y, type = "p",
             groups = NULL,
             pch, col, col.line, col.symbol,
             font, fontfamily, fontface,
             lty, cex, fill, lwd,
             horizontal = FALSE, ...,
             jitter.x = FALSE, jitter.y = FALSE,
             factor = 0.5, amount = NULL)
panel.splom(...)
panel.qq(...)
```

Arguments

<code>x, y</code>	variables to be plotted in the scatterplot
<code>type</code>	character vector consisting of one or more of the following: "p", "l", "h", "b", "o", "s", "S", "r", "a", "g", "smooth". If <code>type</code> has more than one element, an attempt is made to combine the effect of each of the components. The behaviour if any of the first six are included in <code>type</code> is similar to the effect of <code>type</code> in <code>plot</code> (type "b" is actually the same as "o"). "r" adds a regression line (same as <code>panel.lmline</code> , except for default graphical parameters),

and "smooth" adds a loess fit (same as `panel.loess`). "g" adds a reference grid using `panel.grid` in the background. "a" has the effect of calling `panel.linejoin`, which can be useful for creating interaction plots. The effect of several of these specifications depend on the value of `horizontal`. Type "s" (and "S") sorts the values along one of the axes (depending on `horizontal`); this is unlike the behavior in `plot`. For the latter behavior, use `type = "s"` with `panel = panel.points`. See `example(xyplot)` and `demo(lattice)` for examples.

`groups` an optional grouping variable. If present, `panel.superpose` will be used instead to display each subgroup

`col`, `col.line`, `col.symbol` default colours are obtained from `plot.symbol` and `plot.line` using `trellis.par.get`.

`font`, `fontface`, `fontfamily` font used when `pch` is a character

`pch`, `lty`, `cex`, `lwd`, `fill` other graphical parameters. `fill` serves the purpose of `bg` in `points` for certain values of `pch`

... extra arguments, if any, for `panel.xyplot`. In most cases `panel.xyplot` ignores these. For types "r" and "smooth", these are passed on to `panel.lmline` and `panel.loess` respectively.

`horizontal` logical. Controls orientation for certain `type`'s, e.g. one of "h", "s" or "S"

`jitter.x`, `jitter.y` logical, whether the data should be jittered before being plotted.

`factor`, `amount` controls amount of jittering.

Details

Creates scatterplot of `x` and `y`, with various modifications possible via the `type` argument. `panel.qq` draws a 45 degree line before calling `panel.xyplot`.

Note that most of the arguments controlling the display can be supplied directly to the high-level (e.g. `xyplot`) call.

       par.settings =
list(layout.widths = list(strip.left = c(1, 0, 0, 0, 0))),
       panel = function(...) {
         type <- types[panel.number()]
         horizontal <- horiz[panel.number()]
         panel.xyplot(...,
                      type = type,
                      horizontal = horizontal)
       })[rep(1, length(types))]

```

```
prepanel.default Default Prepanel Functions
```

Description

These prepanel functions are used as fallback defaults in various high level plot functions in Lattice. These are rarely useful to normal users but may be helpful in developing new displays.

Usage

```

prepanel.default.bwplot(x, y, horizontal, nlevels, origin, stack, ...)
prepanel.default.histogram(x, breaks, equal.widths, type, nint, ...)
prepanel.default.qq(x, y, ...)
prepanel.default.xyplot(x, y, type, subscripts, groups, ...)
prepanel.default.cloud(perspective, distance,
                       xlim, ylim, zlim,
                       screen = list(z = 40, x = -60),
                       R.mat = diag(4),
                       aspect = c(1, 1), panel.aspect = 1,
                       ..., zoom = 0.8)
prepanel.default.levelplot(x, y, subscripts, ...)
prepanel.default.qqmath(x, f.value, distribution, qtype,
                       groups, subscripts, ...)
prepanel.default.densityplot(x, darg, groups, weights, subscripts, ...)
prepanel.default.parallel(x, y, z, ..., horizontal.axis)
prepanel.default.splom(z, ...)

```

Arguments

<code>x, y</code>	x and y values, numeric or factor
<code>horizontal</code>	logical, applicable when one of the variables is to be treated as categorical (factor or shingle).
<code>horizontal.axis</code>	logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
<code>nlevels</code>	number of levels of such a categorical variable.
<code>origin, stack</code>	for barcharts or the <code>type="h"</code> plot type
<code>breaks, equal.widths, type, nint</code>	details of histogram calculations. <code>type</code> has a different meaning in <code>prepanel.default.xyplot</code> (see panel.xyplot)
<code>groups, subscripts</code>	See xyplot . Whenever appropriate, calculations are done separately for each group and then combined.
<code>weights</code>	numeric vector of weights for the density calculations. If this is specified, it is subsetted by <code>subscripts</code> to match it to <code>x</code> .
<code>perspective, distance, xlim, ylim, zlim, screen, R.mat, aspect, panel.aspect, zoom</code>	see panel.cloud
<code>f.value, distribution</code>	see <code>panel.qqmath</code>
<code>darg</code>	list of arguments passed to density
<code>z</code>	see panel.parallel and panel.pairs
<code>qtype</code>	type of quantile
<code>...</code>	other arguments, usually ignored

Value

A list with components `xlim`, `ylim`, `dx` and `dy`, and possibly `xat` and `yat`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described in the help page for [xyplot](#).

Author(s)

prepanel.functions *Useful Prepanel Function for Lattice*

Description

These are predefined prepanel functions available in Lattice.

Usage

```
prepanel.lmline(x, y, ...)  
prepanel.loess(x, y, span, degree, family, evaluation, ...)  
prepanel.qqmathline(x, y = x, distribution = qnorm,  
                    p = c(0.25, 0.75), qtype = 7,  
                    groups, subscripts,  
                    ...)
```

Arguments

<code>x, y</code>	x and y values, numeric or factor
<code>distribution</code>	quantile function for theoretical distribution. This is automatically passed in when this is used as a prepanel function in <code>qqmath</code> .
<code>qtype</code>	type of quantile
<code>p</code>	numeric vector of length two, representing probabilities. If used with <code>aspect="xy"</code> , the aspect ratio will be chosen to make the line passing through the corresponding quantile pairs as close to 45 degrees as possible.
<code>span, degree, family, evaluation</code>	arguments controlling the underlying loess smooth
<code>groups, subscripts</code>	See xyplot . Whenever appropriate, calculations are done separately for each group and then combined.
<code>...</code>	other arguments

Value

usually a list with components `xlim`, `ylim`, `dx` and `dy`, the first two being used to calculate panel axes limits, the last two for banking computations. The form of these components are described under [xyplot](#). There are also several prepanel functions that serve as the default for high level functions, see [prepanel.default.xyplot](#)

 print.trellis

Plot and Summarize Trellis Objects

Description

The `print` and `plot` methods produce a graph from a "trellis" object. The `print` method is necessary for automatic plotting. `plot` method is essentially an alias, provided for convenience. The `summary` method gives a textual summary of the object. `dim` and `dimnames` describe the cross-tabulation induced by conditioning. `panel.error` is the default handler used when an error occurs while executing the panel function.

Usage

```
## S3 method for class 'trellis':
plot(x, position, split,
     more = FALSE, newpage = TRUE,
     packet.panel = packet.panel.default,
     draw.in = NULL,
     panel.height = lattice.getOption("layout.heights")$panel,
     panel.width = lattice.getOption("layout.widths")$panel,
     save.object = lattice.getOption("save.object"),
     panel.error = lattice.getOption("panel.error"),
     prefix,
     ...)
## S3 method for class 'trellis':
print(x, ...)

## S3 method for class 'trellis':
summary(object, ...)

## S3 method for class 'trellis':
dim(x)
## S3 method for class 'trellis':
dimnames(x)

panel.error(e)
```

Arguments

<code>x</code> , <code>object</code>	an object of class "trellis"
<code>position</code>	a vector of 4 numbers, typically <code>c(xmin, ymin, xmax, ymax)</code> that give the lower-left and upper-right corners of a rectangle in which the Trellis plot of <code>x</code> is to be positioned. The coordinate system for this rectangle is [0-1] in both the <code>x</code> and <code>y</code> directions.
<code>split</code>	a vector of 4 integers, <code>c(x,y,nx,ny)</code> , that says to position the current plot at the <code>x,y</code> position in a regular array of <code>nx</code> by <code>ny</code> plots. (Note: this has origin at top left)
<code>more</code>	A logical specifying whether more plots will follow on this page.

- `newpage` A logical specifying whether the plot should be on a new page. This option is specific to lattice, and is useful for including lattice plots in an arbitrary grid viewport (see the details section).
- `packet.panel` a function that determines which packet (data subset) is plotted in which panel. Panels are always drawn in an order such that columns vary the fastest, then rows and then pages. This function determines, given the column, row and page and other relevant information, the packet (if any) which should be used in that panel. By default, the association is determined by matching panel order with packet order, which is determined by varying the first conditioning variable the fastest, then the second, and so on. This association rule is encoded in the default, namely the function `packet.panel.default`, whose help page details the arguments supplied to whichever function is specified as the `packet.panel` argument.
- `draw.in` An optional (grid) viewport (used as the `name` argument in `downViewport`) in which the plot is to be drawn. If specified, the `newpage` argument is ignored. This feature is not well-tested.
- `panel.width`, `panel.height` lists with 2 components, that should be valid `x` and `units` arguments to `unit()` (the `data` argument cannot be specified currently, but can be considered for addition if needed). The resulting `unit` object will be the width/height of each panel in the Lattice plot. These arguments can be used to explicitly control the dimensions of the panel, rather than letting them expand to maximize available space. Vector widths are allowed, and can specify unequal lengths across rows or columns.
- Note that this option should not be used in conjunction with non-default values of the `aspect` argument in the original high level call (no error will be produced, but the resulting behaviour is undefined).
- `save.object` logical, specifying whether the object being printed is to be saved. The last object thus saved can be subsequently retrieved. This is an experimental feature that should allow access to a panel's data after the plot is done, making it possible to enhance the plot after the fact. This also allows the user to invoke the `update` method on the current plot, even if it was not assigned to a variable explicitly. For more details, see `trellis.focus`.
- `panel.error` a function, or a character string naming a function, that is to be executed when an error occurs during the execution of the panel function. The error is caught (using `tryCatch`) and supplied as the only argument to `panel.error`. The default behaviour (implemented as the `panel.error` function) is to print the corresponding error message in the panel and continue. To stop execution on error, use `panel.error = stop`.
- Normal error recovery and debugging tools are unhelpful when `tryCatch` is used. `tryCatch` can be completely bypassed by setting `panel.error` to `NULL`.
- `prefix` character string used as a prefix in viewport and grob names, used to distinguish similar viewports if a page contains multiple plots. The default is based on the serial number of the current plot on the current page (which is one more than the number of plots that have been drawn on the page before the current plot). If supplied explicitly, this has to be a valid R symbol name (briefly, it must start with a letter or a period followed by a letter) and must not contain the grid path separator (currently `" : "`).
- `e` an error condition caught by `tryCatch`

... extra arguments, ignored by the `print` method. All arguments to the plot method are passed on to the `print` method.

Details

This is the default print method for objects of class "trellis", produced by calls to functions like `xyplot`, `bwplot` etc. It is usually called automatically when a trellis object is produced. It can also be called explicitly to control plot positioning by means of the arguments `split` and `position`.

When `newpage = FALSE`, the current grid viewport is treated as the plotting area, making it possible to embed a Lattice plot inside an arbitrary grid viewport. The `draw.in` argument provides an alternative mechanism that may be simpler to use.

The print method uses the information in `x` (the object to be printed) to produce a display using the Grid graphics engine. At the heart of the plot is a grid layout, of which the entries of most interest to the user are the ones containing the display panels.

Unlike in older versions of Lattice (and Grid), the grid display tree is retained after the plot is produced, making it possible to access individual viewport locations and make additions to the plot. For more details and a lattice level interface to these viewports, see `trellis.focus`.

Note

Unlike S-PLUS, trying to position a multipage display (using `position` and/or `split`) will mess things up.

qq

Quantile-Quantile Plots of Two Samples

Description

Quantile-Quantile plots for comparing two Distributions

Usage

```

qq(x, data, ...)

## S3 method for class 'formula':
qq(x, data, aspect = "fill",
   panel = lattice.getOption("panel.qq"),
   prepanel, scales, strip,
   groups, xlab, xlim, ylab, ylim, f.value = NULL,
   drop.unused.levels = lattice.getOption("drop.unused.levels"),
   ...,
   lattice.options = NULL,
   qtype = 7,
   default.scales = list(),
   subscripts,
   subset)

```

Arguments

<code>x</code>	The object on which method dispatch is carried out. For the formula method, a formula of the form $y \sim x \mid g1 * g2 * \dots$, where <code>x</code> must be a numeric, and <code>y</code> can be a factor, shingle, character or numeric vector, with the restriction that there must be exactly two levels of <code>y</code> , which divide the values of <code>x</code> into two groups. Quantiles for these groups will be plotted along the two axes.
<code>data</code>	For the formula methods, an optional data frame in which variables in the formula (as well as <code>groups</code> and <code>subset</code> , if any) are to be evaluated.
<code>f.value</code>	optional numeric vector of probabilities, quantiles corresponding to which should be plotted. Can also be a function of a single integer (representing sample size) that returns such a numeric vector. The typical value for this argument is the function <code>ppoints</code> , which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, using the <code>quantile</code> function. <code>f.value</code> defaults to <code>NULL</code> , which is equivalent to using <code>function(n) ppoints(n, a = 1)</code> . This has the effect of including the minimum and maximum data values in the computed quantiles. This is similar to what happens for <code>qqplot</code> but different from the default <code>qq</code> behaviour in S-PLUS. For large data, this argument can be useful in plotting a smaller set of quantiles, which is usually enough to capture the pattern.
<code>panel</code>	The function that uses the packet (subset of display variables) corresponding to a panel to create a display. Default panel functions are documented separately, and often have arguments that can be used to customize its display in various ways. Such arguments can usually be directly supplied to the high level function.
<code>qtype</code>	type argument for the <code>quantile</code>
<code>aspect</code> , <code>prepanel</code> , <code>scales</code> , <code>strip</code> , <code>groups</code> , <code>xlab</code> , <code>xlim</code> , <code>ylab</code> , <code>ylim</code> , <code>drop.unused.levels</code>	See <code>xyplot</code>
<code>...</code>	Further arguments. See corresponding entry in <code>xyplot</code> for non-trivial details.

Details

`qq` produces a Q-Q plot of two samples. The default behaviour of `qq` is different from the corresponding S-PLUS function. See the entry for `f.value` for specifics.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

```

Arguments

- | | |
|--------------|--|
| x | The object on which method dispatch is carried out.
For the "formula" method, a formula of the form $\sim x \mid g1 * g2 * \dots$, where x must be a numeric. For the "numeric" method, a numeric vector. |
| data | For the formula method, an optional data frame in which variables in the formula (as well as groups and subset, if any) are to be evaluated. Usualll ignored with a warning in other methods. |
| distribution | a quantile function that takes a vector of probabilities as argument and produces the corresponding quantiles. Possible values are qnorm, qunif etc. Distributions with other required arguments need to be passed in as user defined functions. |

- `f.value` optional numeric vector of probabilities, quantiles corresponding to which should be plotted. Can also be a function of a single integer (representing sample size) that returns such a numeric vector. The typical value for this argument is the function `ppoints`, which is also the S-PLUS default. If specified, the probabilities generated by this function is used for the plotted quantiles, using the `quantile` function for the sample, and the function specified as the `distribution` argument for the theoretical distribution.
- `f.value` defaults to `NULL`, which has the effect of using `ppoints` for the quantiles of the theoretical distribution, but the exact data values for the sample. This is similar to what happens for `qqnorm`, but different from the S-PLUS default of `f.value=ppoints`.
- For large `x`, this argument can be useful in plotting a smaller set of quantiles, which is usually enough to capture the pattern.
- `panel` The panel function to be used. Unlike in older versions, the default panel function does most of the actual computations and has support for grouping. See [panel.qqmath](#) for details.
- `allow.multiple`, `outer`, `auto.key`, `aspect`, `prepanel`, `scales`, `strip`, `groups`, `xlab`,
See [xyplot](#)
- ... Further arguments. See corresponding entry in [xyplot](#) for non-trivial details.

Details

`qqmath` produces a Q-Q plot of the given sample and a theoretical distribution. The default behaviour of `qqmath` is different from the corresponding S-PLUS function, but is similar to `qqnorm`. See the entry for `f.value` for specifics.

The implementation details are also different from S-PLUS. In particular, all the important calculations are done by the `panel` (and `prepanel` function) and not `qqmath` itself. In fact, both the arguments `distribution` and `f.value` are passed unchanged to the `panel` and `prepanel` function. This allows, among other things, display of grouped Q-Q plots, which are often useful. See the help page for [panel.qqmath](#) for further details.

This and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Value

An object of class `"trellis"`. The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Examples

```
qqmath(~ rnorm(100), distribution = function(p) qt(p, df = 10))
qqmath(~ height | voice.part, aspect = "xy", data = singer,
  prepanel = prepanel.qqmathline,
  panel = function(x, ...) {
    panel.qqmathline(x, ...)
    panel.qqmath(x, ...)
  })
vp.comb <-
  factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
    "[", 1),
    levels = c("Bass", "Tenor", "Alto", "Soprano"))
vp.group <-
  factor(sapply(strsplit(as.character(singer$voice.part), split = " "),
    "[", 2))
qqmath(~ height | vp.comb, data = singer,
  groups = vp.group, auto.key = list(space = "right"),
  aspect = "xy",
  prepanel = prepanel.qqmathline,
  panel = function(x, ...) {
    panel.qqmathline(x, ...)
    panel.qqmath(x, ...)
  })
```

rfs

*Residual and Fit Spread Plots***Description**

Plots fitted values and residuals (via qqmath) on a common scale for any object that has methods for fitted values and residuals.

Usage

```
rfs(model, layout=c(2, 1), xlab="f-value", ylab=NULL,
  distribution = qunif,
  panel, prepanel, strip, ...)
```

Arguments

model	a fitted model object with methods <code>fitted.values</code> and <code>residuals</code> . Can be the value returned by <code>oneway</code>
layout	default layout is <code>c(2,1)</code>
xlab	defaults to <code>"f.value"</code>
distribution	the distribution function to be used for <code>qqmath</code>
ylab, panel, prepanel, strip	See xyplot
...	other arguments, passed on to qqmath .

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

```

Rows

Extract rows from a list

Description

Convenience function to extract subset of a list. Usually used in creating keys.

Usage

```
Rows(x, which)
```

Arguments

`x` list with each member a vector of the same length
`which` index for members of `x`

Value

A list similar to `x`, with each `x[[i]]` replaced by `x[[i]][which]`

shingles

*shingles***Description**

Functions to handle shingles

Usage

```
shingle(x, intervals=sort(unique(x)))
equal.count(x, ...)
as.shingle(x)
is.shingle(x)

## S3 method for class 'shingle':
plot(x, panel, xlab, ylab, ...)

## S3 method for class 'shingle':
print(x, showValues = TRUE, ...)

## S3 method for class 'shingleLevel':
as.character(x, ...)

## S3 method for class 'shingleLevel':
print(x, ...)

## S3 method for class 'shingle':
summary(object, showValues = FALSE, ...)

## S3 method for class 'shingle':
x[subset, drop = FALSE]
as.factorOrShingle(x, subset, drop)
```

Arguments

<code>x</code>	numeric variable or R object, <code>shingle</code> in <code>plot.shingle</code> and <code>x[]</code> . An object (list of intervals) of class "shingleLevel" in <code>print.shingleLevel</code>
<code>object</code>	shingle object to be summarized
<code>showValues</code>	logical, whether to print the numeric part. If FALSE, only the intervals are printed
<code>intervals</code>	numeric vector or matrix with 2 columns
<code>subset</code>	logical vector
<code>drop</code>	whether redundant shingle levels are to be dropped
<code>panel, xlab, ylab</code>	standard Trellis arguments (see xyplot)
<code>...</code>	other arguments, passed down as appropriate. For example, extra arguments to <code>equal.count</code> are passed on to <code>co.intervals</code> . graphical parameters can be passed as arguments to the <code>plot</code> method.

Details

A shingle is a data structure used in Trellis, and is a generalization of factors to ‘continuous’ variables. It consists of a numeric vector along with some possibly overlapping intervals. These intervals are the ‘levels’ of the shingle. The `levels` and `nlevels` functions, usually applicable to factors, also work on shingles. The implementation of shingles is slightly different from S.

There are print methods for shingles, as well as for printing the result of `levels()` applied to a shingle. For use in labelling, the `as.character` method can be used to convert levels of a shingle to character strings.

`equal.count` converts `x` to a shingle using the equal count algorithm. This is essentially a wrapper around `co.intervals`. All arguments are passed to `co.intervals`.

`shingle` creates a shingle using the given intervals. If `intervals` is a vector, these are used to form 0 length intervals.

`as.shingle` returns `shingle(x)` if `x` is not a shingle.

`is.shingle` tests whether `x` is a shingle.

`plot.shingle` displays the ranges of shingles via rectangles. `print.shingle` and `summary.shingle` describe the shingle object.

Value

`x$intervals` for `levels.shingle(x)`, logical for `is.shingle`, an object of class "trellis" for `plot` (printed by default by `print.trellis`), and an object of class "shingle" for the others.

z <- equal.count(rnorm(50))
plot(z)
print(z)
print(levels(z))
```

simpleKey

Function to generate a simple key

Description

Simple interface to generate a list appropriate for `draw.key`

Usage

```
simpleKey(text, points = TRUE,  
         rectangles = FALSE,  
         lines = FALSE,  
         col, cex, alpha, font,  
         fontface, fontfamily,  
         lineheight, ...)
```

Arguments

text	character or expression vector, to be used as labels for levels of the grouping variable
points	logical
rectangles	logical
lines	logical
col, cex, alpha, font, fontface, fontfamily, lineheight	Used as top-level components of the list produced, to be used for the text labels. Defaults to the values in <code>trellis.par.get("add.text")</code>
...	further arguments added to the list, eventually passed to <code>draw.key</code>

Details

A lattice plot can include a legend (key) if an appropriate list is specified as the `key` argument to a high level Lattice function such as `xyplot`. This key can be very flexible, but that flexibility comes at the cost of this list being very complicated even in simple situations. The `simpleKey` function is a shortcut, which assumes that the key is being drawn in conjunction with the `groups` argument, and that the default Trellis settings are being used. At most one each of `points`, `rectangles` and `lines` can be drawn.

See also the `auto.key` argument for high level plots.

Value

A list that would work as the `key` argument to `xyplot` etc.

[draw.key](#), [xyplot](#), [Lattice](#)

 simpleTheme

Function to generate a simple theme

Description

Simple interface to generate a list appropriate as a theme, typically used as the `par.settings` argument in a high level call

Usage

```
simpleTheme(col, alpha,
           cex, pch, lty, lwd, font, fill, border,
           col.points, col.line,
           alpha.points, alpha.line)
```

Arguments

`col`, `col.points`, `col.line`

A color specification. `col` is used for components `plot.symbol`, `plot.line`, `plot.polygon`, `superpose.symbol`, `superpose.line`, and `superpose.polygon`. `col.points` overrides `col`, and is used only for `plot.symbol` and `superpose.symbol`. Similarly, `col.lines` overrides `col` for `plot.line` and `superpose.line`. The arguments can be vectors, but only the first component is used for scalar targets (i.e., the ones without "superpose" in their name).

`alpha`, `alpha.points`, `alpha.line`

A numeric alpha transparency specification. The same rules as `col`, etc., apply.

`cex`, `pch`, `font`

Parameters for points. Applicable for components `plot.symbol` (for which only the first component is used) and `superpose.symbol` (for which the arguments can be vectors).

`lty`, `lwd`

Parameters for lines. Applicable for components `plot.line` (for which only the first component is used) and `superpose.line` (for which the arguments can be vectors).

`fill`

fill color, applicable for components `plot.symbol`, `plot.polygon`, `superpose.symbol`, and `superpose.polygon`.

`border`

border color, applicable for components `plot.polygon` and `superpose.polygon`.

Details

The appearance of a lattice display depends partly on the “theme” active when the display is plotted (see [trellis.device](#) for details). This theme is used to obtain defaults for various graphical parameters, and in particular, the `auto.key` argument works on the premise that the same source is used for both the actual graphical encoding and the legend. The easiest way to specify custom settings for a particular display is to use the `par.settings` argument, which is usually tedious to construct as it is a nested list. The `simpleTheme` function can be used in such situations as a wrapper that generates a suitable list given parameters in `simple name=value` form, with the nesting made implicit. This is less flexible, but straightforward and sufficient in most situations.

Value

A list that would work as the `theme` argument to `trellis.device` and `trellis.par.set`, or as the `par.settings` argument to any high level lattice function such as `xyplot`.

Author(s)

Deepayan Sarkar (Deepayan.Sarkar@R-project.org), based on a suggestion from John Maindonald.

dotplot(variety ~ yield | site, data = barley, groups = year,
        auto.key = list(space = "right"),
        par.settings = simpleTheme(pch = 16),
        xlab = "Barley Yield (bushels/acre) ",
        aspect=0.5, layout = c(1,6))
```

singer

Heights of New York Choral Society singers

Description

Heights in inches of the singers in the New York Choral Society in 1979. The data are grouped according to voice part. The vocal range for each voice part increases in pitch according to the following order: Bass 2, Bass 1, Tenor 2, Tenor 1, Alto 2, Alto 1, Soprano 2, Soprano 1.

Usage

```
singer
```

Format

A data frame with 235 observations on the following 2 variables.

height Height in inches of the singers.

voice.part (Unordered) factor with levels "Bass 2", "Bass 1", "Tenor 2", "Tenor 1", "Alto 2", "Alto 1", "Soprano 2", "Soprano 1".

```

Arguments

- | | |
|------|--|
| x | <p>The object on which method dispatch is carried out.</p> <p>For the "formula" method, a formula describing the structure of the plot, which should be of the form $\sim x \mid g1 * g2 * \dots$, where x is a data frame or matrix. Each of $g1, g2, \dots$ must be either factors or shingles. The conditioning variables $g1, g2, \dots$ may be omitted.</p> <p>For the <code>data.frame</code> methods, a data frame.</p> |
| data | <p>For the formula methods, an optional data frame in which variables in the</p> |

	formula (as well as <code>groups</code> and <code>subset</code> , if any) are to be evaluated.
<code>aspect</code>	aspect ratio of each panel (and subpanel), square by default for <code>splom</code> .
<code>between</code>	to avoid confusion between panels and subpanels, the default is to show the panels of a <code>splom</code> plot with space between them.
<code>panel</code>	Usual interpretation for <code>parallel</code> , namely the function that creates the display within each panel. For <code>splom</code> , the terminology is slightly complicated. The role played by the <code>panel</code> function in most other high-level functions is played here by the <code>superpanel</code> function, which is responsible for the display for each conditional data subset. <code>panel</code> is simply an argument to the default <code>superpanel</code> function <code>panel.pairs</code> , and is passed on to it unchanged. It is used there to create each pairwise display. See panel.pairs for more useful options.
<code>superpanel</code>	function that sets up the <code>splom</code> display, by default as a scatterplot matrix.
<code>pscales</code>	a numeric value or a list, meant to be a less functional substitute for the <code>scales</code> argument in <code>xyplot</code> etc. This argument is passed to the <code>superpanel</code> function, and is handled by the default <code>superpanel</code> function <code>panel.pairs</code> . The help page for the latter documents this argument in more detail.
<code>varnames</code>	character vector giving the names of the <code>p</code> variables in <code>x</code> . By default, the column names of <code>x</code> .
<code>horizontal.axis</code>	logical indicating whether the parallel axes should be laid out horizontally (TRUE) or vertically (FALSE).
<code>auto.key</code> , <code>prepanel</code> , <code>scales</code> , <code>strip</code> , <code>groups</code> , <code>xlab</code> , <code>xlim</code> , <code>ylab</code> , <code>ylim</code> , <code>drop.unused.l</code>	See xyplot
<code>...</code>	Further arguments. See corresponding entry in xyplot for non-trivial details.

Details

`splom` produces Scatter Plot Matrices. The role usually played by `panel` is taken over by `superpanel`, which takes a data frame subset and is responsible for plotting it. It is called with the coordinate system set up to have both `x`- and `y`-limits from 0.5 to $n\text{col}(z) + 0.5$. The only built-in option currently available is [panel.pairs](#), which calls a further panel function for each pair (i, j) of variables in `z` inside a rectangle of unit width and height centered at $c(i, j)$ (see [panel.pairs](#) for details).

Many of the finer customizations usually done via arguments to high level function like `xyplot` are instead done by `panel.pairs` for `splom`. These include control of axis limits, tick locations and `prepanel` calculations. If you are trying to fine-tune your `splom` plot, definitely look at the [panel.pairs](#) help page. The `scales` argument is usually not very useful in `splom`, and trying to change it may have undesired effects.

[parallel](#) draws Parallel Coordinate Plots. (Difficult to describe, see example.)

These and all other high level Trellis functions have several arguments in common. These are extensively documented only in the help page for `xyplot`, which should be consulted to learn more detailed usage.

Value

An object of class `"trellis"`. The [update](#) method can be used to update components of the object and the [print](#) method (usually called by default) will plot it on an appropriate plotting device.

      })
parallel(~iris[1:4] | Species, iris)
parallel(~iris[1:4], iris, groups = Species,
        horizontal.axis = FALSE, scales = list(x = list(rot = 90)))
```

strip.default

Default Trellis Strip Function

Description

`strip.default` is the function that draws the strips by default in Trellis plots. Users can write their own strip functions, but most commonly this involves calling `strip.default` with a slightly different arguments. `strip.custom` provides a convenient way to obtain new strip functions that differ from `strip.default` only in the default values of certain arguments.

Usage

```
strip.default(which.given,
              which.panel,
              var.name,
              factor.levels,
              shingle.intervals,
              strip.names = c(FALSE, TRUE),
              strip.levels = c(TRUE, FALSE),
              sep = " : ",
              style = 1,
              horizontal = TRUE,
```

```

      bg = trellis.par.get("strip.background")$col[which.given],
      fg = trellis.par.get("strip.shingle")$col[which.given],
      par.strip.text = trellis.par.get("add.text"))
strip.custom(...)

```

Arguments

- `which.given` integer index specifying which of the conditioning variables this strip corresponds to.
- `which.panel` vector of integers as long as the number of conditioning variables. The contents are indices specifying the current levels of each of the conditioning variables (thus, this would be unique for each distinct packet). This is identical to the return value of `which.packet`, which is a more accurate name.
- `var.name` vector of character strings or expressions as long as the number of conditioning variables. The contents are interpreted as names for the conditioning variables. Whether they are shown on the strip depends on the values of `strip.names` and `style` (see below). By default, the names are shown for shingles, but not for factors.
- `factor.levels` vector of character strings or expressions giving the levels of the conditioning variable currently being drawn. For more than one conditioning variable, this will vary with `which.given`. Whether these levels are shown on the strip depends on the values of `strip.levels` and `style` (see below). `factor.levels` may be specified for both factors and shingles (despite the name), but by default they are shown only for factors. If shown, the labels may optionally be abbreviated by specifying suitable components in `par.strip.text` (see `xyplot`)
- `shingle.intervals` if the current strip corresponds to a shingle, this should be a 2-column matrix giving the levels of the shingle. (of the form that would be produced by `printing.levels(shingle)`). Otherwise, it should be `NULL`
- `strip.names` a logical vector of length 2, indicating whether or not the name of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively. This argument is ignored for a factor when `style` is not one of 1 and 3.
- `strip.levels` a logical vector of length 2, indicating whether or not the level of the conditioning variable that corresponds to the strip being drawn is to be written on the strip. The two components give the values for factors and shingles respectively.
- `sep` character or expression, serving as a separator if the name and level are both to be shown.
- `style` integer, with values 1, 2, 3, 4 and 5 currently supported, controlling how the current level of a factor is encoded. Ignored for shingles (actually, when `shingle.intervals` is non-null.
- The best way to find out what effect the value of `style` has is to try them out. Here is a short description: for a style value of 1, the strip is colored in the background color with the strip text (as determined by other arguments) centered on it. A value of 3 is the same, except that a part of the strip is colored in the foreground color, indicating the current level of the factor. For styles 2 and 4, the part corresponding to the current level remains colored in the foreground color, however, for style = 2, the remaining part is not colored at all, whereas for 4, it

is colored with the background color. For both these, the names of all the levels of the factor are placed on the strip from left to right. Styles 5 and 6 produce the same effect (they are subtly different in S, this implementation corresponds to 5), they are similar to style 1, except that the strip text is not centered, it is instead positioned according to the current level.

Note that unlike S-PLUS, the default value of `style` is 1. `strip.names` and `strip.levels` have no effect if `style` is not 1 or 3.

<code>horizontal</code>	logical, specifying whether the labels etc should be horizontal. <code>horizontal=FALSE</code> is useful for strips on the left of panels using <code>strip.left=TRUE</code>
<code>par.strip.text</code>	list with parameters controlling the text on each strip, with components <code>col</code> , <code>cex</code> , <code>font</code> , etc.
<code>bg</code>	strip background color.
<code>fg</code>	strip foreground color.
<code>...</code>	arguments to be passed on to <code>strip.default</code> , overriding whatever value it would have normally assumed

Details

default strip function for trellis functions. Useful mostly because of the `style` argument — non-default styles are often more informative, especially when the names of the levels of the factor `x` are small. Traditional use is as `strip = function(...)` `strip.default(style=2,...)`, though this can be simplified by the use of `strip.custom`.

Value

`strip.default` is called for its side-effect, which is to draw a strip appropriate for multi-panel Trellis conditioning plots. `strip.custom` returns a function that is similar to `strip.default`, but with different defaults for the arguments specified in the call.

Examples

```
## Traditional use
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = function(..., style) strip.default(..., style = 4))

## equivalent call using strip.custom
xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = strip.custom(style = 4))

xyplot(Petal.Length ~ Petal.Width | Species, iris,
       strip = FALSE,
       strip.left = strip.custom(style = 4, horizontal = FALSE))
```

tmd

*Tukey Mean-Difference Plot***Description**

tmd Creates Tukey Mean-Difference Plots from a trellis object returned by `xyplot`, `qq` or `qqmath`. The `prepanel` and `panel` functions are used as appropriate. The `formula` method for `tmd` is provided for convenience, and simply calls `tmd` on the object created by calling `xyplot` on that formula.

Usage

```
tmd(object, ...)
```

```
## S3 method for class 'trellis':
tmd(object,
     xlab = "mean",
     ylab = "difference",
     panel,
     prepanel,
     ...)
```

```
prepanel.tmd.qqmath(x,
                    f.value = NULL,
                    distribution = qnorm,
                    qtype = 7,
                    groups = NULL,
                    subscripts, ...)
```

```
panel.tmd.qqmath(x,
                 f.value = NULL,
                 distribution = qnorm,
                 qtype = 7,
                 groups = NULL,
                 subscripts, ...)
```

```
panel.tmd.default(x, y, groups = NULL, ...)
```

```
prepanel.tmd.default(x, y, ...)
```

Arguments

<code>object</code>	An object of class "trellis" returned by <code>xyplot</code> , <code>qq</code> or <code>qqmath</code> .
<code>xlab</code>	x label
<code>ylab</code>	y label
<code>panel</code>	panel function to be used. See details below.
<code>prepanel</code>	prepanel function. See details below.
<code>f.value</code> , <code>distribution</code> , <code>qtype</code>	see panel.qqmath .
<code>groups</code> , <code>subscripts</code>	see xyplot .
<code>x</code> , <code>y</code>	data as passed to panel functions in original call.
<code>...</code>	other arguments

Details

The Tukey Mean-difference plot is produced by modifying the (x,y) values of each panel as follows: the new coordinates are given by $x = (x+y) / 2$ and $y = y - x$, which are then plotted. The default panel function(s) add a reference line at $y=0$ as well.

tmd acts on the a "trellis" object, not on the actual plot this object would have produced. As such, it only uses the arguments supplied to the panel function in the original call, and completely ignores what the original panel function might have done with this data. tmd uses these panel arguments to set up its own scales (using its `prepanel` argument) and display (using `panel`). It is thus important to provide suitable `prepanel` and `panel` functions to tmd depending on the original call.

Such functions currently exist for `xyplot`, `qq` (the ones with `default` in their name) and `qqmath`, as listed in the usage section above. These assume the default displays for the corresponding high-level call. If unspecified, the `codeprepanel` and `panel` arguments default to suitable choices.

tmd uses the `update` method for "trellis" objects, which processes all extra arguments supplied to tmd.

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

trellis.device

Initializing Trellis Displays

Description

Initialization of a display device with appropriate graphical parameters.

Usage

```
trellis.device(device = getOption("device"),
              color = !(dev.name == "postscript"),
              theme = lattice.getOption("default.theme"),
              new = TRUE,
              retain = FALSE,
              ...)
```

```
standard.theme(name, color)
canonical.theme(name, color)
col.whitebg()
```

Arguments

device	function (or the name of one as a character string) that starts a device. Admissible values depend on the platform and how R was compiled (see Devices), but usually "pdf", "postscript", "png", "jpeg" and at least one of "X11", "windows" and "quartz" will be available.
color	logical, whether the initial settings should be color or black and white. Defaults to FALSE for postscript devices, TRUE otherwise. Note that this only applies to the initial choice of colors, which can be overridden using <code>theme</code> or subsequent calls to <code>trellis.par.set</code> (and by arguments supplied directly in high level calls for some settings).
theme	list of components that changes the settings of the device opened, or, a function that when called produces such a list. The function name can be supplied as a quoted string. These settings are only used to modify the default settings (determined by other arguments), and need not contain all possible parameters. A possible use of this argument is to change the default settings by specifying <code>lattice.options(default.theme = "col.whitebg")</code> . For back-compatibility, this is initially (when <code>lattice</code> is loaded) set to <code>options(lattice.theme)</code> . If <code>theme</code> is a function, it will not be supplied any arguments, however, it is guaranteed that a device will already be open when it is called, so one may use <code>.Device</code> inside the function to ascertain what device has been opened.
new	logical flag indicating whether a new device should be started. If FALSE, the options for the current device are changed to the defaults determined by the other arguments.
retain	logical. If TRUE and a setting for this device already exists, then that is used instead of the defaults for this device. By default, pre-existing settings are overwritten (and lost).
name	name of the device for which the setting is required, as returned by <code>.Device</code>
...	additional parameters to be passed to the device function, most commonly <code>file</code> for non-screen devices, as well as <code>height</code> , <code>width</code> , etc. See the help file for individual devices for admissible arguments.

Details

Trellis Graphics functions obtain the default values of various graphical parameters (colors, line types, fonts, etc.) from a customizable “settings” list. This functionality is analogous to `par` for standard R graphics and, together with `lattice.options`, mostly supplants it (`par` settings are mostly ignored by Lattice). Unlike `par`, Trellis settings can be controlled separately for each different device type (but not concurrently for different instances of the same device). `standard.theme` and `col.whitebg` produce predefined settings (a.k.a. themes), while `trellis.device` provides a high level interface to control which “theme” will be in effect when a new device is opened. `trellis.device` is called automatically when a "trellis" object is plotted, and the defaults can be used to provide sufficient control, so in a properly configured system it is rarely necessary for the user to call `trellis.device` explicitly.

The `standard.theme` function is intended to provide device specific settings (e.g. light colors on a grey background for screen devices, dark colors or black and white for print devices) which were used as defaults prior to R 2.3.0. However, these defaults are not always appropriate, due to the variety of platforms and hardware settings on which R is used, as well as the fact that a plot created on a particular device may be subsequently used in many different ways. For this reason, a “safe” default is used for all devices from R 2.3.0 onwards. The old behaviour can be reinstated by setting `standard.theme` as the default `theme` argument, e.g. by putting `options(lattice.theme = "standard.theme")` in a startup script (see the entry for `theme` above for details).

Value

`standard.theme` returns a list of components defining graphical parameter settings for Lattice displays. It is used internally in `trellis.device`, and can also be used as the `theme` argument to `trellis.par.set`, or even as `theme` in `trellis.device` to use the defaults for another device. `canonical.theme` is an alias for `standard.theme`.

`col.whitebg` returns a similar (but smaller) list that is suitable as the `theme` argument to `trellis.device` and `trellis.par.set`. It contains settings values which provide colors suitable for plotting on a white background. Note that the name `col.whitebg` is somewhat of a misnomer, since it actually sets the background to transparent rather than white.

Note

Earlier versions of `trellis.device` had a `bg` argument to set the background color, but this is no longer supported. If supplied, the `bg` argument will be passed on to the device function; however, this will have no effect on the Trellis settings. It is rarely meaningful to change the background alone; if you feel the need to change the background, consider using the `theme` argument instead.

[Devices](#) for valid choices of device on your platform.

[trellis.par.get](#) and [trellis.par.set](#) can be used to query and modify the settings *after* a device has been initialized. The `par.settings` argument to high level functions, described in [xyplot](#), can be used to attach transient settings to a "trellis" object.

trellis.object *A Trellis Plot Object*

Description

This class of objects is returned by high level lattice functions, and is usually plotted by default by its `print` method.

Details

A trellis object, as returned by high level lattice functions like `xyplot`, is a list with the "class" attribute set to "trellis". Many of the components of this list are simply the arguments to the high level function that produced the object. Among them are: `as.table`, `layout`, `page`, `panel`, `prepanel`, `main`, `sub`, `par.strip.text`, `strip`, `skip`, `xlab` `ylab`, `par.settings`, `lattice.options` and `plot.args`. Some other typical components are:

formula the Trellis formula used in the call

index.cond list with index for each of the conditioning variables

perm.cond permutation of the order of the conditioning variables

aspect.fill logical, whether aspect is "fill"

aspect.ratio numeric, aspect ratio to be used if `aspect.fill` is FALSE

call call that generated the object.

condlevels list with levels of the conditioning variables

legend list describing the legend(s) to be drawn

panel.args a list as long as the number of panels, each element being a list itself, containing the arguments in named form to be passed to the panel function in that panel.

panel.args.common a list containing the arguments common to all the panel functions in name=value form

x.scales list describing x-scale, can consist of several other lists, paralleling `panel.args`, if x-relation is not "same"

y.scales list describing y-scale, similar to `x.scales`

x.between numeric vector of interpanel x-space

y.between numeric vector of interpanel y-space

x.limits numeric vector of length 2 or list, giving x-axis limits

y.limits similar to `x.limits`

packet.sizes array recording the number of observations in each packet

Graphical Parameters for Trellis Displays

Description

Functions used to query, display and modify graphical parameters for fine control of Trellis displays. Modifications are made to the settings for the currently active device only.

Usage

```
trellis.par.set(name, value, ..., theme, warn = TRUE, strict = FALSE)
trellis.par.get(name = NULL)
show.settings(x = NULL)
```

Arguments

name	character giving the name of a component. If unspecified, <code>names(trellis.par.get())</code> returns a list containing all the current settings (this can be used to get the valid values for name)
value	a list giving the desired value of the component. Components that are already defined as part of the current settings but are not mentioned in <code>value</code> will remain unchanged.
theme	a list describing how to change the settings, similar to what is returned by <code>trellis.par.get()</code> . This is purely for convenience, allowing multiple calls to <code>trellis.par.set</code> to be condensed into one. The name of each component must be a valid name as described above, with the corresponding value a valid value as described above. As in <code>trellis.device</code> , <code>theme</code> can also be a function that produces such a list when called. The function name can be supplied as a quoted string.
...	Multiple settings can be specified in <code>name = value</code> form. Equivalent to calling with <code>theme = list(...)</code>
warn	logical, indicating whether a warning should be issued when <code>trellis.par.get</code> is called when no graphics device is open
strict	logical, indicating whether the <code>value</code> should be interpreted strictly. Usually, assignment of <code>value</code> to the corresponding named component is fuzzy in the sense that sub-components that are absent from <code>value</code> but not currently <code>NULL</code> are retained. By specifying <code>strict = TRUE</code> , the assignment will be exact.
x	optional list of components that change the settings (any valid value of <code>theme</code>). These are used to modify the current settings (obtained by <code>trellis.par.get</code>) before they are displayed.

Details

The various graphical parameters (color, line type, background etc) that control the look and feel of Trellis displays are highly customizable. Also, R can produce graphics on a number of devices, and it is expected that a different set of parameters would be more suited to different devices. These parameters are stored internally in a variable named `lattice.theme`, which is a list whose components define settings for particular devices. The components are identified by the name of the device they represent (as obtained by `.Device`), and are created as and when new devices are

opened for the first time using `trellis.device` (or Lattice plots are drawn on a device for the first time in that session).

The initial settings for each device defaults to values appropriate for that device. In practice, this boils down to three distinct settings, one for screen devices like `x11` and `windows`, one for black and white plots (mostly useful for `postscript`) and one for color printers (`color postscript`, `pdf`).

Once a device is open, its settings can be modified. When another instance of the same device is opened later using `trellis.device`, the settings for that device are reset to its defaults, unless otherwise specified in the call to `trellis.device`. But settings for different devices are treated separately, i.e., opening a `postscript` device will not alter the `x11` settings, which will remain in effect whenever an `x11` device is active.

The functions `trellis.par.*` are meant to be interfaces to the global settings. They always apply on the settings for the currently ACTIVE device.

`trellis.par.get`, called without any arguments, returns the full list of settings for the active device. With the `name` argument present, it returns that component only. `trellis.par.get` sets the value of the `name` component of the current active device settings to `value`.

`trellis.par.get` is usually used inside `trellis` functions to get graphical parameters before plotting. Modifications by users via `trellis.par.set` is traditionally done as follows:

```
add.line <- trellis.par.get("add.line")
```

```
add.line$col <- "red"
```

```
trellis.par.set("add.line", add.line)
```

More convenient (but not S compatible) ways to do this are

```
trellis.par.set(list(add.line = list(col = "red")))
```

and

```
trellis.par.set(add.line = list(col = "red"))
```

The actual list of the components in `trellis.settings` has not been finalized, so I'm not attempting to list them here. The current value can be obtained by `print(trellis.par.get())`. Most names should be self-explanatory.

`show.settings` provides a graphical display summarizing some of the values in the current settings.

Value

`trellis.par.get` returns a list giving parameters for that component. If `name` is missing, it returns the full list.

Note

In some ways, `trellis.par.get` and `trellis.par.set` together are a replacement for the `par` function used in traditional R graphics. In particular, changing `par` settings has little (if any) effect on lattice output. Since lattice plots are implemented using Grid graphics, its parameter system *does* have an effect unless overridden by a suitable lattice parameter setting. Such parameters can be specified as part of a lattice theme by including them in the `grid.pars` component (see `gpar` for a list of valid parameter names).

One of the uses of `par` is to set `par(ask = TRUE)` making R wait for user input before starting a new graphics page. For Grid graphics, this is done using `grid.prompt`. Lattice has no separate interface for this, and the user must call `grid.prompt` directly. If the grid package is not attached (lattice itself only loads the grid namespace), this may be done using `grid::grid.prompt(TRUE)`.

update.trellis *Retrieve and Update Trellis Object*

Description

Update method for objects of class "trellis", and a way to retrieve the last printed trellis object (that was saved).

Usage

```
## S3 method for class 'trellis':  
update(object,  
        panel,  
        aspect,  
        as.table,  
        between,  
        key,  
        auto.key,  
        legend,  
        layout,  
        main,  
        page,  
        par.strip.text,  
        prepanel,  
        scales,  
        skip,  
        strip,  
        strip.left,  
        sub,  
        xlab,  
        xlim,  
        ylab,  
        ylim,  
        par.settings,  
        plot.args,  
        lattice.options,  
        index.cond,  
        perm.cond,  
        ...)
```

```
## S3 method for class 'trellis':
t(x)

## S3 method for class 'trellis':
x[i, j, ..., drop = FALSE]

trellis.last.object(warn = TRUE, ...)
```

Arguments

`object`, `x` The object to be updated, of class "trellis".

`i`, `j` indices to be used. Names are not currently allowed.

`drop` logical, whether dimensions with only one level are to be dropped. Currently ignored, behaves as if it were `FALSE`.

`warn` logical, whether to warn when no plot is saved.

`panel`, `aspect`, `as.table`, `between`, `key`, `auto.key`, `legend`, `layout`, `main`, `page`, `par` arguments that will be used to update `object`. See details below.

Details

All high level lattice functions such as `xyplot` produce an object of (S3) class "trellis", which is usually displayed by its `print` method. However, the object itself can be manipulated and modified to a large extent using the `update` method, and then re-displayed as needed.

Most arguments to high level functions can also be supplied to the `update` method as well, with some exceptions. Generally speaking, anything that would need to change the data within each panel is a no-no (this includes the `formula`, `data`, `groups`, `subscripts` and `subset`). Everything else is technically game, though might not be implemented yet. If you find something missing that you wish to have, feel free to make a request.

Not all arguments accepted by a Lattice function are processed by `update`, but the ones listed above should work. The purpose of these arguments are described in the help page for `xyplot`. Any other argument is added to the list of arguments to be passed to the `panel` function. Because of their somewhat special nature, updates to objects produced by `cloud` and `wireframe` do not work very well yet.

The `"["` method is a convenient shortcut for updating `index.cond`. The `t` method is a convenient shortcut for updating `perm.cond` in the special (but frequent) case where there are exactly two conditioning variables, when it has the effect of switching ('transposing') their order.

The `print` method for "trellis" objects optionally saves the object after printing it. If this feature is enabled, `trellis.last.object` can retrieve it. Note that at most one object can be saved at a time. If `trellis.last.object` is called with arguments, these are used to update the retrieved object before returning it.

Value

An object of class `trellis`, by default plotted by `print.trellis`. `trellis.last.object` returns `NULL` if no saved object is available.

utilities.3d

Utility functions for 3-D plots

Description

These are (related to) the default panel functions for `cloud` and `wireframe`.

Usage

```
ltransform3dMatrix(screen, R.mat)
ltransform3dto3d(x, R.mat, dist)
```

Arguments

<code>x</code>	<code>x</code> can be a numeric matrix with 3 rows for <code>ltransform3dto3d</code>
<code>screen</code>	list, as described in panel.cloud
<code>R.mat</code>	4x4 transformation matrix in homogeneous coordinates
<code>dist</code>	controls transformation to account for perspective viewing

Details

`ltransform3dMatrix` and `ltransform3dto3d` are utility functions to help in computation of projections. These functions are used inside the panel functions for `cloud` and `wireframe`. They may be useful in user-defined panel functions as well.

The first function takes a list of the form of the `screen` argument in `cloud` and `wireframe` and a `R.mat`, a 4x4 transformation matrix in homogeneous coordinates, to return a new 4x4 transformation matrix that is the result of applying `R.mat` followed by the rotations in `screen`. The second function applies a 4x4 transformation matrix in homogeneous coordinates to a 3xn matrix representing points in 3-D space, and optionally does some perspective computations. (There has been no testing with non-trivial transformation matrices, and my knowledge of the homogeneous coordinate system is very limited, so there may be bugs here.)

 xyplot

Common Bivariate Trellis Plots

Description

These are the most commonly used high level Trellis functions to plot pairs of variables. By far the most common is `xyplot`, designed mainly for two continuous variates (though factors can be supplied as well, in which case they will simply be coerced to numeric), which produces Conditional Scatter plots. The others are useful when one of the variates is a factor or a shingle. Most of these arguments are also applicable to other high level functions in the lattice package, but are only documented here.

Usage

```
xyplot(x, data, ...)
dotplot(x, data, ...)
barchart(x, data, ...)
stripplot(x, data, ...)
bwplot(x, data, ...)

## S3 method for class 'formula':
xyplot(x,
  data,
  allow.multiple = is.null(groups) || outer,
  outer = !is.null(groups),
  auto.key = FALSE,
  aspect = "fill",
  panel = lattice.getOption("panel.xyplot"),
  prepanel = NULL,
  scales = list(),
  strip = TRUE,
  groups = NULL,
  xlab,
  xlim,
  ylab,
  ylim,
  drop.unused.levels = lattice.getOption("drop.unused.levels"),
  ...,
  lattice.options = NULL,
  default.scales,
  subscripts = !is.null(groups),
  subset = TRUE)

## S3 method for class 'formula':
dotplot(x,
  data,
  panel = lattice.getOption("panel.dotplot"),
```

```

    ...)
```

```

## S3 method for class 'formula':
barchart(x,
         data,
         panel = lattice.getOption("panel.barchart"),
         box.ratio = 2,
         ...)

## S3 method for class 'formula':
stripplot(x,
          data,
          panel = lattice.getOption("panel.stripplot"),
          ...)

## S3 method for class 'formula':
bwplot(x,
       data,
       allow.multiple = is.null(groups) || outer,
       outer = FALSE,
       auto.key = FALSE,
       aspect = "fill",
       panel = lattice.getOption("panel.bwplot"),
       prepanel = NULL,
       scales = list(),
       strip = TRUE,
       groups = NULL,
       xlab,
       xlim,
       ylab,
       ylim,
       box.ratio = 1,
       horizontal = NULL,
       drop.unused.levels = lattice.getOption("drop.unused.levels"),
       ...,
       lattice.options = NULL,
       default.scales,
       subscripts = !is.null(groups),
       subset = TRUE)

```

Arguments

- x** The object on which method dispatch is carried out.
- For the "formula" methods, a formula describing the form of conditioning plot. The formula is generally of the form $y \sim x \mid g1 * g2 * \dots$, indicating that plots of y (on the y axis) versus x (on the x axis) should be produced conditional on the variables $g1, g2, \dots$. However, the conditioning variables $g1, g2, \dots$ may be omitted. The formula can also be supplied as $y \sim x \mid g1 + g2 + \dots$.
- For all of these functions, with the exception of `xyplot`, a formula of the form $\sim x \mid g1 * g2 * \dots$ is also allowed. In that case, y defaults

to `names(x)` if `x` is named, and a factor with a single level otherwise.

Other usage of the form `dotplot(x)` is handled by method dispatch as appropriate. The `numeric` method is equivalent to a call with no left hand side and no conditioning variables in the formula. For `barchart` and `dotplot`, non-trivial methods exist for tables and arrays, documented under [barchart.table](#).

The conditioning variables `g1`, `g2`, ... must be either factors or shingles. Shingles are a way of processing numeric variables for use in conditioning. See documentation of [shingle](#) for details. Like factors, they have a "levels" attribute, which is used in producing the conditional plots.

Numeric conditioning variables are converted to shingles by the function `shingle` (however, using `equal.count` might be more appropriate in many cases) and character vectors are coerced to factors.

The formula can involve expressions, e.g. `sqrt()`, `log()`.

A special case is when the left and/or right sides of the formula (before the conditioning variables) contain a '+' sign, e.g., `y1+y2 ~ x | a*b`. This formula would be taken to mean that the user wants to plot both `y1~x | a*b` and `y2~x | a*b`, but with the `y1~x` and `y2~x` superposed in each panel (this is slightly more complicated in `barchart`). The two parts would be distinguished by different graphical parameters. This is essentially what the `groups` argument would produce, if `y1` and `y2` were concatenated to produce a longer vector, with the `groups` argument being an indicator of which rows come from which variable. In fact, this is exactly what is done internally using the `reshape` function. This feature cannot be used in conjunction with the `groups` argument.

To interpret `y1 + y2` as a sum, one can either set `allow.multiple=FALSE` or use `I(y1+y2)`.

A variation on this feature is when the `outer` argument is set to `TRUE` as well as `allow.multiple`. In that case, the plots are not superposed in each panel, but instead separated into different panels (as if a new conditioning variable had been added).

The `x` and `y` variables should both be numeric in `xyplot`, and an attempt is made to coerce them if not. However, if either is a factor, the levels of that factor are used as axis labels. In the other four functions documented here, exactly one of `x` and `y` should be numeric, and the other a factor or shingle. Which of these will happen is determined by the `horizontal` argument — if `horizontal=TRUE`, then `y` will be coerced to be a factor or shingle, otherwise `x`. The default value of `horizontal` is `FALSE` if `x` is a factor or shingle, `TRUE` otherwise. (The functionality provided by `horizontal=FALSE` is not S-compatible.)

Note that this argument used to be called `formula` in earlier versions (when the high level functions were not generic and the `formula` method was essentially the only method). This is no longer allowed. It is recommended that this argument not be named in any case, but rather be the first (unnamed) argument.

`data`

For the `formula` method, a data frame containing values (or more precisely, anything that is a valid `envir` argument in `eval`, e.g. a list or an environment) for any variables in the formula, as well as `groups` and `subset` if applicable. If not found in `data`, or if `data` is unspecified, the variables are looked for in the environment of the formula. For other methods (where `x` is not a formula), `data` is usually ignored, often with a warning.

<code>allow.multiple</code> , <code>outer</code>	logical flags to control what happens with formulas like $y_1 + y_2 \sim x$. See the entry for <code>x</code> for details. <code>allow.multiple</code> defaults to <code>TRUE</code> whenever it makes sense, and <code>outer</code> defaults to <code>FALSE</code> except when <code>groups</code> is explicitly specified or grouping doesn't make sense for the default panel function
<code>box.ratio</code>	applicable to <code>bwplot</code> , <code>barchart</code> and <code>stripplot</code> , specifies the ratio of the width of the rectangles to the inter rectangle space.
<code>horizontal</code>	logical, applicable to <code>bwplot</code> , <code>dotplot</code> , <code>barchart</code> and <code>stripplot</code> . Determines which of <code>x</code> and <code>y</code> is to be a factor or shingle (<code>y</code> if <code>TRUE</code> , <code>x</code> otherwise). Defaults to <code>FALSE</code> if <code>x</code> is a factor or shingle, <code>TRUE</code> otherwise. This argument is used to process the arguments to these high level functions, but more importantly, it is passed as an argument to the panel function, which is supposed to use it as appropriate. A potentially useful component of <code>scales</code> in this case might be <code>abbreviate = TRUE</code> , in which case long labels which would usually overlap will be abbreviated. <code>scales</code> could also contain a <code>minlength</code> argument in this case, which would be passed to the <code>abbreviate</code> function.
<code>panel</code>	Once the subset of rows defined by each unique combination of the levels of the grouping variables are obtained (see details), the corresponding <code>x</code> and <code>y</code> variables (or other variables, as appropriate, in the case of other high level functions) are passed on to be plotted in each panel. The actual plotting is done by the function specified by the <code>panel</code> argument. Each high level function has its own default panel function, which could depend on whether the <code>groups</code> argument was supplied. The panel function can be a function object or a character string giving the name of a predefined function. Much of the power of Trellis Graphics comes from the ability to define customized panel functions. A panel function appropriate for the functions described here would usually expect arguments named <code>x</code> and <code>y</code> , which would be provided by the conditioning process. It can also have other arguments. It might be useful to know in this context that all arguments passed to a high level Trellis function (such as <code>xyplot</code>) that are not recognized by it are passed through to the panel function. It is thus generally good practice when defining panel functions to allow a <code>...</code> argument. Such extra arguments typically control graphical parameters, but other uses are also common. See documentation for individual panel functions for specifics. Note that unlike in S-PLUS, it is not guaranteed that panel functions will be supplied only numeric vectors for the <code>x</code> and <code>y</code> arguments; they can be factors as well (but not shingles). Panel functions need to handle this case, which in most cases can be done by simply coercing them to numeric. Technically speaking, panel functions must be written using Grid graphics functions. However, knowledge of Grid is usually not necessary to construct new custom panel functions, there are several predefined panel functions which can help; for example, <code>panel.grid</code> , <code>panel.loess</code> , etc. There are also some grid-compatible replacements of commonly used base R graphics functions useful for this purpose. For example, <code>lines</code> can be replaced by <code>llines</code> (or equivalently, <code>panel.lines</code>). Note that base R graphics functions like <code>lines</code> will not work in a lattice panel function. One case where a bit more is required of the panel function is when the <code>groups</code> argument is not null. In that case, the panel function should also accept arguments named <code>groups</code> and <code>subscripts</code> (see below for details). A useful panel function predefined for use in such cases is <code>panel.superpose</code> ,

which can be combined with different `panel.groups` functions determining what is plotted for each group. See the examples section for an interaction plot constructed in this way. Several other panel functions can also handle the `groups` argument, including the default ones for `barchart`, `dotplot` and `stripplot`.

Even when `groups` is not present, the panel function can have `subscripts` as a formal argument. In either case, the `subscripts` argument passed to the panel function are the indices of the `x` and `y` data for that panel in the original data, BEFORE taking into account the effect of the `subset` argument. Note that `groups` remains unaffected by any subsetting operations, so `groups[subscripts]` gives the values of `groups` that correspond to the data in that panel.

This interpretation of `subscripts` does not hold when the extended formula interface is in use (i.e., when `allow.multiple` is in effect). A comprehensive description would be too complicated (details can be found in the source code of the function `latticeParseFormula`), but in short, the extended interface works by creating an artificial grouping variable that is longer than the original data frame, and consequently, `subscripts` needs to refer to rows beyond those in the original data. To further complicate matters, the artificial grouping variable is created after any effect of `subset`, in which case `subscripts` has practically no relationship with corresponding rows in the original data frame.

One can also use functions called `panel.number` and `packet.number`, representing panel order and packet order respectively, inside the panel function (as well as the `strip` function or while interacting with a lattice display using `trellis.focus` etc). Both provide a simple integer index indicating which panel is currently being drawn, but differ in how the count is calculated. The panel number is a simple incremental counter that starts with 1 and is incremented each time a panel is drawn. The packet number on the other hand indexes the combination of levels of the conditioning variables that is represented by that panel. The two indices coincide unless the order of conditioning variables is permuted and/or the plotting order of levels within one or more conditioning variables is altered (using `perm.cond` and `index.cond` respectively), in which case `packet.number` gives the index corresponding to the 'natural' ordering of that combination of levels of the conditioning variables.

`panel.xyplot` has an argument called `type` which is worth mentioning here because it is quite frequently used (and as mentioned above, can be passed to `xyplot` directly). In the event that a `groups` variable is used, `panel.xyplot` calls `panel.superpose`, arguments of which can also be passed directly to `xyplot`. Panel functions for `bwplot` and friends should have an argument called `horizontal` to account for the cases when `x` is the factor or shingle.

aspect

controls physical aspect ratio of the panels (same for all the panels). It can be specified as a ratio (vertical size/horizontal size) or as a character string. Legitimate values are `"fill"` (the default) which tries to make the panels as big as possible to fill the available space; `"xy"`, which **tries** to compute the aspect based on the 45 degree banking rule (see *Visualizing Data* by William S. Cleveland for details); and `"iso"` for isometric scales, where the relation between physical distance on the device and distance in the data scale are forced to be the same for both axes.

If a `prepanel` function is specified and it returns components `dx` and `dy`, these are used for banking calculations. Otherwise, values from the default `prepanel`

function are used. Currently, only the default prepanel function for `xyplot` can be expected to produce sensible banking calculations. See [banking](#) for details on the implementation of banking .

<code>groups</code>	<p>a variable or expression to be evaluated in the data frame specified by <code>data</code>, expected to act as a grouping variable within each panel, typically used to distinguish different groups by varying graphical parameters like color and line type. Formally, if <code>groups</code> is specified, then <code>groups</code> along with <code>subscripts</code> is passed to the panel function, which is expected to handle these arguments. Not all pre-defined panel functions know how to, but for high level functions where grouping is appropriate, the default panel functions are chosen so that they do. It is very common to use a key (legend) when a grouping variable is specified. See entries for <code>key</code>, <code>auto.key</code> and <code>simpleKey</code> for how to draw a key.</p>
<code>auto.key</code>	<p>A logical (indicating whether a key is to be drawn automatically when a grouping variable is present in the plot), or a list of parameters that would be valid arguments to <code>simpleKey</code> (in effect, most valid components of <code>key</code> can be specified in this manner). If <code>auto.key</code> is not <code>FALSE</code>, <code>groups</code> is non-null and there is no <code>key</code> or <code>legend</code> argument specified in the call, a key is created with <code>simpleKey</code> with <code>levels(groups)</code> as the first argument. (Note: this may not work in all high level functions, but it does work for the ones where grouping makes sense with the default panel function)</p> <p><code>simpleKey</code> uses the trellis settings to determine the graphical parameters in the key, so this will be meaningful only if the settings are used in the plot as well.</p> <p>One disadvantage to using <code>key</code> (or even <code>simpleKey</code>) directly is that the graphical parameters used in the key are absolutely determined at the time when the "trellis" object is created. Consequently, if a plot once created is reprinted with different settings, the parameter settings for the original device will be used. However, with <code>auto.key</code>, the key is actually created at printing time, so the key settings will match the device settings.</p>
<code>prepanel</code>	<p>function that takes the same arguments as the <code>panel</code> function and returns a list, possibly containing components named <code>xlim</code>, <code>ylim</code>, <code>dx</code> and <code>dy</code> (and less frequently, <code>xat</code> and <code>yat</code>).</p> <p>The <code>xlim</code> and <code>ylim</code> components are similar to the high level <code>xlim</code> and <code>ylim</code> arguments (i.e., they are usually a numeric vector of length 2 defining a range of values, or a character vector representing levels of a factor). If the <code>xlim</code> and <code>ylim</code> arguments are not explicitly specified (possibly as components in <code>scales</code>), then the actual limits of the panels are guaranteed to include the limits returned by the <code>prepanel</code> function. This happens globally if the <code>relation</code> component of <code>scales</code> is "same", and on a panel by panel basis otherwise. See <code>xlim</code> to see what forms of the components <code>xlim</code> and <code>ylim</code> are allowed.</p> <p>The <code>dx</code> and <code>dy</code> components are used for banking computations in case <code>aspect</code> is specified as "xy". See documentation for the function <code>banking</code> for details regarding how this is done.</p> <p>The return value of the <code>prepanel</code> function need not have all the components named above; in case some are missing, they are replaced by the usual component-wise defaults.</p> <p>If <code>xlim</code> or <code>ylim</code> is a character vector (which is appropriate when the corresponding variable is a factor), this implicitly indicates that the scale should include the first <code>n</code> integers, where <code>n</code> is the length of <code>xlim</code> or <code>ylim</code>, as the case may be. The elements of the character vector are used as the default labels for these <code>n</code> integers. Thus, to make this information consistent between panels, the</p>

`xlim` or `ylim` values should represent all the levels of the corresponding factor, even if some are not used within that particular panel.

In such cases, an additional component `xat` or `yat` may be returned by the `prepanel` function, which should be a subset of `1:n`, indicating which of the `n` values (levels) are actually represented in the panel. This is useful when calculating the limits with `relation="free"` or `relation="sliced"` in `scales`.

The `prepanel` function is responsible for providing a meaningful return value when the `x`, `y` (etc.) variables are zero-length vectors. When nothing is appropriate, values of `NA` should be returned for the `xlim` and `ylim` components.

<code>strip</code>	logical flag or function. If <code>FALSE</code> , strips are not drawn. Otherwise, strips are drawn using the <code>strip</code> function, which defaults to <code>strip.default</code> . See documentation of <code>strip.default</code> to see the arguments that are available to the <code>strip</code> function. This description also applies to the <code>strip.left</code> argument (see . . . below), which can be used to draw strips on the left of each panel, which can be useful for wide short panels, e.g. in time series plots.
<code>xlab</code>	character string or expression (or a "grob") giving label for the x-axis. Defaults to the expression for <code>x</code> in <code>formula</code> . Can be specified as <code>NULL</code> to omit the label altogether. Finer control is possible, as described in the entry for <code>main</code> , with the additional feature that if the <code>label</code> component is omitted from the list, it is replaced by the default <code>xlab</code> .
<code>ylab</code>	character string or expression (or "grob") giving label for the y-axis. Defaults to the expression for <code>y</code> in <code>formula</code> . Fine control is possible, see entries for <code>main</code> and <code>xlab</code> .
<code>scales</code>	list determining how the x- and y-axes (tick marks and labels) are drawn. The list contains parameters in <code>name=value</code> form, and may also contain two other lists called <code>x</code> and <code>y</code> of the same form (described below). Components of <code>x</code> and <code>y</code> affect the respective axes only, while those in <code>scales</code> affect both. When parameters are specified in both lists, the values in <code>x</code> or <code>y</code> are used. Note that certain high-level functions have defaults that are specific to a particular axis (e.g., <code>bwplot</code> has <code>alternating=FALSE</code> for the y-axis only); these can be overridden only by an entry in the corresponding component of <code>scales</code> .

The possible components are :

relation character string that determines how axis limits are calculated for each panel. Possible values are "same" (default), "free" and "sliced". For `relation="same"`, the same limits, usually large enough to encompass all the data, are used for all the panels. For `relation="free"`, limits for each panel is determined by just the points in that panel. Behavior for `relation="sliced"` is similar, except that the length (max - min) of the scales are constrained to remain the same across panels.

The determination of what axis limits are suitable for each panel can be controlled by the `prepanel` function, which can be overridden by `xlim`, `ylim` or `scales$limits`. If `relation` is not "same", the value of `xlim` etc is normally ignored, except when it is a list, in which case it is treated as if its components were the limit values obtained from the `prepanel` calculations for each panel.

tick.number Suggested number of ticks (ignored for a factor, shingle or character vector, in which case there is no natural rule for leaving out some of the labels. But see `xlim`).

- draw** logical, defaults to TRUE, whether to draw the axis at all.
- alternating** logical specifying whether axis labels should alternate from one side of the group of panels to the other. For finer control, alternating can be a vector (replicated to be as long as the number of rows or columns per page) consisting of the following numbers
- 0: do not draw tick labels
 - 1: bottom/left
 - 2: top/right
 - 3: both.
- alternating applies only when relation="same". The default is TRUE, or equivalently, c(1, 2)
- limits** same as xlim and ylim.
- at** location of tick marks along the axis (in native coordinates), or a list as long as the number of panels describing tick locations for each panel.
- labels** Labels (strings or expressions) to go along with at. Can be a list like at as well.
- cex** numeric multiplier to control character sizes for axis labels. Can be a vector of length 2, to control left/bottom and right/top separately.
- font, fontface, fontfamily** specifies font for axis labels.
- tck** numeric to control length of tick marks. Can be a vector of length 2, to control left/bottom and right/top separately.
- col** color of ticks and labels.
- rot** Angle by which the axis labels are to be rotated. Can be a vector of length 2, to control left/bottom and right/top separately.
- abbreviate** logical, whether to abbreviate the labels using abbreviate. Can be useful for long labels (e.g., in factors), especially on the x-axis.
- minlength** argument passed to abbreviate if abbreviate=TRUE.
- log** Controls whether the corresponding variable (x or y) will be log transformed before being passed to the panel function. Defaults to FALSE, in which case the data are not transformed. Other possible values are any number that works as a base for taking logarithm, TRUE (which is equivalent to 10), and "e" (for the natural logarithm). As a side effect, the corresponding axis is labeled differently. Note that this is a transformation of the data, not the axes. Other than the axis labeling, using this feature is no different than transforming the data in the formula; e.g., scales=list(x = list(log = 2)) is equivalent to $y \sim \log_2(x)$.
- format** the format to use for POSIXct variables. See [strptime](#) for description of valid values.
- axis** character, "r" or "i". In the latter case, the axis limits are calculated as the exact data range, instead of being padded on either side. (May not always work as expected.)

Note that much of the function of scales is accomplished by pscales in splom.

- subscripts** logical specifying whether or not a vector named subscripts should be passed to the panel function. Defaults to FALSE, unless groups is specified, or if the panel function accepts an argument named subscripts. (One should be careful when defining the panel function on-the-fly.)
- subset** logical or integer indexing vector (can be specified in terms of variables in data). Only these rows of data will be used for the plot. If subscripts is

- TRUE, the subscripts will provide indices to the rows of data before the subsetting is done. Whether levels of factors in the data frame that are unused after the subsetting will be dropped depends on the `drop.unused.levels` argument.
- `xlim` Normally a numeric vector of length 2 (possibly a `DateTime` object) giving minimum and maximum for the x-axis, or, a character vector, expected to denote the levels of `x`. The latter form is interpreted as a range containing `c(1, length(xlim))`, with the character vector determining labels at tick positions `1:length(xlim)`
- `xlim` could also be a list, with as many components as the number of panels (recycled if necessary), with each component as described above. This is meaningful only when `scalesxrelation` is "free" or "sliced", in which case these are treated as if they were the corresponding limit components returned by `prepanel` calculations.
- `ylim` similar to `xlim`, applied to the y-axis.
- `drop.unused.levels` logical indicating whether the unused levels of factors will be dropped, usually relevant with a subsetting operation is performed or an [interaction](#) is created. Unused levels are usually dropped, but it is sometimes appropriate to suppress dropping to preserve a useful layout. For finer control, this argument could also be list containing components `cond` and `data`, both logical, indicating desired behavior for conditioning variables and data variables respectively. The default is given by `lattice.getOption("drop.unused.levels")`, which is initially set to TRUE for both components. Note that this argument does not control dropping of levels of the `groups` argument.
- `default.scales` list giving the default values of `scales` for a particular high level function. This should not be of any interest to the normal user, but may be helpful when defining other functions that act as a wrapper to one of the high level lattice functions.
- `lattice.options` a list that could be supplied to `lattice.options`. These options are temporarily in effect for the duration of the call, after which the settings revert back to whatever they were before. The settings are also retained along with the object and reused during plotting. This enables the user to attach options settings to the trellis object itself rather than change the settings globally. See also the `par.settings` argument described below for a similar treatment of graphical settings.
- ... further arguments, usually not directly processed by the high level functions documented here, but rather passed on to other functions. Such arguments can be broadly categorized into two types: those that affect all high level Trellis functions in a similar manner, and those that are meant for the specific panel function used, which may differ across high level functions.
- The first group of arguments are processed by a common, unexported function called `trellis.skeleton`. These arguments affect all high level functions, but are only documented here, except to override the behaviour described here. All other arguments specified in a high level call, specifically those neither described here nor in the help page of the relevant high level function, are passed unchanged to the panel function used. By convention, the default panel function used for any high level function is named as "panel." followed by the name of the high level function; for example, the default panel function for `bwplot` is `panel.bwplot`. In practical terms, this means that in addition to the help

page of the high level function being used, the user should also consult the help page of the corresponding panel function for arguments that may be specified in the high level call.

The effect of the first group of common arguments are as follows:

as.table: logical that controls the order in which panels should be plotted: if FALSE (the default), panels are drawn left to right, bottom to top (as in a graph); if TRUE, left to right, top to bottom.

between: a list with components `x` and `y` (both usually 0 by default), numeric vectors specifying the space between the panels (units are character heights). `x` and `y` are repeated to account for all panels in a page and any extra components are ignored. The result is used for all pages in a multi page display. (In other words, it is not possible to use different `between` values for different pages).

key: A list of arguments that define a legend to be drawn on the plot. This list is used as an argument to the `draw.key` function, which produces a grid object eventually plotted by the print method for "trellis" objects.

There is also a less flexible but usually sufficient shortcut function `simpleKey` that can generate such a list, as well as the argument `auto.key` that can be convenient in the most common situation where legends are used, namely when there is a grouping variable. To use more than one legend, or to have arbitrary legends not constrained by the structure imposed by `key`, use the `legend` argument.

The position of the key can be controlled in either of two possible ways. If a component called `space` is present, the key is positioned outside the plot region, in one of the four sides, determined by the value of `space`, which can be one of "top", "bottom", "left" and "right". Alternatively, the key can be positioned inside the plot region by specifying components `x`, `y` and `corner`. `x` and `y` determine the location of the corner of the key given by `corner`, which is usually one of `c(0, 0)`, `c(1, 0)`, `c(1, 1)` and `c(0, 1)`, which denote the corners of the unit square. Fractional values are also allowed, in which case `x` and `y` determine the position of an arbitrary point inside (or outside for values outside the unit interval) the key.

`x` and `y` should be numbers between 0 and 1, giving coordinates with respect to the "display area". Depending on the value of `lattice.getOption("legend.bbox")`, this can be either the full figure region ("full"), or just the region that bounds the panels and strips ("panel").

The key essentially consists of a number of columns, possibly divided into blocks, each containing some rows. The contents of the key are determined by (possibly repeated) components named "rectangles", "lines", "points" or "text". Each of these must be lists with relevant graphical parameters (see later) controlling their appearance. The `key` list itself can contain graphical parameters, these would be used if relevant graphical components are omitted from the other components.

The length (number of rows) of each such column (except "text"s) is taken to be the largest of the lengths of the graphical components, including the ones specified outside (see the entry for `rep` below for details on this). The "text" component has to have a character or expression vector as its first component, and the length of this vector determines the number of rows.

The graphical components that can be included in `key` (and also in the com-

ponents named "text", "lines", "points" and "rectangles" as appropriate) are:

- `cex=1`
- `col="black"`
- `alpha=1`
- `lty=1`
- `lwd=1`
- `font=1`
- `fontface`
- `fontfamily`
- `pch=8`
- `adj=0`
- `type="l"`
- `size=5`
- `angle=0`
- `density=-1`

`angle` and `density` are currently unimplemented. `size` determines the width of columns of rectangles and lines in character widths. `type` is relevant for lines; "l" denotes a line, "p" denotes a point, and "b" and "o" both denote both together.

Other possible components of `key` are:

reverse.rows logical, defaulting to `FALSE`. If `TRUE`, all components are reversed *after* being replicated (the details of which may depend on the value of `rep`). This is useful in certain situations, e.g. with a grouped barchart with `stack = FALSE` with the categorical variable on the vertical axis, where the bars in the plot will usually be ordered from bottom to top, but the corresponding legend will have the levels from top to bottom (unless, of course, `reverse.rows = TRUE`). Note that in this case, unless all columns have the same number of rows, they will no longer be aligned.

between numeric vector giving the amount of space (character widths) surrounding each column (split equally on both sides)

title string or expression giving a title for the key

rep logical, defaults to `TRUE`. By default, it's assumed that all columns in the key (except the "text"s) will have the same number of rows, and all components are replicated to be as long as the longest. This can be suppressed by specifying `rep=FALSE`, in which case the length of each column will be determined by components of that column alone.

cex.title `cex` for the title

lines.title how many lines the title should occupy (in multiples of itself). Defaults to 2.

padding.text how much space (padding) should be used above and below each row containing text, in multiples of the default, which is currently $0.2 * \text{"lines"}$. This padding is in addition to the normal height of any row that contains text, which is the minimum amount necessary to contain all the text entries.

background background color, defaults to default background

alpha.background An alpha transparency value between 0 and 1

border either a color for the border, or a logical. In the latter case, the border color is black if `border` is TRUE, and no border is drawn if it is FALSE (the default)

transparent=FALSE logical, whether key area should have a transparent background

columns the number of columns column-blocks the key is to be divided into, which are drawn side by side.

between.columns Space between column blocks, in addition to `between`.

divide Number of point symbols to divide each line when `type` is "b" or "o" in lines.

legend: the legend argument can be useful if one wants to place more than one key. It also allows one to use arbitrary "grob"s (grid objects) as legends.

If used, `legend` must be a list, with an arbitrary number of components. Each component must be named one of "left", "right", "top", "bottom" or "inside". The name "inside" can be repeated, but not the others. This name will be used to determine the location for that component, and is similar to the `space` component of `key`. If `key` (or `colorkey` for `levelplot` and `wireframe`) is specified, their `space` component must not conflict with the name of any component of `legend`. Each component of `legend` must have a component called `fun`. This can be a "grob", or a function or the name of a function that produces a "grob" when called. If this function expects any arguments, they must be supplied as a list in another component called `args`. For components named "inside", there can be additional components called `x`, `y` and `corner`, which work in the same way as it does for `key`.

page: a function of one argument (page number) to be called after drawing each page. The function must be 'grid-compliant', and is called with the whole display area as the default viewport.

main: typically a character string or expression describing the main title to be placed on top of each page. Defaults to NULL. `main` (as well as `xlab`, `ylab` and `sub`) is usually a character string or an expression that gets used as the label, but can also be a list that controls further details. Expressions are treated as specification of LaTeX-like markup as described in `plotmath`. The label can be a vector, in which case the components will be spaced out horizontally (or vertically for `ylab`). This feature can be used to provide column or row labels rather than a single axis label.

When `main` (etc.) is a list, the actual label should be specified as the `label` component (which may be unnamed if it is the first component). The label can be missing, in which case the default will be used (`xlab` and `ylab` usually have defaults, but `main` and `sub` do not). Further named arguments are passed on to `textGrob`; this can include arguments controlling positioning like `just` and `rot` as well as graphical parameters such as `col` and `font` (see `gpar` for a full list).

`main`, `xlab`, `ylab` and `sub` can also be an arbitrary "grob" (grid graphical object).

sub: character string or expression (or a list or "grob") for a subtitle to be placed at the bottom of each page. See entry for `main` for finer control options.

par.strip.text: list of parameters to control the appearance of strip text.

Notable components are `col`, `cex`, `font` and `lines`. The first three control graphical parameters while the last is a means of altering the height of the strips. This can be useful, for example, if the strip labels (derived from factor levels, say) are double height (i.e., contains "\n"-s) or if the default height seems too small or too large. The `lineheight` component can control the space between multiple lines. Also, the labels can be abbreviated when shown by specifying `abbreviate = TRUE`, in which case the components `minlength` and `dot` (passed along to the `abbreviate` function) can be specified to control the details of how this is done.

layout: In general, a Trellis conditioning plot consists of several panels arranged in a rectangular array, possibly spanning multiple pages. `layout` determines this arrangement.

`layout` is a numeric vector giving the number of columns, rows and pages in a multi panel display. By default, the number of columns is the number of levels of the first conditioning variable and the number of rows is the number of levels of the second conditioning variable. If there is only one conditioning variable, the default layout vector is `c(0, n)`, where `n` is the number of levels of the given vector. Any time the first value in the layout vector is 0, the second value is used as the desired number of panels per page and the actual layout is computed from this, taking into account the aspect ratio of the panels and the device dimensions (via `par("din")`). The number of pages is by default set to as many as is required to plot all the panels. In general, giving a high value of `layout[3]` is not wasteful because blank pages are never created.

skip: logical vector (default `FALSE`), replicated to be as long as the number of panels (spanning all pages). For elements that are `TRUE`, the corresponding panel position is skipped; i.e., nothing is plotted in that position. The panel that was supposed to be drawn there is now drawn in the next available panel position, and the positions of all the subsequent panels are bumped up accordingly. This is often useful for arranging plots in an informative manner.

strip.left: `strip.left` can be used to draw strips on the left of each panel, which can be useful for wide short panels, as in time series (or similar) plots. It is a function similar to `strip`.

xlab.default, ylab.default: fallback default for `xlab` and `ylab` when they are not specified. If `NULL`, the defaults are parsed from the Trellis formula. This is rarely useful for the end-user, but can be helpful when developing new Trellis functions.

xscale.components, yscale.components: functions that determine axis annotation for the x and y axes respectively. See documentation for `xscale.components.default`, the default values of these arguments, to learn more.

axis: function that draws axis annotation. See documentation for `axis.default`, the default value of this argument, to learn more.

perm.cond: numeric vector, a permutation of `1:n`, where `n` is the number of conditioning variables. By default, the order in which panels are drawn depends on the order of the conditioning variables specified in the formula. `perm.cond` can modify this order. If the trellis display is thought of as an n-dimensional array, then during printing, its dimensions are permuted using `perm.cond` as the `perm` argument to `aperm`.

index.cond: While `perm.cond` permutes the dimensions of the multidimensional array of panels, `index.cond` can be used to subset (or reorder)

margins of that array. `index.cond` can be a list or a function, with behavior in each case described below.

The panel display order within each conditioning variable depends on the order of their levels. `index.cond` can be used to choose a ‘subset’ (in the R sense) of these levels, which is then used as the display order for that variable. If `index.cond` is a list, it has to be as long as the number of conditioning variables, and the *i*-th component has to be a valid indexing vector for the integer vector `1:nlevels(g_i)` (which can, among other things, repeat some of the levels or drop some altogether). The result of this indexing determines the order of panels within that conditioning variable. To keep the order of a particular variable unchanged, the corresponding component must be set to `TRUE`.

Note that the components of `index.cond` are in the order of the conditioning variables in the original call, and is not affected by `perm.cond`.

Another possibility is to specify `index.cond` as a function. In this case, this function is called once for each panel, potentially with all arguments that are passed to the panel function for that panel. (More specifically, if this function has a `...` argument, then all panel arguments are passed, otherwise, only named arguments that match are passed.) For a single conditioning variable, the levels of that variable are then sorted so that these values are in ascending order. For multiple conditioning variables, the order for each variable is determined by first taking the average over all other conditioning variables.

Although they can be supplied in high level function calls directly, it is more typical to use `perm.cond` and `index.cond` to update an existing "trellis" object, thus allowing it to be displayed in a different arrangement without re-calculating the data subsets that go into each panel. In the `update` method, both can be set to `NULL`, which reverts these back to their defaults.

par.settings: a list that could be supplied to `trellis.par.set`. This enables the user to attach some display settings to the trellis object itself rather than change the settings globally. When the object is plotted, these settings are temporarily in effect for the duration of the plot, after which the settings revert back to whatever they were before.

plot.args: a list of possible arguments to `plot.trellis`, which will be used by the `plot` or `print` methods when drawing the object, unless overridden explicitly. This enables the user to attach such arguments to the trellis object itself. Partial matching is not performed.

Details

All the functions documented here are generic, with the `formula` method usually doing the actual work. The structure of the plot that is produced is mostly controlled by the formula. For each unique combination of the levels of the conditioning variables `g1, g2, ...`, a separate panel is produced using the points (x, y) for the subset of the data (also called packet) defined by that combination. The display can be thought of as a 3-dimensional array of panels, consisting of one 2-dimensional matrix per page. The dimensions of this array are determined by the `layout` argument. If there are no conditioning variables, the plot produced consists of a single panel.

The coordinate system used by lattice by default is like a graph, with the origin at the bottom left, with axes increasing to left and up. In particular, panels are by default drawn starting from the bottom left corner, going right and then up; unless `as.table = TRUE`, in which case panels are drawn from the top left corner, going right and then down. One might wish to set a global

preference for a table-like arrangement by changing the default to `as.table=TRUE`; this can be done by setting `lattice.options(default.args = list(as.table = TRUE))`. In fact, default values can be set in this manner for the following arguments: `as.table`, `aspect`, `between`, `page`, `main`, `sub`, `par.strip.text`, `layout`, `skip` and `strip`. Note that these global defaults are sometimes overridden by individual functions.

The order of the panels depends on the order in which the conditioning variables are specified, with `g1` varying fastest. Within a conditioning variable, the order depends on the order of the levels (which for factors is usually in alphabetical order). Both of these orders can be modified using the `index.cond` and `perm.cond` arguments, possibly using the `update` (and other related) method(s).

Value

An object of class "trellis". The `update` method can be used to update components of the object and the `print` method (usually called by default) will plot it on an appropriate plotting device.

Note

Most of the arguments documented here are also applicable for the other high level functions in the lattice package. These are not described in any detail elsewhere unless relevant, and this should be considered the canonical documentation for such arguments.

Any arguments passed to these functions and not recognized by them will be passed to the panel function. Most predefined panel functions have arguments that customize its output. These arguments are described only in the help pages for these panel functions, but can usually be supplied as arguments to the high level plot.

Chapter 18

The `mgcv` package

`mgcv`-package

GAMs with GCV smoothness estimation and GAMMs by REML/PQL

Description

`mgcv` provides functions for generalized additive modelling and generalized additive mixed modelling. The term GAM is taken to include any GLM estimated by quadratically penalized (possibly quasi-) likelihood maximization.

Particular features of the package are facilities for automatic smoothness selection, and the provision of a variety of smooths of more than one variable. User defined smooths can be added. A Bayesian approach to confidence/credible interval calculation is provided. Linear functionals of smooths, penalization of parametric model terms and linkage of smoothing parameters are all supported. Lower level routines for generalized ridge regression and penalized linearly constrained least squares are also provided.

Details

`mgcv` provides generalized additive modelling functions `gam`, `predict.gam` and `plot.gam`, which are very similar in use to the S functions of the same name designed by Trevor Hastie (with some extensions). However the underlying representation and estimation of the models is based on a penalized regression spline approach, with automatic smoothness selection. A number of other functions such as `summary.gam` and `anova.gam` are also provided, for extracting information from a fitted `gamObject`.

Use of `gam` is much like use of `glm`, except that within a `gam` model formula, isotropic smooths of any number of predictors can be specified using `s` terms, while scale invariant smooths of any number of predictors can be specified using `te` terms. `smooth.terms` provides an overview of the built in smooth classes. Estimation is by penalized likelihood or quasi-likelihood maximization, with smoothness selection by GCV or gAIC/ UBRE. See `gam`, `gam.models`, `linear.functional.terms` and `gam.selection` for some discussion of model specification and selection. For detailed control of fitting see `gam.convergence`, `gam.method` and `gam.control`. For checking and visualization see `gam.check`, `choose.k`, `vis.gam` and `plot.gam`. While a number of types of smoother are built into the package, it is also extendable with user defined smooths, see `smooth.construct`, for example.

A Bayesian approach to smooth modelling is used to derive standard errors on predictions, and hence credible intervals. The Bayesian covariance matrix for the model coefficients is returned in

Vp of the `gamObject`. See `predict.gam` for examples of how this can be used to obtain credible regions for any quantity derived from the fitted model, either directly, or by direct simulation from the posterior distribution of the model coefficients. Approximate p-values can also be obtained for testing individual smooth terms for equality to the zero function, using similar ideas. Frequentist approximations can be used for hypothesis testing based model comparison. See `anova.gam` and `summary.gam` for more on hypothesis testing.

The package also provides a generalized additive mixed modelling function, `gamm`, based on a PQL approach and `lme` from the `nlme` library. `gamm` is particularly useful for modelling correlated data (i.e. where a simple independence model for the residual variation is inappropriate). In addition, low level routine `magic` can fit models to data with a known correlation structure.

Some underlying GAM fitting methods are available as low level fitting functions: see `magic` and `mgcv`. But there is little functionality that can not be more conveniently accessed via `gam`. Penalized weighted least squares with linear equality and inequality constraints is provided by `pcls`.

For a complete list of functions type `library(help=mgcv)`.

anova.gam

Hypothesis tests related to GAM fits

Description

Performs hypothesis tests relating to one or more fitted `gam` objects. For a single fitted `gam` object, Wald tests of the significance of each parametric and smooth term are performed. Otherwise the fitted models are compared using an analysis of deviance table. The tests are usually approximate, unless the models are un-penalized.

Usage

```
## S3 method for class 'gam':
anova(object, ..., dispersion = NULL, test = NULL)
## S3 method for class 'anova.gam':
print(x, digits = max(3, getOption("digits") - 3), ...)
```

Arguments

<code>object, ...</code>	fitted model objects of class <code>gam</code> as produced by <code>gam()</code> .
<code>x</code>	an <code>anova.gam</code> object produced by a single model call to <code>anova.gam()</code> .
<code>dispersion</code>	a value for the dispersion parameter: not normally used.
<code>test</code>	what sort of test to perform for a multi-model call. One of "Chisq", "F" or "Cp".
<code>digits</code>	number of digits to use when printing output.

Details

If more than one fitted model is provided than `anova.glm` is used. If only one model is provided then the significance of each model term is assessed using Wald tests: see [summary.gam](#) for details of the actual computations. In the latter case `print.anova.gam` is used as the printing method. Note that the p-values for smooth terms are approximate only.

Value

In the multi-model case `anova.gam` produces output identical to [anova.glm](#), which it in fact uses.

In the single model case an object of class `anova.gam` is produced, which is in fact an object returned from [summary.gam](#).

`print.anova.gam` simply produces tabulated output.

WARNING

P-values for smooth terms are only approximate.

anova(b, b1, test="F")
```

`choose.k`*Basis dimension choice for smooths*

Description

Choosing the basis dimension, and checking the choice, when using penalized regression smoothers.

Penalized regression smoothers gain computational efficiency by virtue of being defined using a basis of relatively modest size, k . When setting up models in the `mgcv` package, using `s` or `te` terms in a model formula, k must be chosen.

In practice $k-1$ (or k) sets the upper limit on the degrees of freedom associated with an `s` smooth (1 degree of freedom is usually lost to the identifiability constraint on the smooth). For `te` smooths the upper limit of the degrees of freedom is given by the product of the k values provided for each marginal smooth less one, for the constraint. However the actual effective degrees of freedom are controlled by the degree of penalization selected during fitting, by GCV, AIC or whatever is specified. The exception to this is if a smooth is specified using the `fx=TRUE` option, in which case it is unpenalized.

So, exact choice of k is not generally critical: it should be chosen to be large enough that you are reasonably sure of having enough degrees of freedom to represent the underlying ‘truth’ reasonably well, but small enough to maintain reasonable computational efficiency. Clearly ‘large’ and ‘small’ are dependent on the particular problem being addressed.

As with all model assumptions, it is useful to be able to check the choice of k informally. If the effective degrees of freedom for a model term are estimated to be much less than $k-1$ then this is unlikely to be very worthwhile, but as the EDF approach $k-1$, checking can be important. A useful general purpose approach goes as follows: (i) fit your model and extract the deviance residuals; (ii) for each smooth term in your model, fit an equivalent, single, smooth to the residuals, using a substantially increased k to see if there is pattern in the residuals that could potentially be explained by increasing k . Examples are provided below.

More sophisticated approaches based on partial residuals are also possible.

One scenario that can cause confusion is this: a model is fitted with $k=10$ for a smooth term, and the EDF for the term is estimated as 7.6, some way below the maximum of 9. The model is then refitted with $k=20$ and the EDF increases to 8.7 - what is happening - how come the EDF was not 8.7 the first time around? The explanation is that the function space with $k=20$ contains a larger subspace of functions with EDF 8.7 than did the function space with $k=10$: one of the functions in this larger subspace fits the data a little better than did any function in the smaller subspace. These subtleties seldom have much impact on the statistical conclusions to be drawn from a model fit, however.

```

## Simulate some data ....
library(mgcv)
set.seed(0)
dat <- gamSim(1,n=400,scale=2)
## fit a GAM with quite low `k'
b<-gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),data=dat)
plot(b,pages=1)

## check for residual pattern, removeable by increasing `k'
## typically `k', below, should be substantially larger than
## the original, `k' but certainly less than n/2.
## Note use of cheap "cs" shrinkage smoothers, and gamma=1.4
## to reduce chance of overfitting...
rsd <- residuals(b)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## original `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

## similar example with multi-dimensional smooth
b1 <- gam(y~s(x0)+s(x1,x2,k=15)+s(x3),data=dat)
rsd <- residuals(b1)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,x2,k=100,bs="ts"),gamma=1.4,data=dat) ## original `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

## and a `te' example
b2 <- gam(y~s(x0)+te(x1,x2,k=4)+s(x3),data=dat)
rsd <- residuals(b2)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~te(x1,x2,k=10,bs="cs"),gamma=1.4,data=dat) ## original `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

## same approach works with other families in the original model
dat <- gamSim(1,n=400,scale=.25,dist="poisson")
bp<-gam(y~s(x0,k=6)+s(x1,k=6)+s(x2,k=6)+s(x3,k=6),
        family=poisson,data=dat)
rsd <- residuals(bp)
gam(rsd~s(x0,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x1,k=40,bs="cs"),gamma=1.4,data=dat) ## fine
gam(rsd~s(x2,k=40,bs="cs"),gamma=1.4,data=dat) ## original `k' too low
gam(rsd~s(x3,k=40,bs="cs"),gamma=1.4,data=dat) ## fine

rm(dat)

```

Description

Uses splineDesign to set up the model matrix for a cyclic B-spline basis.

Usage

```
cSplineDes(x, knots, ord = 4)
```

Arguments

x	covariate values for smooth.
knots	The knot locations: the range of these must include all the data.
ord	order of the basis. 4 is a cubic spline basis. Must be >1.

Details

The routine is a wrapper that sets up a B-spline basis, where the basis functions wrap at the first and last knot locations.

Value

A matrix with `length(x)` rows and `length(knots) - 1` columns.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

See Also

[cyclic.p.spline](#)

Examples

```
x <- 0:100/100;k<- 0:5/5
X <- cSplineDes(x,k)
plot(x,X[,1],type="l"); for (i in 2:5) lines(x,X[,i],col=i)
```

`exclude.too.far` *Exclude prediction grid points too far from data*

Description

Takes two arrays defining the nodes of a grid over a 2D covariate space and two arrays defining the location of data in that space, and returns a logical vector with elements TRUE if the corresponding node is too far from data and FALSE otherwise. Basically a service routine for `vis.gam` and `plot.gam`.

Usage

```
exclude.too.far(g1, g2, d1, d2, dist)
```

Arguments

<code>g1</code>	co-ordinates of grid relative to first axis.
<code>g2</code>	co-ordinates of grid relative to second axis.
<code>d1</code>	co-ordinates of data relative to first axis.
<code>d2</code>	co-ordinates of data relative to second axis.
<code>dist</code>	how far away counts as too far. Grid and data are first scaled so that the grid lies exactly in the unit square, and <code>dist</code> is a distance within this unit square.

Details

Linear scalings of the axes are first determined so that the grid defined by the nodes in `g1` and `g2` lies exactly in the unit square (i.e. on $[0,1]$ by $[0,1]$). These scalings are applied to `g1`, `g2`, `d1` and `d2`. The minimum Euclidean distance from each node to a datum is then determined and if it is greater than `dist` the corresponding entry in the returned array is set to `TRUE` (otherwise to `FALSE`). The distance calculations are performed in compiled code for speed without storage overheads.

Value

A logical array with `TRUE` indicating a node in the grid defined by `g1`, `g2` that is ‘too far’ from any datum.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

[vis.gam](#)

Examples

```
library(mgcv)
x<-rnorm(100);y<-rnorm(100) # some "data"
n<-40 # generate a grid...
mx<-seq(min(x),max(x),length=n)
my<-seq(min(y),max(y),length=n)
gx<-rep(mx,n);gy<-rep(my,rep(n,n))
tf<-exclude.too.far(gx,gy,x,y,0.1)
plot(gx[!tf],gy[!tf],pch=".");points(x,y,col=2)
```

`extract.lme.cov` *Extract the data covariance matrix from an lme object*

Description

This is a service routine for `gamm`. Extracts the estimated covariance matrix of the data from an `lme` object, allowing the user control about which levels of random effects to include in this calculation. `extract.lme.cov` forms the full matrix explicitly: `extract.lme.cov2` tries to be more economical than this.

Usage

```
extract.lme.cov(b, data, start.level=1)
extract.lme.cov2(b, data, start.level=1)
```

Arguments

<code>b</code>	A fitted model object returned by a call to <code>lme</code>
<code>data</code>	The data frame/ model frame that was supplied to <code>lme</code> .
<code>start.level</code>	The level of nesting at which to start including random effects in the calculation. This is used to allow smooth terms to be estimated as random effects, but treated like fixed effects for variance calculations.

Details

The random effects, correlation structure and variance structure used for a linear mixed model combine to imply a covariance matrix for the response data being modelled. These routines extract that covariance matrix. The process is slightly complicated, because different components of the fitted model object are stored in different orders (see function code for details!).

The `extract.lme.cov` calculation is not optimally efficient, since it forms the full matrix, which may in fact be sparse. `extract.lme.cov2` is more efficient. If the covariance matrix is diagonal, then only the leading diagonal is returned; if it can be written as a block diagonal matrix (under some permutation of the original data) then a list of matrices defining the non-zero blocks is returned along with an index indicating which row of the original data each row/column of the block diagonal matrix relates to. The block sizes are defined by the coarsest level of grouping in the random effect structure.

`gamm` uses `extract.lme.cov2`.

`extract.lme.cov` does not currently deal with the situation in which the grouping factors for a correlation structure are finer than those for the random effects. `extract.lme.cov2` does deal with this situation.

Value

For `extract.lme.cov` an estimated covariance matrix.

For `extract.lme.cov2` a list containing the estimated covariance matrix and an indexing array. The covariance matrix is stored as the elements on the leading diagonal, a list of the matrices defining a block diagonal matrix, or a full matrix if the previous two options are not possible.

fix.family.link *Modify families for use in GAM fitting*

Description

Generalized Additive Model fitting by ‘outer’ iteration, requires extra derivatives of the variance and link functions to be added to family objects. The functions add what is needed.

Usage

```
fix.family.link(fam)
fix.family.var(fam)
```

Arguments

fam A family.

Details

Outer iteration GAM estimation requires derivatives of the GCV/UBRE score, which are obtained by differentiating the P-IRLS GAM fitting iteration w.r.t. the model smoothing parameters. The expressions for the derivatives require the second and third derivatives of the link w.r.t. the mean, and the first and second derivatives of the variance function w.r.t. the mean. These functions add functions evaluating these quantities to a family.

If the family already has functions `dvar`, `d2var`, `d2link` and `d3link` then these functions simply return the family unmodified: this allows non-standard links to be used with `gam` when using outer iteration (performance iteration operates with unmodified families).

The `dvar` function is a function of a mean vector, `mu`, and returns a vector of corresponding first derivatives of the family variance function. The `d2link` function is also a function of a vector of mean values, `mu`: it returns a vector of second derivatives of the link, evaluated at `mu`. Higher derivatives are defined similarly.

If modifying your own family, note that you can often get away with supplying only a `dvar` and `d2var`, function if your family only requires links that occur in one of the standard families.

Value

A family object with extra component functions `dvar`, `d2var`, `d2link` and `d3link`.

[gam.fit3](#)

fixDependence

Detect linear dependencies of one matrix on another

Description

Identifies columns of a matrix $X2$ which are linearly dependent on columns of a matrix $X1$. Primarily of use in setting up identifiability constraints for nested GAMs.

Usage

```
fixDependence(X1, X2, tol = .Machine$double.eps^0.5)
```

Arguments

<code>X1</code>	A matrix.
<code>X2</code>	A matrix, the columns of which may be partially linearly dependent on the columns of <code>X1</code> .
<code>tol</code>	The tolerance to use when assessing linear dependence.

Details

The algorithm uses a simple approach based on QR decomposition: see Wood (2006, section 4.10.2) for details.

Value

An array of the columns of X2 which are linearly dependent on columns of X1. NULL if the two matrices are independent.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

References

Examples

```
n<-20;c1<-4;c2<-7
X1<-matrix(runif(n*c1),n,c1)
X2<-matrix(runif(n*c2),n,c2)
X2[,3]<-X1[,2]+X2[,4]*.1
X2[,5]<-X1[,1]*.2+X1[,2]*.04
fixDependence(X1,X2)
```

 formula.gam

GAM formula

Description

Description of [gam](#) formula (see [Details](#)), and how to extract it from a fitted [gam](#) object.

Usage

```
## S3 method for class 'gam':
formula(x,...)
```

Arguments

x fitted model objects of class [gam](#) (see [gamObject](#)) as produced by [gam\(\)](#).

... un-used in this case

Details

The formula supplied to [gam](#) is exactly like that supplied to [glm](#) except that smooth terms, [s](#) and [te](#) can be added to the right hand side (and [.](#) is not supported in [gam](#) formulae).

Smooth terms are specified by expressions of the form:

```
s(x1,x2,...,k=12,fx=FALSE,bs="tp",by=z,id=1)
```

where [x1](#), [x2](#), etc. are the covariates which the smooth is a function of, and [k](#) is the dimension of the basis used to represent the smooth term. If [k](#) is not specified then basis specific defaults are used. [fx](#) is used to indicate whether or not this term should be unpenalized, and therefore have a fixed number of degrees of freedom set by [k](#) (almost always $k-1$). [bs](#) indicates the basis to use for the smooth: the built in options are described in [smooth.terms](#), and user defined smooths can be added (see [user.defined.smooth](#)). If [bs](#) is not supplied then the default

"tp" ([tprs](#)) basis is used. `by` can be used to specify a variable by which the smooth should be multiplied. For example `gam(y~s(x,by=z))` would specify a model $E(y) = f(x)z$ where $f(\cdot)$ is a smooth function. The `by` option is particularly useful for models in which different functions of the same variable are required for each level of a factor and for 'varying coefficient models': see [gam.models](#). `id` is used to give smooths identities: smooths with the same identity have the same basis, penalty and smoothing parameter (but different coefficients, so they are different functions).

An alternative for specifying smooths of more than one covariate is e.g.:

```
te(x, z, bs=c("tp", "tp"), m=c(2, 3), k=c(5, 10))
```

which would specify a tensor product smooth of the two covariates `x` and `z` constructed from marginal t.p.r.s. bases of dimension 5 and 10 with marginal penalties of order 2 and 3. Any combination of basis types is possible, as is any number of covariates. `te` provides further information.

Both `s` and `te` terms accept an `sp` argument of supplied smoothing parameters: positive values are taken as fixed values to be used, negative to indicate that the parameter should be estimated. If `sp` is supplied then it over-rides whatever is in the `sp` argument to `gam`, if it is not supplied then it defaults to all negative, but does not over-ride the `sp` argument to `gam`.

Formulae can involve nested or "overlapping" terms such as

```
y~s(x)+s(z)+s(x,z) or y~s(x,z)+s(z,v):
```

see [gam.side](#) for further details and examples.

Smooth terms in a `gam` formula will accept matrix arguments as covariates (and corresponding `by` variable), in which case a 'summation convention' is invoked. Consider the example of `s(X,Z,by=L)` where `X`, `Z` and `L` are n by m matrices. Let `F` be the n by m matrix that results from evaluating the smooth at the values in `X` and `Z`. Then the contribution to the linear predictor from the term will be `rowSums(F*L)` (note the element-wise multiplication). This convention allows the linear predictor of the GAM to depend on (a discrete approximation to) any linear functional of a smooth: see [linear.functional.terms](#) for more information and examples (including functional linear models/signal regression).

Note that `gam` allows any term in the model formula to be penalized (possibly by multiple penalties), via the `paraPen` argument. See [gam.models](#) for details and example code.

Value

Returns the model formula, `x$formula`. Provided so that `anova` methods print an appropriate description of the model.

[gam](#)

Description

This is a service routine for [gamm](#). Given, V , an estimated covariance matrix obtained using [extract.lme.cov2](#) this routine forms $X^T V^{-1} X$ as efficiently as possible, given the structure of V (usually sparse).

Usage

```
formXtViX(V, X)
```

Arguments

V A data covariance matrix list returned from `extract.lme.cov2`
X A model matrix.

Details

The covariance matrix returned by `extract.lme.cov2` may be in a packed and re-ordered format, since it is usually sparse. Hence a special service routine is required to form the required products involving this matrix.

Value

A matrix.

full.score

GCV/UBRE score for use within nlm

Description

Evaluates GCV/UBRE score for a GAM, given smoothing parameters. The routine calls `gam.fit` to fit the model, and is usually called by `nlm` to optimize the smoothing parameters.

This is basically a service routine for `gam`, and is not usually called directly by users. It is only used in this context for GAMs fitted by outer iteration (see `gam.outer`) when the the outer method is "nlm.fd" (see `gam.method`).

Usage

```
full.score(sp, G, family, control, gamma, ...)
```

Arguments

<code>sp</code>	The logs of the smoothing parameters
<code>G</code>	a list returned by <code>gam.setup</code>
<code>family</code>	The family object for the GAM.
<code>control</code>	a list returned by <code>gam.control</code>
<code>gamma</code>	the degrees of freedom inflation factor (usually 1).
<code>...</code>	other arguments, typically for passing on to <code>gam.fit</code> .

Value

The value of the GCV/UBRE score, with attribute `"full.gam.object"` which is the full object returned by `gam.fit`.

Author(s)

Simon N. Wood <simon.wood@r-project.org>

gam

Generalized additive models with integrated smoothness estimation

Description

Fits a generalized additive model (GAM) to data, the term ‘GAM’ being taken to include any quadratically penalized GLM. The degree of smoothness of model terms is estimated as part of fitting. `gam` can also fit any GLM subject to multiple quadratic penalties (including estimation of degree of penalization). Isotropic or scale invariant smooths of any number of variables are available as model terms, as are linear functionals of such smooths; confidence/credible intervals are readily available for any quantity predicted using a fitted model; `gam` is extendable: users can add smooths.

Smooth terms are represented using penalized regression splines (or similar smoothers) with smoothing parameters selected by GCV/UBRE/AIC or by regression splines with fixed degrees of freedom (mixtures of the two are permitted). Multi-dimensional smooths are available using penalized thin plate regression splines (isotropic) or tensor product splines (when an isotropic smooth is inappropriate). For an overview of the smooths available see `smooth.terms`. For more on specifying models see `gam.models` and `linear.functional.terms`. For more on model selection see `gam.selection`.

`gam()` is not a clone of what S-PLUS provides: the major differences are (i) that by default estimation of the degree of smoothness of model terms is part of model fitting, (ii) a Bayesian approach to variance estimation is employed that makes for easier confidence interval calculation (with good coverage probabilities), (iii) that the model can depend on any (bounded) linear functional of smooth terms, and, (iv) the parametric part of the model can be penalized, and (v) the facilities for incorporating smooths of more than one variable are different: specifically there are no `lo` smooths, but instead (a) `s` terms can have more than one argument, implying an isotropic smooth and (b) `te` smooths are provided as an effective means for modelling smooth interactions of any number of variables via scale invariant tensor product smooths. If you want a clone of what S-PLUS provides use `gam` from package `gam`.

Usage

```
gam(formula, family=gaussian(), data=list(), weights=NULL, subset=NULL,
    na.action, offset=NULL, control=gam.control(), method=gam.method(),
    scale=0, knots=NULL, sp=NULL, min.sp=NULL, H=NULL, gamma=1,
    fit=TRUE, paraPen=NULL, G=NULL, in.out, ...)
```

Arguments

formula	A GAM formula (see formula.gam and also gam.models). This is exactly like the formula for a GLM except that smooth terms, <code>s</code> and <code>te</code> can be added to the right hand side to specify that the linear predictor depends on smooth functions of predictors (or linear functionals of these).
family	This is a family object specifying the distribution and link to use in fitting etc. See glm and family for more details. A negative binomial family is provided: see negbin .
data	A data frame or list containing the model response variable and covariates required by the formula. By default the variables are taken from <code>environment(formula)</code> : typically the environment from which <code>gam</code> is called.
weights	prior weights on the data.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
na.action	a function which indicates what should happen when the data contain 'NA's. The default is set by the 'na.action' setting of 'options', and is 'na.fail' if that is unset. The "factory-fresh" default is 'na.omit'.
offset	Can be used to supply a model offset for use in fitting. Note that this offset will always be completely ignored when predicting, unlike an offset included in formula: this conforms to the behaviour of <code>lm</code> and <code>glm</code> .
control	A list of fit control parameters returned by gam.control .
method	A list controlling the fitting methods used. This can make a difference to computational speed, and, in some cases, reliability of convergence: see gam.method for details.
scale	If this is zero then GCV is used for all distributions except Poisson and binomial where UBRE is used with scale parameter assumed to be 1. If this is greater than 1 it is assumed to be the scale parameter/variance and UBRE is used. If <code>scale</code> is negative GCV is always used, which means that the scale parameter will be estimated by GCV and the Pearson estimator. For binomial models in particular, it is probably worth comparing UBRE and GCV results; for "over-dispersed Poisson" GCV is probably more appropriate than UBRE.
knots	this is an optional list containing user specified knot values to be used for basis construction. For most bases the user simply supplies the knots to be used, which must match up with the <code>k</code> value supplied (note that the number of knots is not always just <code>k</code>). See tprs for what happens in the " <code>tp</code> " / " <code>ts</code> " case. Different terms can use different numbers of knots, unless they share a covariate.
sp	A vector of smoothing parameters can be provided here. Smoothing parameters must be supplied in the order that the smooth terms appear in the model formula. Negative elements indicate that the parameter should be estimated, and hence a mixture of fixed and estimated parameters is possible. If smooths share smoothing parameters then <code>length(sp)</code> must correspond to the number of underlying smoothing parameters.

<code>min.sp</code>	Lower bounds can be supplied for the smoothing parameters. Note that if this option is used then the smoothing parameters <code>full.sp</code> , in the returned object, will need to be added to what is supplied here to get the smoothing parameters actually multiplying the penalties. <code>length(min.sp)</code> should always be the same as the total number of penalties (so it may be longer than <code>sp</code> , if smooths share smoothing parameters).
<code>H</code>	A user supplied fixed quadratic penalty on the parameters of the GAM can be supplied, with this as its coefficient matrix. A common use of this term is to add a ridge penalty to the parameters of the GAM in circumstances in which the model is close to un-identifiable on the scale of the linear predictor, but perfectly well defined on the response scale.
<code>gamma</code>	It is sometimes useful to inflate the model degrees of freedom in the GCV or UBRE/AIC score by a constant multiplier. This allows such a multiplier to be supplied.
<code>fit</code>	If this argument is <code>TRUE</code> then <code>gam</code> sets up the model and fits it, but if it is <code>FALSE</code> then the model is set up and an object <code>G</code> containing what would be required to fit is returned. See argument <code>G</code> .
<code>paraPen</code>	optional list specifying any penalties to be applied to parametric model terms. gam.models explains more.
<code>G</code>	Usually <code>NULL</code> , but may contain the object returned by a previous call to <code>gam</code> with <code>fit=FALSE</code> , in which case all other arguments are ignored except for <code>gamma</code> , <code>in.out</code> , <code>control</code> , <code>method</code> and <code>fit</code> .
<code>in.out</code>	optional list for initializing outer iteration. If supplied then this must contain two elements: <code>sp</code> should be an array of initialization values for all smoothing parameters (there must be a value for all smoothing parameters, whether fixed or to be estimated, but those for fixed s.p.s are not used); <code>scale</code> is the typical scale of the GCV/UBRE function, for passing to the outer optimizer.
<code>...</code>	further arguments for passing on e.g. to <code>gam.fit</code> (such as <code>mustart</code>).

Details

A generalized additive model (GAM) is a generalized linear model (GLM) in which the linear predictor is given by a user specified sum of smooth functions of the covariates plus a conventional parametric component of the linear predictor. A simple example is:

$$\log(E(y_i)) = f_1(x_{1i}) + f_2(x_{2i})$$

where the (independent) response variables $y_i \sim \text{Poi}$, and f_1 and f_2 are smooth functions of covariates x_1 and x_2 . The `log` is an example of a link function.

If absolutely any smooth functions were allowed in model fitting then maximum likelihood estimation of such models would invariably result in complex overfitting estimates of f_1 and f_2 . For this reason the models are usually fit by penalized likelihood maximization, in which the model (negative log) likelihood is modified by the addition of a penalty for each smooth function, penalizing its ‘wiggleness’. To control the tradeoff between penalizing wiggleness and penalizing badness of fit each penalty is multiplied by an associated smoothing parameter: how to estimate these parameters, and how to practically represent the smooth functions are the main statistical questions introduced by moving from GLMs to GAMs.

The `mgcv` implementation of `gam` represents the smooth functions using penalized regression splines, and by default uses basis functions for these splines that are designed to be optimal, given the number basis functions used. The smooth terms can be functions of any number of covariates and the user has some control over how smoothness of the functions is measured.

`gam` in `mgcv` solves the smoothing parameter estimation problem by using the Generalized Cross Validation (GCV) criterion

$$nD/(n - DoF)^2$$

or an Un-Biased Risk Estimator (UBRE) criterion

$$D/n + 2sDoF/n - s$$

where D is the deviance, n the number of data, s the scale parameter and DoF the effective degrees of freedom of the model. Notice that UBRE is effectively just AIC rescaled, but is only used when s is known. An alternative is GACV (again see [gam.method](#)). Smoothing parameters are chosen to minimize the GCV or UBRE/AIC score for the model, and the main computational challenge solved by the `mgcv` package is to do this efficiently and reliably. Various alternative numerical methods are provided: see [gam.method](#).

Broadly `gam` works by first constructing basis functions and one or more quadratic penalty coefficient matrices for each smooth term in the model formula, obtaining a model matrix for the strictly parametric part of the model formula, and combining these to obtain a complete model matrix (/design matrix) and a set of penalty matrices for the smooth terms. Some linear identifiability constraints are also obtained at this point. The model is fit using `gam.fit`, a modification of `glm.fit`. The GAM penalized likelihood maximization problem is solved by Penalized Iteratively Reweighted Least Squares (P-IRLS) (see e.g. Wood 2000). Smoothing parameter selection is integrated in one of two ways. (i) ‘Performance iteration’ uses the fact that at each P-IRLS iteration a penalized weighted least squares problem is solved, and the smoothing parameters of that problem can be estimated by GCV or UBRE. Eventually, in most cases, both model parameter estimates and smoothing parameter estimates converge. (ii) Alternatively the P-IRLS scheme is iterated to convergence for each trial set of smoothing parameters, and GCV or UBRE scores are only evaluated on convergence - optimization is then ‘outer’ to the P-IRLS loop: in this case the P-IRLS iteration has to be differentiated, to facilitate optimization, and `gam.fit3` is used in place of `gam.fit`. The default is the second method, outer iteration.

Several alternative basis-penalty types are built in for representing model smooths, but alternatives can easily be added (see [smooth.terms](#) for an overview and [smooth.construct](#) for how to add smooth classes). In practice the default basis is usually the best choice, but the choice of the basis dimension (k in the `s` and `te` terms) is something that should be considered carefully (the exact value is not critical, but it is important not to make it restrictively small, nor very large and computationally costly). The basis should be chosen to be larger than is believed to be necessary to approximate the smooth function concerned. The effective degrees of freedom for the smooth will then be controlled by the smoothing penalty on the term, and (usually) selected automatically (with an upper limit set by $k-1$ or occasionally k). Of course the k should not be made too large, or computation will be slow (or in extreme cases there will be more coefficients to estimate than there are data).

Note that `gam` assumes a very inclusive definition of what counts as a GAM: basically any penalized GLM can be used: to this end `gam` allows the non smooth model components to be penalized via argument `paraPen` and allows the linear predictor to depend on general linear functionals of smooths, via the summation convention mechanism described in [linear.functional.terms](#).

Details of the default underlying fitting methods are given in Wood (2004 and 2008). Some alternative methods are discussed in Wood (2000 and 2006).

Value

If `fit=FALSE` the function returns a list `G` of items needed to fit a GAM, but doesn’t actually fit it. Otherwise the function returns an object of class `"gam"` as described in [gamObject](#).

WARNINGS

You must have more unique combinations of covariates than the model has total parameters. (Total parameters is sum of basis dimensions plus sum of non-spline terms less the number of spline terms).

Automatic smoothing parameter selection is not likely to work well when fitting models to very few response data.

For data with many zeroes clustered together in the covariate space it is quite easy to set up GAMs which suffer from identifiability problems, particularly when using Poisson or binomial families. The problem is that with e.g. log or logit links, mean value zero corresponds to an infinite range on the linear predictor scale.

Author(s)

Simon N. Wood (simon.wood@r-project.org)

Front end design inspired by the S function of the same name based on the work of Hastie and Tibshirani (1990). Underlying methods owe much to the work of Wahba (e.g. 1990) and Gu (e.g. 2002).

`gam.check`*Some diagnostics for a fitted gam model*

Description

Takes a fitted `gam` object produced by `gam()` and produces some diagnostic information about the fitting procedure and results. The default is to produce 4 residual plots, and some information about the convergence of the smoothness selection optimization.

Usage

```
gam.check(b)
```

Arguments

`b` a fitted `gam` object as produced by `gam()`.

Details

This function plots 4 standard diagnostic plots, and some other convergence diagnostics. Usually the 4 plots are various residual plots. The printed information relates to the optimization used to select smoothing parameters. For the default optimization methods the information is summarized in a readable way, but for other optimization methods, whatever is returned by way of convergence diagnostics is simply printed.

plot(b, pages=1)
gam.check(b)
```

gam.control

*Setting GAM fitting defaults***Description**

This is an internal function of package `mgcv` which allows control of the numerical options for fitting a GAM. Typically users will want to modify the defaults if model fitting fails to converge, or if the warnings are generated which suggest a loss of numerical stability during fitting. To change the default choice of fitting method, see [gam.method](#).

Usage

```
gam.control(irls.reg=0.0, epsilon = 1e-06, maxit = 100,
            mgcv.tol=1e-7, mgcv.half=15, trace = FALSE,
            rank.tol=.Machine$double.eps^0.5,
            nlm=list(), optim=list(), newton=list(),
            outerPIsteps=1, idLinksBases=TRUE, scalePenalty=TRUE)
```

Arguments

<code>irls.reg</code>	For most models this should be 0. The iteratively re-weighted least squares method by which GAMs are fitted can fail to converge in some circumstances. For example, data with many zeroes can cause problems in a model with a log link, because a mean of zero corresponds to an infinite range of linear predictor values. Such convergence problems are caused by a fundamental lack of identifiability, but do not show up as lack of identifiability in the penalized linear model problems that have to be solved at each stage of iteration. In such circumstances it is possible to apply a ridge regression penalty to the model to impose identifiability, and <code>irls.reg</code> is the size of the penalty.
<code>epsilon</code>	This is used for judging conversion of the GLM IRLS loop in gam.fit or gam.fit3 .
<code>maxit</code>	Maximum number of IRLS iterations to perform.
<code>mgcv.tol</code>	The convergence tolerance parameter to use in GCV/UBRE optimization.
<code>mgcv.half</code>	If a step of the GCV/UBRE optimization method leads to a worse GCV/UBRE score, then the step length is halved. This is the number of halvings to try before giving up.
<code>trace</code>	Set this to TRUE to turn on diagnostic output.
<code>rank.tol</code>	The tolerance used to estimate the rank of the fitting problem, for methods which deal with rank deficient cases (basically all except those based on mgcv).
<code>nlm</code>	list of control parameters to pass to <code>nlm</code> if this is used for outer estimation of smoothing parameters (not default). See details.

<code>optim</code>	list of control parameters to pass to <code>optim</code> if this is used for outer estimation of smoothing parameters (not default). See details.
<code>newton</code>	list of control parameters to pass to default Newton optimizer used for outer estimation of log smoothing parameters. See details.
<code>outerPIsteps</code>	The number of performance iteration steps used to initialize outer iteration. Less than 1 means that only one performance iteration step is taken to get the function scale, but the corresponding smoothing parameter estimates are discarded.
<code>idLinksBases</code>	If smooth terms have their smoothing parameters linked via the <code>id</code> mechanism (see <code>s</code>), should they also have the same bases. Set this to <code>FALSE</code> only if you are sure you know what you are doing (you should almost surely set <code>scalePenalty</code> to <code>FALSE</code> as well in this case).
<code>scalePenalty</code>	<code>gam</code> is somewhat sensitive to the absolute scaling of the penalty matrices of a smooth relative to its model matrix. This option rescales the penalty matrices to accommodate this problem. Probably should be set to <code>FALSE</code> if you are linking smoothing parameters but have set <code>idLinkBases</code> to <code>FALSE</code> .

Details

Outer iteration using `newton` is controlled by the list `newton` with the following elements: `conv.tol` (default `1e-6`) is the relative convergence tolerance; `maxNstep` is the maximum length allowed for an element of the Newton search direction (default 5); `maxSstep` is the maximum length allowed for an element of the steepest descent direction (only used if Newton fails - default 2); `maxHalf` is the maximum number of step halvings to permit before giving up (default 30); `use.svd` determines whether to use an SVD step or QR step for the part of fitting that determines problem rank, etc. (defaults to `FALSE`).

If outer iteration using `nlm` is used for fitting, then the control list `nlm` stores control arguments for calls to routine `nlm`. The list has the following named elements: (i) `ndigit` is the number of significant digits in the GCV/UBRE score - by default this is worked out from `epsilon`; (ii) `gradtol` is the tolerance used to judge convergence of the gradient of the GCV/UBRE score to zero - by default set to `100*epsilon`; (iii) `stepmax` is the maximum allowable log smoothing parameter step - defaults to 2; (iv) `steptol` is the minimum allowable step length - defaults to `1e-4`; (v) `iterlim` is the maximum number of optimization steps allowed - defaults to 200; (vi) `check.analyticals` indicates whether the built in exact derivative calculations should be checked numerically - defaults to `FALSE`. Any of these which are not supplied and named in the list are set to their default values.

Outer iteration using `optim` is controlled using list `optim`, which currently has one element: `factr` which takes default value `1e7`.

gam.convergence *GAM convergence and performance issues*

Description

When fitting GAMs there is a tradeoff between speed of fitting and probability of fit convergence. The default fitting options specified by [gam.method](#) (as the default for argument `method` of [gam](#)), always opt for certainty of convergence over speed of fit. In the Generalized Additive Model case it means using ‘outer’ iteration in preference to ‘performance iteration’: see [gam.outer](#) for details.

It is possible for the default ‘outer’ iteration to fail when finding initial smoothing parameters using a few steps of performance iteration (if you get a convergence failure message from `magic` when outer iterating, then this is what has happened): lower `outerPIsteps` in [gam.control](#) to fix this.

There are three things that you can try to speed up GAM fitting. (i) if you have large numbers of smoothing parameters in the generalized case, then try the “`bfgs`” method as the `outer` option in [gam.method](#): this can be faster than the default. (ii) Change the `method` argument to [gam](#) so that ‘performance iteration’ is used in place of the default outer iteration. See the `gam="perf"` option under [gam.method](#), for example. Usually performance iteration converges well and it can sometimes be quicker than the default outer iteration. (iii) For large datasets it may be worth changing the smoothing basis to use `bs="cr"` (see [s](#) for details) for 1-d smooths, and to use `te` smooths in place of `s` smooths for smooths of more than one variable. This is because the default thin plate regression spline basis “`tp`” is costly to set up for large datasets (much over 1000 data, say).

If the GAM estimation process fails to converge when using performance iteration, then switch to outer iteration via the `method` argument of [gam](#) (see [gam.method](#)). If it still fails, try increasing the number of IRLS iterations (see [gam.control](#)) or perhaps experiment with the convergence tolerance.

If you still have problems, it’s worth noting that a GAM is just a (penalized) GLM and the IRLS scheme used to estimate GLMs is not guaranteed to converge. Hence non convergence of a GAM may relate to a lack of stability in the basic IRLS scheme. Therefore it is worth trying to establish whether the IRLS iterations are capable of converging. To do this fit the problematic GAM with all smooth terms specified with `fx=TRUE` so that the smoothing parameters are all fixed at zero. If this ‘largest’ model can converge then, then the maintainer would quite like to know about your problem! If it doesn’t converge, then its likely that your model is just too flexible for the IRLS process itself. Having tried increasing `maxit` in [gam.control](#), there are several other possibilities for stabilizing the iteration. It is possible to try (i) setting lower bounds on the smoothing parameters using the `min.sp` argument of [gam](#): this may or may not change the model being fitted; (ii) reducing the flexibility of the model by reducing the basis dimensions `k` in the specification of `s` and `te` model terms: this obviously changes the model being fitted somewhat; (iii) introduce a small regularization term into the fitting via the `irls.reg` argument of [gam.control](#): this option obviously changes the nature of the fit somewhat, since parameter estimates are pulled towards zero by doing this.

Usually, a major contributor to fitting difficulties is that the model is a very poor description of the data.

gam.fit

GAM P-IRLS estimation with GCV/UBRE smoothness estimation

Description

This is an internal function of package `mgcv`. It is a modification of the function `glm.fit`, designed to be called from `gam`. The major modification is that rather than solving a weighted least squares problem at each IRLS step, a weighted, penalized least squares problem is solved at each IRLS step with smoothing parameters associated with each penalty chosen by GCV or UBRE, using routine `magic`. For further information on usage see code for `gam`. Some regularization of the IRLS weights is also permitted as a way of addressing identifiability related problems (see `gam.control`). Negative binomial parameter estimation is supported.

The basic idea of estimating smoothing parameters at each step of the P-IRLS is due to Gu (1992), and is termed ‘performance iteration’ or ‘performance oriented iteration’.

gam.fit3

P-IRLS GAM estimation with GCV & UBRE/AIC derivative calculation

Description

Estimation of GAM smoothing parameters is most stable if optimization of the UBRE/AIC or GCV score is outer to the penalized iteratively re-weighted least squares scheme used to estimate the model given smoothing parameters.

This routine estimates a GAM (any quadratically penalized GLM) given log smoothing parameters, and evaluates derivatives of the GCV and UBRE/AIC scores of the model with respect to the log smoothing parameters. Calculation of exact derivatives is generally faster than approximating them by finite differencing, as well as generally improving the reliability of GCV/UBRE/AIC score minimization.

The approach is to run the P-IRLS to convergence, and only then to iterate for first and second derivatives.

Not normally called directly, but rather service routines for `gam`.

Usage

```
gam.fit3(x, y, sp, S=list(), rS=list(), off, H=NULL,
         weights = rep(1, nobs), start = NULL, etastart = NULL,
         mustart = NULL, offset = rep(0, nobs), family = gaussian(),
         control = gam.control(), intercept = TRUE, deriv=2, use.svd=TRUE,
         gamma=1, scale=1, printWarn=TRUE, ...)
```

Arguments

<code>x</code>	The model matrix for the GAM (or any penalized GLM).
<code>y</code>	The response variable.
<code>sp</code>	The log smoothing parameters.
<code>S</code>	A list of penalty matrices. Typically penalty matrices contain only a smallish square sub-matrix which is non-zero: this is what is actually stored. <code>off[i]</code> indicates which parameter is the first one penalized by <code>S[[i]]</code> .
<code>rS</code>	List of square roots of penalty matrices, each having as few columns as possible, but as many rows as there are parameters.
<code>off</code>	<code>off[i]</code> indicates which parameter <code>S[[i]][1,1]</code> relates to.
<code>H</code>	The fixed penalty matrix for the model.
<code>weights</code>	prior weights for fitting.
<code>start</code>	optional starting parameter guesses.
<code>etastart</code>	optional starting values for the linear predictor.
<code>mustart</code>	optional starting values for the mean.
<code>offset</code>	the model offset
<code>family</code>	the family - actually this routine would never be called with <code>gaussian()</code>
<code>control</code>	control list as returned from <code>glm.control</code>
<code>intercept</code>	does the model have an intercept, TRUE or FALSE
<code>deriv</code>	Should derivatives of the GCV and UBRE/AIC scores be calculated? 0, 1 or 2, indicating the maximum order of differentiation to apply.
<code>use.svd</code>	Should the algorithm use SVD (TRUE) or the cheaper QR (FALSE) as the second matrix decomposition of the final derivative/coefficient evaluation method?
<code>gamma</code>	The weight given to each degree of freedom in the GCV and UBRE scores can be varied (usually increased) using this parameter.

scale	The scale parameter - needed for the UBRE/AIC score.
printWarn	Set to FALSE to suppress some warnings. Useful in order to ensure that some warnings are only printed if they apply to the final fitted model, rather than an intermediate used in optimization.
...	Other arguments: ignored.

Details

This routine is basically `glm.fit` with some modifications to allow (i) for quadratic penalties on the log likelihood; (ii) derivatives of the model coefficients with respect to log smoothing parameters to be obtained by an extra iteration and (iii) derivatives of the GAM GCV and UBRE/AIC scores to be evaluated at convergence.

In addition the routines apply step halving to any step that increases the penalized deviance substantially.

The most costly parts of the calculations are performed by calls to compiled C code (which in turn calls LAPACK routines) in place of the compiled code that would usually perform least squares estimation on the working model in the IRLS iteration.

Estimation of smoothing parameters by optimizing GCV scores obtained at convergence of the P-IRLS iteration was proposed by O'Sullivan et al. (1986), and is here termed 'outer' iteration.

Note that use of non-standard families with this routine requires modification of the families as described in [fix.family.link](#).

Author(s)

Simon N. Wood <simon.wood@r-project.org>

The routine has been modified from `glm.fit` in R 2.0.1, written by the R core (see `glm.fit` for further credits).

gam.method

Setting GAM fitting method

Description

This is a function of package `mgcv` which allows selection of the numerical method used to optimize the smoothing parameter estimation criterion for a `gam`. It is used to set argument `method` of `gam`.

Usage

```
gam.method(gam="outer", outer="newton", gcv="deviance",
           family=NULL)
```

Arguments

gam	Which method to use in the generalized case (i.e. all case other than gaussian with identity link). "perf" for the performance iteration (see details) with <code>magic</code> as the basic estimation engine. "perf.outer" for <code>magic</code> based performance iteration followed by outer iteration (see details). "outer" for pure outer iteration.
outer	The optimization approach to use to optimize log smoothing parameters by outer iteration. "newton" (default) for modified Newton method backed up by steepest descent, based on exact first and second derivatives. "bfgs" for a hybrid Newton- Quasi-Newton approach which can be faster for models with many smoothing parameters. "nlm" to use <code>nlm</code> with exact first derivatives to optimize the smoothness selection criterion. "nlm.fd" to use <code>nlm</code> with finite differenced first derivatives (slower and less reliable). "optim" to use the "L-BFGS-B" quasi-Newton method option of routine <code>optim</code> , with exact first derivatives.
gcv	One of "deviance" or "GACV", specifying the flavour of GCV to use with outer iteration. "deviance" simply replaces the residual sum of squares term in a GCV score with the deviance, following Hastie and Tibshirani (1990, section 6.9). "GACV" (only available with outer method "newton") uses a variant of Gu and Xiang's (2001) generalized approximate cross validation, modified to deal with arbitrary link-error combinations (see Wood, 2008).
family	The routine is called by <code>gam</code> to check the supplied method argument. In this circumstance the family argument is passed, to check that it works with the specified method.

Details

The default methods used by `gam` are based on Newton type optimization of GCV/UBRE/AIC scores with respect to smoothing parameters, as described in Wood (2004) and Wood (2008) for the additive and generalized additive model cases respectively. The smoothing criteria (GCV etc) are evaluated for the fitted model itself (rather than some working approximate model). Since this involves optimizing the criteria 'outside' the PIRLS or LS method used for fitting, it is referred to as 'outer' iteration.

In the generalized case several alternative optimisation methods can be used for outer optimization. Usually the fastest and most reliable approach is to use a modified Newton optimizer with exact first and second derivatives, and this is the default. However if there are large numbers of smoothing parameters then it can be faster to use a hybrid Newton-BFGS quasi-Newton approach, which avoids the expense of frequent full second derivative evaluation.

`nlm` can be used with finite differenced first derivatives. This is not ideal theoretically, since it is possible for the finite difference estimates of derivatives to be very badly in error on rare occasions when the P-IRLS convergence tolerance is close to being matched exactly, so that two components of a finite differenced derivative require different numbers of iterations of P-IRLS in their evaluation. An alternative is provided in which `nlm` uses numerically exact first derivatives, this is faster and less problematic than the other scheme. A further alternative is to use a quasi-Newton scheme with exact derivatives, based on `optim`. In practice this usually seems to be slower than the `nlm` method.

The alternative approach of ‘performance oriented iteration’ was suggested by Gu (and is rather similar to the PQL method in generalized linear mixed modelling). At each step of the P-IRLS (penalized iteratively reweighted least squares) iteration, by which a gam is fitted, the smoothing parameters are estimated by GCV or UBRE applied to the working penalized linear modelling problem. In most cases, this process converges and gives smoothness estimates that perform well (see e.g. Wood 2004).

The performance iteration has two disadvantages. (i) in the presence of co-linearity or concavity (a frequent problem when spatial smoothers are included in a model with other covariates) then the process can fail to converge. Suppose we start with some coefficient and smoothing parameter estimates, implying a working penalized linear model: the optimal smoothing parameters and coefficients for this working model may in turn imply a working model for which the original estimates are better than the most recent estimates. This sort of effect can prevent convergence.

Secondly it is often possible to find a set of smoothing parameters that result in a lower GCV or UBRE score, for the final working model, than the final score that results from the performance iterations. This is because the performance iteration is only approximately optimizing this score (since optimization is only performed on the working model). The disadvantage here is not that the model with lower score would perform better (it usually doesn’t), but rather that it makes model comparison on the basis of GCV/UBRE score rather difficult.

In summary: performance iteration can fail to converge. It may occasionally be faster than outer iteration, but since the Wood (2008) method ‘outer’ iteration is faster in most cases.

gam.models

Specifying generalized additive models

Description

This page is intended to provide some more information on how to specify GAMs. A GAM is a GLM in which the linear predictor depends, in part, on a sum of smooth functions of predictors and (possibly) linear functionals of smooth functions of (possibly dummy) predictors.

Specifically let y_i denote an independent random variable with mean μ_i and an exponential family distribution, or failing that a known mean variance relationship suitable for use of quasi-likelihood methods. Then the the linear predictor of a GAM has a structure something like

$$g(\mu_i) = \mathbf{X}_i\beta + f_1(x_{1i}, x_{2i}) + f_2(x_{3i}) + L_i f_3(x_4) + \dots$$

where g is a known smooth monotonic ‘link’ function, $\mathbf{X}_i\beta$ is the parametric part of the linear predictor, the x_j are predictor variables, the f_j are smooth functions and L_i is some linear functional of f_3 . There may of course be multiple linear functional terms, or none.

The key idea here is that the dependence of the response on the predictors can be represented as a parametric sub-model plus the sum of some (functionals of) smooth functions of one or more of the predictor variables. Thus the model is quite flexible relative to strictly parametric linear or generalized linear models, but still has much more structure than the completely general model that says that the response is just some smooth function of all the covariates.

Note one important point. In order for the model to be identifiable the smooth functions usually have to be constrained to have zero mean (usually taken over the set of covariate values). The constraint is needed if the term involving the smooth includes a constant function in its span. `gam` always applies such constraints unless there is a `by` variable present, in which case an assessment is made of whether the constraint is needed or not (see below).

The following sections discuss specifying model structures for `gam`. Specification of the distribution and link function is done using the `family` argument to `gam` and works in the same way as for `glm`. This page therefore concentrates on the model formula for `gam`.

Models with simple smooth terms

Consider the example model.

$$g(\mu_i) = \beta_0 + \beta_1 x_{1i} + \beta_2 x_{2i} + f_1(x_{3i}) + f_2(x_{4i}, x_{5i})$$

where the response variables y_i has expectation μ_i and g is a link function.

The `gam` formula for this would be

```
y ~ x1 + x2 + s(x3) + s(x4, x5).
```

This would use the default basis for the smooths (a thin plate regression spline basis for each), with automatic selection of the effective degrees of freedom for both smooths. The dimension of the smoothing basis is given a default value as well (the dimension of the basis sets an upper limit on the maximum possible degrees of freedom for the basis - the limit is typically one less than basis dimension). Full details of how to control smooths are given in `s` and `te`, and further discussion of basis dimension choice can be found in `choose.k`. For the moment suppose that we would like to change the basis of the first smooth to a cubic regression spline basis with a dimension of 20, while fixing the second term at 25 degrees of freedom. The appropriate formula would be:

```
y ~ x1 + x2 + s(x3, bs="cr", k=20) + s(x4, x5, k=26, fx=TRUE).
```

The above assumes that x_4 and x_5 are naturally on similar scales (e.g. they might be co-ordinates), so that isotropic smoothing is appropriate. If this assumption is false then tensor product smoothing might be better (see `te`).

```
y ~ x1 + x2 + s(x3) + te(x4, x5)
```

would generate a tensor product smooth of x_4 and x_5 . By default this smooth would have basis dimension 25 and use cubic regression spline marginals. Varying the defaults is easy. For example

```
y ~ x1 + x2 + s(x3) + te(x4, x5, bs=c("cr", "ps"), k=c(6, 7))
```

specifies that the tensor product should use a rank 6 cubic regression spline marginal and a rank 7 P-spline marginal to create a smooth with basis dimension 42.

Nested terms

Another common modelling task is to decide if a model like:

$$E(y_i) = f(x_i, z_i)$$

is really necessary or whether:

$$E(y_i) = f_1(x_i) + f_2(z_i)$$

would do just as well. One possibility is to examine the results of fitting:

$$y \sim s(x) + s(z) + s(x, z).$$

gam automatically generates side conditions to make this model identifiable. You can also estimate ‘overlapping’ models like:

$$y \sim s(x, z) + s(z, v).$$

‘by’ variables

by variables are the means for constructing ‘varying-coefficient models’ (geographic regression models) and for letting smooths ‘interact’ with factors or parametric terms. They are also the key to specifying general linear functionals of smooths.

The `s` and `te` terms used to specify smooths accept an argument `by`, which is a numeric or factor variable of the same dimension as the covariates of the smooth. If a `by` variable is numeric, then its i^{th} element multiplies the i^{th} row of the model matrix corresponding to the smooth term concerned. If a `by` variable is a factor then it generates an indicator vector for each level of the factor. The model matrix for the smooth term is then replicated for each factor level, and each copy has its rows multiplied by the corresponding rows of its indicator variable. The smoothness penalties are also duplicated for each factor level. In short a different smooth is generated for each factor level (the `id` argument to `s` and `te` can be used to force all such smooths to have the same smoothing parameter).

As an example, consider the model

$$E(y_i) = \beta_0 + f(x_i)z_i$$

where f is a smooth function, and z_i is a numeric variable. The appropriate formula is:

$$y \sim s(x, by=z)$$

- the `by` argument ensures that the smooth function gets multiplied by covariate z . Note that when using factor variables, then the presence of centering constraints usually means that the `by` variable should be included as a parametric term, as well.

The example code below also illustrates the use of factor `by` variables.

`by` variables may be supplied as numeric matrices as part of specifying general linear functional terms.

If a `by` variable is present and numeric (rather than a factor) then the corresponding smooth is only subjected to an identifiability constraint if (i) the `by` variable is a constant vector, or, (ii) for a matrix `by` variable, `L %*% rep(1, ncol(L))` is constant or (iii) if a user defined smooth constructor supplies an identifiability constraint explicitly.

Linking smooths with ‘id’

It is sometimes desirable to insist that different smooth terms have the same degree of smoothness. This can be done by using the `id` argument to `s` or `te` terms. Smooths which share an `id` will have the same smoothing parameter. Really this only makes sense if the smooths use the same basis functions, and the default behaviour is to force this to happen: all smooths sharing an `id` have the same basis functions as the first smooth occurring with that `id`. Note that if you want exactly the same function for each smooth, then this is best achieved by making use of the summation convention covered under ‘linear functional terms’.

As an example suppose that $E(y_i) \equiv \mu_i$ and

$$g(\mu_i) = f_1(x_{1i}) + f_2(x_{2i}, x_{3i}) + f_3(x_{4i})$$

but that f_1 and f_3 should have the same smoothing parameters (and x_2 and x_3 are on different scales). Then the `gam` formula

```
y ~ s(x1, id=1) + te(x_2, x3) + s(x4, id=1)
```

would achieve the desired result. `id` can be numbers or character strings. Giving an `id` to a term with a factor `by` variable causes the smooths at each level of the factor to have the same smoothing parameter.

Smooth term `ids` are not supported by `gamm`.

Linear functional terms
