Chapter 1

The base package

base-package

The R Base Package

Description

Base R functions

Details

This package contains the basic functions which let R function as a language: arithmetic, input/output, basic programming support, etc. Its contents are available through inheritance from any environment.

For a complete list of functions, use `library(help="base")`.

.Device

Lists of Open/Active Graphics Devices

Description

A pairlist of the names of open graphics devices is stored in `.Devices`. The name of the active device (see `dev.cur`) is stored in `.Device`. Both are symbols and so appear in the base name space.

Value

`.Device` is a length-one character vector.

`.Devices` is a [pairlist](#) of length-one character vectors. The first entry is always "null device", and there are as many entries as the maximal number of graphics devices which have been simultaneously active. If a device has been removed, its entry will be "" until the device number is reused.

.Machine

*Numerical Characteristics of the Machine***Description**

.Machine is a variable holding information on the numerical characteristics of the machine R is running on, such as the largest double or integer and the machine's precision.

Usage

.Machine

Details

The algorithm is based on Cody's (1988) subroutine MACHAR. As almost all current implements of R use 32-bit integers and IEC 60059 floating-point (double precision) arithmetic, most of these values are the same for almost all R builds.

Note that on most platforms smaller positive values than .Machine\$double.xmin can occur. On a typical R platform the smallest positive double is about $5e-324$.

Value

A list with components (for simplicity, the prefix 'double' is omitted in the explanations)

double.eps	the smallest positive floating-point number x such that $1 + x \neq 1$. It equals $\text{base}^{\text{ulp.digits}}$ if either base is 2 or rounding is 0; otherwise, it is $(\text{base}^{\text{ulp.digits}}) / 2$. Normally $2.220446e-16$.
double.neg.eps	a small positive floating-point number x such that $1 - x \neq 1$. It equals $\text{base}^{\text{neg.ulp.digits}}$ if base is 2 or round is 0; otherwise, it is $(\text{base}^{\text{neg.ulp.digits}}) / 2$. Normally $1.110223e-16$. As neg.ulp.digits is bounded below by $-(\text{digits} + 3)$, neg.eps may not be the smallest number that can alter 1 by subtraction.
double.xmin	the smallest non-vanishing normalized floating-point power of the radix, i.e., $\text{base}^{\text{min.exp}}$. Normally $2.225074e-308$.
double.xmax	the largest finite floating-point number. Typically, it is equal to $(1 - \text{neg.eps}) * \text{base}^{\text{max.exp}}$, but on some machines it is only the second, or perhaps third, largest number, being too small by 1 or 2 units in the last digit of the significand. Normally $1.797693e+308$.
double.base	the radix for the floating-point representation: normally 2.
double.digits	the number of base digits in the floating-point significand: normally 53.
double.rounding	the rounding action. 0 if floating-point addition chops; 1 if floating-point addition rounds, but not in the IEEE style; 2 if floating-point addition rounds in the IEEE style; 3 if floating-point addition chops, and there is partial underflow; 4 if floating-point addition rounds, but not in the IEEE style, and there is partial underflow;

5 if floating-point addition rounds in the IEEE style, and there is partial underflow. Normally 5.

`double.guard` the number of guard digits for multiplication with truncating arithmetic. It is 1 if floating-point arithmetic truncates and more than `digits` `base` `base` `digits` participate in the post-normalization shift of the floating-point significand in multiplication, and 0 otherwise.

`double.ulp.digits`
the largest negative integer `i` such that $1 + \text{base}^i \neq 1$, except that it is bounded below by $-(\text{digits} + 3)$. Normally -52.

`double.neg.ulp.digits`
the largest negative integer `i` such that $1 - \text{base}^i \neq 1$, except that it is bounded below by $-(\text{digits} + 3)$. Normally -53.

`double.exponent`
the number of bits (decimal places if `base` is 10) reserved for the representation of the exponent (including the bias or sign) of a floating-point number. Normally 11.

`double.min.exp`
the largest in magnitude negative integer `i` such that `base` `^` `i` is positive and normalized. Normally -1022.

`double.max.exp`
the smallest positive power of `base` that overflows. Normally 1024.

`integer.max` the largest integer which can be represented. Always 2147483647.

`sizeof.long` the number of bytes in a C `long` type: 4 or 8 (most 64-bit systems, but not Windows).

`sizeof.longlong`
the number of bytes in a C `long long` type. Will be zero if there is no such type, otherwise usually 8.

`sizeof.longdouble`
the number of bytes in a C `long double` type. Will be zero if there is no such type, otherwise possibly 12 (Windows, 32-bit Linux/Solaris) or 16 (64-bit Linux/Solaris, Intel Mac OS X).

`sizeof.pointer`
the number of bytes in a C `SEXP` type. Will be 4 on 32-bit builds and 8 on 64-bit builds of R.

References

Cody, W. J. (1988) MACHAR: A subroutine to dynamically determine machine parameters. *Transactions on Mathematical Software*, **14**, 4, 303–311.

See Also

[.Platform](#) for details of the platform.

Examples

```
.Machine
## or for a neat printout
noquote(unlist(format(.Machine)))
```

`.Platform`*Platform Specific Variables*

Description

`.Platform` is a list with some details of the platform under which R was built. This provides means to write OS-portable R code.

Usage

```
.Platform
```

Value

A list with at least the following components:

<code>OS.type</code>	character string, giving the Operating System (family) of the computer. One of "unix" or "windows".
<code>file.sep</code>	character string, giving the file separator used on your platform: "/" on both Unix-alikes <i>and</i> on Windows (but not on the now abandoned port to Classic MacOS).
<code>dynlib.ext</code>	character string, giving the file name extension of dynamically loadable libraries , e.g., ".dll" on Windows and ".so" or ".sl" on Unix-alikes. (Note for Mac OS X users: these are shared objects as loaded by <code>dyn.load</code> and not dylibs: see <code>dyn.load</code> .)
<code>GUI</code>	character string, giving the type of GUI in use, or "unknown" if no GUI can be assumed. Possible values are for Unix-alikes the values given via the '-g' command-line flag ("X11", "Tk", "GNOME"), "AQUA" (running under R.app on MacOS X), "Rgui" and "RTerm" (Windows) and perhaps others under alternative front-ends or embedded R.
<code>endian</code>	character string, "big" or "little", giving the endianness of the processor in use. This is relevant when it is necessary to know the order to read/write bytes of e.g. an integer or double from/to a connection: see <code>readBin</code> .
<code>pkgType</code>	character string, the preferred setting for <code>options("pkgType")</code> . Values "source", "mac.binary" and "win.binary" are currently in use.
<code>path.sep</code>	character string, giving the path separator , used on your platform, e.g., ":" on Unix-alikes and ";" on Windows. Used to separate paths in variables such as PATH and TEXINPUTS.
<code>r_arch</code>	character string, possibly "". The name of the architecture-specific directories used in this build of R.

See Also

`R.version` and `Sys.info` give more details about the OS. In particular, `R.version$platform` is the canonical name of the platform under which R was compiled.

`.Machine` for details of the arithmetic used, and `system` for invoking platform-specific system commands.

Examples

```
## Note: this can be done in a system-independent way
## by file.info()$isdir
if(.Platform$OS.type == "unix") {
  system.test <- function(...) { system(paste("test", ...)) == 0 }
  dir.exists <- function(dir)
    sapply(dir, function(d) system.test("-d", d))
  dir.exists(c(R.home(), "/tmp", "~", "/NO"))# > T T T F
}
```

.Script

Scripting Language Interface

Description

Run a script through its interpreter with given arguments.

Usage

```
.Script(interpreter, script, args, ...)
```

Arguments

interpreter	a character string naming the interpreter for the script.
script	a character string with the base file name of the script, which must be located in the 'interpreter' subdirectory of ' <i>R_SHARE_DIR</i> ' (normally ' <i>R_HOME/share</i> ').
args	a character string giving the arguments to pass to the script.
...	further arguments to be passed to <code>system</code> when invoking the interpreter on the script.

Note

This function is for R internal use only.

Examples

```
## not useful on Windows, where the help is zipped.
.Script("perl", "message-Examples.pl",
  paste("tools", system.file("R-ex", package = "tools")))
```

 abbreviate *Abbreviate Strings*

Description

Abbreviate strings to at least `minlength` characters, such that they remain *unique* (if they were), unless `strict=TRUE`.

Usage

```
abbreviate(names.arg, minlength = 4, use.classes = TRUE,
           dot = FALSE, strict = FALSE, method = c("left.kept", "both.sides"))
```

Arguments

<code>names.arg</code>	a character vector of names to be abbreviated, or an object to be coerced to a character vector by <code>as.character</code> .
<code>minlength</code>	the minimum length of the abbreviations.
<code>use.classes</code>	logical (currently ignored by R).
<code>dot</code>	logical: should a dot (".") be appended?
<code>strict</code>	logical: should <code>minlength</code> be observed strictly? Note that setting <code>strict=TRUE</code> may return <i>non-unique</i> strings.
<code>method</code>	a string specifying the method used with default "left.kept", see 'Details' below.

Details

The algorithm (`method = "left.kept"`) used is similar to that of `S`. For a single string it works as follows. First all spaces at the beginning of the string are stripped. Then (if necessary) any other spaces are stripped. Next, lower case vowels are removed (starting at the right) followed by lower case consonants. Finally if the abbreviation is still longer than `minlength` upper case letters are stripped.

Characters are always stripped from the end of the word first. If an element of `names.arg` contains more than one word (words are separated by space) then at least one letter from each word will be retained.

Missing (NA) values are unaltered.

If `use.classes` is `FALSE` then the only distinction is to be between letters and space. This has NOT been implemented.

Value

A character vector containing abbreviations for the strings in its first argument. Duplicates in the original `names.arg` will be given identical abbreviations. If any non-duplicated elements have the same `minlength` abbreviations then, if `method = "both.sides"` the basic internal `abbreviate()` algorithm is applied to the characterwise *reversed* strings; if there are still duplicated abbreviations and if `strict=FALSE` as by default, `minlength` is incremented by one and new abbreviations are found for those elements only. This process is repeated until all unique elements of `names.arg` have unique abbreviations.

The character version of `names.arg` is attached to the returned value as a `names` argument: no other attributes are retained.

Warning

This is really only suitable for English, and does not work correctly with non-ASCII characters in multibyte locales. It will warn if used with non-ASCII characters.

See Also

[substr](#).

Examples

```
x <- c("abcd", "efgh", "abce")
abbreviate(x, 2)
abbreviate(x, 2, strict=TRUE) # >> 1st and 3rd are == "ab"

(st.abb <- abbreviate(state.name, 2))
table(nchar(st.abb)) # out of 50, 3 need 4 letters :
as <- abbreviate(state.name, 3, strict=TRUE)
as[which(as == "Mss")]

## method="both.sides" helps: no 4-letters, and only 4 3-letters:
st.ab2 <- abbreviate(state.name, 2, method="both")
table(nchar(st.ab2))
## Compare the two methods:
cbind(st.abb, st.ab2)
```

agrep

Approximate String Matching (Fuzzy Matching)

Description

Searches for approximate matches to `pattern` (the first argument) within the string `x` (the second argument) using the Levenshtein edit distance.

Usage

```
agrep(pattern, x, ignore.case = FALSE, value = FALSE,
       max.distance = 0.1, useBytes = FALSE)
```

Arguments

<code>pattern</code>	a non-empty character string to be matched (<i>not</i> a regular expression!). Coerced by <code>as.character</code> to a string if possible.
<code>x</code>	character vector where matches are sought. Coerced by <code>as.character</code> to a character vector if possible.
<code>ignore.case</code>	if <code>FALSE</code> , the pattern matching is <i>case sensitive</i> and if <code>TRUE</code> , case is ignored during matching.
<code>value</code>	if <code>FALSE</code> , a vector containing the (integer) indices of the matches determined is returned and if <code>TRUE</code> , a vector containing the matching elements themselves is returned.

`max.distance` Maximum distance allowed for a match. Expressed either as integer, or as a fraction of the *pattern* length (will be replaced by the smallest integer not less than the corresponding fraction of the pattern length), or a list with possible components

all: maximal (overall) distance

insertions: maximum number/fraction of insertions

deletions: maximum number/fraction of deletions

substitutions: maximum number/fraction of substitutions

If `all` is missing, it is set to 10%, the other components default to `all`. The component names can be abbreviated.

`useBytes` logical. in a multibyte locale, should the comparison be character-by-character (the default) or byte-by-byte.

Details

The Levenshtein edit distance is used as measure of approximateness: it is the total number of insertions, deletions and substitutions required to transform one string into another.

The function is a simple interface to the `apse` library developed by Jarkko Hietaniemi (also used in the Perl `String::Approx` module), modified to work with multibyte character sets. To save space it only supports the first 65536 characters of UTF-8 (where all the characters for human languages lie). Note that it can be quite slow in UTF-8, and `useBytes = TRUE` will be much faster.

Value

Either a vector giving the indices of the elements that yielded a match, or, if `value` is `TRUE`, the matched elements (after coercion, preserving names but no other attributes).

Author(s)

Original version by David Meyer, based on C code by Jarkko Hietaniemi.

See Also

[grep](#)

Examples

```
agrep("lasy", "1 lazy 2")
agrep("lasy", c(" 1 lazy 2", "1 lasy 2"), max = list(sub = 0))
agrep("laysy", c("1 lazy", "1", "1 LAZY"), max = 2)
agrep("laysy", c("1 lazy", "1", "1 LAZY"), max = 2, value = TRUE)
agrep("laysy", c("1 lazy", "1", "1 LAZY"), max = 2, ignore.case = TRUE)
```

all *Are All Values True?*

Description

Given a set of logical vectors, are all of the values true?

Usage

```
all(..., na.rm = FALSE)
```

Arguments

`...` zero or more logical vectors. Other objects of zero length are ignored, and the rest are coerced to logical ignoring any class.

`na.rm` logical. If true NA values are removed before the result is computed.

Details

This is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

Coercion of types other than integer (raw, double, complex, character, list) gives a warning as from R 2.7.0, as this was often unintentional.

Value

The value is a logical vector of length one.

Let `x` denote the concatenation of all the logical vectors in `...` (after coercion), after removing NAs if requested by `na.rm = TRUE`.

The value returned is `TRUE` if all of the values in `x` are `TRUE` (including if there are no values), and `FALSE` if at least one of the values in `x` is `FALSE`. Otherwise the value is `NA` (which can only occur if `na.rm = FALSE` and `...` contains no `FALSE` values and at least one `NA` value).

S4 methods

This is part of the S4 [Summary](#) group generic. Methods for it must use the signature `x, ..., na.rm`.

Note

That `all(logical(0))` is true is a useful convention: it ensures that

```
all(all(x), all(y)) == all(x, y)
```

even if `x` has length zero.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[any](#), the ‘complement’ of `all`, and `stopifnot` (*) which is an `all` (*) ‘insurance’.

Examples

```
range(x <- sort(round(stats::rnorm(10) - 1.2, 1)))
if(all(x < 0)) cat("all x values are negative\n")

all(logical(0)) # true, as all zero of the elements are true.
```

all.equal

Test if Two Objects are (Nearly) Equal

Description

`all.equal(x, y)` is a utility to compare R objects `x` and `y` testing ‘near equality’. If they are different, comparison is still made to some extent, and a report of the differences is returned. Don’t use `all.equal` directly in `if` expressions—either use `isTRUE(all.equal(...))` or `identical` if appropriate.

Usage

```
all.equal(target, current, ...)

## S3 method for class 'numeric':
all.equal(target, current,
          tolerance = .Machine$double.eps ^ 0.5,
          scale = NULL, check.attributes = TRUE, ...)

attr.all.equal(target, current,
               check.attributes = TRUE, check.names = TRUE, ...)
```

Arguments

<code>target</code>	R object.
<code>current</code>	other R object, to be compared with <code>target</code> .
<code>...</code>	Further arguments for different methods, notably the following two, for numerical comparison:
<code>tolerance</code>	numeric ≥ 0 . Differences smaller than <code>tolerance</code> are not considered.
<code>scale</code>	numeric scalar > 0 (or <code>NULL</code>). See ‘Details’.
<code>check.attributes</code>	logical indicating if the <code>attributes(.)</code> of <code>target</code> and <code>current</code> should be compared as well.
<code>check.names</code>	logical indicating if the <code>names(.)</code> of <code>target</code> and <code>current</code> should be compared as well (and separately from the <code>attributes</code>).

Details

There are several methods available, most of which are dispatched by the default method, see `methods("all.equal")`. `all.equal.list` and `all.equal.language` provide comparison of recursive objects.

Numerical comparisons for `scale = NULL` (the default) are done by first computing the mean absolute difference of the two numerical vectors. If this is smaller than `tolerance` or not finite, absolute differences are used, otherwise relative differences scaled by the mean absolute difference.

If `scale` is positive, absolute comparisons are made after scaling (dividing) by `scale`.

For complex arguments, the modulus `Mod` of the difference is used: `all.equal.numeric` is called so arguments `tolerance` and `scale` are available.

`attr.all.equal` is used for comparing `attributes`, returning `NULL` or a character vector.

Value

Either `TRUE` (`NULL` for `attr.all.equal`) or a vector of mode `"character"` describing the differences between `target` and `current`.

References

See Also

`identical`, `isTRUE`, `==`, and `all` for exact equality testing.

Examples

```
all.equal(pi, 355/113)
# not precise enough (default tol) > relative error

d45 <- pi*(1/4 + 1:10)
stopifnot(
  all.equal(tan(d45), rep(1,10))          # TRUE, but
  all      (tan(d45) == rep(1,10))       # FALSE, since not exactly
  all.equal(tan(d45), rep(1,10), tol=0)  # to see difference
```

all.names

Find All Names in an Expression

Description

Return a character vector containing all the names which occur in an expression or call.

Usage

```
all.names(expr, functions = TRUE, max.names = -1L, unique = FALSE)
```

```
all.vars(expr, functions = FALSE, max.names = -1L, unique = TRUE)
```

Arguments

<code>expr</code>	an expression or call from which the names are to be extracted.
<code>functions</code>	a logical value indicating whether function names should be included in the result.
<code>max.names</code>	the maximum number of names to be returned. <code>-1</code> indicates no limit (other than vector size limits).
<code>unique</code>	a logical value which indicates whether duplicate names should be removed from the value.

Details

These functions differ only in the default values for their arguments.

Value

A character vector with the extracted names.

Examples

```
all.names(expression(sin(x+y)))
all.vars(expression(sin(x+y)))
```

any

Are Some Values True?

Description

Given a set of logical vectors, is at least one of the values true?

Usage

```
any(..., na.rm = FALSE)
```

Arguments

<code>...</code>	zero or more logical vectors. Other objects of zero length are ignored, and the rest are coerced to logical ignoring any class.
<code>na.rm</code>	logical. If true NA values are removed before the result is computed.

Details

This is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

Coercion of types other than integer (raw, double, complex, character, list) gives a warning as from R 2.7.0, as this was often unintentional.

Value

The value is a logical vector of length one.

Let `x` denote the concatenation of all the logical vectors in `...` (after coercion), after removing NAs if requested by `na.rm = TRUE`.

The value returned is `TRUE` if at least one of the values in `x` is `TRUE`, and `FALSE` if all of the values in `x` are `FALSE` (including if there are no values). Otherwise the value is `NA` (which can only occur if `na.rm = FALSE` and `...` contains no `TRUE` values and at least one `NA` value).

S4 methods

This is part of the S4 [Summary](#) group generic. Methods for it must use the signature `x, ..., na.rm`.

See Also

[all](#), the ‘complement’ of `any`.

Examples

```
range(x <- sort(round(stats::rnorm(10) - 1.2, 1)))
if(any(x < 0)) cat("x contains negative values\n")
```

 aperm

Array Transposition

Description

Transpose an array by permuting its dimensions and optionally resizing it.

Usage

```
aperm(a, perm, resize = TRUE)
```

Arguments

<code>a</code>	the array to be transposed.
<code>perm</code>	the subscript permutation vector, which must be a permutation of the integers <code>1:n</code> , where <code>n</code> is the number of dimensions of <code>a</code> . The default is to reverse the order of the dimensions.
<code>resize</code>	a flag indicating whether the vector should be resized as well as having its elements reordered (default <code>TRUE</code>).

Value

A transposed version of array `a`, with subscripts permuted as indicated by the array `perm`. If `resize` is `TRUE`, the array is reshaped as well as having its elements permuted, the `dimnames` are also permuted; if `resize = FALSE` then the returned object has the same dimensions as `a`, and the `dimnames` are dropped. In each case other attributes are copied from `a`.

The function `t` provides a faster and more convenient way of transposing matrices.

Author(s)

Jonathan Rougier, J.C.Rougier@durham.ac.uk did the faster C implementation.

References

See Also

`t`, to transpose matrices.

Examples

```
# interchange the first two subscripts on a 3-way array x
x <- array(1:24, 2:4)
xt <- aperm(x, c(2,1,3))
stopifnot(t(xt[, , 2]) == x[, , 2],
          t(xt[, , 3]) == x[, , 3],
          t(xt[, , 4]) == x[, , 4])
```

append

Vector Merging

Description

Add elements to a vector.

Usage

```
append(x, values, after = length(x))
```

Arguments

<code>x</code>	the vector to be modified.
<code>values</code>	to be included in the modified vector.
<code>after</code>	a subscript, after which the values are to be appended.

Value

A vector containing the values in `x` with the elements of `values` appended after the specified element of `x`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

Examples

```
append(1:5, 0:1, after=3)
```

 apply

Apply Functions Over Array Margins

Description

Returns a vector or array or list of values obtained by applying a function to margins of an array.

Usage

```
apply(X, MARGIN, FUN, ...)
```

Arguments

X	the array to be used.
MARGIN	a vector giving the subscripts which the function will be applied over. 1 indicates rows, 2 indicates columns, c(1, 2) indicates rows and columns.
FUN	the function to be applied: see ‘Details’. In the case of functions like +, %*%, etc., the function name must be backquoted or quoted.
...	optional arguments to FUN.

Details

If X is not an array but has a dimension attribute, `apply` attempts to coerce it to an array via `as.matrix` if it is two-dimensional (e.g., data frames) or via `as.array`.

FUN is found by a call to `match.fun` and typically is either a function or a symbol (e.g. a back-quoted name) or a character string specifying a function to be searched for from the environment of the call to `apply`.

Value

If each call to FUN returns a vector of length n, then `apply` returns an array of dimension c(n, dim(X)[MARGIN]) if n > 1. If n equals 1, `apply` returns a vector if MARGIN has length 1 and an array of dimension dim(X)[MARGIN] otherwise. If n is 0, the result has length 0 but not necessarily the ‘correct’ dimension.

If the calls to FUN return vectors of different lengths, `apply` returns a list of length prod(dim(X)[MARGIN]) with dim set to MARGIN if this has length greater than one.

In all cases the result is coerced by `as.vector` to one of the basic vector types before the dimensions are set, so that (for example) factor results will be coerced to a character array.

Examples

```
## Compute row and column sums for a matrix:
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
dimnames(x)[[1]] <- letters[1:8]
apply(x, 2, mean, trim = .2)
col.sums <- apply(x, 2, sum)
row.sums <- apply(x, 1, sum)
rbind(cbind(x, Rtot = row.sums), Ctot = c(col.sums, sum(col.sums)))

stopifnot( apply(x, 2, is.vector) )

## Sort the columns of a matrix
apply(x, 2, sort)

##- function with extra args:
cave <- function(x, c1, c2) c(mean(x[c1]), mean(x[c2]))
apply(x,1, cave, c1="x1", c2=c("x1","x2"))

ma <- matrix(c(1:4, 1, 6:8), nrow = 2)
ma
apply(ma, 1, table) #--> a list of length 2
apply(ma, 1, stats::quantile)# 5 x n matrix with rownames

stopifnot(dim(ma) == dim(apply(ma, 1:2, sum)))

## Example with different lengths for each call
z <- array(1:24, dim=2:4)
zseq <- apply(z, 1:2, function(x) seq_len(max(x)))
zseq ## a 2 x 3 matrix
typeof(zseq) ## list
dim(zseq) ## 2 3
zseq[1,]
apply(z, 3, function(x) seq_len(max(x)))
# a list without a dim attribute
```

args

Argument List of a Function

Description

Displays the argument names and corresponding default values of a function or primitive.

Usage

```
args(name)
```

Arguments

name a function (a closure or a primitive). If name is a character string then the function with that name is found and used.

Details

This function is mainly used interactively to print the argument list of a function. For programming, consider using `formals` instead.

Value

For a closure, a closure with identical formal argument list but an empty (NULL) body.

For a primitive, a closure with the documented usage and NULL body. Note that in almost all cases primitives do not make use of named arguments and match by position rather than name. (`rep` and `seq.int` are exceptions.)

NULL in case of a non-function.

```

Arithmetic

Arithmetic Operators

Description

These binary operators perform arithmetic on numeric or complex vectors (or objects which can be coerced to them).

Usage

```
x + y
x - y
x * y
x / y
x ^ y
x %% y
x %/% y
```

Arguments

`x`, `y` numeric or complex vectors or objects which can be coerced to such, or other objects for which methods have been written.

Details

The binary arithmetic operators are generic functions: methods can be written for them individually or via the `Ops` group generic function. (See `Ops` for how dispatch is computed.)

If applied to arrays the result will be an array if this is sensible (for example it will not if the recycling rule has been invoked).

Logical vectors will be coerced to integer or numeric vectors, `FALSE` having value zero and `TRUE` having value one.

$1 \wedge y$ and $y \wedge 0$ are 1, *always*. $x \wedge y$ should also give the proper limit result when either argument is infinite (i.e., $+- \text{Inf}$).

Objects such as arrays or time-series can be operated on this way provided they are conformable.

For real arguments, `%%` can be subject to catastrophic loss of accuracy if `x` is much larger than `y`, and a warning is given if this is detected.

Value

These operators return vectors containing the result of the element by element operations. The elements of shorter vectors are recycled as necessary (with a `warning` when they are recycled only *fractionally*). The operators are `+` for addition, `-` for subtraction, `*` for multiplication, `/` for division and `^` for exponentiation.

`%%` indicates `x mod y` and `%%/%` indicates integer division. It is guaranteed that `x == (x %% y) + y * (x %/% y)` (up to rounding error) unless `y == 0` where the result is `NA_integer_` or `NaN` (depending on the `typeof` of the arguments). See http://en.wikipedia.org/wiki/Modulo_operation for the rationale.

If either argument is complex the result will be complex, and if one or both arguments are numeric, the result will be numeric. If both arguments are integer, the result of `/` and `^` is numeric and of the other operators integer (with overflow returned as `NA` with a warning).

The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument, the first if they are of the same length. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. For time series, these operations are allowed only if the series are compatible, when the class and `tsp` attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and `dimnames` are taken from first argument if it is an array, otherwise the second.

S4 methods

These operators are members of the S4 `Arith` group generic, and so methods can be written for them individually as well as for the group generic (or the `Ops` group generic), with arguments `c(e1, e2)`.

Note

`**` is translated in the parser to `^`, but this was undocumented for many years. It appears as an index entry in Becker *et al* (1988), pointing to the help for `Deprecated` but is not actually mentioned on that page. Even though it has been deprecated in S for 20 years, it is still accepted.

Examples

```
x <- -1:12
x + 1
2 * x + 3
x %% 2 #-- is periodic
x %/% 5
```

array

*Multi-way Arrays***Description**

Creates or tests for arrays.

Usage

```
array(data = NA, dim = length(data), dimnames = NULL)
as.array(x, ...)
is.array(x)
```

Arguments

<code>data</code>	a vector (including a list) giving data to fill the array.
<code>dim</code>	the <code>dim</code> attribute for the array to be created, that is a vector of length one or more giving the maximal indices in each dimension.
<code>dimnames</code>	either <code>NULL</code> or the names for the dimensions. This is a list with one component for each dimension, either <code>NULL</code> or a character vector of the length given by <code>dim</code> for that dimension. The list can be named, and the list names will be used as names for the dimensions. If the list is shorter than the number of dimensions, it is extended by <code>NULL</code> s to the length required
<code>x</code>	an R object.
<code>...</code>	additional arguments to be passed to or from methods.

Value

`array` returns an array with the extents specified in `dim` and naming information in `dimnames`. The values in `data` are taken to be those in the array with the leftmost subscript moving fastest. If there are too few elements in `data` to fill the array, then the elements in `data` are recycled. If `data` has length zero, `NA` of an appropriate type is used for atomic vectors (0 for raw vectors) and `NULL` for lists.

`as.array` is a generic function for coercing to arrays. The default method does so by attaching a `dim` attribute to it. It also attaches `dimnames` if `x` has `names`. The sole purpose of this is to make it possible to access the `dim[names]` attribute at a later time.

`is.array` returns TRUE or FALSE depending on whether its argument is an array (i.e., has a `dim` attribute of positive length) or not. It is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

#[1,]    1    3    2    1
#[2,]    2    1    3    2
```

as.data.frame

Coerce to a Data Frame

Description

Functions to check if an object is a data frame, or coerce it if possible.

Usage

```
as.data.frame(x, row.names = NULL, optional = FALSE, ...)
## S3 method for class 'character':
as.data.frame(x, ...,
              stringsAsFactors = default.stringsAsFactors())
## S3 method for class 'matrix':
as.data.frame(x, row.names = NULL, optional = FALSE, ...,
              stringsAsFactors = default.stringsAsFactors())

is.data.frame(x)
```

Arguments

<code>x</code>	any R object.
<code>row.names</code>	NULL or a character vector giving the row names for the data frame. Missing values are not allowed.
<code>optional</code>	logical. If TRUE, setting row names and converting column names (to syntactic names: see make.names) is optional.
<code>...</code>	additional arguments to be passed to or from methods.
<code>stringsAsFactors</code>	logical: should the character vector be converted to a factor?

Details

`as.data.frame` is a generic function with many methods, and users and packages can supply further methods.

If a list is supplied, each element is converted to a column in the data frame. Similarly, each column of a matrix is converted separately. This can be overridden if the object has a class which has a method for `as.data.frame`: two examples are matrices of class `"model.matrix"` (which are included as a single column) and list objects of class `"POSIXlt"` which are coerced to class `"POSIXct"`.

Arrays can be converted to data frames. One-dimensional arrays are treated like vectors and two-dimensional arrays like matrices. Arrays with more than two dimensions are converted to matrices by ‘flattening’ all dimensions after the first and creating suitable column labels.

Character variables are converted to factor columns unless protected by [I](#).

If a data frame is supplied, all classes preceding `"data.frame"` are stripped, and the row names are changed if that argument is supplied.

If `row.names = NULL`, row names are constructed from the names or dimnames of `x`, otherwise are the integer sequence starting at one. Few of the methods check for duplicated row names. Names are removed from vector columns unless [I](#).

Value

`as.data.frame` returns a data frame, normally with all row names `" "` if `optional = TRUE`.
`is.data.frame` returns `TRUE` if its argument is a data frame (that is, has `"data.frame"` amongst its classes) and `FALSE` otherwise.

[data.frame](#), [as.data.frame.table](#) for the `table` method (which has additional arguments if called directly).

as.environment *Coerce to an Environment Object*

Description

Converts a number or a character string to the corresponding environment on the search path.

Usage

```
as.environment(object)
```

Arguments

`object` the object to convert. If it is already an environment, just return it. If it is a number, return the environment corresponding to that position on the search list. If it is a character string, match the string to the names on the search list.

Value

The corresponding environment object.

Author(s)

John Chambers

See Also

[environment](#) for creation and manipulation, [search](#).

Examples

```
as.environment(1) ## the global environment
identical(globalenv(), as.environment(1)) ## is TRUE
try(as.environment("package:stats"))      ## stats need not be loaded
```

as.function	<i>Convert Object to Function</i>
-------------	-----------------------------------

Description

as.function is a generic function which is used to convert objects to functions.

as.function.default works on a list `x`, which should contain the concatenation of a formal argument list and an expression or an object of mode "call" which will become the function body. The function will be defined in a specified environment, by default that of the caller.

Usage

```
as.function(x, ...)

## Default S3 method:
as.function(x, envir = parent.frame(), ...)
```

Arguments

<code>x</code>	object to convert, a list for the default method.
<code>...</code>	additional arguments, depending on object
<code>envir</code>	environment in which the function should be defined

Value

The desired function.

Note

For ancient historical reasons, `envir = NULL` uses the global environment rather than the base environment. Please use `envir = globalenv()` instead if this is what you want, as the special handling of NULL may change in a future release.

Author(s)

Peter Dalgaard

See Also`function`; `alist` which is handy for the construction of argument lists, etc.**Examples**

```
as.function(alist(a=,b=2,a+b))
as.function(alist(a=,b=2,a+b))(3)
```

as.POSIX*

Date-time Conversion Functions

Description

Functions to manipulate objects of classes "POSIXlt" and "POSIXct" representing calendar dates and times.

Usage

```
as.POSIXct(x, tz = "", ...)
as.POSIXlt(x, tz = "", ...)

## S3 method for class 'character':
as.POSIXlt(x, tz = "", format, ...)

## S3 method for class 'numeric':
as.POSIXlt(x, tz = "", origin, ...)

## S3 method for class 'POSIXlt':
as.double(x, ...)
```

Arguments

<code>x</code>	An object to be converted.
<code>tz</code>	A timezone specification to be used for the conversion, <i>if one is required</i> . System-specific (see time zones), but "" is the current timezone, and "GMT" is UTC (Universal Time, Coordinated).
<code>...</code>	further arguments to be passed to or from other methods.
<code>format</code>	character string giving a date-time format as used by <code>strptime</code> .
<code>origin</code>	a date-time object, or something which can be coerced by <code>as.POSIXct(tz="GMT")</code> to such an object.

Details

The `as.POSIX*` functions convert an object to one of the two classes used to represent date/times (calendar dates plus time to the nearest second). They can convert a wide variety of objects, including objects of the other class and of classes "Date", "date" (from package `date` or `survival`), "chron" and "dates" (from package `chron`) to these classes. Dates without times are treated as being at midnight UTC.

They can also convert character strings of the formats "2001-02-03" and "2001/02/03" optionally followed by white space and a time in the format "14:52" or "14:52:03". (Formats such as "01/02/03" are ambiguous but can be converted via a format specification by `strptime`.) Fractional seconds are allowed. Alternatively, `format` can be specified for character vectors or factors.

Logical NAs can be converted to either of the classes, but no other logical vectors can be.

The `as.double` method converts "POSIXlt" objects to "POSIXct".

If you are given a numeric time as the number of seconds since an epoch, see the examples.

Value

`as.POSIXct` and `as.POSIXlt` return an object of the appropriate class. If `tz` was specified, `as.POSIXlt` will give an appropriate "tzone" attribute.

Note

If you want to extract specific aspects of a time (such as the day of the week) just convert it to class "POSIXlt" and extract the relevant component(s) of the list, or if you want a character representation (such as a named day of the week) use `format.POSIXlt` or `format.POSIXct`.

If a timezone is needed and that specified is invalid on your system, what happens is system-specific but it will probably be ignored.

See Also

[DateTimeClasses](#) for details of the classes; [strptime](#) for conversion to and from character representations. [Sys.timezone](#) for details of the (system-specific)naming of time zones.

Examples

```
(z <- Sys.time())           # the current datetime, as class "POSIXct"
unclass(z)                  # a large integer
floor(unclass(z)/86400)     # the number of days since 1970-01-01
(z <- as.POSIXlt(Sys.time())) # the current datetime, as class "POSIXlt"
unlist(unclass(z))         # a list shown as a named vector

## suppose we have a time in seconds since 1960-01-01 00:00:00 GMT
z <- 1472562988
# ways to convert this
as.POSIXct(z, origin="1960-01-01")           # local
as.POSIXct(z, origin="1960-01-01", tz="GMT") # in UTC
as.POSIXct(z, origin=ISOdatetime(1960,1,1,0,0,0)) # local
ISOdatetime(1960,1,1,0,0,0) + z              # local

## SPSS dates (R-help 2006-02-17)
z <- c(10485849600, 10477641600, 10561104000, 10562745600)
as.Date(as.POSIXct(z, origin="1582-10-14", tz="GMT"))
```

```

as.POSIXlt(Sys.time(), "GMT") # the current time in UTC
## Not run:
## These may not be correct names on your system
as.POSIXlt(Sys.time(), "America/New_York") # in New York
as.POSIXlt(Sys.time(), "EST5EDT") # alternative.
as.POSIXlt(Sys.time(), "EST" ) # somewhere in Eastern Canada
as.POSIXlt(Sys.time(), "HST") # in Hawaii
as.POSIXlt(Sys.time(), "Australia/Darwin")
## End(Not run)

```

AsIs

Inhibit Interpretation/Conversion of Objects

Description

Change the class of an object to indicate that it should be treated ‘as is’.

Usage

```
I(x)
```

Arguments

x an object

Details

Function `I` has two main uses.

- In function `data.frame`. Protecting an object by enclosing it in `I()` in a call to `data.frame` inhibits the conversion of character vectors to factors and the dropping of names, and ensures that matrices are inserted as single columns. `I` can also be used to protect objects which are to be added to a data frame, or converted to a data frame *via* `as.data.frame`.

It achieves this by prepending the class "AsIs" to the object's classes. Class "AsIs" has a few of its own methods, including for `[], as.data.frame, print` and `format`.

- In function `formula`. There it is used to inhibit the interpretation of operators such as "+", "-", "*" and "^" as formula operators, so they are used as arithmetical operators. This is interpreted as a symbol by `terms.formula`.

Value

A copy of the object with class "AsIs" prepended to the class(es).

`data.frame`, `formula`

`assign`*Assign a Value to a Name*

Description

Assign a value to a name in an environment.

Usage

```
assign(x, value, pos = -1, envir = as.environment(pos),
       inherits = FALSE, immediate = TRUE)
```

Arguments

<code>x</code>	a variable name, given as a character string. No coercion is done, and the first element of a character vector of length greater than one will be used, with a warning.
<code>value</code>	a value to be assigned to <code>x</code> .
<code>pos</code>	where to do the assignment. By default, assigns into the current environment. See the details for other possibilities.
<code>envir</code>	the environment to use. See the details section.
<code>inherits</code>	should the enclosing frames of the environment be inspected?
<code>immediate</code>	an ignored compatibility feature.

Details

There are no restrictions on name: it can be a non-syntactic name (see [make.names](#)).

The `pos` argument can specify the environment in which to assign the object in any of several ways: as an integer (the position in the [search](#) list); as the character string name of an element in the search list; or as an [environment](#) (including using [sys.frame](#) to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

`assign` does not dispatch assignment methods, so it cannot be used to set elements of vectors, names, attributes, etc.

Note that assignment to an attached list or data frame changes the attached copy and not the original object: see [attach](#) and [with](#).

Value

This function is invoked for its side effect, which is assigning `value` to the variable `x`. If no `envir` is specified, then the assignment takes place in the currently active environment.

If `inherits` is `TRUE`, enclosing environments of the supplied environment are searched until the variable `x` is encountered. The value is then assigned in the environment in which the variable is encountered (provided that the binding is not locked: see [lockBinding](#): if it is, an error is signaled). If the symbol is not encountered then assignment takes place in the user's workspace (the global environment).

If `inherits` is `FALSE`, assignment takes place in the initial frame of `envir`, unless an existing binding is locked or there is no existing binding and the environment is locked.

`<-`, `get`, `exists`, `environment`.

Examples

```
for(i in 1:6) { #-- Create objects 'r.1', 'r.2', ... 'r.6' --
  nam <- paste("r",i, sep=".")
  assign(nam, 1:i)
}
ls(pattern = "^r..$")

##-- Global assignment within a function:
myf <- function(x) {
  innerf <- function(x) assign("Global.res", x^2, envir = .GlobalEnv)
  innerf(x+1)
}
myf(3)
Global.res # 16

a <- 1:4
assign("a[1]", 2)
a[1] == 2 #FALSE
get("a[1]") == 2 #TRUE
```

 assignOps

Assignment Operators

Description

Assign a value to a name.

Usage

```
x <- value
x <<- value
value -> x
value ->> x

x = value
```

Arguments

`x` a variable name (possibly quoted).
`value` a value to be assigned to `x`.

Details

There are three different assignment operators: two of them have leftwards and rightwards forms.

The operators `<-` and `=` assign into the environment in which they are evaluated. The operator `<-` can be used anywhere, whereas the operator `=` is only allowed at the top level (e.g., in the complete expression typed at the command prompt) or as one of the subexpressions in a braced list of expressions.

The operators `<<-` and `->>` cause a search to be made through the environment for an existing definition of the variable being assigned. If such a variable is found (and its binding is not locked) then its value is redefined, otherwise assignment takes place in the global environment. Note that their semantics differ from that in the S language, but are useful in conjunction with the scoping rules of R. See ‘The R Language Definition’ manual for further details and examples.

In all the assignment operator expressions, `x` can be a name or an expression defining a part of an object to be replaced (e.g., `z[[1]]`). A syntactic name does not need to be quoted, though it can be (preferably by [backticks](#)).

The leftwards forms of assignment `<- = <<-` group right to left, the other from left to right.

Value

value. Thus one can use `a <- b <- c <- 6`.

attach

Attach Set of R Objects to Search Path

Description

The database is attached to the R search path. This means that the database is searched by R when evaluating a variable, so objects in the database can be accessed by simply giving their names.

Usage

```
attach(what, pos = 2, name = deparse(substitute(what)),  
       warn.conflicts = TRUE)
```

Arguments

<code>what</code>	'database'. This can be a <code>data.frame</code> or a <code>list</code> or a R data file created with <code>save</code> or <code>NULL</code> or an environment. See also 'Details'.
<code>pos</code>	integer specifying position in <code>search()</code> where to attach.
<code>name</code>	name to use for the attached database.
<code>warn.conflicts</code>	logical. If <code>TRUE</code> , warnings are printed about <code>conflicts</code> from attaching the database, unless that database contains an object <code>.conflicts.OK</code> . A conflict is a function masking a function, or a non-function masking a non-function.

Details

When evaluating a variable or function name R searches for that name in the databases listed by `search`. The first name of the appropriate type is used.

By attaching a data frame (or list) to the search path it is possible to refer to the variables in the data frame by their names alone, rather than as components of the data frame (e.g. in the example below, `height` rather than `women$height`).

By default the database is attached in position 2 in the search path, immediately after the user's workspace and before all previously loaded packages and previously attached databases. This can be altered to attach later in the search path with the `pos` option, but you cannot attach at `pos=1`.

The database is not actually attached. Rather, a new environment is created on the search path and the elements of a list (including columns of a data frame) or objects in a save file or an environment are *copied* into the new environment. If you use `<<-` or `assign` to assign to an attached database, you only alter the attached copy, not the original object. (Normal assignment will place a modified version in the user's workspace: see the examples.) For this reason `attach` can lead to confusion.

One useful 'trick' is to use `what = NULL` (or equivalently a length-zero list) to create a new environment on the search path into which objects can be assigned by `assign` or `load` or `sys.source`.

Names starting "package:" are reserved for `library` and should not be used by end users. The name given for the attached environment will be used by `search` and can be used as the argument to `as.environment`.

There are hooks to attach user-defined table objects of class "UserDefinedDatabase", supported by the Omegahat package **RObjectTables**. See <http://www.omegahat.org/RObjectTables/>.

Value

The `environment` is returned invisibly with a "name" attribute.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`library`, `detach`, `search`, `objects`, `environment`, `with`.

Examples

```

require(utils)

summary(women$height) # refers to variable 'height' in the data frame
attach(women)
summary(height)      # The same variable now available by name
height <- height*2.54 # Don't do this. It creates a new variable
                    # in the user's workspace

find("height")
summary(height)      # The new variable in the workspace
rm(height)
summary(height)      # The original variable.
height <-< height*25.4 # Change the copy in the attached environment
find("height")
summary(height)      # The changed copy
detach("women")
summary(women$height) # unchanged

## Not run:
## create an environment on the search path and populate it
sys.source("myfuns.R", envir=attach(NULL, name="myfuns"))
## End(Not run)

```

attr

*Object Attributes***Description**

Get or set specific attributes of an object.

Usage

```

attr(x, which, exact = FALSE)
attr(x, which) <- value

```

Arguments

x	an object whose attributes are to be accessed.
which	a non-empty character string specifying which attribute is to be accessed.
exact	logical: should <code>which</code> be matched exactly?
value	an object, the new value of the attribute, or <code>NULL</code> to remove the attribute.

Details

These functions provide access to a single attribute of an object. The replacement form causes the named attribute to take the value specified (or create a new attribute with the value given).

The extraction function first looks for an exact match to `which` amongst the attributes of `x`, then (unless `exact = TRUE`) a unique partial match. (Setting `options(warnPartialMatchAttr=TRUE)` causes partial matches to give warnings.)

The replacement function only uses exact matches.

Note that some attributes (namely `class`, `comment`, `dim`, `dimnames`, `names`, `row.names` and `tsp`) are treated specially and have restrictions on the values which can be set. (Note that this is not true of `levels` which should be set for factors via the `levels` replacement function.)

The extractor function allows (and does not match) empty and missing values of `which`: the replacement function does not.

Value

For the extractor, the value of the attribute matched, or `NULL` if no exact match is found and no or more than one partial match is found.

`attributes`

Examples

```
# create a 2 by 5 matrix
x <- 1:10
attr(x, "dim") <- c(2, 5)
```

attributes

Object Attribute Lists

Description

These functions access an object's attributes. The first form below returns the object's attribute list. The replacement forms uses the list on the right-hand side of the assignment as the object's attributes (if appropriate).

Usage

```
attributes(obj)
attributes(obj) <- value
mostattributes(obj) <- value
```

Arguments

<code>obj</code>	an object
<code>value</code>	an appropriate named list of attributes, or <code>NULL</code> .

Details

Unlike `attr` it is possible to set attributes on a `NULL` object: it will first be coerced to an empty list.

Note that some attributes (namely `class`, `comment`, `dim`, `dimnames`, `names`, `row.names` and `tsp`) are treated specially and have restrictions on the values which can be set. (Note that this is not true of `levels` which should be set for factors via the `levels` replacement function.)

Attributes are not stored internally as a list and should be thought of as a set and not a vector. They must have unique names (and `NA` is taken as `"NA"`, not a missing value).

Assigning attributes first removes all attributes, then sets any `dim` attribute and then the remaining attributes in the order given: this ensures that setting a `dim` attribute always precedes the `dimnames` attribute.

The `mostattributes` assignment takes special care for the `dim`, `names` and `dimnames` attributes, and assigns them only when valid whereas an `attributes` assignment would give an error if any are not.

The names of a pairlist are not stored as attributes, but are reported as if they were (and can be set by the replacement method for attributes).

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`attr`.

Examples

```
x <- cbind(a=1:3, pi=pi) # simple matrix w/ dimnames
attributes(x)

## strip an object's attributes:
attributes(x) <- NULL
x # now just a vector of length 6

mostattributes(x) <- list(mycomment = "really special", dim = 3:2,
  dimnames = list(LETTERS[1:3], letters[1:5]), names = paste(1:6))
x # dim(), but not {dim}names
```

autoload

On-demand Loading of Packages

Description

`autoload` creates a promise-to-evaluate autoloader and stores it with name `name` in `.AutoloadEnv` environment. When `R` attempts to evaluate `name`, autoloader is run, the package is loaded and `name` is re-evaluated in the new package's environment. The result is that `R` behaves as if `file` was loaded but it does not occupy memory.

`.Autoloaded` contains the names of the packages for which autoloading has been promised.

Usage

```

autoload(name, package, reset = FALSE, ...)
autoloader(name, package, ...)

.AutoloadEnv
.Autoloaded

```

Arguments

name	string giving the name of an object.
package	string giving the name of a package containing the object.
reset	logical: for internal use by autoloader.
...	other arguments to library .

Value

This function is invoked for its side-effect. It has no return value.

See Also

[delayedAssign](#), [library](#)

Examples

```

require(stats)
autoload("interpSpline", "splines")
search()
ls("Autoloads")
.Autoloaded

x <- sort(stats::rnorm(12))
y <- x^2
is <- interpSpline(x,y)
search() ## now has splines
detach("package:splines")
search()
is2 <- interpSpline(x,y+x)
search() ## and again
detach("package:splines")

```

backsolve

Solve an Upper or Lower Triangular System

Description

Solves a system of linear equations where the coefficient matrix is upper or lower triangular.

Usage

```

backsolve(r, x, k=ncol(r), upper.tri=TRUE, transpose=FALSE)
forwardsolve(l, x, k=ncol(l), upper.tri=FALSE, transpose=FALSE)

```

Arguments

<code>r, l</code>	an upper (or lower) triangular matrix giving the coefficients for the system to be solved. Values below (above) the diagonal are ignored.
<code>x</code>	a matrix whose columns give the right-hand sides for the equations.
<code>k</code>	The number of columns of <code>r</code> and rows of <code>x</code> to use.
<code>upper.tri</code>	logical; if TRUE (default), the <i>upper triangular</i> part of <code>r</code> is used. Otherwise, the lower one.
<code>transpose</code>	logical; if TRUE, solve $r' * y = x$ for y , i.e., <code>t(r) %*% y == x</code> .

Value

The solution of the triangular system. The result will be a vector if `x` is a vector and a matrix if `x` is a matrix.

Examples

```
## upper triangular matrix 'r':
r <- rbind(c(1,2,3),
           c(0,1,1),
           c(0,0,2))
( y <- backsolve(r, x <- c(8,4,2)) ) # -1 3 1
r %*% y # == x = (8,4,2)
backsolve(r, x, transpose = TRUE) # 8 -12 -5
```

base-deprecated *Deprecated Functions in Base package*

Description

These functions are provided for compatibility with older versions of R only, and may be defunct as soon as the next release.

Usage

```
Sys.putenv(...)
```

Arguments

`...` named arguments with values coercible to a character string.

Details

The original help page for these functions is often available at `help("oldName-deprecated")` (note the quotes). Functions in packages other than the base package are listed in `help("pkg-deprecated")`.

`Sys.putenv` is a deprecated synonym for `Sys.setenv`.

See Also

[Deprecated](#), [base-defunct](#)

basename

Manipulate File Paths

Description

`basename` removes all of the path up to the last path separator (if any).

`dirname` returns the part of the path up to (but excluding) the last path separator, or "." if there is no path separator.

Usage

```
basename(path)
dirname(path)
```

Arguments

`path` character vector, containing path names.

Details

For `dirname` tilde expansion is done: see the description of [path.expand](#).

Trailing file separators are removed before dissecting the path, and for `dirname` any trailing file separators are removed from the result.

If an element of `path` is `NA`, so is the result.

Value

A character vector of the same length as `path`. A zero-length input will give a zero-length output with no error.

See Also

[file.path](#), [path.expand](#).

Examples

```
basename(file.path("", "p1", "p2", "p3", c("file1", "file2")))
dirname(file.path("", "p1", "p2", "p3", "filename"))
```

Bessel

*Bessel Functions***Description**

Bessel Functions of integer and fractional order, of first and second kind, J_ν and Y_ν , and Modified Bessel functions (of first and third kind), I_ν and K_ν .

Usage

```
besselI(x, nu, expon.scaled = FALSE)
besselK(x, nu, expon.scaled = FALSE)
besselJ(x, nu)
besselY(x, nu)
```

Arguments

`x` numeric, ≥ 0 .
`nu` numeric; The *order* (maybe fractional!) of the corresponding Bessel function.
`expon.scaled` logical; if TRUE, the results are exponentially scaled in order to avoid overflow (I_ν) or underflow (K_ν), respectively.

Details

If `expon.scaled = TRUE`, $e^{-x}I_\nu(x)$, or $e^xK_\nu(x)$ are returned.

For $\nu < 0$, formulae 9.1.2 and 9.6.2 from Abramowitz & Stegun are applied (which is probably suboptimal), except for `besselK` which is symmetric in `nu`.

Value

Numeric vector of the same length of `x` with the (scaled, if `expon.scale=TRUE`) values of the corresponding Bessel function.

```

bindenv

Binding and Environment Adjustments

Description

These functions represent an experimental interface for adjustments to environments and bindings within environments. They allow for locking environments as well as individual bindings, and for linking a variable to a function.

Usage

```

lockEnvironment(env, bindings = FALSE)
environmentIsLocked(env)
lockBinding(sym, env)
unlockBinding(sym, env)
bindingIsLocked(sym, env)
makeActiveBinding(sym, fun, env)
bindingIsActive(sym, env)

```

Arguments

env	an environment.
bindings	logical specifying whether bindings should be locked.
sym	a name object or character string
fun	a function taking zero or one arguments

Details

The function `lockEnvironment` locks its environment argument, which must be a normal environment (not base). (Locking the base environment and name space may be supported later.) Locking the environment prevents adding or removing variable bindings from the environment. Changing the value of a variable is still possible unless the binding has been locked. The name space environments of packages with name spaces are locked when loaded.

`lockBinding` locks individual bindings in the specified environment. The value of a locked binding cannot be changed. Locked bindings may be removed from an environment unless the environment is locked.

`makeActiveBinding` installs `fun` so that getting the value of `sym` calls `fun` with no arguments, and assigning to `sym` calls `fun` with one argument, the value to be assigned. This allows the implementation of things like C variables linked to R variables and variables linked to databases. It may also be useful for making thread-safe versions of some system globals.

Value

The `*isLocked` functions return a length-one logical vector. The remaining functions return `NULL`, invisibly.

Author(s)

Luke Tierney

Examples

```
# locking environments
e <- new.env()
assign("x", 1, envir = e)
get("x", envir = e)
lockEnvironment(e)
get("x", envir = e)
assign("x", 2, envir = e)
try(assign("y", 2, envir = e)) # error

# locking bindings
e <- new.env()
assign("x", 1, envir = e)
get("x", envir = e)
lockBinding("x", e)
try(assign("x", 2, envir = e)) # error
unlockBinding("x", e)
assign("x", 2, envir = e)
get("x", envir = e)

# active bindings
f <- local( {
  x <- 1
  function(v) {
    if (missing(v))
      cat("get\n")
    else {
      cat("set\n")
      x <<- v
    }
  }
  x
})
makeActiveBinding("fred", f, .GlobalEnv)
bindingIsActive("fred", .GlobalEnv)
fred
fred <- 2
fred
```

Description

Get or set the body of a function.

Usage

```
body(fun = sys.function(sys.parent()))
body(fun, envir = environment(fun)) <- value
```

Arguments

fun	a function object, or see ‘Details’.
envir	environment in which the function should be defined.
value	an object, usually a language object: see section ‘Value’.

Details

For the first form, `fun` can be a character string naming the function to be manipulated, which is searched for from the parent environment. If it is not specified, the function calling `body` is used.

To set the value to a list call the replacement function with `value` a length-one list containing the desired value.

Value

`body` returns the body of the function specified. This is normally a language object, most often a call to `{`, but it can also be an object (e.g. `pi`) to be the return value of the function.

The replacement form sets the body of a function to the object on the right hand side, and (potentially) resets the environment of the function. If `value` is of class `"expression"` or a length-one list, the first element is used as the body. For expressions (but not lists) any additional elements are ignored, with a warning.

See Also

[alist](#), [args](#), [function](#).

Examples

```
body(body)
f <- function(x) x^5
body(f) <- expression(5^x)
## or equivalently body(f) <- list(quote(5^x))
f(3) # = 125
body(f)
```

bquote

Partial substitution in expressions

Description

An analogue of the LISP backquote macro. `bquote` quotes its argument except that terms wrapped in `.()` are evaluated in the specified `where` environment.

Usage

```
bquote(expr, where = parent.frame())
```

Arguments

`expr` A language object.
`where` An environment.

Value

A language object.

See Also

[quote](#), [substitute](#)

Examples

```
require(graphics)

a <- 2

bquote(a == a)
quote(a == a)

bquote(a == .(a))
substitute(a == A, list(A = a))

plot(1:10, a*(1:10), main = bquote(a == .(a)))
```

browser

Environment Browser

Description

Interrupt the execution of an expression and allow the inspection of the environment where `browser` was called from.

Usage

```
browser()
```

Details

A call to `browser` can be included in the body of a function. When reached, this causes a pause in the execution of the current expression and allows access to the R interpreter.

At the browser prompt the user can enter commands or R expressions. The commands are

c (or just return) exit the browser and continue execution at the next statement.

cont synonym for `c`.

n enter the step-through debugger. This changes the meaning of `c`: see the documentation for [debug](#).

where print a stack trace of all active function calls.

Q exit the browser and the current evaluation and return to the top-level prompt.

(Leading and trailing whitespace is ignored, except for return).

Anything else entered at the browser prompt is interpreted as an R expression to be evaluated in the calling environment: in particular typing an object name will cause the object to be printed, and `ls()` lists the objects in the calling frame. (If you want to look at an object with a name such as `n`, print it explicitly.)

The number of lines printed for the deparsed call can be limited by setting `options(deparse.max.lines)`.

See Also

`debug`, and `traceback` for the stack on error.

`builtins`

Returns the Names of All Built-in Objects

Description

Return the names of all the built-in objects. These are fetched directly from the symbol table of the R interpreter.

Usage

```
builtins(internal = FALSE)
```

Arguments

`internal` a logical indicating whether only ‘internal’ functions (which can be called via `.Internal`) should be returned.

Details

`builtins()` returns an unsorted list of the objects in the symbol table, that is all the objects in the base environment. These are the built-in objects plus any that have been added subsequently when the base package was loaded. It is less confusing to use `ls(baseenv(), all=TRUE)`.

`builtins(TRUE)` returns an unsorted list of the names of internal functions, that is those which can be accessed as `.Internal(foo(args ...))` for `foo` in the list.

Value

A character vector.

`by`*Apply a Function to a Data Frame split by Factors*

Description

Function `by` is an object-oriented wrapper for `tapply` applied to data frames.

Usage

```
by(data, INDICES, FUN, ..., simplify = TRUE)
```

Arguments

<code>data</code>	an R object, normally a data frame, possibly a matrix.
<code>INDICES</code>	a factor or a list of factors, each of length <code>nrow(data)</code> .
<code>FUN</code>	a function to be applied to data frame subsets of <code>data</code> .
<code>...</code>	further arguments to <code>FUN</code> .
<code>simplify</code>	logical: see <code>tapply</code> .

Details

A data frame is split by row into data frames subsetted by the values of one or more factors, and function `FUN` is applied to each subset in turn.

Object `data` will be coerced to a data frame by the default method, *but* if this results in a 1-column data frame, the objects passed to `FUN` are dropped to a subsets of that column. (This was the long-term behaviour, but only documented since R 2.7.0.)

Value

An object of class "by", giving the results for each subset. This is always a list if `simplify` is false, otherwise a list or array (see `tapply`).

See Also

`tapply`

Examples

```
require(stats)
attach(warpbreaks)
by(warpbreaks[, 1:2], tension, summary)
by(warpbreaks[, 1], list(wool = wool, tension = tension), summary)
by(warpbreaks, tension, function(x) lm(breaks ~ wool, data = x))

## now suppose we want to extract the coefficients by group
tmp <- by(warpbreaks, tension, function(x) lm(breaks ~ wool, data = x))
sapply(tmp, coef)

detach("warpbreaks")
```

c

*Combine Values into a Vector or List***Description**

This is a generic function which combines its arguments.

The default method combines its arguments to form a vector. All arguments are coerced to a common type which is the type of the returned value, and all attributes except names are removed.

Usage

```
c(..., recursive=FALSE)
```

Arguments

<code>...</code>	objects to be concatenated.
<code>recursive</code>	logical. If <code>recursive = TRUE</code> , the function recursively descends through lists (and pairlists) combining all their elements into a vector.

Details

The output type is determined from the highest type of the components in the hierarchy `NULL < raw < logical < integer < real < complex < character < list < expression`. Pairlists are treated as lists, but non-vector components (such names and calls) are treated as one-element lists which cannot be unlisted even if `recursive = TRUE`.

`c` is sometimes used for its side effect of removing attributes except names, for example to turn an array into a vector. `as.vector` is a more intuitive way to do this, but also drops names. Note too that methods other than the default are not required to do this (and they will almost certainly preserve a class attribute).

Value

`NULL` or an expression or a vector of an appropriate mode. (With no arguments the value is `NULL`.)

S4 methods

This function is S4 generic, but with argument list `(x, ..., recursive = FALSE)`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`unlist` and `as.vector` to produce attribute-free vectors.

Examples

```

c(1,7:9)
c(1:5, 10.5, "next")

## uses with a single argument to drop attributes
x <- 1:4
names(x) <- letters[1:4]
x
c(x)          # has names
as.vector(x) # no names
dim(x) <- c(2,2)
x
c(x)
as.vector(x)

## append to a list:
ll <- list(A = 1, c="C")
## do *not* use
c(ll, d = 1:3) # which is == c(ll, as.list(c(d=1:3)))
## but rather
c(ll, d = list(1:3))# c() combining two lists

c(list(A=c(B=1)), recursive=TRUE)

c(options(), recursive=TRUE)
c(list(A=c(B=1,C=2), B=c(E=7)), recursive=TRUE)

```

call

Function Calls

Description

Create or test for objects of mode "call".

Usage

```

call(name, ...)
is.call(x)
as.call(x)

```

Arguments

name	a non-empty character string naming the function to be called.
...	arguments to be part of the call.
x	an arbitrary R object.

Details

`call` returns an unevaluated function call, that is, an unevaluated expression which consists of the named function applied to the given arguments (`name` must be a quoted string which gives the name of a function to be called). Note that although the call is unevaluated, the arguments ... are evaluated.

`call` is a primitive, so the first argument (named or not) is taken as name and the remaining arguments as arguments for the constructed call: `call(x="c", 1, 3, name="foo")` is a call to `c` and not to `foo`.

`is.call` is used to determine whether `x` is a call (i.e., of mode `"call"`).

Objects of mode `"list"` can be coerced to mode `"call"`. The first element of the list becomes the function part of the call, so should be a function or the name of one (as a symbol; a quoted string will not do).

See Also

[do.call](#) for calling a function by name and argument list; [Recall](#) for recursive calling of functions; further [is.language](#), [expression](#), [function](#).

Examples

```
is.call(call) #-> FALSE: Functions are NOT calls

## set up a function call to round with argument 10.5
cl <- call("round", 10.5)
is.call(cl) # TRUE
cl
## such a call can also be evaluated.
eval(cl) # [1] 10

A <- 10.5
call("round", A)          # round(10.5)
call("round", quote(A)) # round(A)
f <- "round"
call(f, quote(A))       # round(A)
## if we want to supply a function we need to use as.call or similar
f <- round
## Not run: call(f, quote(A)) # error: first arg must be character
(g <- as.call(list(f, quote(A))))
eval(g)
## alternatively but less transparently
g <- list(f, quote(A))
mode(g) <- "call"
g
eval(g)
## see also the examples in the help for do.call
```

callCC

Call With Current Continuation

Description

A downward-only version of Scheme's `call with current continuation`.

Usage

```
callCC(fun)
```

Arguments

`fun` function of one argument, the exit procedure.

Details

`callCC` provides a non-local exit mechanism that can be useful for early termination of a computation. `callCC` calls `fun` with one argument, an *exit function*. The exit function takes a single argument, the intended return value. If the body of `fun` calls the exit function then the call to `callCC` immediately returns, with the value supplied to the exit function as the value returned by `callCC`.

Author(s)

Luke Tierney

Examples

```
# The following all return the value 1
callCC(function(k) 1)
callCC(function(k) k(1))
callCC(function(k) {k(1); 2})
callCC(function(k) repeat k(1))
```

capabilities

Report Capabilities of this Build of R

Description

Report on the optional features which have been compiled into this build of R.

Usage

```
capabilities(what = NULL)
```

Arguments

`what` character vector or NULL, specifying required components. NULL implies that all are required.

Value

A named logical vector. Current components are

<code>jpeg</code>	Is the <code>jpeg</code> function operational?
<code>png</code>	Is the <code>png</code> function operational?
<code>tiff</code>	Is the <code>tiff</code> function operational?
<code>tcltk</code>	Is the <code>tcltk</code> package operational? Note that to make use of Tk you will almost always need to check that "X11" is also available.

X11	Are the X11 graphics device and the X11-based data editor available? This loads the X11 module if not already loaded, and checks that the default display can be contacted unless a X11 device has already been used.
aqua	Are the R.app GUI components and the quartz function operational? Only on some Mac OS X builds. Note that this is distinct from <code>.Platform\$GUI == "AQUA"</code> , which is true when using the Mac R.app console.
http/ftp	Are url and the internal method for download.file available?
sockets	Are make.socket and related functions available?
libxml	Is there support for integrating libxml with the R event loop?
fifo	are FIFO connections supported?
cledit	Is command-line editing available in the current R session? This is false in non-interactive sessions. It will be true for the command-line interface if readline support has been compiled in and <code>'--no-readline'</code> was <i>not</i> used when R was invoked.
iconv	is internationalization conversion via iconv supported?
NLS	is there Natural Language Support (for message translations)?
profmem	is there support for memory profiling?
cairo	is there support for <code>type="Cairo"</code> in X11 , png , jpeg , tiff and bmp , and for the svg , cairo_pdf and cairo_ps devices?

Note to Mac OS X users

Capabilities "jpeg", "png" and "tiff" refer to the X11-based versions of these devices. If `capabilities("aqua")` is true, then these devices with `type="quartz"` will be available, and out-of-the-box will be the default type. Thus for example the [tiff](#) device will be available if `capabilities("aqua") || capabilities("tiff")` if the defaults are unchanged.

[.Platform](#)

Examples

```
capabilities()

if(!capabilities("http/ftp"))
  warning("internal download.file() is not available")

## See also the examples for 'connections'.
```

cat

Concatenate and Print

Description

Outputs the objects, concatenating the representations. `cat` performs much less conversion than [print](#).

Usage

```
cat(... , file = "", sep = " ", fill = FALSE, labels = NULL,
     append = FALSE)
```

Arguments

...	R objects (see ‘Details’ for the types of objects allowed).
file	A connection, or a character string naming the file to print to. If "" (the default), <code>cat</code> prints to the standard output connection, the console unless redirected by <code>sink</code> . If it is " <code> cmd</code> ", the output is piped to the command given by ‘ <code>cmd</code> ’, by opening a pipe connection.
sep	a character vector of strings to append after each element.
fill	a logical or (positive) numeric controlling how the output is broken into successive lines. If <code>FALSE</code> (default), only newlines created explicitly by ‘ <code>\n</code> ’ are printed. Otherwise, the output is broken into lines with print width equal to the option <code>width</code> if <code>fill</code> is <code>TRUE</code> , or the value of <code>fill</code> if this is numeric. Non-positive <code>fill</code> values are ignored, with a warning.
labels	character vector of labels for the lines printed. Ignored if <code>fill</code> is <code>FALSE</code> .
append	logical. Only used if the argument <code>file</code> is the name of file (and not a connection or " <code> cmd</code> "). If <code>TRUE</code> output will be appended to <code>file</code> ; otherwise, it will overwrite the contents of <code>file</code> .

Details

`cat` is useful for producing output in user-defined functions. It converts its arguments to character vectors, concatenates them to a single character vector, appends the given `sep=` string(s) to each element and then outputs them.

No linefeeds are output unless explicitly requested by ‘`\n`’ or if generated by filling (if argument `fill` is `TRUE` or numeric.)

If `file` is a connection and open for writing it is written from its current position. If it is not open, it is opened for the duration of the call in "`wt`" mode and then closed again.

Currently only atomic vectors (and so not lists) and `names` are handled. Character strings are output ‘as is’ (unlike `print.default` which escapes non-printable characters and backslash — use `encodeString` if you want to output encoded strings using `cat`). Other types of R object should be converted (e.g. by `as.character` or `format`) before being passed to `cat`.

`cat` converts numeric/complex elements in the same way as `print` (and not in the same way as `as.character` which is used by the S equivalent), so `options` "`digits`" and "`scipen`" are relevant. However, it uses the minimum field width necessary for each element, rather than the same field width for all elements.

Value

None (invisible `NULL`).

Note

Despite its name and earlier documentation, `sep` is a vector of terminators rather than separators, being output after every vector element (including the last). Entries are recycled as needed.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[print](#), [format](#), and [paste](#) which concatenates into a string.

Examples

```
iter <- stats::rpois(1, lambda=10)
## print an informative message
cat("iteration = ", iter <- iter + 1, "\n")

## 'fill' and label lines:
cat(paste(letters, 100* 1:26), fill = TRUE,
    labels = paste("{",1:10,"}:",sep=""))
```

cbind

Combine R Objects by Rows or Columns

Description

Take a sequence of vector, matrix or data frames arguments and combine by columns or rows, respectively. These are generic functions with methods for other R classes.

Usage

```
cbind(..., deparse.level = 1)
rbind(..., deparse.level = 1)
```

Arguments

... vectors or matrices. These can be given as named arguments. Other R objects will be coerced as appropriate: see sections ‘Details’ and ‘Value’. (For the "data.frame" method of `cbind` these can be further arguments to [data.frame](#) such as `stringsAsFactors`.)

`deparse.level`

integer controlling the construction of labels in the case of non-matrix-like arguments (for the default method):

`deparse.level = 0` constructs no labels; the default, `deparse.level = 1` or `2` constructs labels from the argument names, see the ‘Value’ section below.

Details

The functions `cbind` and `rbind` are S3 generic, with methods for data frames. The data frame method will be used if at least one argument is a data frame and the rest are vectors or matrices. There can be other methods; in particular, there is one for time series objects. See the section on ‘Dispatch’ for how the method to be used is selected.

In the default method, all the vectors/matrices must be atomic (see [vector](#)) or lists. Expressions are not allowed. Language objects (such as formulae and calls) and pairlists will be coerced to lists:

other objects (such as names and external pointers) will be included as elements in a list result. Any classes the inputs might have are discarded (in particular, factors are replaced by their internal codes).

If there are several matrix arguments, they must all have the same number of columns (or rows) and this will be the number of columns (or rows) of the result. If all the arguments are vectors, the number of columns (rows) in the result is equal to the length of the longest vector. Values in shorter arguments are recycled to achieve this length (with a [warning](#) if they are recycled only *fractionally*).

When the arguments consist of a mix of matrices and vectors the number of columns (rows) of the result is determined by the number of columns (rows) of the matrix arguments. Any vectors have their values recycled or subsetted to achieve this length.

For `cbind` (`rbind`), vectors of zero length (including `NULL`) are ignored unless the result would have zero rows (columns), for S compatibility. (Zero-extent matrices do not occur in S3 and are not ignored in R.)

Value

For the default method, a matrix combining the . . . arguments column-wise or row-wise. (Exception: if there are no inputs or all the inputs are `NULL`, the value is `NULL`.)

The type of a matrix result determined from the highest type of any of the inputs in the hierarchy `raw < logical < integer < real < complex < character < list`.

For `cbind` (`rbind`) the column (row) names are taken from the `colnames` (`rownames`) of the arguments if these are matrix-like. Otherwise from the names of the arguments or where those are not supplied and `deparse.level > 0`, by `deparse`ing the expressions given, for `deparse.level = 1` only if that gives a sensible name (a ‘symbol’, see [is.symbol](#)).

For `cbind` row names are taken from the first argument with appropriate names: `rownames` for a matrix, or names for a vector of length the number of rows of the result.

For `rbind` column names are taken from the first argument with appropriate names: `colnames` for a matrix, or names for a vector of length the number of columns of the result.

Data frame methods

The `cbind` data frame method is just a wrapper for `data.frame(..., check.names = FALSE)`. This means that it will split matrix columns in data frame arguments, and convert character columns to factors unless `stringsAsFactors = FALSE` is specified.

The `rbind` data frame method first drops all zero-column and zero-row arguments. (If that leaves none, it returns the first argument with columns otherwise a zero-column zero-row data frame.) It then takes the classes of the columns from the first data frame, and matches columns by name (rather than by position). Factors have their levels expanded as necessary (in the order of the levels of the levelsets of the factors encountered) and the result is an ordered factor if and only if all the components were ordered factors. (The last point differs from S-PLUS.) Old-style categories (integer vectors with levels) are promoted to factors.

Dispatch

The method dispatching is *not* done via `UseMethod()`, but by C-internal dispatching. Therefore there is no need for, e.g., `rbind.default`.

The dispatch algorithm is described in the source file (`‘.../src/main/bind.c’`) as

1. For each argument we get the list of possible class memberships from the class attribute.

2. We inspect each class in turn to see if there is an applicable method.
3. If we find an applicable method we make sure that it is identical to any method determined for prior arguments. If it is identical, we proceed, otherwise we immediately drop through to the default code.

If you want to combine other objects with data frames, it may be necessary to coerce them to data frames first. (Note that this algorithm can result in calling the data frame method if all the arguments are either data frames or vectors, and this will result in the coercion of character vectors to factors.)

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`c` to combine vectors (and lists) as vectors, `data.frame` to combine vectors and matrices as a data frame.

Examples

```
m <- cbind(1, 1:7) # the '1' (= shorter vector) is recycled
m
m <- cbind(m, 8:14)[, c(1, 3, 2)] # insert a column
m
cbind(1:7, diag(3))# vector is subset -> warning

cbind(0, rbind(1, 1:3))
cbind(I=0, X=rbind(a=1, b=1:3)) # use some names
xx <- data.frame(I=rep(0,2))
cbind(xx, X=rbind(a=1, b=1:3)) # named differently

cbind(0, matrix(1, nrow=0, ncol=4))#> Warning (making sense)
dim(cbind(0, matrix(1, nrow=2, ncol=0)))#-> 2 x 1

## deparse.level
dd <- 10
rbind(1:4, c=2, "a++" = 10, dd, deparse.level=0)# middle 2 rownames
rbind(1:4, c=2, "a++" = 10, dd, deparse.level=1)# 3 rownames (default)
rbind(1:4, c=2, "a++" = 10, dd, deparse.level=2)# 4 rownames
```

char.expand

Expand a String with Respect to a Target Table

Description

Seeks a unique match of its first argument among the elements of its second. If successful, it returns this element; otherwise, it performs an action specified by the third argument.

Usage

```
char.expand(input, target, nomatch = stop("no match"))
```

Arguments

<code>input</code>	a character string to be expanded.
<code>target</code>	a character vector with the values to be matched against.
<code>nomatch</code>	an R expression to be evaluated in case expansion was not possible.

Details

This function is particularly useful when abbreviations are allowed in function arguments, and need to be uniquely expanded with respect to a target table of possible values.

Value

A length-one character vector, one of the elements of `target` (unless `nomatch` is changed to be a non-error, when it can be a zero-length character string).

See Also

[charmatch](#) and [pmatch](#) for performing partial string matching.

Examples

```
locPars <- c("mean", "median", "mode")
char.expand("me", locPars, warning("Could not expand!"))
char.expand("mo", locPars)
```

character

Character Vectors

Description

Create or test for objects of type "character".

Usage

```
character(length = 0)
as.character(x, ...)
is.character(x)
```

Arguments

<code>length</code>	desired length.
<code>x</code>	object to be coerced or tested.
<code>...</code>	further arguments passed to or from other methods.

Details

`as.character` and `is.character` are generic: you can write methods to handle specific classes of objects, see [InternalMethods](#). Further, for `as.character` the default method calls `as.vector`, so dispatch is first on methods for `as.character` and then for methods for `as.vector`.

`as.character` represents real and complex numbers to 15 significant digits (technically the compiler's setting of the ISO C constant `DBL_DIG`, which will be 15 on machines supporting IEC60559 arithmetic according to the C99 standard). This ensures that all the digits in the result will be reliable (and not the result of representation error), but does mean that conversion to character and back to numeric may change the number. If you want to convert numbers to character with the maximum possible precision, use `format`.

Value

`character` creates a character vector of the specified length. The elements of the vector are all equal to `" "`.

`as.character` attempts to coerce its argument to character type; like `as.vector` it strips attributes including names. For lists it deparses the elements individually, except that it extracts the first element of length-one character vectors.

`is.character` returns `TRUE` or `FALSE` depending on whether its argument is of character type or not.

Note

`as.character` truncates components of language objects to 500 characters (was about 70 before 1.3.1).

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`paste`, `substr` and `strsplit` for character concatenation and splitting, `chartr` for character translation and casefolding (e.g., upper to lower case) and `sub`, `grep` etc for string matching and substitutions. Note that `help.search(keyword = "character")` gives even more links. `deparse`, which is normally preferable to `as.character` for language objects.

Examples

```
form <- y ~ a + b + c
as.character(form) ## length 3
deparse(form)     ## like the input

a0 <- 11/999      # has a repeating decimal representation
(a1 <- as.character(a0))
format(a0, digits=16) # shows one more digit
a2 <- as.numeric(a1)
a2 - a0           # normally around -1e-17
as.character(a2)  # normally different from a1
print(c(a0, a2), digits = 16)
```

Description

`charmatch` seeks matches for the elements of its first argument among those of its second.

Usage

```
charmatch(x, table, nomatch = NA_integer_)
```

Arguments

<code>x</code>	the values to be matched: converted to a character vector by <code>as.character</code> .
<code>table</code>	the values to be matched against: converted to a character vector.
<code>nomatch</code>	the (integer) value to be returned at non-matching positions.

Details

Exact matches are preferred to partial matches (those where the value to be matched has an exact match to the initial part of the target, but the target is longer).

If there is a single exact match or no exact match and a unique partial match then the index of the matching value is returned; if multiple exact or multiple partial matches are found then 0 is returned and if no match is found then `nomatch` is returned.

NA values are treated as the string constant "NA".

Value

An integer vector of the same length as `x`, giving the indices of the elements in `table` which matched, or `nomatch`.

Author(s)

This function is based on a C function written by Terry Therneau.

See Also

[pmatch](#), [match](#).

[grep](#) or [regexpr](#) for more general (regex) matching of strings.

Examples

```
charmatch("", "") # returns 1
charmatch("m", c("mean", "median", "mode")) # returns 0
charmatch("med", c("mean", "median", "mode")) # returns 2
```

`chartr`*Character Translation and Casefolding*

Description

Translate characters in character vectors, in particular from upper to lower case or vice versa.

Usage

```
chartr(old, new, x)
tolower(x)
toupper(x)
casefold(x, upper = FALSE)
```

Arguments

<code>x</code>	a character vector, or an object that can be coerced to character by as.character .
<code>old</code>	a character string specifying the characters to be translated.
<code>new</code>	a character string specifying the translations.
<code>upper</code>	logical: translate to upper or lower case?.

Details

`chartr` translates each character in `x` that is specified in `old` to the corresponding character specified in `new`. Ranges are supported in the specifications, but character classes and repeated characters are not. If `old` contains more characters than `new`, an error is signaled; if it contains fewer characters, the extra characters at the end of `new` are ignored.

`tolower` and `toupper` convert upper-case characters in a character vector to lower-case, or vice versa. Non-alphabetic characters are left unchanged.

`casefold` is a wrapper for `tolower` and `toupper` provided for compatibility with S-PLUS.

Value

A character vector of the same length and with the same attributes as `x` (after possible coercion).

Elements of the result will have the encoding declared as that of the current locale (see [Encoding](#) if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8. The result will be in the current locale's encoding unless the corresponding input was in UTF-8, when it will be in UTF-8 when the system has Unicode wide characters.

See Also

[sub](#) and [gsub](#) for other substitutions in strings.

Examples

```

x <- "MiXeD cAsE 123"
chartr("iXs", "why", x)
chartr("a-cX", "D-Fw", x)
tolower(x)
toupper(x)

## "Mixed Case" Capitalizing - toupper( every first letter of a word ) :

.simpleCap <- function(x) {
  s <- strsplit(x, " ")[[1]]
  paste(toupper(substring(s, 1,1)), substring(s, 2),
        sep=" ", collapse=" ")
}
.simpleCap("the quick red fox jumps over the lazy brown dog")
## -> [1] "The Quick Red Fox Jumps Over The Lazy Brown Dog"

## and the better, more sophisticated version:
capwords <- function(s, strict = FALSE) {
  cap <- function(s) paste(toupper(substring(s,1,1)),
                           {s <- substring(s,2); if(strict) tolower(s) else s},
                           sep = " ", collapse = " ")
  sapply(strsplit(s, split = " "), cap, USE.NAMES = !is.null(names(s)))
}
capwords(c("using AIC for model selection"))
## -> [1] "Using AIC For Model Selection"
capwords(c("using AIC", "for MODEL selection"), strict=TRUE)
## -> [1] "Using Aic" "For Model Selection"
##          ^^^      ^^^^^
##          'bad'   'good'

## -- Very simple insecure crypto --
rot <- function(ch, k = 13) {
  p0 <- function(...) paste(c(...), collapse="")
  A <- c(letters, LETTERS, " ")
  I <- seq_len(k); chartr(p0(A), p0(c(A[-I], A[I])), ch)
}

pw <- "my secret pass phrase"
(cryp <- rot(pw, 13)) #-> you can send this off

## now ``decrypt`` :
rot(cryp, 54 - 13) # -> the original:
stopifnot(identical(pw, rot(cryp, 54 - 13)))

```

Description

Compute the Choleski factorization of a real symmetric positive-definite square matrix.

Usage

```
chol(x, ...)

## Default S3 method:
chol(x, pivot = FALSE, LINPACK = pivot, ...)
```

Arguments

<code>x</code>	an object for which a method exists. The default method applies to real symmetric, positive-definite matrices.
<code>...</code>	arguments to be based to or from methods.
<code>pivot</code>	Should pivoting be used?
<code>LINPACK</code>	logical. Should LINPACK be used in the non-pivoting case (for compatibility with R < 1.7.0)?

Details

`chol` is generic: the description here applies to the default method.

This is an interface to the LAPACK routine DPOTRF and the LINPACK routines DPOFA and DCHDC.

Note that only the upper triangular part of `x` is used, so that $R'R = x$ when `x` is symmetric.

If `pivot = FALSE` and `x` is not non-negative definite an error occurs. If `x` is positive semi-definite (i.e., some zero eigenvalues) an error will also occur, as a numerical tolerance is used.

If `pivot = TRUE`, then the Choleski decomposition of a positive semi-definite `x` can be computed. The rank of `x` is returned as `attr(Q, "rank")`, subject to numerical errors. The pivot is returned as `attr(Q, "pivot")`. It is no longer the case that `t(Q) %*% Q` equals `x`. However, setting `pivot <- attr(Q, "pivot")` and `oo <- order(pivot)`, it is true that `t(Q[, oo]) %*% Q[, oo]` equals `x`, or, alternatively, `t(Q) %*% Q` equals `x[pivot, pivot]`. See the examples.

Value

The upper triangular factor of the Choleski decomposition, i.e., the matrix R such that $R'R = x$ (see example).

If pivoting is used, then two additional attributes `"pivot"` and `"rank"` are also returned.

Warning

The code does not check for symmetry.

If `pivot = TRUE` and `x` is not non-negative definite then there will be a warning message but a meaningless result will occur. So only use `pivot = TRUE` when `x` is non-negative definite by construction.

Examples

```
( m <- matrix(c(5,1,1,3),2,2) )
( cm <- chol(m) )
t(cm) %*% cm #-- = 'm'
crossprod(cm) #-- = 'm'

# now for something positive semi-definite
x <- matrix(c(1:5, (1:5)^2), 5, 2)
x <- cbind(x, x[, 1] + 3*x[, 2])
m <- crossprod(x)
qr(m)$rank # is 2, as it should be

# chol() may fail, depending on numerical rounding:
# chol() unlike qr() does not use a tolerance.
try(chol(m))

(Q <- chol(m, pivot = TRUE)) # NB wrong rank here - see Warning section.
## we can use this by
pivot <- attr(Q, "pivot")
oo <- order(pivot)
t(Q[, oo]) %*% Q[, oo] # recover m

## now for a non-positive-definite matrix
( m <- matrix(c(5,-5,-5,3),2,2) )
try(chol(m)) # fails
try(chol(m, LINPACK=TRUE)) # fails
(Q <- chol(m, pivot = TRUE)) # warning
crossprod(Q) # not equal to m
```

chol2inv

Inverse from Choleski (or QR) Decomposition

Description

Invert a symmetric, positive definite square matrix from its Choleski decomposition. Equivalently, compute $(X'X)^{-1}$ from the (*R* part) of the QR decomposition of *X*.

Usage

```
chol2inv(x, size = NCOL(x), LINPACK = FALSE)
```

Arguments

<code>x</code>	a matrix. The first <code>size</code> columns of the upper triangle contain the Choleski decomposition of the matrix to be inverted.
<code>size</code>	the number of columns of <code>x</code> containing the Choleski decomposition.
<code>LINPACK</code>	logical. Should LINPACK be used (for compatibility with R < 1.7.0)?

Details

This is an interface to the LAPACK routine DPOTRI and the LINPACK routine DPODI.

Value

The inverse of the matrix whose Choleski decomposition was given.

ma %*% chol2inv(cma)
```

class

Object Classes

Description

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class of the first argument to the generic function.

Usage

```
class(x)
class(x) <- value
unclass(x)
inherits(x, what, which = FALSE)

oldClass(x)
oldClass(x) <- value
```

Arguments

`x` a R object

`what`, `value` a character vector naming classes. `value` can also be NULL.

`which` logical affecting return value: see 'Details'.

Details

Many R objects have a `class` attribute, a character vector giving the names of the classes from which the object *inherits*. If the object does not have a class attribute, it has an implicit class, `"matrix"`, `"array"` or the result of `mode(x)` (except that integer vectors have implicit class `"integer"`). (Functions `oldClass` and `oldClass<-` get and set the attribute, which can also be done directly.)

When a generic function `fun` is applied to an object with class attribute `c("first", "second")`, the system searches for a function called `fun.first` and, if it finds it, applies it to the object. If no such function is found, a function called `fun.second` is tried. If no class name produces a suitable function, the function `fun.default` is used (if it exists). If there is no class attribute, the implicit class is tried, then the default method.

The function `class` prints the vector of names of classes an object inherits from. Correspondingly, `class<-` sets the classes an object inherits from. Assigning a zero-length vector or `NULL` removes the class attribute.

`unclass` returns (a copy of) its argument with its class attribute removed. (It is not allowed for objects which cannot be copied, namely environments and external pointers.)

`inherits` indicates whether its first argument inherits from any of the classes specified in the `what` argument. If `which` is `TRUE` then an integer vector of the same length as `what` is returned. Each element indicates the position in the `class(x)` matched by the element of `what`; zero indicates no match. If `which` is `FALSE` then `TRUE` is returned by `inherits` if any of the names in `what` match with any `class`.

Formal classes

An additional mechanism of *formal* classes is available in packages **methods** which is attached by default. For objects which have a formal class, its name is returned by `class` as a character vector of length one.

The replacement version of the function sets the class to the value provided. For classes that have a formal definition, directly replacing the class this way is strongly deprecated. The expression `as(object, value)` is the way to coerce an object to a particular class.

The analogue of `inherits` for formal classes is `is`.

Note

Functions `oldClass` and `oldClass<-` behave in the same way as functions of those names in S-PLUS 5/6, *but* in R `UseMethod` dispatches on the class as returned by `class` (with some interpolated classes: see the link) rather than `oldClass`. *However*, [group generics](#) dispatch on the `oldClass` for efficiency, and [internal generics](#) only dispatch on objects for which `is.object` is `true`.

See Also

[UseMethod](#), [NextMethod](#), [‘group generic’](#), [‘internal generic’](#)

Examples

```
x <- 10
class(x) # "numeric"
oldClass(x) # NULL
inherits(x, "a") #FALSE
class(x) <- c("a", "b")
```

```
inherits(x, "a") #TRUE
inherits(x, "a", TRUE) # 1
inherits(x, c("a", "b", "c"), TRUE) # 1 2 0
```

col

Column Indexes

Description

Returns a matrix of integers indicating their column number in a matrix-like object, or a factor of column labels.

Usage

```
col(x, as.factor = FALSE)
```

Arguments

`x` a matrix-like object, that is one with a two-dimensional `dim`.

`as.factor` a logical value indicating whether the value should be returned as a factor of column labels (created if necessary) rather than as numbers.

Value

An integer (or factor) matrix with the same dimensions as `x` and whose i j -th element is equal to j (or the j -th column label).

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[row](#) to get rows.

Examples

```
# extract an off-diagonal of a matrix
ma <- matrix(1:12, 3, 4)
ma[row(ma) == col(ma) + 1]

# create an identity 5-by-5 matrix
x <- matrix(0, nrow = 5, ncol = 5)
x[row(x) == col(x)] <- 1
```

Colon

Colon Operator

Description

Generate regular sequences.

Usage

```
from:to  
a:b
```

Arguments

from	starting value of sequence.
to	(maximal) end value of the sequence.
a, b	factors of same length.

Details

The binary operator `:` has two meanings: for factors `a:b` is equivalent to [interaction](#)(a, b) (but the levels are ordered and labelled differently).

For numeric arguments `from:to` is equivalent to `seq(from, to)`, and generates a sequence from `from` to `to` in steps of 1 or 1-. Value `to` will be included if it differs from `from` by an integer up to a numeric fuzz of about $1e-7$.

Value

For numeric arguments, a numeric vector. This will be of type [integer](#) if `from` and `to` are both integers and representable in the integer type, otherwise of type [numeric](#).

For factors, an unordered factor with levels labelled as `1a:1b` and ordered lexicographically (that is, `1b` varies fastest).

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.
(for numeric arguments: S does not have `:` for factors.)

See Also

[seq](#).

As an alternative to using `:` for factors, [interaction](#).

For `:` used in the formal representation of an interaction, see [formula](#).

Examples

```

1:4
pi:6 # real
6:pi # integer

f1 <- gl(2,3); f1
f2 <- gl(3,2); f2
f1:f2 # a factor, the "cross"  f1 x f2

```

colSums

*Form Row and Column Sums and Means***Description**

Form row and column sums and means for numeric arrays.

Usage

```

colSums(x, na.rm = FALSE, dims = 1)
rowSums(x, na.rm = FALSE, dims = 1)
colMeans(x, na.rm = FALSE, dims = 1)
rowMeans(x, na.rm = FALSE, dims = 1)

```

Arguments

<code>x</code>	an array of two or more dimensions, containing numeric, complex, integer or logical values, or a numeric data frame.
<code>na.rm</code>	logical. Should missing values (including NaN) be omitted from the calculations?
<code>dims</code>	Which dimensions are regarded as ‘rows’ or ‘columns’ to sum over. For <code>row*</code> , the sum or mean is over dimensions <code>dims+1, ...</code> ; for <code>col*</code> it is over dimensions <code>1:dims</code> .

Details

These functions are equivalent to use of `apply` with `FUN = mean` or `FUN = sum` with appropriate margins, but are a lot faster. As they are written for speed, they blur over some of the subtleties of NaN and NA. If `na.rm = FALSE` and either NaN or NA appears in a sum, the result will be one of NaN or NA, but which might be platform-dependent.

Value

A numeric or complex array of suitable size, or a vector if the result is one-dimensional. The `dimnames` (or `names` for a vector result) are taken from the original array.

If there are no values in a range to be summed over (after removing missing values with `na.rm = TRUE`), that component of the output is set to 0 (`*Sums`) or NA (`*Means`), consistent with `sum` and `mean`.

See Also

Examples

```
## Compute row and column sums for a matrix:
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
rowSums(x); colSums(x)
dimnames(x)[[1]] <- letters[1:8]
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
x[] <- as.integer(x)
rowSums(x); colSums(x)
x[] <- x < 3
rowSums(x); colSums(x)
x <- cbind(x1 = 3, x2 = c(4:1, 2:5))
x[3, ] <- NA; x[4, 2] <- NA
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
rowSums(x, na.rm = TRUE); colSums(x, na.rm = TRUE)
rowMeans(x, na.rm = TRUE); colMeans(x, na.rm = TRUE)

## an array
dim(UCBAdmissions)
rowSums(UCBAdmissions); rowSums(UCBAdmissions, dims = 2)
colSums(UCBAdmissions); colSums(UCBAdmissions, dims = 2)

## complex case
x <- cbind(x1 = 3 + 2i, x2 = c(4:1, 2:5) - 5i)
x[3, ] <- NA; x[4, 2] <- NA
rowSums(x); colSums(x); rowMeans(x); colMeans(x)
rowSums(x, na.rm = TRUE); colSums(x, na.rm = TRUE)
rowMeans(x, na.rm = TRUE); colMeans(x, na.rm = TRUE)
```

commandArgs

Extract Command Line Arguments

Description

Provides access to a copy of the command line arguments supplied when this R session was invoked.

Usage

```
commandArgs(trailingOnly = FALSE)
```

Arguments

`trailingOnly` logical. Should only arguments after `--args` be returned?

Details

These arguments are captured before the standard R command line processing takes place. This means that they are the unmodified values. This is especially useful with the `--args` command-line flag to R, as all of the command line after that flag is skipped.

Value

A character vector containing the name of the executable and the user-supplied command line arguments. The first element is the name of the executable by which R was invoked. The exact form of this element is platform dependent: it may be the fully qualified name, or simply the last component (or basename) of the application, or for an embedded R it can be anything the programmer supplied.

If `trailingOnly = TRUE`, a character vector of those arguments (if any) supplied after `--args`.

See Also

[Startup BATCH](#)

Examples

```
commandArgs()
## Spawn a copy of this application as it was invoked,
## subject to shell quoting issues
## system(paste(commandArgs(), collapse=" "))
```

comment

Query or Set a 'Comment' Attribute

Description

These functions set and query a *comment* attribute for any R objects. This is typically useful for [data.frames](#) or model fits.

Contrary to other [attributes](#), the `comment` is not printed (by `print` or `print.default`).

Assigning `NULL` or a zero-length character vector removes the comment.

Usage

```
comment(x)
comment(x) <- value
```

Arguments

<code>x</code>	any R object
<code>value</code>	a character vector, or <code>NULL</code> .

See Also

[attributes](#) and [attr](#) for other attributes.

Examples

```
x <- matrix(1:12, 3, 4)
comment(x) <- c("This is my very important data from experiment #0234",
               "Jun 5, 1998")
x
comment(x)
```

Description

Binary operators which allow the comparison of values in atomic vectors.

Usage

```
x < y
x > y
x <= y
x >= y
x == y
x != y
```

Arguments

`x`, `y` atomic vectors, symbols, calls, or other objects for which methods have been written.

Details

The binary comparison operators are generic functions: methods can be written for them individually or via the `Ops` group generic function. (See `Ops` for how dispatch is computed.)

Comparison of strings in character vectors is lexicographic within the strings using the collating sequence of the locale in use: see `locales`. The collating sequence of locales such as `'en_US'` is normally different from `'C'` (which should use ASCII) and can be surprising. Beware of making *any* assumptions about the collation order: e.g. in Estonian `Z` comes between `S` and `T`, and collation is not necessarily character-by-character – in Danish `aa` sorts as a single letter, after `z`. In Welsh `ng` may or may not be a single sorting unit: if it is it follows `g`. Some platforms may not respect the locale and always sort in numerical order of the bytes in an 8-bit locale, or in Unicode point order for a UTF-8 locale (and may not sort in the same order for the same language in different character sets). Collation of non-letters (spaces, punctuation signs, hyphens, fractions and so on) is even more problematic.

At least one of `x` and `y` must be an atomic vector, but if the other is a list `R` attempts to coerce it to the type of the atomic vector: this will succeed if the list is made up of elements of length one that can be coerced to the correct type.

If the two arguments are atomic vectors of different types, one is coerced to the type of the other, the (decreasing) order of precedence being character, complex, numeric, integer, logical and raw.

Missing values (`NA`) and `NaN` values are regarded as non-comparable even to themselves, so comparisons involving them will always result in `NA`. Missing values can also result when character strings are compared and one is not valid in the current collation locale.

Language objects such as symbols and calls are deparsed to character strings before comparison.

Value

A logical vector indicating the result of the element by element comparison. The elements of shorter vectors are recycled as necessary.

Objects such as arrays or time-series can be compared this way provided they are conformable.

S4 methods

These operators are members of the S4 `Compare` group generic, and so methods can be written for them individually as well as for the group generic (or the `Ops` group generic), with arguments `c(e1, e2)`.

Note

Do not use `==` and `!=` for tests, such as in `if` expressions, where you must get a single `TRUE` or `FALSE`. Unless you are absolutely sure that nothing unusual can happen, you should use the `identical` function instead.

For numerical and complex values, remember `==` and `!=` do not allow for the finite representation of fractions, nor for rounding error. Using `all.equal` with `identical` is almost always preferable. See the examples.

Examples

```
x <- stats::rnorm(20)
x < 1
x[x > 0]

x1 <- 0.5 - 0.3
x2 <- 0.3 - 0.1
x1 == x2 # FALSE on most machines
identical(all.equal(x1, x2), TRUE) # TRUE everywhere

z <- c(32:126, 160:255) # range of most 8-bit charsets, Latin-1 in Unicode
x <- if(l10n_info()$MBCS) {
  intToUtf8(z, multiple = TRUE)
} else rawToChar(as.raw(z), multiple= TRUE)
## by number
writeLines(strwrap(paste(x, collapse=" "), width = 60))
## by locale collation
writeLines(strwrap(paste(sort(x), collapse=" "), width = 60))
```

complex

*Complex Vectors***Description**

Basic functions which support complex arithmetic in R.

Usage

```
complex(length.out = 0, real = numeric(), imaginary = numeric(),
        modulus = 1, argument = 0)
as.complex(x, ...)
is.complex(x)
```

```
Re(z)
Im(z)
Mod(z)
Arg(z)
Conj(z)
```

Arguments

<code>length.out</code>	numeric. Desired length of the output vector, inputs being recycled as needed.
<code>real</code>	numeric vector.
<code>imaginary</code>	numeric vector.
<code>modulus</code>	numeric vector.
<code>argument</code>	numeric vector.
<code>x</code>	an object, probably of mode <code>complex</code> .
<code>z</code>	an object of mode <code>complex</code> , or one of a class for which a methods has been defined.
<code>...</code>	further arguments passed to or from other methods.

Details

Complex vectors can be created with `complex`. The vector can be specified either by giving its length, its real and imaginary parts, or modulus and argument. (Giving just the length generates a vector of complex zeroes.)

`as.complex` attempts to coerce its argument to be of complex type: like `as.vector` it strips attributes including names. All forms of NA and NaN are coerced to a complex NA, for which both the real and imaginary parts are NA.

Note that `is.complex` and `is.numeric` are never both TRUE.

The functions `Re`, `Im`, `Mod`, `Arg` and `Conj` have their usual interpretation as returning the real part, imaginary part, modulus, argument and complex conjugate for complex values. Modulus and argument are also called the *polar coordinates*. If $z = x + iy$ with real x and y , for $r = \text{Mod}(z) = \sqrt{x^2 + y^2}$, and $\phi = \text{Arg}(z)$, $x = r * \cos(\phi)$ and $y = r * \sin(\phi)$. They are all generic functions: methods can be defined for them individually or via the `Complex` group generic.

In addition, the elementary trigonometric, logarithmic and exponential functions are available for complex values.

S4 methods

`as.complex` is primitive and can have S4 methods set.

`Re`, `Im`, `Mod`, `Arg` and `Conj` constitute the S4 group generic `Complex` and so S4 methods can be set for them individually or via the group generic.

Examples

```
require(graphics)

0i ^ (-3:3)

matrix(1i ^ (-6:5), nrow=4) #- all columns are the same
0 ^ 1i # a complex NaN

## create a complex normal vector
z <- complex(real = stats::rnorm(100), imaginary = stats::rnorm(100))
## or also (less efficiently):
z2 <- 1:2 + 1i*(8:9)

## The Arg(.) is an angle:
zz <- (rep(1:4, len=9) + 1i*(9:1))/10
zz.shift <- complex(modulus = Mod(zz), argument= Arg(zz) + pi)
plot(zz, xlim=c(-1,1), ylim=c(-1,1), col="red", asp = 1,
     main = expression(paste("Rotation by ", " ", pi == 180^o)))
abline(h=0, v=0, col="blue", lty=3)
points(zz.shift, col="orange")
```

conditions

Condition Handling and Recovery

Description

These functions provide a mechanism for handling unusual conditions, including errors and warnings.

Usage

```
tryCatch(expr, ..., finally)
withCallingHandlers(expr, ...)

signalCondition(cond)

simpleCondition(message, call = NULL)
simpleError      (message, call = NULL)
simpleWarning   (message, call = NULL)
simpleMessage   (message, call = NULL)
```

```

## S3 method for class 'condition':
as.character(x, ...)
## S3 method for class 'error':
as.character(x, ...)
## S3 method for class 'condition':
print(x, ...)
## S3 method for class 'restart':
print(x, ...)

conditionCall(c)
## S3 method for class 'condition':
conditionCall(c)
conditionMessage(c)
## S3 method for class 'condition':
conditionMessage(c)

withRestarts(expr, ...)

computeRestarts(cond = NULL)
findRestart(name, cond = NULL)
invokeRestart(r, ...)
invokeRestartInteractively(r)

isRestart(x)
restartDescription(r)
restartFormals(r)

.signalSimpleWarning(msg, call)
.handleSimpleError(h, msg, call)

```

Arguments

<code>c</code>	a condition object.
<code>call</code>	call expression.
<code>cond</code>	a condition object.
<code>expr</code>	expression to be evaluated.
<code>finally</code>	expression to be evaluated before returning or exiting.
<code>h</code>	function.
<code>message</code>	character string.
<code>msg</code>	character string.
<code>name</code>	character string naming a restart.
<code>r</code>	restart object.
<code>x</code>	object.
<code>...</code>	additional arguments; see details below.

Details

The condition system provides a mechanism for signaling and handling unusual conditions, including errors and warnings. Conditions are represented as objects that contain information about the

condition that occurred, such as a message and the call in which the condition occurred. Currently conditions are S3-style objects, though this may eventually change.

Conditions are objects inheriting from the abstract class `condition`. Errors and warnings are objects inheriting from the abstract subclasses `error` and `warning`. The class `simpleError` is the class used by `stop` and all internal error signals. Similarly, `simpleWarning` is used by `warning`, and `simpleMessage` is used by `message`. The constructors by the same names take a string describing the condition as argument and an optional call. The functions `conditionMessage` and `conditionCall` are generic functions that return the message and call of a condition.

Conditions are signaled by `signalCondition`. In addition, the `stop` and `warning` functions have been modified to also accept condition arguments.

The function `tryCatch` evaluates its expression argument in a context where the handlers provided in the `...` argument are available. The `finally` expression is then evaluated in the context in which `tryCatch` was called; that is, the handlers supplied to the current `tryCatch` call are not active when the `finally` expression is evaluated.

Handlers provided in the `...` argument to `tryCatch` are established for the duration of the evaluation of `expr`. If no condition is signaled when evaluating `expr` then `tryCatch` returns the value of the expression.

If a condition is signaled while evaluating `expr` then established handlers are checked, starting with the most recently established ones, for one matching the class of the condition. When several handlers are supplied in a single `tryCatch` then the first one is considered more recent than the second. If a handler is found then control is transferred to the `tryCatch` call that established the handler, the handler found and all more recent handlers are disestablished, the handler is called with the condition as its argument, and the result returned by the handler is returned as the value of the `tryCatch` call.

Calling handlers are established by `withCallingHandlers`. If a condition is signaled and the applicable handler is a calling handler, then the handler is called by `signalCondition` in the context where the condition was signaled but with the available handlers restricted to those below the handler called in the handler stack. If the handler returns, then the next handler is tried; once the last handler has been tried, `signalCondition` returns `NULL`.

User interrupts signal a condition of class `interrupt` that inherits directly from class `condition` before executing the default interrupt action.

Restarts are used for establishing recovery protocols. They can be established using `withRestarts`. One pre-established restart is an `abort` restart that represents a jump to top level.

`findRestart` and `computeRestarts` find the available restarts. `findRestart` returns the most recently established restart of the specified name. `computeRestarts` returns a list of all restarts. Both can be given a condition argument and will then ignore restarts that do not apply to the condition.

`invokeRestart` transfers control to the point where the specified restart was established and calls the restart's handler with the arguments, if any, given as additional arguments to `invokeRestart`. The restart argument to `invokeRestart` can be a character string, in which case `findRestart` is used to find the restart.

New restarts for `withRestarts` can be specified in several ways. The simplest is in `name=function` form where the function is the handler to call when the restart is invoked. Another simple variant is as `name=string` where the string is stored in the `description` field of the restart object returned by `findRestart`; in this case the handler ignores its arguments and returns `NULL`. The most flexible form of a restart specification is as a list that can include several fields, including `handler`, `description`, and `test`. The `test` field should contain a function

of one argument, a condition, that returns `TRUE` if the restart applies to the condition and `FALSE` if it does not; the default function returns `TRUE` for all conditions.

One additional field that can be specified for a restart is `interactive`. This should be a function of no arguments that returns a list of arguments to pass to the restart handler. The list could be obtained by interacting with the user if necessary. The function `invokeRestartInteractively` calls this function to obtain the arguments to use when invoking the restart. The default `interactive` method queries the user for values for the formal arguments of the handler function.

`.signalSimpleWarning` and `.handleSimpleError` are used internally and should not be called directly.

References

The `tryCatch` mechanism is similar to Java error handling. Calling handlers are based on Common Lisp and Dylan. Restarts are based on the Common Lisp restart mechanism.

See Also

`stop` and `warning` signal conditions, and `try` is essentially a simplified version of `tryCatch`.

Examples

```
tryCatch(1, finally=print("Hello"))
e <- simpleError("test error")
## Not run:
  stop(e)
  tryCatch(stop(e), finally=print("Hello"))
  tryCatch(stop("fred"), finally=print("Hello"))
## End(Not run)
tryCatch(stop(e), error = function(e) e, finally=print("Hello"))
tryCatch(stop("fred"), error = function(e) e, finally=print("Hello"))
withCallingHandlers({ warning("A"); 1+2 }, warning = function(w) {})
## Not run:
  { withRestarts(stop("A"), abort = function() {}); 1 }
## End(Not run)
withRestarts(invokeRestart("foo", 1, 2), foo = function(x, y) {x + y})
```

conflicts

Search for Masked Objects on the Search Path

Description

`conflicts` reports on objects that exist with the same name in two or more places on the [search path](#), usually because an object in the user's workspace or a package is masking a system object of the same name. This helps discover unintentional masking.

Usage

```
conflicts(where = search(), detail = FALSE)
```

Arguments

`where` A subset of the search path, by default the whole search path.

`detail` If `TRUE`, give the masked or masking functions for all members of the search path.

Value

If `detail=FALSE`, a character vector of masked objects. If `detail=TRUE`, a list of character vectors giving the masked or masking objects in that member of the search path. Empty vectors are omitted.

Examples

```
lm <- 1:3
conflicts(, TRUE)
## gives something like
# $.GlobalEnv
# [1] "lm"
#
# $package:base
# [1] "lm"

## Remove things from your "workspace" that mask others:
remove(list = conflicts(detail=TRUE)$GlobalEnv)
```

connections

Functions to Manipulate Connections

Description

Functions to create, open and close connections.

Usage

```
file(description = "", open = "", blocking = TRUE,
      encoding = getOption("encoding"))

url(description, open = "", blocking = TRUE,
     encoding = getOption("encoding"))

gzfile(description, open = "", encoding = getOption("encoding"),
       compression = 6)

bzfile(description, open = "", encoding = getOption("encoding"))

unz(description, filename, open = "",
     encoding = getOption("encoding"))

pipe(description, open = "", encoding = getOption("encoding"))

fifo(description, open = "", blocking = FALSE,
```

```

        encoding = getOption("encoding"))

socketConnection(host = "localhost", port, server = FALSE,
                 blocking = FALSE, open = "a+",
                 encoding = getOption("encoding"))

open(con, ...)
## S3 method for class 'connection':
open(con, open = "r", blocking = TRUE, ...)

close(con, ...)
## S3 method for class 'connection':
close(con, type = "rw", ...)

flush(con)

isOpen(con, rw = "")
isIncomplete(con)

```

Arguments

<code>description</code>	character string. A description of the connection: see ‘Details’.
<code>open</code>	character. A description of how to open the connection (if at all). See ‘Details’ for possible values.
<code>blocking</code>	logical. See the ‘Blocking’ section below.
<code>encoding</code>	The name of the encoding to be used. See the ‘Encoding’ section below.
<code>compression</code>	integer in 0–9. The amount of compression to be applied when writing, from none to maximal. The default is a good space/time compromise.
<code>filename</code>	a filename within a zip file.
<code>host</code>	character. Host name for port.
<code>port</code>	integer. The TCP port number.
<code>server</code>	logical. Should the socket be a client or a server?
<code>con</code>	a connection.
<code>type</code>	character. Currently ignored.
<code>rw</code>	character. Empty or "read" or "write", partial matches allowed.
<code>...</code>	arguments passed to or from other methods.

Details

The first eight functions create connections. By default the connection is not opened (except for `socketConnection`), but may be opened by setting a non-empty value of argument `open`.

For `file` the description is either a path to the file to be opened or a complete URL, or "" (the default) or "stdin" or "clipboard" (see below).

For `url` the description is a complete URL, including scheme (such as `http://`, `ftp://` or `file://`).

For `gzipfile` the description is the path to a file that is compressed by `gzip`: it can also opened uncompressed files.

For `bzfile` the description is the path to a file that is compressed by `bzip2`.

`unz` reads (only) single files within zip files, in binary mode. The description is the full path to the zip file, with `.zip` extension if required.

For `pipe` the description is the command line to be piped to or from.

For `fifo` the description is the path of the fifo.

`file` allows `description="stdin"` to refer to the C-level `stdin` of the process (which need not be connected to anything in a console or embedded version of R), provided the C99 function `fdopen` is supported on the platform.

`gzfile` and `bzfile` open the actual file in binary mode and so no translations are done if the original file was a text file. (See `gzcon` for a way to add compression to non-file connections such as URLs.)

All platforms support `file`, `gzfile`, `bzfile`, `unz` and `url("file://")` connections. The other types may be partially implemented or not implemented at all. (They do work on most Unix platforms, and all but `fifo` on Windows.)

Proxies can be specified for `url` connections: see `download.file`.

`open`, `close` and `seek` are generic functions: the following applies to the methods relevant to connections.

`open` opens a connection. In general functions using connections will open them if they are not open, but then close them again, so to leave a connection open call `open` explicitly.

Possible values for the mode `open` to open a connection are

"r" or "rt" Open for reading in text mode.

"w" or "wt" Open for writing in text mode.

"a" or "at" Open for appending in text mode.

"rb" Open for reading in binary mode.

"wb" Open for writing in binary mode.

"ab" Open for appending in binary mode.

"r+", "r+b" Open for reading and writing.

"w+", "w+b" Open for reading and writing, truncating file initially.

"a+", "a+b" Open for reading and appending.

Not all modes are applicable to all connections: for example URLs can only be opened for reading. Only file and socket connections can be opened for reading and writing/appending. For many connections there is little or no difference between text and binary modes, but there is for file-like connections on Windows, and `pushBack` is text-oriented and is only allowed on connections open for reading in text mode. If a file or fifo is created on a Unix-alike, its permissions will be the maximal allowed by the current setting of `umask` (see `Sys.umask`).

`gzfile` connections are an exception, as the file always has to be opened in binary mode. Thus modes such as `r` are binary, and `rt` is needed to have a text-mode connection.

`close` closes and destroys a connection. Note that this will happen automatically in due course if there is no R object referring to the connection.

A maximum of 128 connections can be allocated (not necessarily open) at any one time. Three of these are pre-allocated (see `stdout`). The OS will impose limits on the numbers of connections of various types, but these are usually larger than 125.

`flush` flushes the output stream of a connection open for write/append (where implemented).

If for a `file` or `fifo` connection the description is `"`, the file/fifo is immediately opened (in `"w+"` mode unless `open="w+b"` is specified) and unlinked from the file system. This provides a temporary file/fifo to write to and then read from.

A note on `file://` URLs. The most general form (from RFC1738) is `file://host/path/to/file`, but R only accepts the form with an empty host field referring to the local machine. This is then `file:///path/to/file`, where `path/to/file` is relative to `.`. So although the third slash is strictly part of the specification not part of the path, this can be regarded as a way to specify the file `'/path/to/file'`. It is not possible to specify a relative path using a file URL. Also, no attempt is made to decode an encoded URL: call `URLdecode` if necessary.

Note that `https://` connections are not supported.

Value

`file`, `pipe`, `fifo`, `url`, `gzfile`, `bzfile`, `unz` and `socketConnection` return a connection object which inherits from class `"connection"` and has a first more specific class.

`isOpen` returns a logical value, whether the connection is currently open.

`isIncomplete` returns a logical value, whether last read attempt was blocked, or for an output text connection whether there is unflushed output.

Encoding

The encoding of the input/output stream of a connection in *text* mode can be specified by name, in the same way as it would be given to `iconv`: see that help page for how to find out what names are recognized on your platform. Additionally, `"` and `"native.enc"` both mean the 'native' encoding, that is the internal encoding of the current locale and hence no translation is done. Not all builds of R support this, and if yours does not, specifying a non-default encoding will give an error when the connection is opened.

Re-encoding only works for connections in text mode.

The encoding `"UCS-2LE"` is treated specially, as it is the appropriate value for Windows 'Unicode' text files. If the first two bytes are the Byte Order Mark `0xFFFE` then these are removed as most implementations of `iconv` do not accept BOMs. Note that some implementations will handle BOMs using encoding `"UCS-2"` but many will not.

Exactly what happens when the requested translation cannot be done is in general undocumented. Requesting a conversion that is not supported is an error, reported when the connection is opened. On output the result is likely to be that up to the error, with a warning. On input, it will most likely be all or some of the input up to the error.

Blocking

The default condition for all but `fifo` and `socket` connections is to be in blocking mode. In that mode, functions do not return to the R evaluator until they are complete. In non-blocking mode, operations return as soon as possible, so on input they will return with whatever input is available (possibly none) and for output they will return whether or not the write succeeded.

The function `readLines` behaves differently in respect of incomplete last lines in the two modes: see its help page.

Even when a connection is in blocking mode, attempts are made to ensure that it does not block the event loop and hence the operation of GUI parts of R. These do not always succeed, and the whole process will be blocked during a DNS lookup on Unix, for example.

Most blocking operations on URLs and sockets are subject to the timeout set by `options("timeout")`. Note that this is a timeout for no response at all, not for the whole operation. The timeout is set at the time the connection is opened (more precisely, when the last connection of that type – `http:`, `ftp:` or `socket` – was opened).

Fifos

Fifos default to non-blocking. That follows S version 4 and is probably most natural, but it does have some implications. In particular, opening a non-blocking fifo connection for writing (only) will fail unless some other process is reading on the fifo.

Opening a fifo for both reading and writing (in any mode: one can only append to fifos) connects both sides of the fifo to the R process, and provides an similar facility to `file()`.

Clipboard

`file` can also be used with `description = "clipboard"` in mode `"r"` only. This reads the X11 primary selection (see <http://standards.freedesktop.org/clipboards-spec/clipboards-latest.txt>), which can also be specified as `"X11_primary"` and the secondary selection as `"X11_secondary"`. On most systems the clipboard selection (that used by 'Copy' from an 'Edit' menu) can be specified as `"X11_clipboard"`.

When a clipboard is opened for reading, the contents are immediately copied to internal storage in the connection.

Unix users wishing to *write* to one of the selections may be able to do so via `xclip` (<http://people.debian.org/~kims/xclip/>), for example by `pipe("xclip -i", "w")` for the primary selection.

MacOS X users can use `pipe("pbpaste")` and `pipe("pbcopy", "w")` to read from and write to that system's clipboard.

Note

R's connections are modelled on those in S version 4 (see Chambers, 1998). However R goes well beyond the S model, for example in output text connections and URL, `gzfile`, `bzfile` and socket connections.

The default mode in R is `"r"` except for socket connections. This differs from S, where it is the equivalent of `"r+"`, known as `"*"`.

On (rare) platforms where `vsnprintf` does not return the needed length of output there is a 100,000 character output limit on the length of line for `fifo`, `gzfile` and `bzfile` connections: longer lines will be truncated with a warning.

Functions making direct use of connections are [readLines](#), [readBin](#), [readChar](#), [writeLines](#), [writeBin](#), [writeChar](#), [cat](#), [sink](#), [scan](#), [parse](#), [read.dcf](#), [load](#), [save](#), [dput](#) and [dump](#).

[capabilities](#) to see if `url`, `fifo` and `socketConnection` are supported by this build of R.

[gzcon](#) to wrap `gzip` (de)compression around a connection.

Examples

```

zz <- file("ex.data", "w") # open an output file connection
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
cat("One more line\n", file = zz)
close(zz)
readLines("ex.data")
unlink("ex.data")

zz <- gzfile("ex.gz", "w") # compressed file
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzfile("ex.gz"))
close(zz)
unlink("ex.gz")

zz <- bzfile("ex.bz2", "w") # bzip2-ed file
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
print(readLines(zz <- bzfile("ex.bz2")))
close(zz)
unlink("ex.bz2")

## An example of a file open for reading and writing
Tfile <- file("test1", "w+")
c(isOpen(Tfile, "r"), isOpen(Tfile, "w")) # both TRUE
cat("abc\ndef\n", file=Tfile)
readLines(Tfile)
seek(Tfile, 0, rw="r") # reset to beginning
readLines(Tfile)
cat("ghi\n", file=Tfile)
readLines(Tfile)
close(Tfile)
unlink("test1")

## We can do the same thing with an anonymous file.
Tfile <- file()
cat("abc\ndef\n", file=Tfile)
readLines(Tfile)
close(Tfile)

## fifo example -- may fail, e.g. on Cygwin, even with OS support for fifos
if(capabilities("fifo")) {
  zz <- fifo("foo-fifo", "w+")
  writeLines("abc", zz)
  print(readLines(zz))
  close(zz)
  unlink("foo-fifo")
}

## Unix examples of use of pipes

# read listing of current directory
readLines(pipe("ls -l"))

# remove trailing commas. Suppose

```

```

## Not run:
% cat data2
450, 390, 467, 654, 30, 542, 334, 432, 421,
357, 497, 493, 550, 549, 467, 575, 578, 342,
446, 547, 534, 495, 979, 479
## End(Not run)
# Then read this by
scan(pipe("sed -e s/,,$// data2_"), sep=",")

# convert decimal point to comma in output: see also write.table
# both R strings and (probably) the shell need \ doubled
zz <- pipe(paste("sed s/\\\\. / >", "outfile"), "w")
cat(format(round(stats::rnorm(48), 4)), fill=70, file = zz)
close(zz)
file.show("outfile", delete.file=TRUE)

## example for a machine running a finger daemon

con <- socketConnection(port = 79, blocking = TRUE)
writeLines(paste(system("whoami", intern=TRUE), "\r", sep=""), con)
gsub(" *$", "", readLines(con))
close(con)

## Not run:
## two R processes communicating via non-blocking sockets
# R process 1
con1 <- socketConnection(port = 6011, server=TRUE)
writeLines(LETTERS, con1)
close(con1)

# R process 2
con2 <- socketConnection(Sys.info()["nodename"], port = 6011)
# as non-blocking, may need to loop for input
readLines(con2)
while(isIncomplete(con2)) {Sys.sleep(1); readLines(con2)}
close(con2)

## examples of use of encodings
cat(x, file = (con <- file("foo", "w", encoding="UTF-8"))); close(con)
# read a 'Windows Unicode' file
A <- read.table(con <- file("students", encoding="UCS-2LE")); close(con)
## End(Not run)

```

Constants

Built-in Constants

Description

Constants built into R.

Usage

```
LETTERS
letters
month.abb
month.name
pi
```

Details

R has a small number of built-in constants (there is also a rather larger library of data sets which can be loaded with the function [data](#)).

The following constants are available:

- `LETTERS`: the 26 upper-case letters of the Roman alphabet;
- `letters`: the 26 lower-case letters of the Roman alphabet;
- `month.abb`: the three-letter abbreviations for the English month names;
- `month.name`: the English names for the months of the year;
- `pi`: the ratio of the circumference of a circle to its diameter.

These are implemented as variables in the base name space taking appropriate values.

Examples

```
## John Machin (ca 1706) computed pi to over 100 decimal places
## using the Taylor series expansion of the second term of
pi - 4*(4*atan(1/5) - atan(1/239))

## months in English
month.name
## months in your current locale
format(ISOdate(2000, 1:12, 1), "%B")
format(ISOdate(2000, 1:12, 1), "%b")
```

contributors

R Project Contributors

Description

The R Who-is-who, describing who made significant contributions to the development of R.

Usage

```
contributors()
```

Control

Control Flow

Description

These are the basic control-flow constructs of the R language. They function in much the same way as control statements in any Algol-like language. They are all [reserved](#) words.

Usage

```
if(cond) expr
if(cond) cons.expr else alt.expr

for(var in seq) expr
while(cond) expr
repeat expr
break
next
```

Arguments

<code>cond</code>	A length-one logical vector that is not NA. Conditions of length greater than one are accepted with a warning, but only the first element is used. Other types are coerced to logical if possible, ignoring any class.
<code>var</code>	A syntactical name for a variable.
<code>seq</code>	An expression evaluating to a vector (including a list and an expression) or to a pairlist or NULL.
<code>expr, cons.expr, alt.expr</code>	An <i>expression</i> in a formal sense. This is either a simple expression or a so called <i>compound expression</i> , usually of the form { <code>expr1 ; expr2</code> }.

Details

`break` breaks out of a `for`, `while` or `repeat` loop; control is transferred to the first statement outside the inner-most loop. `next` halts the processing of the current iteration and advances the looping index. Both `break` and `next` apply only to the innermost of nested loops.

Note that it is a common mistake to forget to put braces (`{ ... }`) around your statements, e.g., after `if(...)` or `for(...)`. In particular, you should not have a newline between `}` and `else` to avoid a syntax error in entering a `if ... else` construct at the keyboard or via `source`. For that reason, one (somewhat extreme) attitude of defensive programming is to always use braces, e.g., for `if` clauses.

The index `seq` in a `for` loop is evaluated at the start of the loop; changing it subsequently does not affect the loop. The variable `var` has the same type as `seq`, and is read-only: assigning to it does not alter `seq`. If `seq` is a factor (which is not strictly allowed) then its internal codes are used: the effect is that of `as.integer` not `as.vector`.

Value

`if` returns the value of the expression evaluated, or `NULL` if none was (which may happen if there is no `else`).

`for`, `while` and `repeat` return the value of the last expression evaluated (or `NULL` if none was), invisibly. `for` sets `var` to the last used element of `seq`, or to `NULL` if it was of length zero.

`break` and `next` have value `NULL`, although it would be strange to look for a return value.

crossprod

*Matrix Crossproduct***Description**

Given matrices `x` and `y` as arguments, return a matrix cross-product. This is formally equivalent to (but usually slightly faster than) the call `t(x) %*% y` (`crossprod`) or `x %*% t(y)` (`tcrossprod`).

Usage

```
crossprod(x, y = NULL)
```

```
tcrossprod(x, y = NULL)
```

Arguments

`x`, `y` numeric or complex matrices: `y = NULL` is taken to be the same matrix as `x`. Vectors are promoted to single-column matrices.

Value

A double or complex matrix, with appropriate `dimnames` taken from `x` and `y`.

Note

When `x` or `y` are not matrices, they are treated as column or row matrices, but their `names` are usually **not** promoted to `dimnames`. Hence, currently, the last example has empty `dimnames`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`%*%` and outer product `%O%`.

Examples

```
(z <- crossprod(1:4))      # = sum(1 + 2^2 + 3^2 + 4^2)
drop(z)                   # scalar
x <- 1:4; names(x) <- letters[1:4]; x
tcrossprod(as.matrix(x)) # is
identical(tcrossprod(as.matrix(x)),
          crossprod(t(x)))
tcrossprod(x)             # no dimnames
```

Cstack_info	<i>Report Information on C Stack Size and Usage</i>
-------------	---

Description

Report information on the C stack size and usage (if available).

Usage

```
Cstack_info()
```

Details

On most platforms, C stack information is recorded when R is initialized and used for stack-checking. If this information is unavailable, the `size` will be returned as `NA`, and stack-checking is not performed.

The information on the stack base address is thought to be accurate on Windows, Linux and FreeBSD (including MacOS X), but a heuristic is used on other platforms. Because this might be slightly inaccurate, the current usage could be estimated as negative. (The heuristic is not used on embedded uses of R on platforms where the stack base is not thought to be accurate.)

Value

An integer vector. This has named elements

<code>size</code>	The size of the stack (in bytes), or <code>NA</code> if unknown.
<code>current</code>	The estimated current usage (in bytes), possibly <code>NA</code> .
<code>direction</code>	1 (stack grows down, the usual case) or -1 (stack grows up).
<code>eval_depth</code>	The current evaluation depth (including two calls for the call to <code>Cstack_info</code>).

Examples

```
Cstack_info()
```

cumsum	<i>Cumulative Sums, Products, and Extremes</i>
--------	--

Description

Returns a vector whose elements are the cumulative sums, products, minima or maxima of the elements of the argument.

Usage

```
cumsum(x)
cumprod(x)
cummax(x)
cummin(x)
```

Arguments

`x` a numeric or complex (not `cummin` or `cummax`) object, or an object that can be coerced to one of these.

Details

These are generic functions: methods can be defined for them individually or via the `Math` group generic.

Value

A vector of the same length and type as `x` (after coercion), except that `cumprod` returns a numeric vector for integer input (for consistency with `*`). Names are preserved.

An NA value in `x` causes the corresponding and following elements of the return value to be NA, as does integer overflow in `cumsum` (with a warning).

S4 methods

`cumsum` and `cumprod` are S4 generic functions: methods can be defined for them individually or via the `Math` group generic. `cummax` and `cummin` are individually S4 generic functions.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole. (`cumsum` only.)

Examples

```
cumsum(1:10)
cumprod(1:10)
cummin(c(3:1, 2:0, 4:2))
cummax(c(3:1, 2:0, 4:2))
```

cut

Convert Numeric to Factor

Description

`cut` divides the range of `x` into intervals and codes the values in `x` according to which interval they fall. The leftmost interval corresponds to level one, the next leftmost to level two and so on.

Usage

```
cut(x, ...)

## Default S3 method:
cut(x, breaks, labels = NULL,
     include.lowest = FALSE, right = TRUE, dig.lab = 3,
     ordered_result = FALSE, ...)
```

Arguments

<code>x</code>	a numeric vector which is to be converted to a factor by cutting.
<code>breaks</code>	either a numeric vector of two or more cut points or a single number (greater than or equal to 2) giving the number of intervals into which <code>x</code> is to be cut.
<code>labels</code>	labels for the levels of the resulting category. By default, labels are constructed using " <code>(a,b]</code> " interval notation. If <code>labels = FALSE</code> , simple integer codes are returned instead of a factor.
<code>include.lowest</code>	logical, indicating if an ' <code>x[i]</code> ' equal to the lowest (or highest, for <code>right = FALSE</code>) ' <code>breaks</code> ' value should be included.
<code>right</code>	logical, indicating if the intervals should be closed on the right (and open on the left) or vice versa.
<code>dig.lab</code>	integer which is used when labels are not given. It determines the number of digits used in formatting the break numbers.
<code>ordered_result</code>	logical: should the result be an ordered factor?
<code>...</code>	further arguments passed to or from other methods.

Details

When `breaks` is specified as a single number, the range of the data is divided into `breaks` pieces of equal length, and then the outer limits are moved away by 0.1% of the range to ensure that the extreme values both fall within the break intervals. (If `x` is a constant vector, equal-length intervals are created that cover the single value.)

If a `labels` parameter is specified, its values are used to name the factor levels. If none is specified, the factor level labels are constructed as "`(b1, b2]`", "`(b2, b3]`" etc. for `right = TRUE` and as "`[b1, b2)`", ...if `right = FALSE`. In this case, `dig.lab` indicates the minimum number of digits should be used in formatting the numbers `b1, b2, ...`. A larger value (up to 12) will be used if needed to distinguish between any pair of endpoints: if this fails labels such as "Range3" will be used.

Value

A `factor` is returned, unless `labels = FALSE` which results in the mere integer level codes.

Note

Instead of `table(cut(x, br))`, `hist(x, br, plot = FALSE)` is more efficient and less memory hungry. Instead of `cut(*, labels = FALSE)`, `findInterval()` is more efficient.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`split` for splitting a variable according to a group factor; `factor`, `tabulate`, `table`, `findInterval()`.

`quantile` for ways of choosing breaks of roughly equal content (rather than length), `cut2` in package **Hmisc** for a canned way to form quantile groups.

Examples

```

Z <- stats::rnorm(10000)
table(cut(Z, breaks = -6:6))
sum(table(cut(Z, breaks = -6:6, labels=FALSE)))
sum(graphics::hist(Z, breaks = -6:6, plot=FALSE)$counts)

cut(rep(1,5),4)##-- dummy
tx0 <- c(9, 4, 6, 5, 3, 10, 5, 3, 5)
x <- rep(0:8, tx0)
stopifnot(table(x) == tx0)

table( cut(x, b = 8))
table( cut(x, breaks = 3*(-2:5)))
table( cut(x, breaks = 3*(-2:5), right = FALSE))

##--- some values OUTSIDE the breaks :
table(cx <- cut(x, breaks = 2*(0:4)))
table(cx1 <- cut(x, breaks = 2*(0:4), right = FALSE))
which(is.na(cx)); x[is.na(cx)] ##-- the first 9 values 0
which(is.na(cx1)); x[is.na(cx1)] ##-- the last 5 values 8

## Label construction:
y <- stats::rnorm(100)
table(cut(y, breaks = pi/3*(-3:3)))
table(cut(y, breaks = pi/3*(-3:3), dig.lab=4))

table(cut(y, breaks = 1*(-3:3), dig.lab=4))
# extra digits don't "harm" here
table(cut(y, breaks = 1*(-3:3), right = FALSE))
#- the same, since no exact INT!

## sometimes the default dig.lab is not enough to be avoid confusion:
aaa <- c(1,2,3,4,5,2,3,4,5,6,7)
cut(aaa, 3)
cut(aaa, 3, dig.lab=4, ordered = TRUE)

## one way to extract the breakpoints
labs <- levels(cut(aaa, 3))
cbind(lower = as.numeric( sub("\\((.+),.*", "\\1", labs) ),
      upper = as.numeric( sub("[^,]*, ([^]]*)\\]", "\\1", labs) ))

```

cut.POSIXt

*Convert a Date or Date-Time Object to a Factor***Description**

Method for `cut` applied to date-time objects.

Usage

```

## S3 method for class 'POSIXt':
cut(x, breaks, labels = NULL, start.on.monday = TRUE,
    right = FALSE, ...)

```

```
## S3 method for class 'Date':
cut(x, breaks, labels = NULL, start.on.monday = TRUE,
     right = FALSE, ...)
```

Arguments

`x` an object inheriting from class "POSIXt" or "Date".

`breaks` a vector of cut points *or* number giving the number of intervals which `x` is to be cut into *or* an interval specification, one of "sec", "min", "hour", "day", "DSTday", "week", "month", "quarter" or "year", optionally preceded by an integer and a space, or followed by "s". For "Date" objects only "day", "week", "month", "quarter" and "year" are allowed.

`labels` labels for the levels of the resulting category. By default, labels are constructed from the left-hand end of the intervals (which are include for the default value of `right`). If `labels = FALSE`, simple integer codes are returned instead of a factor.

`start.on.monday` logical. If `breaks = "weeks"`, should the week start on Mondays or Sundays?

`right, ...` arguments to be passed to or from other methods.

Details

Using both `right = TRUE` and `include.lowest = TRUE` will include both ends of the range of dates.

Using `breaks = "quarter"` will create intervals of 3 calendar months, with the intervals beginning on January 1, April 1, July 1 or October 1, based upon `min(x)` as appropriate.

Value

A factor is returned, unless `labels = FALSE` which returns the integer level codes.

Examples

```
## random dates in a 10-week period
cut(ISOdate(2001, 1, 1) + 70*86400*stats::runif(100), "weeks")
cut(as.Date("2001/1/1") + 70*stats::runif(100), "weeks")
```

data.class

Object Classes

Description

Determine the class of an arbitrary R object.

Usage

```
data.class(x)
```

Arguments

`x` an R object.

Value

character string giving the *class* of `x`.

The class is the (first element) of the `class` attribute if this is non-NULL, or inferred from the object's `dim` attribute if this is non-NULL, or `mode(x)`.

Simply speaking, `data.class(x)` returns what is typically useful for method dispatching. (Or, what the basic creator functions already and maybe eventually all will attach as a class attribute.)

Note

For compatibility reasons, there is one exception to the rule above: When `x` is `integer`, the result of `data.class(x)` is `"numeric"` even when `x` is classed.

See Also

`class`

Examples

```
x <- LETTERS
data.class(factor(x))           # has a class attribute
data.class(matrix(x, ncol = 13)) # has a dim attribute
data.class(list(x))            # the same as mode(x)
data.class(x)                  # the same as mode(x)

stopifnot(data.class(1:2) == "numeric") # compatibility "rule"
```

data.frame

Data Frames

Description

This function creates data frames, tightly coupled collections of variables which share many of the properties of matrices and of lists, used as the fundamental data structure by most of R's modeling software.

Usage

```
data.frame(..., row.names = NULL, check.rows = FALSE,
           check.names = TRUE,
           stringsAsFactors = default.stringsAsFactors())

default.stringsAsFactors()
```

Arguments

<code>...</code>	these arguments are of either the form <code>value</code> or <code>tag = value</code> . Component names are created based on the tag (if present) or the deparsed argument itself.
<code>row.names</code>	NULL or a single integer or character string specifying a column to be used as row names, or a character or integer vector giving the row names for the data frame.
<code>check.rows</code>	if TRUE then the rows are checked for consistency of length and names.
<code>check.names</code>	logical. If TRUE then the names of the variables in the data frame are checked to ensure that they are syntactically valid variable names and are not duplicated. If necessary they are adjusted (by <code>make.names</code>) so that they are.
<code>stringsAsFactors</code>	logical: should character vectors be converted to factors? The 'factory-fresh' default is TRUE, but this can be changed by setting <code>options(stringsAsFactors = FALSE)</code> .

Details

A data frame is a list of variables of the same length with unique row names, given class "data.frame". If there are zero variables, the row names determine the number of rows.

Duplicate column names are allowed, but you need to use `check.names=FALSE` for `data.frame` to generate such a data frame. However, not all operations on data frames will preserve duplicated column names: for example matrix-like subsetting will force column names in the result to be unique.

`data.frame` converts each of its arguments to a data frame by calling `as.data.frame(optional=TRUE)`. As that is a generic function, methods can be written to change the behaviour of arguments according to their classes: R comes with many such methods. Character variables passed to `data.frame` are converted to factor columns unless protected by `I`. If a list or data frame or matrix is passed to `data.frame` it is as if each component or column had been passed as a separate argument (except for matrices of class "model.matrix" and those protected by `I`).

Objects passed to `data.frame` should have the same number of rows, but atomic vectors, factors and character vectors protected by `I` will be recycled a whole number of times if necessary.

If row names are not supplied in the call to `data.frame`, the row names are taken from the first component that has suitable names, for example a named vector or a matrix with `rownames` or a data frame. (If that component is subsequently recycled, the names are discarded with a warning.) If `row.names` was supplied as NULL or no suitable component was found the row names are the integer sequence starting at one (and such row names are considered to be 'automatic', and not preserved by `as.matrix`).

If row names are supplied of length one and the data frame has a single row, the `row.names` is taken to specify the row names and not a column (by name or number).

Names are removed from vector inputs not protected by `I`.

`default.stringsAsFactors` is a utility that takes `getOption("stringsAsFactors")` and ensures the result is TRUE or FALSE (or throws an error if the value is not NULL).

Value

A data frame, a matrix-like structure whose columns may be of differing types (numeric, logical, factor and character and so on).

How the names of the data frame are created is complex, and the rest of this paragraph is only the basic story. If the arguments are all named and simple objects (not lists, matrices of data frames) then the argument names give the column names. For an unnamed simple argument, a deparsed version of the argument is used as the name (with an enclosing `I(...)` removed). For a named matrix/list/data frame argument with one or more named columns, the names of the columns are the name of the argument followed by a dot and the column name inside the argument: if the argument is unnamed, the argument's column names are used. For a named or unnamed matrix/list/data frame argument that contains a single column, the column name in the result is the column name in the argument. Finally, the names are adjusted to be unique and syntactically valid unless `check.names = FALSE`.

Note

In versions of R prior to 2.4.0 `row.names` had to be character: to ensure compatibility with earlier versions of R, supply a character vector as the `row.names` argument.

[I](#), [plot.data.frame](#), [print.data.frame](#), [row.names](#), [names](#) (for the column names), [\[.data.frame](#) for subsetting methods, [Math.data.frame](#) etc, about *Group* methods for data.frames; [read.table](#), [make.names](#).

Examples

```
L3 <- LETTERS[1:3]
(d <- data.frame(cbind(x=1, y=1:10), fac=sample(L3, 10, replace=TRUE)))

## The same with automatic column names:
data.frame(cbind( 1, 1:10), sample(L3, 10, replace=TRUE))

is.data.frame(d)

## do not convert to factor, using I() :
(dd <- cbind(d, char = I(letters[1:10])))
rbind(class=sapply(dd, class), mode=sapply(dd, mode))

stopifnot(1:10 == row.names(d)) # {coercion}

(d0 <- d[, FALSE]) # NULL data frame with 10 rows
(d.0 <- d[FALSE, ]) # <0 rows> data frame (3 cols)
(d00 <- d0[FALSE,]) # NULL data frame with 0 rows
```

Description

Return the matrix obtained by converting all the variables in a data frame to numeric mode and then binding them together as the columns of a matrix. Factors and ordered factors are replaced by their internal codes.

Usage

```
data.matrix(frame, rownames.force = NA)
```

Arguments

`frame` a data frame whose components are logical vectors, factors or numeric vectors.
`rownames.force` logical indicating if the resulting matrix should have character (rather than NULL) `rownames`. The default, NA, uses NULL `rownames` if the data frame has ‘automatic’ `row.names` or for a zero-row data frame.

Details

Logical and factor columns are converted to integers. Any other column which is not numeric (according to `is.numeric`) is converted by `as.numeric` or, for S4 objects, `as(, "numeric")`. If all columns are integer (after conversion) the result is an integer matrix, otherwise a numeric (double) matrix.

Value

If `frame` inherits from class "data.frame", an integer or numeric matrix of the same dimensions as `frame`, with `dimnames` taken from the `row.names` (or NULL, depending on `rownames.force`) and `names`.

Otherwise, the result of `as.matrix`.

Note

The default behaviour for data frames differs from R < 2.5.0 which always gave the result character `rownames`.

See Also

`as.matrix`, `data.frame`, `matrix`.

Examples

```
DF <- data.frame(a=1:3, b=letters[10:12],
                 c=seq(as.Date("2004-01-01"), by = "week", len = 3),
                 stringsAsFactors = TRUE)
data.matrix(DF[1:2])
data.matrix(DF)
```

date *System Date and Time*

Description

Returns a character string of the current system date and time.

Usage

```
date()
```

Value

The string has the form "Fri Aug 20 11:11:00 1999", i.e., length 24, since it relies on POSIX's `ctime` ensuring the above fixed format. Timezone and Daylight Saving Time are taken account of, but *not* indicated in the result.

The day and month abbreviations are always in English, irrespective of locale.

Examples

```
(d <- date())
nchar(d) == 24

## something similar in the current locale
format(Sys.time(), "%a %b %d %H:%M:%S %Y")
```

Dates *Date Class*

Description

Description of the class "Date" representing calendar dates.

Usage

```
## S3 method for class 'Date':
summary(object, digits = 12, ...)
```

Arguments

<code>object</code>	An object summarized.
<code>digits</code>	Number of significant digits for the computations.
<code>...</code>	Further arguments to be passed from or to other methods.

Details

Dates are represented as the number of days since 1970-01-01, with negative values for earlier dates. They are always printed following the rules of the current Gregorian calendar, even though that calendar was not in use long ago (it was adopted in 1752 in Great Britain and its colonies).

It is intended that the date should be an integer, but this is not enforced in the internal representation. Fractional days will be ignored when printing. It is possible to produce fractional days via the `mean` method or by adding or subtracting (see [Ops.Date](#)).

See Also

[Sys.Date](#) for the current date.
[Ops.Date](#) for operators on "Date" objects.
[format.Date](#) for conversion to and from character strings.

[weekdays](#) for convenience extraction functions.
[seq.Date](#), [cut.Date](#), [round.Date](#) for utility operations.
[DateClasses](#) for date-time classes.

Examples

```
(today <- Sys.Date())
format(today, "%d %b %Y") # with month as a word
(tenweeks <- seq(today, length.out=10, by="1 week")) # next ten weeks
weekdays(today)
months(tenweeks)
as.Date(.leap.seconds)
```

DateClasses *Date-Time Classes*

Description

Description of the classes "POSIXlt" and "POSIXct" representing calendar dates and times (to the nearest second).

Usage

```
## S3 method for class 'POSIXct':
print(x, ...)

## S3 method for class 'POSIXct':
summary(object, digits = 15, ...)
```

```
time + z
time - z
time1 lop time2
```

Arguments

<code>x</code> , <code>object</code>	An object to be printed or summarized from one of the date-time classes.
<code>digits</code>	Number of significant digits for the computations: should be high enough to represent the least important time unit exactly.
<code>...</code>	Further arguments to be passed from or to other methods.
<code>time</code>	date-time objects
<code>time1</code> , <code>time2</code>	date-time objects or character vectors. (Character vectors are converted by <code>as.POSIXct</code> .)
<code>z</code>	a numeric vector (in seconds)
<code>lop</code>	One of <code>==</code> , <code>!=</code> , <code><</code> , <code><=</code> , <code>></code> or <code>>=</code> .

Details

There are two basic classes of date/times. Class `"POSIXct"` represents the (signed) number of seconds since the beginning of 1970 as a numeric vector. Class `"POSIXlt"` is a named list of vectors representing

sec 0–61: seconds

min 0–59: minutes

hour 0–23: hours

mday 1–31: day of the month

mon 0–11: months after the first of the year.

year Years since 1900.

wday 0–6 day of the week, starting on Sunday.

yday 0–365: day of the year.

isdst Daylight savings time flag. Positive if in force, zero if not, negative if unknown.

The classes correspond to the POSIX/C99 constructs of ‘calendar time’ (the `time_t` data type) and ‘local time’ (or broken-down time, the `struct tm` data type), from which they also inherit their names.

`"POSIXct"` is more convenient for including in data frames, and `"POSIXlt"` is closer to human-readable forms. A virtual class `"POSIXt"` inherits from both of the classes: it is used to allow operations such as subtraction to mix the two classes.

Components `wday` and `yday` of `"POSIXlt"` are for information, and are not used in the conversion to calendar time. However, `isdst` is needed to distinguish times at the end of DST: typically 1am to 2am occurs twice, first in DST and then in standard time. At all other times `isdst` can be deduced from the first six values, but the behaviour if it is set incorrectly is platform-dependent.

Logical comparisons and limited arithmetic are available for both classes. One can add or subtract a number of seconds from a date-time object, but not add two date-time objects. Subtraction of two date-time objects is equivalent to using `difftime`. Be aware that `"POSIXlt"` objects will be interpreted as being in the current timezone for these operations, unless a timezone has been specified.

"POSIXlt" objects will often have an attribute "tzzone", a character vector of length 3 giving the timezone name from the TZ environment variable and the names of the base timezone and the alternate (daylight-saving) timezone. Sometimes this may just be of length one, giving the timezone name.

"POSIXct" objects may also have an attribute "tzzone", a character vector of length one. If set, it will determine how the object is converted to class "POSIXlt" and in particular how it is printed. This is usually desirable, but if you want to specify an object in a particular timezone but to be printed in the current timezone you may want to remove the "tzzone" attribute (e.g. by `c(x)`).

Unfortunately, the conversion is complicated by the operation of time zones and leap seconds (23 days have been 86401 seconds long so far: the times of the extra seconds are in the object `.leap.seconds`). The details of this are entrusted to the OS services where possible. This always covers the period 1970–2037, and on most machines back to 1902 (when time zones were in their infancy). Outside the platform limits we use our own C code. This uses the offset from GMT in use either for 1902 (when there was no DST) or that predicted for one of 2030 to 2037 (chosen so that the likely DST transition days are Sundays), and uses the alternate (daylight-saving) timezone only if `isdst` is positive or (if `-1`) if DST was predicted to be in operation in the 2030s on that day. (There is no reason to suppose that the DST rules will remain the same in the future, and indeed the US legislated in 2005 to change its rules as from 2007, with a possible future reversion.)

It seems that some rare systems use leap seconds, but most ignore them (as required by POSIX). This is detected and corrected for at build time, so all "POSIXct" times used by R do not include leap seconds. (Conceivably this could be wrong if the system has changed since build time, just possibly by changing locales or the 'zoneinfo' database.)

Using `c` on "POSIXlt" objects converts them to the current time zone.

A few times have specific issues. First, the leapseconds are ignored, and real times such as "2005-12-31 23:59:60" are (probably) treated as the next second. However, they will never be generated by R, and are unlikely to arise as input. Second, on some OSes there is a problem in the POSIX/C99 standard with "1969-12-31 23:59:59", which is `-1` in calendar time and is used as an error code. Thus `as.POSIXct("1969-12-31 23:59:59", format="%Y-%m-%d %H:%M:%S", tz="UTC")` may give NA, and hence `as.POSIXct("1969-12-31 23:59:59", tz="UTC")` will give "1969-12-31 23:59:50". Other OSes report errors separately and so are able to handle that time as valid.

Sub-second Accuracy

Classes "POSIXct" and "POSIXlt" are able to express fractions of a second. (Conversion of fractions between the two forms may not be exact, but will have better than microsecond accuracy.)

Fractional seconds are printed only if `options("digits.secs")` is set: see `strptime`.

Warning

Some Unix-like systems (especially Linux ones) do not have "TZ" set, yet have internal code that expects it (as does POSIX). We have tried to work around this, but if you get unexpected results try setting "TZ". See `as.POSIXlt` for valid settings.

See Also

`Dates` for dates without times.

`as.POSIXct` and `as.POSIXlt` for conversion between the classes.

`strptime` for conversion to and from character representations.

`Sys.time` for clock time as a "POSIXct" object.

`difftime` for time intervals.

`cut.POSIXt`, `seq.POSIXt`, `round.POSIXt` and `trunc.POSIXt` for methods for these classes.

`weekdays.POSIXt` for convenience extraction functions.

Examples

```
(z <- Sys.time())           # the current date, as class "POSIXct"

Sys.time() - 3600           # an hour ago

as.POSIXlt(Sys.time(), "GMT") # the current time in GMT
format(.leap.seconds)        # all 23 leapseconds in your timezone
print(.leap.seconds, tz="PST8PDT") # and in Seattle's
```

dcf

Read and Write Data in DCF Format

Description

Reads or writes an R object from/to a file in Debian Control File format.

Usage

```
read.dcf(file, fields = NULL, all = FALSE)

write.dcf(x, file = "", append = FALSE,
          indent = 0.1 * getOption("width"),
          width = 0.9 * getOption("width"))
```

Arguments

<code>file</code>	either a character string naming a file or a connection. "" indicates output to the console. For <code>read.dcf</code> this can name a gzip-compressed file.
<code>fields</code>	Fields to read from the DCF file. Default is to read all fields.
<code>all</code>	a logical indicating whether in case of multiple occurrences of a field in a record, all these should be gathered. If <code>all</code> is false (default), only the last such occurrence is used.
<code>x</code>	the object to be written, typically a data frame. If not, it is attempted to coerce <code>x</code> to a data frame.
<code>append</code>	logical. If TRUE, the output is appended to the file. If FALSE, any existing file of the name is destroyed.
<code>indent</code>	a positive integer specifying the indentation for continuation lines in output entries.
<code>width</code>	a positive integer giving the target column for wrapping lines in the output.

Details

DCF is a simple format for storing databases in plain text files that can easily be directly read and written by humans. DCF is used in various places to store R system information, like descriptions and contents of packages.

The DCF rules as implemented in R are:

1. A database consists of one or more records, each with one or more named fields. Not every record must contain each field. Fields may appear more than once in a record.
2. Regular lines start with a non-whitespace character.
3. Regular lines are of form `tag:value`, i.e., have a name `tag` and a value for the field, separated by `:` (only the first `:` counts). The value can be empty (=whitespace only).
4. Lines starting with whitespace are continuation lines (to the preceding field) if at least one character in the line is non-whitespace. Continuation lines where the only non-whitespace character is a `'.'` are taken as blank lines (allowing for multi-paragraph field values).
5. Records are separated by one or more empty (=whitespace only) lines.

By default, `read.dcf` returns a character matrix with one row per record and one column per field. Leading and trailing whitespace of field values is ignored. If a tag name is specified, but the corresponding value is empty, then an empty string is returned. If the tag name of a field is never used in a record, then `NA` is returned. If fields are repeated within a record, the last one encountered is returned. Malformed lines lead to an error. If `all` is true, a data frame is returned, again with one row per record and one column per field, and columns lists of character vectors for fields with multiple occurrences, and character vectors otherwise.

`write.dcf` does not write `NA` fields.

See Also

[write.table](#).

Examples

```
## Create a reduced version of the 'CONTENTS' file in package 'splines'
x <- read.dcf(file = system.file("CONTENTS", package = "splines"),
              fields = c("Entry", "Description"))
write.dcf(x)
```

debug

Debug a Function

Description

Set or unset the debugging flag on a function.

Usage

```
debug (fun)
undebug (fun)
```

Arguments

`fun` any interpreted R function.

Details

When a function flagged for debugging is entered, normal execution is suspended and the body of function is executed one statement at a time. A new browser context is initiated for each step (and the previous one destroyed).

At the debug prompt the user can enter commands or R expressions. The commands are

n (or just return). Advance to the next step.

c continue to the end of the current context: e.g. to the end of the loop if within a loop or to the end of the function.

cont synonym for *c*.

where print a stack trace of all active function calls.

Q exit the browser and the current evaluation and return to the top-level prompt.

(Leading and trailing whitespace is ignored, except for return).

Anything else entered at the debug prompt is interpreted as an R expression to be evaluated in the calling environment: in particular typing an object name will cause the object to be printed, and `ls()` lists the objects in the calling frame. (If you want to look at an object with a name such as *n*, print it explicitly.)

If a function is defined inside a function, single-step though to the end of its definition, and then call `debug` on its name.

In order to debug S4 methods (see [Methods](#)), you need to use `trace`, typically calling `browser`, e.g., as

```
trace("plot", browser, exit=browser, signature = c("track",
"missing"))
```

See Also

`browser`, `trace`; `traceback` to see the stack after an `Error: ... message`; `recover` for another debugging approach.

Defunct

Marking Objects as Defunct

Description

When a function is removed from R it should be replaced by a function which calls `.Defunct`.

Usage

```
.Defunct(new, package = NULL, msg)
```

Arguments

<code>new</code>	character string: A suggestion for a replacement function.
<code>package</code>	character string: The package to be used when suggesting where the defunct function might be listed.
<code>msg</code>	character string: A message to be printed, if missing a default message is used.

Details

`.Defunct` is called from `defunct` functions. Functions should be listed in `help("pkg-defunct")` for an appropriate `pkg`, including `base`.

See Also

[Deprecated.](#)

`base-defunct` and so on which list the `defunct` functions in the packages.

delayedAssign *Delay Evaluation*

Description

`delayedAssign` creates a *promise* to evaluate the given expression if its value is requested. This provides direct access to the *lazy evaluation* mechanism used by **R** for the evaluation of (interpreted) functions.

Usage

```
delayedAssign(x, value, eval.env = parent.frame(1),
              assign.env = parent.frame(1))
```

Arguments

<code>x</code>	a variable name (given as a quoted string in the function call)
<code>value</code>	an expression to be assigned to <code>x</code>
<code>eval.env</code>	an environment in which to evaluate <code>value</code>
<code>assign.env</code>	an environment in which to assign <code>x</code>

Details

Both `eval.env` and `assign.env` default to the currently active environment.

The expression assigned to a promise by `delayedAssign` will not be evaluated until it is eventually ‘forced’. This happens when the variable is first accessed.

When the promise is eventually forced, it is evaluated within the environment specified by `eval.env` (whose contents may have changed in the meantime). After that, the value is fixed and the expression will not be evaluated again.

Value

This function is invoked for its side effect, which is assigning a promise to evaluate `value` to the variable `x`.

See Also

[substitute](#), to see the expression associated with a promise.

Examples

```

msg <- "old"
delayedAssign("x", msg)
msg <- "new!"
x #- new!
substitute(x) #- msg

delayedAssign("x", {
  for(i in 1:3)
    cat("yippee!\n")
  10
})

x^2 #- yippee
x^2 #- simple number

e <- (function(x, y = 1, z) environment())(1+2, "y", {cat(" HO! "); pi+2})
(le <- as.list(e)) # evaluates the promises

```

deparse

*Expression Deparsing***Description**

Turn unevaluated expressions into character strings.

Usage

```

deparse(expr, width.cutoff = 60,
        backtick = mode(expr) %in% c("call", "expression", "(", "function"),
        control = c("keepInteger", "showAttributes", "keepNA"),
        nlines = -1)

```

Arguments

<code>expr</code>	any R expression.
<code>width.cutoff</code>	integer in [20, 500] determining the cutoff at which line-breaking is tried.
<code>backtick</code>	logical indicating whether symbolic names should be enclosed in backticks if they do not follow the standard syntax.
<code>control</code>	character vector of deparsing options. See .deparseOpts .
<code>nlines</code>	the maximum number of lines to produce. Negative values indicate no limit.

Details

This function turns unevaluated expressions (where ‘expression’ is taken in a wider sense than the strict concept of a vector of mode "expression" used in [expression](#)) into character strings (a kind of inverse to [parse](#)).

A typical use of this is to create informative labels for data sets and plots. The example shows a simple use of this facility. It uses the functions `deparse` and `substitute` to create labels for a plot which are character string versions of the actual arguments to the function `myplot`.

The default for the `backtick` option is not to quote single symbols but only composite expressions. This is a compromise to avoid breaking existing code.

Using `control = "all"` comes closest to making `deparse()` an inverse of `parse()`. However, not all objects are deparse-able even with this option and a warning will be issued if the function recognizes that it is being asked to do the impossible.

Numeric and complex vectors are converted using 15 significant digits: see `as.character` for more details.

`width.cutoff` is a lower bound for the line lengths: deparsing a line proceeds until at least `width.cutoff` bytes have been output and e.g. `arg = value` expressions will not be split across lines.

Note

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be deparsed as an attribute.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`substitute`, `parse`, `expression`.

Quotes for quoting conventions, including backticks.

Examples

```
require(stats); require(graphics)

deparse(args(lm))
deparse(args(lm), width = 500)
myplot <-
function(x, y) {
  plot(x, y, xlab=deparse(substitute(x)),
       ylab=deparse(substitute(y)))
}
e <- quote(`foo bar`)
deparse(e)
deparse(e, backtick=TRUE)
e <- quote(`foo bar`+1)
deparse(e)
deparse(e, control = "all")
```

deparseOpts

Options for Expression Deparsing

Description

Process the deparsing options for `deparse`, `dput` and `dump`.

Usage

```
.deparseOpts(control)
```

Arguments

`control` character vector of deparsing options.

Details

This is called by `deparse`, `dput` and `dump` to process their `control` argument.

The `control` argument is a vector containing zero or more of the following strings. Partial string matching is used.

keepInteger Either surround integer vectors by `as.integer()` or use suffix `L`, so they are not converted to type `double` when parsed. This includes making sure that integer NAs are preserved (via `NA_integer_` if there are no non-NA values in the vector, unless `"S_compatible"` is set).

quoteExpressions Surround expressions with `quote()`, so they are not evaluated when parsed.

showAttributes If the object has attributes (other than a `source` attribute), use `structure()` to display them as well as the object value. This is the default for `deparse` and `dput`.

useSource If the object has a `source` attribute, display that instead of deparsing the object. Currently only applies to function definitions.

warnIncomplete Some exotic objects such as `environments`, external pointers, etc. can not be deparsed properly. This option causes a warning to be issued if any of those may give problems.

Also, the parser in `R < 2.7.0` would only accept strings of up to 8192 bytes, and this option gives a warning for longer strings.

keepNA Integer, real and character NAs are surrounded by coercion where necessary to ensure that they are parsed to the same type.

all An abbreviated way to specify all of the options listed above. This is the default for `dump`, and the options used by `edit` (which are fixed).

delayPromises Deparse promises in the form `<promise: expression>` rather than evaluating them. The value and the environment of the promise will not be shown and the deparsed code cannot be sourced.

S_compatible Make deparsing as far as possible compatible with `S` and `R < 2.5.0`. For compatibility with `S`, integer values of double vectors are deparsed with a trailing decimal point.

For the most readable (but perhaps incomplete) display, use `control = NULL`. This displays the object's value, but not its attributes. The default in `deparse` is to display the attributes as well, but not to use any of the other options to make the result parseable. (`dput` and `dump` do use more default options, and printing of functions without sources uses `c("keepInteger", "keepNA")`.)

Using `control = "all"` comes closest to making `deparse()` an inverse of `parse()`. However, not all objects are deparse-able even with this option. A warning will be issued if the function recognizes that it is being asked to do the impossible.

Value

A numerical value corresponding to the options selected.

Deprecated

Marking Objects as Deprecated

Description

When an object is about removed from R it is first deprecated and should include a call to `.Deprecated`.

Usage

```
.Deprecated(new, package=NULL, msg)
```

Arguments

<code>new</code>	character string: A suggestion for a replacement function.
<code>package</code>	character string: The package to be used when suggesting where the deprecated function might be listed.
<code>msg</code>	character string: A message to be printed, if missing a default message is used.

Details

`.Deprecated("<new name>")` is called from deprecated functions. The original help page for these functions is often available at `help("oldName-deprecated")` (note the quotes). Functions should be listed in `help("pkg-deprecated")` for an appropriate `pkg`, including `base`.

See Also

[Defunct](#)

[base-deprecated](#) and so on which list the deprecated functions in the packages.

det

Calculate the Determinant of a Matrix

Description

`det` calculates the determinant of a matrix. `determinant` is a generic function that returns separately the modulus of the determinant, optionally on the logarithm scale, and the sign of the determinant.

Usage

```
det(x, ...)  
determinant(x, logarithm = TRUE, ...)
```

Arguments

<code>x</code>	numeric matrix.
<code>logarithm</code>	logical; if TRUE (default) return the logarithm of the modulus of the determinant.
<code>...</code>	Optional arguments. At present none are used. Previous versions of <code>det</code> allowed an optional <code>method</code> argument. This argument will be ignored but will not produce an error.

Details

The determinant function uses an LU decomposition and the `det` function is simply a wrapper around a call to `determinant`.

Often, computing the determinant is *not* what you should be doing to solve a given problem.

Value

For `det`, the determinant of `x`. For `determinant`, a list with components

<code>modulus</code>	a numeric value. The modulus (absolute value) of the determinant if <code>logarithm</code> is FALSE; otherwise the logarithm of the modulus.
<code>sign</code>	integer; either +1 or -1 according to whether the determinant is positive or negative.

Examples

```
(x <- matrix(1:4, ncol=2))
unlist(determinant(x))
det(x)

det(print(cbind(1,1:3,c(2,0,1))))
```

 detach

Detach Objects from the Search Path

Description

Detach a database, i.e., remove it from the `search()` path of available R objects. Usually, this is either a `data.frame` which has been `attached` or a package which was required previously.

Usage

```
detach(name, pos = 2, version, unload = FALSE)
```

Arguments

<code>name</code>	The object to detach. Defaults to <code>search()[pos]</code> . This can be an unquoted name or a character string but <i>not</i> a character vector. If a number is supplied this is taken as <code>pos</code> .
<code>pos</code>	Index position in <code>search()</code> of database to detach. When <code>name</code> is a number, <code>pos = name</code> is used.

version	A character string denoting a version number of the package to be removed. This should be used only with a versioned installation of the package: see library .
unload	A logical value indicating whether or not to attempt to unload the namespace and S4 methods when a package is being detached. If the package has a namespace and <code>unload</code> is TRUE, then <code>detach</code> will attempt to unload the namespace and remove any S4 methods defined by the package. If the namespace is in use or <code>unload</code> is FALSE, no unloading will occur.

Details

This most commonly used with a single number argument referring to a position on the search list, and can also be used with a unquoted or quoted name of an item on the search list such as `package:tools`.

When a package have been loaded with an explicit version number it can be detached using the name shown by [search](#) or by supplying `name` and `version`: see the examples.

If a package has a namespace, detaching it does not by default unload the namespace (and may not even with `unload=TRUE`), and detaching will not in general unload any dynamically loaded compiled code (DLLs). Further, registered S3 methods from the namespace will not be removed. If you use [library](#) on a package whose name space is loaded, it attaches the exports of the loaded name space. So detaching and re-attaching a package may not refresh some or all components of the package, and is inadvisable.

Value

The attached database is returned invisibly, either as `data.frame` or as `list`.

Note

You cannot detach either the workspace (position 1) or the **base** package (the last item in the search list).

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[attach](#), [library](#), [search](#), [objects](#), [unloadNamespace](#), [library.dynam.unload](#).

Examples

```
require(splines) # package
detach(package:splines)
## could equally well use detach("package:splines")
## but NOT pkg <- "package:splines"; detach(pkg)
## Instead, use
library(splines)
pkg <- "package:splines"
detach(pos = match(pkg, search()))

## careful: do not do this unless 'splines' is not already loaded.
library(splines)
detach(2) # 'pos' used for 'name'
```

```
## an example of the name argument to attach
## and of detaching a database named by a character vector
attach_and_detach <- function(db, pos=2)
{
  name <- deparse(substitute(db))
  attach(db, pos=pos, name=name)
  print(search()[pos])
  eval(substitute(detach(n), list(n=name)))
}
attach_and_detach(women, pos=3)

## Not run:
## Using a versioned install
library(ash, version="1.0-9") # or perhaps just library(ash)
# then one of
detach("package:ash", version="1.0-9")
# or
detach("package:ash_1.0-9")
## End(Not run)
```

diag

*Matrix Diagonals***Description**

Extract or replace the diagonal of a matrix, or construct a diagonal matrix.

Usage

```
diag(x = 1, nrow, ncol)
diag(x) <- value
```

Arguments

<code>x</code>	a matrix, vector or 1D array.
<code>nrow, ncol</code>	Optional dimensions for the result.
<code>value</code>	either a single value or a vector of length equal to that of the current diagonal. Should be of a mode which can be coerced to that of <code>x</code> .

Value

If `x` is a matrix then `diag(x)` returns the diagonal of `x`. The resulting vector will have `names` if the matrix `x` has matching column and row names.

If `x` is a vector (or 1D array) of length two or more, then `diag(x)` returns a diagonal matrix whose diagonal is `x`.

If `x` is a vector of length one then `diag(x)` returns an identity matrix of order the nearest integer to `x`. The dimension of the returned matrix can be specified by `nrow` and `ncol` (the default is square).

The replacement form sets the diagonal of the matrix `x` to the given value(s).

Note

Using `diag(x)` can have unexpected effects if `x` is a vector that could be of length one. Use `diag(x, nrow = length(x))` for consistent behaviour.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`upper.tri`, `lower.tri`, `matrix`.

Examples

```
require(stats)
dim(diag(3))
diag(10,3,4) # guess what?
all(diag(1:3) == {m <- matrix(0,3,3); diag(m) <- 1:3; m})

diag(var(M <- cbind(X = 1:5, Y = stats::rnorm(5))))
#-> vector with names "X" and "Y"

rownames(M) <- c(colnames(M), rep("", 3));
M; diag(M) # named as well
```

diff

Lagged Differences

Description

Returns suitably lagged and iterated differences.

Usage

```
diff(x, ...)

## Default S3 method:
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'POSIXt':
diff(x, lag = 1, differences = 1, ...)

## S3 method for class 'Date':
diff(x, lag = 1, differences = 1, ...)
```

Arguments

<code>x</code>	a numeric vector or matrix containing the values to be differenced.
<code>lag</code>	an integer indicating which lag to use.
<code>differences</code>	an integer indicating the order of the difference.
<code>...</code>	further arguments to be passed to or from methods.

Details

`diff` is a generic function with a default method and ones for classes `"ts"`, `"POSIXt"` and `"Date"`.

`NA`'s propagate.

Value

If `x` is a vector of length `n` and `differences=1`, then the computed result is equal to the successive differences `x[(1+lag):n] - x[1:(n-lag)]`.

If `difference` is larger than one this algorithm is applied recursively to `x`. Note that the returned value is a vector which is shorter than `x`.

If `x` is a matrix then the difference operations are carried out on each column separately.

`diff.ts`, `diffinv`.

Examples

```
diff(1:10, 2)
diff(1:10, 2, 2)
x <- cumsum(cumsum(1:10))
diff(x, lag = 2)
diff(x, differences = 2)

diff(.leap.seconds)
```

`difftime`

Time Intervals

Description

Create, print and round time intervals.

Usage

```
time1 - time2

difftime(time1, time2, tz = "",
         units = c("auto", "secs", "mins", "hours",
                  "days", "weeks"))

as.difftime(tim, format = "%X", units="auto")

## S3 method for class 'difftime':
round(x, digits = 0, ...)
```

```
## S3 method for class 'difftime':
format(x, ...)
## S3 method for class 'difftime':
units(x)
## S3 replacement method for class 'difftime':
units(x) <- value
## S3 method for class 'difftime':
as.double(x, units="auto", ...)
```

Arguments

`time1`, `time2` [date-time](#) or [date](#) objects.

`tz` a timezone specification to be used for the conversion. System-specific, but "" is the current time zone, and "GMT" is UTC.

`units` character. Units in which the results are desired. Can be abbreviated.

`value` character. Like `units` above, except that abbreviations are not allowed.

`tim` character string or numeric value specifying a time interval.

`format` character specifying the format of `tim`: see [strptime](#). The default is a locale-specific time format.

`x` an object inheriting from class "difftime".

`digits` integer. Number of significant digits to retain.

... arguments to be passed to or from other methods.

Details

Function `difftime` calculates a difference of two date/time objects and returns an object of class "difftime" with an attribute indicating the units. There is a [round](#) method for objects of this class, as well as methods for the group-generic (see [Ops](#)) logical and arithmetic operations.

If `units = "auto"`, a suitable set of units is chosen, the largest possible (excluding "weeks") in which all the absolute differences are greater than one.

Subtraction of date-time objects gives an object of this class, by calling `difftime` with `units="auto"`. Alternatively, `as.difftime()` works on character-coded or numeric time intervals; in the latter case, `units` must be specified, and `format` has no effect.

Limited arithmetic is available on "difftime" objects: they can be added or subtracted, and multiplied or divided by a numeric vector. In addition, adding or subtracting a numeric vector implicitly converts the numeric vector to a "difftime" object with the same units as the "difftime" object.

The units of a "difftime" object can be extracted by the `units` function, which also has an replacement form. If the units are changed, the numerical value is scaled accordingly.

The `as.double` method returns the numeric value expressed in the specified units. Using `units="auto"` means the units of the object.

The `format` method simply formats the numeric value and appends the units as a text string.

See Also

[DateTimeClasses](#).

Examples

```
(z <- Sys.time() - 3600)
Sys.time() - z           # just over 3600 seconds.

## time interval between releases of R 1.2.2 and 1.2.3.
ISODate(2001, 4, 26) - ISODate(2001, 2, 26)

as.difftime(c("0:3:20", "11:23:15"))
as.difftime(c("3:20", "23:15", "2:"), format= "%H:%M")# 3rd gives NA
(z <- as.difftime(c(0,30,60), units="mins"))
as.numeric(z, units="secs")
as.numeric(z, units="hours")
format(z)
```

dim

Dimensions of an Object

Description

Retrieve or set the dimension of an object.

Usage

```
dim(x)
dim(x) <- value
```

Arguments

x	an R object, for example a matrix, array or data frame.
value	For the default method, either NULL or a numeric vector, which is coerced to integer (by truncation).

Details

The functions `dim` and `dim<-` are generic.

`dim` has a method for `data.frames`, which returns the lengths of the `row.names` attribute of `x` and of `x` (as the numbers of rows and columns respectively).

Value

For an array (and hence in particular, for a matrix) `dim` retrieves the `dim` attribute of the object. It is NULL or a vector of mode `integer`.

The replacement method changes the "dim" attribute (provided the new value is compatible) and removes any "dimnames" *and* "names" attributes.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[ncol](#), [nrow](#) and [dimnames](#).

Examples

```
x <- 1:12 ; dim(x) <- c(3,4)
x

# simple versions of nrow and ncol could be defined as follows
nrow0 <- function(x) dim(x)[1]
ncol0 <- function(x) dim(x)[2]
```

 dimnames

Dimnames of an Object

Description

Retrieve or set the dimnames of an object.

Usage

```
dimnames(x)
dimnames(x) <- value
```

Arguments

`x` an R object, for example a matrix, array or data frame.
`value` a possible value for `dimnames(x)`: see the ‘Value’ section.

Details

The functions `dimnames` and `dimnames<-` are generic.

For an [array](#) (and hence in particular, for a [matrix](#)), they retrieve or set the `dimnames` attribute (see [attributes](#)) of the object. A list `value` can have names, and these will be used to label the dimensions of the array where appropriate.

The replacement method for arrays/matrices coerces vector and factor elements of `value` to character, but does not dispatch methods for `as.character`. It coerces zero-length elements to `NULL`, and a zero-length list to `NULL`. If `value` is a list shorter than the number of dimensions, as from R 2.8.0 it is extended with `NULL`s to the needed length.

Both have methods for data frames. The `dimnames` of a data frame are its `row.names` and its `names`. For the replacement method each component of `value` will be coerced by `as.character`.

For a 1D matrix the `names` are the same thing as the (only) component of the `dimnames`.

Value

The `dimnames` of a matrix or array can be `NULL` or a list of the same length as `dim(x)`. If a list, its components are either `NULL` or a character vector with positive length of the appropriate dimension of `x`. The list can be named.

For the `"data.frame"` method both `dimnames` are character vectors, and the `rownames` must contain no duplicates nor missing values.

Note

Setting components of the `dimnames`, e.g. `dimnames(A)[[1]] <- value` is a common paradigm, but note that it will not work if the value assigned is `NULL`. Use `rownames` instead, or (as it does) manipulate the whole `dimnames` list.

colnames0 <- function(x) dimnames(x)[[2]]
```

do.call

Execute a Function Call

Description

`do.call` constructs and executes a function call from a name or a function and a list of arguments to be passed to it.

Usage

```
do.call(what, args, quote = FALSE, envir = parent.frame())
```

Arguments

<code>what</code>	either a function or a non-empty character string naming the function to be called.
<code>args</code>	a <i>list</i> of arguments to the function call. The <code>names</code> attribute of <code>args</code> gives the argument names.
<code>quote</code>	a logical value indicating whether to quote the arguments.
<code>envir</code>	an environment within which to evaluate the call. This will be most useful if <code>what</code> is a character string and the arguments are symbols or quoted expressions.

Details

If `quote` is `FALSE`, the default, then the arguments are evaluated (in the calling environment, not `envir`). If `quote` is `TRUE` then each argument is quoted (see `quote`) so that the effect of argument evaluation is to remove the quotes – leaving the original arguments unevaluated when the call is constructed.

The behavior of some functions, such as `substitute`, will not be the same for functions evaluated using `do.call` as if they were evaluated from the interpreter. The precise semantics are currently undefined and subject to change.

Value

The result of the (evaluated) function call.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

`call` which creates an unevaluated call.

Examples

```
do.call("complex", list(imag = 1:3))

## if we already have a list (e.g. a data frame)
## we need c() to add further arguments
tmp <- expand.grid(letters[1:2], 1:3, c("+", "-"))
do.call("paste", c(tmp, sep=""))

do.call(paste, list(as.name("A"), as.name("B")), quote=TRUE)

## examples of where objects will be found.
A <- 2
f <- function(x) print(x^2)
env <- new.env()
assign("A", 10, envir = env)
assign("f", f, envir = env)
f <- function(x) print(x)
f(A) # 2
do.call("f", list(A)) # 2
do.call("f", list(A), envir=env) # 4
do.call(f, list(A), envir=env) # 2
do.call("f", list(quote(A)), envir=env) # 100
do.call(f, list(quote(A)), envir=env) # 10
do.call("f", list(as.name("A")), envir=env) # 100

eval(call("f", A)) # 2
eval(call("f", quote(A))) # 2
eval(call("f", A), envir=env) # 4
eval(call("f", quote(A)), envir=env) # 100
```

double

Double-Precision Vectors

Description

Create, coerce to or test for a double-precision vector.

Usage

```
double(length = 0)
as.double(x, ...)
is.double(x)

single(length = 0)
as.single(x, ...)
```

Arguments

<code>length</code>	desired length.
<code>x</code>	object to be coerced or tested.
<code>...</code>	further arguments passed to or from other methods.

Details

`double` creates a double-precision vector of the specified length. The elements of the vector are all equal to 0. It is identical to `numeric` (and `real`).

`as.double` is a generic function. It is identical to `as.numeric` (and `as.real`). Methods should return an object of base type "double".

`is.double` is a test of double [type](#).

R has no single precision data type. All real numbers are stored in double precision format. The functions `as.single` and `single` are identical to `as.double` and `double` except they set the attribute `Csingle` that is used in the `.C` and `.Fortran` interface, and they are intended only to be used in that context.

Value

`double` creates a double-precision vector of the specified length. The elements of the vector are all equal to 0.

`as.double` attempts to coerce its argument to be of double type: like `as.vector` it strips attributes including names. (To ensure that an object is of double type without stripping attributes, use `storage.mode`.) Character strings containing either a decimal representation or a hexadecimal representation (starting with `0x` or `0X`) can be converted. `as.double` for factors yields the codes underlying the factor levels, not the numeric representation of the labels, see also `factor`.

`is.double` returns TRUE or FALSE depending on whether its argument is of double [type](#) or not.

Note on names

It is a historical anomaly that **R** has three names for its floating-point vectors, `double`, `numeric` and `real`.

`double` is the name of the [type](#). `numeric` is the name of the [mode](#) and also of the implicit [class](#). As an S4 formal class, use "numeric" (there was a formal class "double" prior to **R** 2.7.0).

`real` is deprecated and should not be used in new code.

The potential confusion is that **R** has used [mode](#) "numeric" to mean 'double or integer', which conflicts with the S4 usage. Thus `is.numeric` tests the mode, not the class, but `as.numeric` (which is identical to `as.double`) coerces to the class.

all(double(3) == 0)
```

dput

Write an Object to a File or Recreate it

Description

Writes an ASCII text representation of an R object to a file or connection, or uses one to recreate the object.

Usage

```
dput(x, file = "",
      control = c("keepNA", "keepInteger", "showAttributes"))

dget(file)
```

Arguments

<code>x</code>	an object.
<code>file</code>	either a character string naming a file or a connection. "" indicates output to the console.
<code>control</code>	character vector indicating deparsing options. See .deparseOpts for their description.

Details

`dput` opens `file` and deparses the object `x` into that file. The object name is not written (unlike `dump`). If `x` is a function the associated environment is stripped. Hence scoping information can be lost.

Deparsing an object is difficult, and not always possible. With the default `control`, `dput()` attempts to deparse in a way that is readable, but for more complex or unusual objects (see [dump](#), not likely to be parsed as identical to the original. Use `control = "all"` for the most complete deparsing; use `control = NULL` for the simplest deparsing, not even including attributes.

`dput` will warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

To display saved source rather than deparsing the internal representation include `"useSource"` in `control`. R currently saves source only for function definitions.

Value

For `dput`, the first argument invisibly.

For `dget`, the object created.

Note

To avoid the risk of a source attribute out of sync with the actual function definition, the source attribute of a function will never be written as an attribute.

See Also

[deparse](#), [dump](#), [write](#).

Examples

```
## Write an ASCII version of mean to the file "foo"
dput(mean, "foo")
## And read it back into 'bar'
bar <- dget("foo")
unlink("foo")
## Create a function with comments
baz <- function(x) {
  # Subtract from one
  1-x
}
## and display it
dput(baz)
## and now display the saved source
dput(baz, control = "useSource")
```

drop

Drop Redundant Extent Information

Description

Delete the dimensions of an array which have only one level.

Usage

```
drop(x)
```

Arguments

`x` an array (including a matrix).

Value

If `x` is an object with a `dim` attribute (e.g., a matrix or `array`), then `drop` returns an object like `x`, but with any extents of length one removed. Any accompanying `dimnames` attribute is adjusted and returned with `x`: if the result is a vector the names are taken from the `dimnames` (if any). If the result is a length-one vector, the names are taken from the first dimension with a `dimname`.

Array subsetting (`[]`) performs this reduction unless used with `drop = FALSE`, but sometimes it is useful to invoke `drop` directly.

See Also

`drop1` which is used for dropping terms in models.

Examples

```
dim(drop(array(1:12, dim=c(1,3,1,1,2,1,2))))# = 3 2 2
drop(1:3 %**% 2:4)# scalar product
```

 dump

Text Representations of R Objects

Description

This function takes a vector of names of R objects and produces text representations of the objects on a file or connection. A dump file can usually be `sourced` into another R (or S) session.

Usage

```
dump(list, file = "dumpdata.R", append = FALSE,
      control = "all", envir = parent.frame(), evaluate = TRUE)
```

Arguments

<code>list</code>	character. The names of one or more R objects to be dumped.
<code>file</code>	either a character string naming a file or a connection. "" indicates output to the console.
<code>append</code>	if TRUE and <code>file</code> is a character string, output will be appended to <code>file</code> ; otherwise, it will overwrite the contents of <code>file</code> .
<code>control</code>	character vector indicating deparsing options. See <code>.deparseOpts</code> for their description.
<code>envir</code>	the environment to search for objects.
<code>evaluate</code>	logical. Should promises be evaluated?

Details

If some of the objects named do not exist (in scope), they are omitted, with a warning. If `file` is a file and no objects exist then no file is created.

`sourceing` may not produce an identical copy of dumped objects. A warning is issued if it is likely that problems will arise, for example when dumping exotic or complex objects (see the Note).

`dump` will also warn if fewer characters were written to a file than expected, which may indicate a full or corrupt file system.

A `dump` file can be `sourced` into another R (or perhaps S) session, but the function `save` is designed to be used for transporting R data, and will work with R objects that `dump` does not handle.

To produce a more readable representation of an object, use `control = NULL`. This will skip attributes, and will make other simplifications that make `source` less likely to produce an identical copy. See `deparse` for details.

To deparse the internal representation of a function rather than displaying the saved source, use `control = c("keepInteger", "warnIncomplete", "keepNA")`. This will lose all formatting and comments, but may be useful in those cases where the saved source is no longer correct.

Promises will normally only be encountered by users as a result of lazy-loading (when the default `evaluate = TRUE` is essential) and after the use of `delayedAssign`, when `evaluate = FALSE` might be intended.

Value

An invisible character vector containing the names of the objects which were dumped.

Note

As `dump` is defined in the base name space, the **base** package will be searched *before* the global environment unless `dump` is called from the top level prompt or the `envir` argument is given explicitly.

To avoid the risk of a source attribute becoming out of sync with the actual function definition, the source attribute of a function will never be dumped as an attribute.

Currently environments, external pointers, weak references and objects of type `S4` are not deparsed in a way that can be `sourced`. In addition, language objects are deparsed in a simple way whatever the value of `control`, and this includes not dumping their attributes (which will result in a warning).

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`dput`, `dget`, `write`.
`save` for a more reliable way to save R objects.

Examples

```
x <- 1; y <- 1:10
dump(ls(pattern = '[xyz]'), "xyz.Rdmped")
print(.Last.value)
unlink("xyz.Rdmped")
```

duplicated

*Determine Duplicate Elements***Description**

Determines which elements of a vector or data frame are duplicates of elements with smaller subscripts, and returns a logical vector indicating which elements (rows) are duplicates.

Usage

```
duplicated(x, incomparables = FALSE, ...)

## Default S3 method:
duplicated(x, incomparables = FALSE,
           fromLast = FALSE, ...)

## S3 method for class 'array':
duplicated(x, incomparables = FALSE, MARGIN = 1,
           fromLast = FALSE, ...)
```

Arguments

<code>x</code>	a vector or a data frame or an array or NULL.
<code>incomparables</code>	a vector of values that cannot be compared. <code>FALSE</code> is a special value, meaning that all values can be compared, and may be the only value accepted for methods other than the default. It will be coerced internally to the same type as <code>x</code> .
<code>fromLast</code>	logical indicating if duplication should be considered from the reverse side, i.e., the last (or rightmost) of identical elements would correspond to <code>duplicated=FALSE</code> .
<code>...</code>	arguments for particular methods.
<code>MARGIN</code>	the array margin to be held fixed: see apply .

Details

This is a generic function with methods for vectors (including lists), data frames and arrays (including matrices).

`duplicated(x, fromLast=TRUE)` is equivalent to but faster than `rev(duplicated(rev(x)))`.

The data frame method works by pasting together a character representation of the rows separated by `\r`, so may be imperfect if the data frame has characters with embedded carriage returns or columns which do not reliably map to characters.

The array method calculates for each element of the sub-array specified by `MARGIN` if the remaining dimensions are identical to those for an earlier (or later, when `fromLast=TRUE`) element (in row-major order). This would most commonly be used to find duplicated rows (the default) or columns (with `MARGIN = 2`).

Missing values are regarded as equal, but `NaN` is not equal to `NA_real_`.

Values in `incomparables` will never be marked as duplicated. This is intended to be used for a fairly small set of values and will not be efficient for a very large set.

Value

For a vector input, a logical vector of the same length as `x`. For a data frame, a logical vector with one element for each row. For a matrix or array, a logical array with the same dimensions and `dimnames`.

Warning

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see [vector](#)) or differ only in their attributes. In the worst case it is $O(n^2)$.

[unique](#).

Examples

```
x <- c(9:20, 1:5, 3:7, 0:8)
## extract unique elements
(xu <- x[!duplicated(x)])
## similar, but not the same:
(xu2 <- x[!duplicated(x, fromLast = TRUE)])

## xu == unique(x) but unique(x) is more efficient
stopifnot(identical(xu, unique(x)),
          identical(xu2, unique(x, fromLast = TRUE)))

duplicated(iris)[140:143]

duplicated(iris3, MARGIN = c(1, 3))
```

dyn.load

Foreign Function Interface

Description

Load or unload DLLs (also known as shared objects), and test whether a C function or Fortran subroutine is available.

Usage

```

dyn.load(x, local = TRUE, now = TRUE, ...)
dyn.unload(x)

is.loaded(symbol, PACKAGE = "", type = "")

```

Arguments

x	a character string giving the pathname to a DLL, also known as a dynamic shared object. (See ‘Details’ for what these terms mean.)
local	a logical value controlling whether the symbols in the DLL are stored in their own local table and not shared across DLLs, or added to the global symbol table. Whether this has any effect is system-dependent.
now	a logical controlling whether all symbols are resolved (and relocated) immediately the library is loaded or deferred until they are used. This control is useful for developers testing whether a library is complete and has all the necessary symbols, and for users to ignore missing symbols. Whether this has any effect is system-dependent.
...	other arguments for future expansion.
symbol	a character string giving a symbol name.
PACKAGE	if supplied, confine the search for the name to the DLL given by this argument (plus the conventional extension, ‘.so’, ‘.sl’, ‘.dll’, ...). This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols. Use PACKAGE="base" for symbols linked in to R. This is used in the same way as in <code>.C</code> , <code>.Call</code> , <code>.Fortran</code> and <code>.External</code> functions
type	The type of symbol to look for: can be any ("", the default), "Fortran", "Call" or "External".

Details

The objects `dyn.load` loads are called ‘dynamically loadable libraries’ (abbreviated to ‘DLL’ on all platforms except Mac OS X, which unfortunately uses the term for a different sort of object). On Unix-alikes they are also called ‘dynamic shared objects’ (‘DSO’), or ‘shared objects’ for short. (The POSIX standards use ‘executable object file’, but no one else does.)

See ‘See Also’ and the *Writing R Extensions* and *R Installation and Administration* manuals for how to create and install a suitable DLL. Note that unlike some versions of S-PLUS, `dyn.load` does not load an object (‘.o’) file but a shared object or DLL.

Unfortunately a very few platforms (e.g. Compaq Tru64) do not handle the `PACKAGE` argument correctly, and may incorrectly find symbols linked into R.

The additional arguments to `dyn.load` mirror the different aspects of the `mode` argument to the `dlopen()` routine on POSIX systems. They are available so that users can exercise greater control over the loading process for an individual library. In general, the default values are appropriate and you should override them only if there is good reason and you understand the implications.

The `local` argument allows one to control whether the symbols in the DLL being attached are visible to other DLLs. While maintaining the symbols in their own name space is good practice, the ability to share symbols across related ‘chapters’ is useful in many cases. Additionally, on certain platforms and versions of an operating system, certain libraries must have their symbols loaded globally to successfully resolve all symbols.

One should be careful of the potential side-effect of using lazy loading via the `now` argument as `FALSE`. If a routine is called that has a missing symbol, the process will terminate immediately and unsaved session variables will be lost. The intended use is for library developers to call specify a value `TRUE` to check that all symbols are actually resolved and for regular users to all with `FALSE` so that missing symbols can be ignored and the available ones can be called.

The initial motivation for adding these was to avoid such termination in the `_init()` routines of the Java virtual machine library. However, symbols loaded locally may not be (read probably) available to other DLLs. Those added to the global table are available to all other elements of the application and so can be shared across two different DLLs.

Some systems do not provide (explicit) support for local/global and lazy/eager symbol resolution. This can be the source of subtle bugs. One can arrange to have warning messages emitted when unsupported options are used. This is done by setting either of the options `verbose` or `warn` to be non-zero via the `options` function. Currently, we know of only 2 platforms that do not provide a value for local load (`RTLD_LOCAL`). These are IRIX6.4 and unpatched versions of Solaris 2.5.1.

There is a short discussion of these additional arguments with some example code available at <http://cm.bell-labs.com/stat/duncan/R/dynload>.

Value

The function `dyn.load` is used for its side effect which links the specified DLL to the executing R image. Calls to `.C`, `.Call`, `.Fortran` and `.External` can then be used to execute compiled C functions or Fortran subroutines contained in the library. The return value of `dyn.load` is an object of class `DLLInfo`. See [getLoadedDLLs](#) for information about this class.

The function `dyn.unload` unlinks the DLL.

`is.loaded` checks if the symbol name is loaded and hence available for use in `.C` or `.Fortran` or `.Call` or `.External`. It will succeed if any one of the four calling functions would succeed in using the entry point unless `type` is specified. (See `.Fortran` for how Fortran symbols are mapped.)

Warning

Do not use `dyn.unload` on a DLL loaded by `library.dynam`: use `library.dynam.unload`. This is needed for system housekeeping.

Note

`is.loaded` requires the name you would give to `.C` etc and **not** (as in S) that remapped by defunct functions `symbol.C` or `symbol.For`.

The creation of DLLs and the runtime linking of them into executing programs is very platform dependent. In recent years there has been some simplification in the process because the C subroutine call `dlopen` has become the POSIX standard for doing this. Under Unix-alikes `dyn.load` uses the `dlopen` mechanism and should work on all platforms which support it. On Windows it uses the standard mechanism (`LoadLibrary`) for loading DLLs.

The original code for loading DLLs in Unix-alikes was provided by Heiner Schwarte. The compatibility code for HP-UX was provided by Luke Tierney.

`.C`, `.Fortran`, `.External`, `.Call`.

Examples

```
is.loaded("hcass2") #-> probably TRUE, as stats is loaded
is.loaded("supsmu") # Fortran entry point in stats
is.loaded("supsmu", "stats", "Fortran")
is.loaded("PDF", type = "External")
```

eapply

Apply a Function over values in an environment

Description

`eapply` applies `FUN` to the named values from an environment and returns the results as a list. The user can request that all named objects are used (normally names that begin with a dot are not). The output is not sorted and no parent environments are searched.

Usage

```
eapply(env, FUN, ..., all.names = FALSE)
```

Arguments

<code>env</code>	environment to be used.
<code>FUN</code>	the function to be applied, found <i>via</i> <code>match.fun</code> . In the case of functions like <code>+</code> , <code>%*%</code> , etc., the function name must be backquoted or quoted.
<code>...</code>	optional arguments to <code>FUN</code> .
<code>all.names</code>	a logical indicating whether to apply the function to all values

See Also

`lapply`.

Examples

```
require(utils); require(stats)

env <- new.env()
env$a <- 1:10
env$beta <- exp(-3:3)
env$logic <- c(TRUE,FALSE,FALSE,TRUE)
# what have we there?
eapply(env, str)

# compute the mean for each list element
eapply(env, mean)
# median and quartiles for each list element
eapply(env, quantile, probs = 1:3/4)
eapply(env, quantile)
```

eigen

*Spectral Decomposition of a Matrix***Description**

Computes eigenvalues and eigenvectors of real or complex matrices.

Usage

```
eigen(x, symmetric, only.values = FALSE, EISPACK = FALSE)
```

Arguments

<code>x</code>	a matrix whose spectral decomposition is to be computed.
<code>symmetric</code>	if TRUE, the matrix is assumed to be symmetric (or Hermitian if complex) and only its lower triangle (diagonal included) is used. If <code>symmetric</code> is not specified, the matrix is inspected for symmetry.
<code>only.values</code>	if TRUE, only the eigenvalues are computed and returned, otherwise both eigenvalues and eigenvectors are returned.
<code>EISPACK</code>	logical. Should EISPACK be used (for compatibility with R < 1.7.0)?

Details

By default `eigen` uses the LAPACK routines DSYEVR, DGEEV, ZHEEV and ZGEEV whereas `eigen(EISPACK=TRUE)` provides an interface to the EISPACK routines RS, RG, CH and CG.

If `symmetric` is unspecified, the code attempts to determine if the matrix is symmetric up to plausible numerical inaccuracies. It is faster and surer to set the value yourself.

`eigen` is preferred to `eigen(EISPACK = TRUE)` for new projects, but its eigenvectors may differ in sign and (in the asymmetric case) in normalization. (They may also differ between methods and between platforms.)

Computing the eigenvectors is the slow part for large matrices.

Computing the eigendecomposition of a matrix is subject to errors on a real-world computer: the definitive analysis is Wilkinson (1965). All you can hope for is a solution to a problem suitably close to `x`. So even though a real asymmetric `x` may have an algebraic solution with repeated real eigenvalues, the computed solution may be of a similar matrix with complex conjugate pairs of eigenvalues.

Value

The spectral decomposition of `x` is returned as components of a list with components

<code>values</code>	a vector containing the p eigenvalues of <code>x</code> , sorted in <i>decreasing</i> order, according to <code>Mod(values)</code> in the asymmetric case when they might be complex (even for real matrices). For real asymmetric matrices the vector will be complex only if complex conjugate pairs of eigenvalues are detected.
<code>vectors</code>	either a $p \times p$ matrix whose columns contain the eigenvectors of <code>x</code> , or NULL if <code>only.values</code> is TRUE.

For `eigen(, symmetric = FALSE, EISPACK = TRUE)` the choice of length of the eigenvectors is not defined by EISPACK. In all other cases the vectors are normalized to unit length.

Recall that the eigenvectors are only defined up to a constant: even when the length is specified they are still only defined up to a scalar of modulus one (the sign for real matrices).

See Also

`svd`, a generalization of `eigen`; `qr`, and `chol` for related decompositions.

To compute the determinant of a matrix, the `qr` decomposition is much more efficient: `det`.

Examples

```
eigen(cbind(c(1, -1), c(-1, 1)))
eigen(cbind(c(1, -1), c(-1, 1)), symmetric = FALSE)
# same (different algorithm).

eigen(cbind(1, c(1, -1)), only.values = TRUE)
eigen(cbind(-1, 2:1)) # complex values
eigen(print(cbind(c(0, 1i), c(-1i, 0)))) # Hermite ==> real Eigen values
## 3 x 3:
eigen(cbind( 1, 3:1, 1:3))
eigen(cbind(-1, c(1:2, 0), 0:2)) # complex values
```

encodeString

Encode Character Vector as for Printing

Description

`encodeString` escapes the strings in a character vector in the same way `print.default` does, and optionally fits the encoded strings within a field width.

Usage

```
encodeString(x, width = 0, quote = "\"", na.encode = TRUE,
             justify = c("left", "right", "centre", "none"))
```

Arguments

<code>x</code>	A character vector, or an object that can be coerced to one by <code>as.character</code> .
<code>width</code>	integer: the minimum field width. If <code>NULL</code> or <code>NA</code> , this is taken to be the largest field width needed for any element of <code>x</code> .
<code>quote</code>	character: quoting character, if any.
<code>na.encode</code>	logical: should <code>NA</code> strings be encoded?
<code>justify</code>	character: partial matches are allowed. If padding to the minimum field width is needed, how should spaces be inserted? <code>justify == "none"</code> is equivalent to <code>width = 0</code> , for consistency with <code>format.default</code> .

Details

This escapes backslash and the control characters `\a` (bell), `\b` (backspace), `\f` (formfeed), `\n` (line feed), `\r` (carriage return), `\t` (tab) and `\v` (vertical tab) as well as any non-printable characters in a single-byte locale, which are printed in octal notation (`\xyz` with leading zeroes). (Which characters are non-printable depends on the current locale.) See `print.default` for how non-printable characters are handled in multi-byte locales.

If `quote` is a single or double quote any embedded quote of the same type is escaped. Note that justification is of the quoted string, hence spaces are added outside the quotes.

Value

A character vector of the same length as `x`, with the same attributes (including names and dimensions) but with no class set.

Note

The default for `width` is different from `format.default`, which does similar things for character vectors but without encoding using escapes.

See Also

[print.default](#)

Examples

```
x <- "ab\bc\ndef"
print(x)
cat(x) # interprets escapes
cat(encodeString(x), "\n", sep="") # similar to print()

factor(x) # makes use of this to print the levels

x <- c("a", "ab", "abcde")
encodeString(x, width = NA) # left justification
encodeString(x, width = NA, justify = "c")
encodeString(x, width = NA, justify = "r")
encodeString(x, width = NA, quote = "'", justify = "r")
```

Encoding

Read or Set the Declared Encodings for a Character Vector

Description

Read or set the declared encodings for a character vector.

Usage

```
Encoding(x)
```

```
Encoding(x) <- value
```

Arguments

<code>x</code>	A character vector.
<code>value</code>	A character vector of positive length.

Details

Character strings in R can be declared to be in "latin1" or "UTF-8". These declarations can be read by `Encoding`, which will return a character vector of values "latin1", "UTF-8" or "unknown", or set, when `value` is recycled as needed and other values are silently treated as "unknown". As from R 2.8.0, ASCII strings will never be marked with a declared encoding, since their representation is the same in all encodings.

There are other ways for character strings to acquire a declared encoding apart from explicitly setting it. Functions `scan`, `read.table`, `readLines` and `parse` have an `encoding` argument that is used to declare encodings, `iconv` declares encodings from its `from` argument, and console input in suitable locales is also declared. `intToUtf8` declares its output as "UTF-8", and output text connections are marked if running in a suitable locale.

Most character manipulation functions will set the encoding on output strings if it was declared on the corresponding input. These include `chartr`, `strsplit`, `strtrim`, `substr`, `tolower` and `toupper` as well as `sub` (`useBytes = FALSE`) and `gsub` (`useBytes = FALSE`). (Also, under some circumstances `paste` will set an encoding.) Note that such functions do not *preserve* the encoding, but if they know the input encoding and that the string has been successfully re-encoded to the current encoding, they mark the output with the latter (if it is "latin1" or "UTF-8").

As from R 2.7.0 `substr` does preserve the encoding, and `chartr`, `tolower` and `toupper` preserve UTF-8 encoding on systems with Unicode wide characters. With their `fixed` and `perl` options, `strsplit`, `sub` and `gsub` will give a UTF-8 result if any of the inputs are UTF-8.

As from R 2.8.0 `paste` and `sprintf` return a UTF-8 encoded element if any of the inputs to that element are UTF-8.

Value

A character vector.

Examples

```
## x is intended to be in latin1
x <- "fa\xE7ile"
Encoding(x)
Encoding(x) <- "latin1"
x
xx <- iconv(x, "latin1", "UTF-8")
Encoding(c(x, xx))
c(x, xx)
```

environment

*Environment Access***Description**

Get, set, test for and create environments.

Usage

```
environment(fun = NULL)
environment(fun) <- value
```

```
is.environment(x)
```

```
.GlobalEnv
globalenv()
.BaseNamespaceEnv
```

```
emptyenv()
baseenv()
```

```
new.env(hash = FALSE, parent = parent.frame(), size = 29L)
```

```
parent.env(env)
parent.env(env) <- value
```

```
environmentName(env)
```

```
env.profile(env)
```

Arguments

fun	a function , a formula , or NULL, which is the default.
value	an environment to associate with the function
x	an arbitrary R object.
hash	a logical, if TRUE the environment will be hashed
parent	an environment to be used as the enclosure of the environment created.
env	an environment
size	an integer specifying the initial size for a hashed environment. An internal default value will be used if size is NA or zero. This argument is ignored if hash is FALSE.

Details

Environments consist of a *frame*, or collection of named objects, and a pointer to an *enclosing environment*. The most common example is the frame of variables local to a function call; its enclosure is the environment where the function was defined. The enclosing environment is distinguished from the *parent frame*: the latter (returned by `parent.frame`) refers to the environment of the caller of a function.

When `get` or `exists` search an environment with the default `inherits = TRUE`, they look for the variable in the frame, then in the enclosing frame, and so on.

The global environment `.GlobalEnv`, more often known as the user's workspace, is the first item on the search path. It can also be accessed by `globalenv()`. On the search path, each item's enclosure is the next item.

The object `.BaseNamespaceEnv` is the name space environment for the base package. The environment of the base package itself is available as `baseenv()`. The ultimate enclosure of any environment is the empty environment `emptyenv()`, to which nothing may be assigned. If one follows the `parent.env()` chain of enclosures back far enough from any environment, eventually one reaches the empty environment.

The replacement function `parent.env<-` is extremely dangerous as it can be used to destructively change environments in ways that violate assumptions made by the internal C code. It may be removed in the near future.

Value

If `fun` is a function or a formula then `environment(fun)` returns the environment associated with that function or formula. If `fun` is `NULL` then the current evaluation environment is returned.

The replacement form sets the environment of the function or formula `fun` to the `value` given.

`is.environment(obj)` returns `TRUE` if and only if `obj` is an environment.

`new.env` returns a new (empty) environment enclosed in the parent's environment, by default.

`parent.env` returns the parent environment of its argument.

`parent.env<-` sets the enclosing environment of its first argument.

`environmentName` returns a character string, that given when the environment is printed or `"` if it is not a named environment.

`env.profile` returns a list with the following components: `size` the number of chains that can be stored in the hash table, `nchains` the number of non-empty chains in the table (as reported by `HASHPRI`), and `counts` an integer vector giving the length of each chain (zero for empty chains). This function is intended to assess the performance of hashed environments. When `env` is a non-hashed environment, `NULL` is returned.

See Also

The `envir` argument of `eval`, `get`, and `exists`.

`ls` may be used to view the objects in an environment, and hence `ls.str` may be useful for an overview.

`sys.source` can be used to populate an environment.

Examples

```
f <- function() "top level function"

##-- all three give the same:
```

```

environment()
environment(f)
.GlobalEnv

ls(envir=environment(stats::approxfun(1:2,1:2, method="const")))

is.environment(.GlobalEnv) # TRUE

e1 <- new.env(parent = baseenv()) # this one has enclosure package:base.
e2 <- new.env(parent = e1)
assign("a", 3, envir=e1)
ls(e1)
ls(e2)
exists("a", envir=e2) # this succeeds by inheritance
exists("a", envir=e2, inherits = FALSE)
exists("+", envir=e2) # this succeeds by inheritance

```

EnvVar

Environment Variables

Description

Details of some of the environment variables which affect an R session.

Details

It is impossible to list all the environment variables which can affect an R session: some affect the OS system functions which R uses, and others will affect add-on packages. But here are notes on some of the more important ones. Those that set the defaults for options are consulted only at startup (as are some of the others).

HOME: The user's 'home' directory.

LANGUAGE: Optional. The language(s) to be used for message translations. This is consulted when needed.

LC_ALL: (etc) Optional. Use to set various aspects of the locale – see [Sys.getlocale](#). Consulted at startup.

R_BATCH: Optional – set in a batch session.

R_COMPLETION: Optional. If set to `FALSE`, command-line completion is not used. (Not used by Mac OS GUI.)

R_DEFAULT_PACKAGES: A comma-separated list of packages which are to be loaded in every session. See [options](#).

R_DOC_DIR: The location of the R 'doc' directory. Set by R.

R_DVIPSCMD: The path to `dvips`. Defaults to the value of `DVIPSPS`, and if that is unset to a value determined when R was built. Used by R CMD `Rd2dvi`, and at startup to set the default for [options\("latexcmd"\)](#), used by [help\(offline = TRUE\)](#).

R_ENVIRON: Optional. The path to the site environment file: see [Startup](#). Consulted at startup.

R_GSCMD: Optional. The path to GhostScript, used by [dev2bitmap](#).

R_HISTFILE: Optional. The path of the history file: see [Startup](#). Consulted at startup and when the history is saved.

- R_HISTSIZE:** Optional. The maximum size of the history file, in lines. Exactly how this is used depends on the interface. For the `readline` command-line interface it takes effect when the history is saved (by `savehistory` or at the end of a session).
- R_HOME:** The top-level directory of the R installation: see [R.home](#). Set by R.
- R_INCLUDE_DIR:** The location of the R ‘include’ directory. Set by R.
- R_LATEXCMD:** The path to `latex`. Defaults to the value of `LATEX`, and if that is unset to a value determined when R was built. Used by R CMD `Rd2dvi`, and at startup to set the default for `options("latexcmd")`, used by `help(offline = TRUE)`.
- R_LIBS:** Optional. Used for initial setting of `.libPaths`.
- R_LIBS_SITE:** Optional. Used for initial setting of `.libPaths`.
- R_LIBS_USER:** Optional. Used for initial setting of `.libPaths`.
- R_MAKEINDEXCMD:** The path to `makeindex`. Defaults at startup to the value of `MAKEINDEX`, and if that is unset to a value determined when R was built. Used by R CMD `Rd2dvi`.
- R_PAPERSIZE:** Optional. Use to set the default for `options("papersize")`, e.g. used by `pdf`, `postscript` and `help(offline = TRUE)`.
- R_PDFLATEXCMD:** The path to `pdflatex`. Defaults at startup to the value of `PDFLATEX`, and if that is unset to a value determined when R was built. Used by R CMD `Rd2dvi`.
- R_PDFVIEWER:** The path to the default PDF viewer. Used by R CMD `Rd2dvi`.
- R_PLATFORM:** The platform – a string of the form `cpu-vendor-os`, see [R.Version](#).
- R_PROFILE:** Optional. The path to the site profile file: see [Startup](#). Consulted at startup.
- R_RD4DVI:** Options for `latex` processing of Rd files. Used by R CMD `Rd2dvi` and `help(offline = TRUE)`.
- R_RD4PDF:** Options for `pdflatex` processing of Rd files. Used by R CMD `Rd2dvi`.
- R_SHARE_DIR:** The location of the R ‘share’ directory. Set by R.
- R_UNZIPCMD:** The path to `unzip`. Sets the default value for `options("unzip")`.
- R_ZIPCMD:** The path to `zip`.
- TMPDIR, TMP, TEMP:** Consulted (in that order) when setting the temporary directory. See [tempdir](#).
- TZ:** Optional. The current timezone. See [Sys.timezone](#) for the system-specific formats. Consulted as needed.
- no_proxy, http_proxy, ftp_proxy:** (and more). Optional. Settings for `download.file`: see its help for further details.

Unix-specific

Some variables set on Unix-alikes, and not (in general) on Windows.

- DISPLAY:** Optional: used by `X11`, Tk (in package `tcltk`), the data editor and various packages.
- EDITOR:** The path to the default editor.
- PAGER:** The path to the default pager.
- R_BROWSER:** The path to the default browser. Used to set the default value of `options("browser")`.
- R_PDFVIEWER:** The path to the default PDF viewer. Used by R CMD `Rd2dvi`.
- R_PRINTCMD:** Sets the default for `options("printcmd")`, which sets the default print command to be used by `postscript`.

[Sys.getenv](#) and [Sys.setenv](#) to read and set environmental variables in an R session.

eval

*Evaluate an (Unevaluated) Expression***Description**

Evaluate an R expression in a specified environment.

Usage

```
eval(expr, envir = parent.frame(),
      enclos = if(is.list(envir) || is.pairlist(envir))
                 parent.frame() else baseenv())
evalq(expr, envir, enclos)
eval.parent(expr, n = 1)
local(expr, envir = new.env())
```

Arguments

<code>expr</code>	an object to be evaluated. See ‘Details’.
<code>envir</code>	the environment in which <code>expr</code> is to be evaluated. May also be <code>NULL</code> , a list, a data frame, a pairlist or an integer as specified to sys.call .
<code>enclos</code>	Relevant when <code>envir</code> is a (pair)list or a data frame. Specifies the enclosure, i.e., where R looks for objects not found in <code>envir</code> . This can be <code>NULL</code> (interpreted as the base package environment) or an environment.
<code>n</code>	number of parent generations to go back

Details

`eval` evaluates the `expr` argument in the environment specified by `envir` and returns the computed value. If `envir` is not specified, then the default is `parent.frame()` (the environment where the call to `eval` was made).

Objects to be evaluated can be of types [call](#) or [expression](#) or [name](#) (when the name is looked up in the current scope and its binding is evaluated), a [promise](#) or any of the basic types such as vectors, functions and environments (which are returned unchanged).

The `evalq` form is equivalent to `eval(quote(expr), ...)`. `eval` evaluates its first argument in the current scope before passing it to the evaluator: `evalq` avoids this.

`eval.parent(expr, n)` is a shorthand for `eval(expr, parent.frame(n))`.

If `envir` is a list (such as a data frame) or pairlist, it is copied into a temporary environment (with enclosure `enclos`), and the temporary environment is used for evaluation. So if `expr` changes any of the components named in the (pair)list, the changes are lost.

If `envir` is `NULL` it is interpreted as an empty list so no values could be found in `envir` and look-up goes directly to `enclos`.

`local` evaluates an expression in a local environment. It is equivalent to `evalq` except that its default argument creates a new, empty environment. This is useful to create anonymous recursive functions and as a kind of limited name space feature since variables defined in the environment are not visible from the outside.

Value

The result of evaluating the object: for an expression vector this is the result of evaluating the last elements.

Note

Due to the difference in scoping rules, there are some differences between R and S in this area. In particular, the default enclosure in S is the global environment.

When evaluating expressions in data frames that has been passed as argument to a function, the relevant enclosure is often the caller's environment, i.e., one needs `eval(x, data, parent.frame())`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole. (eval only.)

See Also

[expression](#), [quote](#), [sys.frame](#), [parent.frame](#), [environment](#).

Further, [force](#) to *force* evaluation, typically of function arguments.

Examples

```
eval(2 ^ 2 ^ 3)
mEx <- expression(2^2^3); mEx; 1 + eval(mEx)
eval({ xx <- pi; xx^2}) ; xx

a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, list(a=1)), list(b=5)) # == 10
a <- 3 ; aa <- 4 ; evalq(evalq(a+b+aa, -1), list(b=5))      # == 12

ev <- function() {
  e1 <- parent.frame()
  ## Evaluate a in e1
  aa <- eval(expression(a), e1)
  ## evaluate the expression bound to a in e1
  a <- expression(x+y)
  list(aa = aa, eval = eval(a, e1))
}
tst.ev <- function(a = 7) { x <- pi; y <- 1; ev() }
tst.ev()#-> aa : 7,  eval : 4.14

a <- list(a=3, b=4)
with(a, a <- 5) # alters the copy of a from the list, discarded.

##
## Example of evalq()
##

N <- 3
env <- new.env()
assign("N", 27, envir=env)
## this version changes the visible copy of N only, since the argument
## passed to eval is '4'.
eval(N <- 4, env)
```

```

N
get("N", envir=env)
## this version does the assignment in env, and changes N only there.
evalq(N <- 5, env)
N
get("N", envir=env)

##
## Uses of local()
##

# Mutually recursive.
# gg gets value of last assignment, an anonymous version of f.

gg <- local({
  k <- function(y) f(y)
  f <- function(x) if(x) x*k(x-1) else 1
})
gg(10)
sapply(1:5, gg)

# Nesting locals. a is private storage accessible to k
gg <- local({
  k <- local({
    a <- 1
    function(y) {print(a <- a+1); f(y)}
  })
  f <- function(x) if(x) x*k(x-1) else 1
})
sapply(1:5, gg)

ls(envir=environment(gg))
ls(envir=environment(get("k", envir=environment(gg))))

```

exists

Is an Object Defined?

Description

Look for an R object of the given name.

Usage

```
exists(x, where = -1, envir = , frame, mode = "any",
      inherits = TRUE)
```

Arguments

x	a variable name (given as a character string).
where	where to look for the object (see the details section); if omitted, the function will search as if the name of the object appeared unquoted in an expression.
envir	an alternative way to specify an environment to look in, but it is usually simpler to just use the <code>where</code> argument.

<code>frame</code>	a frame in the calling list. Equivalent to giving <code>where</code> as <code>sys.frame(frame)</code> .
<code>mode</code>	the mode or type of object sought: see the ‘Details’ section.
<code>inherits</code>	should the enclosing frames of the environment be searched?

Details

The `where` argument can specify the environment in which to look for the object in any of several ways: as an integer (the position in the `search` list); as the character string name of an element in the search list; or as an `environment` (including using `sys.frame` to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

This function looks to see if the name `x` has a value bound to it in the specified environment. If `inherits` is `TRUE` and a value is not found for `x` in the specified environment, the enclosing frames of the environment are searched until the name `x` is encountered. See `environment` and the ‘R Language Definition’ manual for details about the structure of environments and their enclosures.

Warning: `inherits = TRUE` is the default behaviour for `R` but not for `S`.

If `mode` is specified then only objects of that type are sought. The `mode` may specify one of the collections `"numeric"` and `"function"` (see `mode`): any member of the collection will suffice. (This is true even if a member of a collection is specified, so for example `mode="special"` will seek any type of function.)

Value

Logical, true if and only if an object of the correct name and mode is found.

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[get](#).

Examples

```
## Define a substitute function if necessary:
if(!exists("some.fun", mode="function"))
  some.fun <- function(x) { cat("some.fun(x)\n"); x }
search()
exists("ls", 2) # true even though ls is in pos=3
exists("ls", 2, inherits = FALSE) # false
```

`expand.grid`*Create a Data Frame from All Combinations of Factors*

Description

Create a data frame from all combinations of the supplied vectors or factors. See the description of the return value for precise details of the way this is done.

Usage

```
expand.grid(..., KEEP.OUT.ATTRS = TRUE)
```

Arguments

`...` vectors, factors or a list containing these.
`KEEP.OUT.ATTRS` a logical indicating the "out.attrs" attribute (see below) should be computed and returned.

Value

A data frame containing one row for each combination of the supplied factors. The first factors vary fastest. The columns are labelled by the factors if these are supplied as named arguments or named components of a list. The row names are 'automatic'.

Attribute "out.attrs" is a list which gives the dimension and dimnames for use by `predict` methods.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

`combn` (package `utils`) for the generation of all combinations of `n` elements, taken `m` at a time.

Examples

```
require(utils)

expand.grid(height = seq(60, 80, 5), weight = seq(100, 300, 50),
            sex = c("Male", "Female"))

x <- seq(0,10, length.out=100)
y <- seq(-1,1, length.out=20)
d1 <- expand.grid(x=x, y=y)
d2 <- expand.grid(x=x, y=y, KEEP.OUT.ATTRS = FALSE)
object.size(d1) - object.size(d2)
##-> 5992 or 8832 (on 32- / 64-bit platform)
```

expression *Unevaluated Expressions*

Description

Creates or tests for objects of mode "expression".

Usage

```
expression(...)  
  
is.expression(x)  
as.expression(x, ...)
```

Arguments

...	expression: R objects, typically calls, symbols or constants. as.expression: arguments to be passed to methods.
x	an arbitrary R object.

Details

'Expression' here is not being used in its colloquial sense, that of mathematical expressions. Those are calls (see [call](#)) in R, and an R expression vector is a list of calls, symbols etc, typically as returned by [parse](#).

As an object of mode "expression" is a list, it can be subsetted by both `[` and by `[[`, the latter extracting individual calls etc.

Value

`expression` returns a vector of type "expression" containing its arguments (unevaluated).

`is.expression` returns TRUE if `expr` is an expression object and FALSE otherwise.

`as.expression` attempts to coerce its argument into an expression object. It is generic, and only the default method is described here. NULL, calls, symbols (see [as.symbol](#)) and pairlists are returned as the element of a length-one expression vector. Vectors (including lists) are placed element-by-element into an expression vector. Other types are not currently supported.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[call](#), [eval](#), [function](#). Further, [text](#) and [legend](#) for plotting mathematical expressions.

Examples

```
length(ex1 <- expression(1+ 0:9))# 1
ex1
eval(ex1)# 1:10

length(ex3 <- expression(u,v, 1+ 0:9))# 3
mode(ex3 [3]) # expression
mode(ex3[[3]])# call
rm(ex3)
```

Extract

*Extract or Replace Parts of an Object***Description**

Operators acting on vectors, matrices, arrays and lists to extract or replace parts.

Usage

```
x[i]
x[i, j, ... , drop = TRUE]
x[[i, exact = TRUE]]
x[[i, j, ..., exact = TRUE]]
x$name
```

Arguments

<code>x</code>	object from which to extract element(s) or in which to replace element(s).
<code>i, j, ...</code>	indices specifying elements to extract or replace. Indices are numeric or character vectors or empty (missing) or <code>NULL</code> . Numeric values are coerced to integer as by <code>as.integer</code> (and hence truncated towards zero). Character vectors will be matched to the <code>names</code> of the object (or for matrices/arrays, the <code>dimnames</code>): see ‘Character indices’ below for further details. For [-indexing only: <code>i, j, ...</code> can be logical vectors, indicating elements/slices to select. Such vectors are recycled if necessary to match the corresponding extent. <code>i, j, ...</code> can also be negative integers, indicating elements/slices to leave out of the selection. When indexing arrays by <code>[</code> a single argument <code>i</code> can be a matrix with as many columns as there are dimensions of <code>x</code> ; the result is then a vector with elements corresponding to the sets of indices in each row of <code>i</code> . An index value of <code>NULL</code> is treated as if it were <code>integer(0)</code> .
<code>name</code>	A literal character string or a <code>name</code> (possibly <code>backtick</code> quoted). For extraction, this is normally (see under ‘Environments’) partially matched to the <code>names</code> of the object.
<code>drop</code>	For matrices and arrays. If <code>TRUE</code> the result is coerced to the lowest possible dimension (see the examples). This only works for extracting elements, not for the replacement. See <code>drop</code> for further details.
<code>exact</code>	Controls possible partial matching of <code>[</code> when extracting by a character vector (for most objects, but see under ‘Environments’). The default is no partial matching. Value <code>NA</code> allows partial matching but issues a warning when it occurs. Value <code>FALSE</code> allows partial matching without any warning.

Details

These operators are generic. You can write methods to handle indexing of specific classes of objects, see [InternalMethods](#) as well as `[.data.frame]` and `[.factor]`. The descriptions here apply only to the default methods. Note that separate methods are required for the replacement functions `[<-`, `[[<-` and `$<-` for use when indexing occurs on the assignment side of an expression.

The most important distinction between `[`, `[[` and `$` is that the `[` can select more than one element whereas the other two select a single element.

The default methods work somewhat differently for atomic vectors, matrices/arrays and for recursive (list-like, see [is.recursive](#)) objects. `$` is only valid for recursive objects, and is only discussed in the section below on recursive objects. Its use on non-recursive objects was deprecated in R 2.5.0 and removed in R 2.7.0.

Subsetting (except by an empty index) will drop all attributes except `names`, `dim` and `dimnames`.

Indexing can occur on the right-hand-side of an expression for extraction, or on the left-hand-side for replacement. When an index expression appears on the left side of an assignment (known as *subassignment*) then that part of `x` is set to the value of the right hand side of the assignment. In this case no partial matching of character indices is done, and the left-hand-side is coerced as needed to accept the values. Attributes are preserved (although `names`, `dim` and `dimnames` will be adjusted suitably). Subassignment is done sequentially, so if an index is specified more than once the latest assigned value for an index will result.

It is an error to apply any of these operators to an object which is not subsettable (e.g. a function).

Atomic vectors

The usual form of indexing is `"["`. `"[[` can be used to select a single element, but `"["` can also do so.

The index object `i` can be numeric, logical, character or empty. Indexing by factors is allowed and is equivalent to indexing by the numeric codes (see [factor](#)) and not by the character values which are printed (for which use `[as.character(i)]`).

An empty index selects all values: this is most often used to replace all the entries but keep the [attributes](#).

Matrices and arrays

Matrices and arrays are vectors with a dimension attribute and so all the vector forms of indexing can be used with a single index. The result will be an unnamed vector unless `x` is one-dimensional when it will be a one-dimensional array.

The most common form of indexing a k -dimensional array is to specify k indices to `[`. As for vector indexing, the indices can be numeric, logical, character, empty or even factor. An empty index (a comma separated blank) indicates that all entries in that dimension are selected. The argument `drop` applies to this form of indexing.

A third form of indexing is via a numeric matrix with the one column for each dimension: each row of the index matrix then selects a single element of the array, and the result is a vector. Negative indices are not allowed in the index matrix. `NA` and zero values are allowed: rows of an index matrix containing a zero are ignored, whereas rows containing an `NA` produce an `NA` in the result.

A vector obtained by matrix indexing will be unnamed unless `x` is one-dimensional when the row names (if any) will be indexed to provide names for the result.

Recursive (list-like) objects

Indexing by `[]` is similar to atomic vectors and selects a list of the specified element(s).

Both `[]` and `$` select a single element of the list. The main difference is that `$` does not allow computed indices, whereas `[]` does. `x$name` is equivalent to `x[["name", exact = FALSE]]`. Also, the partial matching behavior of `[]` can be controlled using the `exact` argument.

`[]` and `[]` are sometimes applied to other recursive objects such as [calls](#) and [expressions](#). Pairlists are coerced to lists for extraction by `[]`, but all three operators can be used for replacement.

`[]` can be applied recursively to lists, so that if the single index `i` is a vector of length `p`, `alist[[i]]` is equivalent to `alist[[i1]]...[[ip]]` providing all but the final indexing results in a list.

When either `[]` or `$` is used for replacement, a value of `NULL` deletes the corresponding item of the list.

When `$<-` is applied to a `NULL` `x`, it first coerces `x` to `list()`. This is what also happens with `[]<-` if the replacement value `value` is of length greater than one: if `value` has length 1 or 0, `x` is first coerced to a zero-length vector of the type of `value`.

Environments

Both `$` and `[]` can be applied to environments. Only character indices are allowed and no partial matching is done. The semantics of these operations are those of `get(i, env=x, inherits=FALSE)`. If no match is found then `NULL` is returned. The replacement versions, `$<-` and `[]<-`, can also be used. Again, only character arguments are allowed. The semantics in this case are those of `assign(i, value, env=x, inherits=FALSE)`. Such an assignment will either create a new binding or change the existing binding in `x`.

NAs in indexing

When extracting, a numerical, logical or character `NA` index picks an unknown element and so returns `NA` in the corresponding element of a logical, integer, numeric, complex or character result, and `NULL` for a list. (It returns `00` for a raw result.)

When replacing (that is using indexing on the lhs of an assignment) `NA` does not select any element to be replaced. As there is ambiguity as to whether an element of the rhs should be used or not, this is only allowed if the rhs value is of length one (so the two interpretations would have the same outcome).

Argument matching

Note that these operations do not match their index arguments in the standard way: argument names are ignored and positional matching only is used. So `m[j=2, i=1]` is equivalent to `m[2, 1]` and **not** to `m[1, 2]`.

This may not be true for methods defined for them; for example it is not true for the `data.frame` methods described in [\[.data.frame\]](#).

To avoid confusion, do not name index arguments (but `drop` and `exact` must be named).

S4 methods

These operators are also S4 generic, but as primitives, S4 methods will be dispatched only on S4 objects.

S4 methods for `$` will be passed `name` as a character vector: despite the message given by `getGeneric("$")` you cannot usefully write methods based on the class of `name`.

Character indices

Character indices can in some circumstances be partially matched (see `pmatch`) to the names or dimnames of the object being subsetted (but never for subassignment). Unlike S (Becker *et al* p. 358), R has never used partial matching when extracting by `[]`. As from R 2.7.0, partial matching is not by default used by `[]` (see argument `exact`).

Thus the default behaviour is to use partial matching only when extracting from recursive objects (except environments) by `$.` Even in that case, warnings can be switched on by `options(warnPartialMatchAttr = TRUE)`.

Neither empty (`" "`) nor `NA` indices match any names, not even empty nor missing names. If any object has no names or appropriate dimnames, they are taken as all `" "` and so match nothing.

Note

The documented behaviour of S is that an `NA` replacement index ‘goes nowhere’ but uses up an element of `value` (Becker *et al* p. 359). However, that has not been true of other implementations.

Examples

```
x <- 1:12; m <- matrix(1:6, nrow=2); li <- list(pi=pi, e = exp(1))
x[10]                # the tenth element of x
x <- x[-1]           # delete the 1st element of x
m[1,]                # the first row of matrix m
m[1, , drop = FALSE] # is a 1-row matrix
m[,c(TRUE,FALSE,TRUE)] # logical indexing
m[cbind(c(1,2,1),3:1)] # matrix index
m <- m[,-1]          # delete the first column of m
li[[1]]              # the first element of list li
y <- list(1,2,a=4,5)
y[c(3,4)]            # a list containing elements 3 and 4 of y
y$a                  # the element of y named a

## non-integer indices are truncated:
(i <- 3.999999999) # "4" is printed
(1:5)[i]          # 3

## recursive indexing into lists
z <- list( a=list( b=9, c='hello'), d=1:5)
unlist(z)
z[[c(1, 2)]]
z[[c(1, 2, 1)]] # both "hello"
z[[c("a", "b")]] <- "new"
```

```

unlist(z)

## check $ and [[ for environments
e1 <- new.env()
e1$a <- 10
e1[["a"]]
e1[["b"]] <- 20
e1$b
ls(e1)

```

Extract.data.frame *Extract or Replace Parts of a Data Frame*

Description

Extract or replace subsets of data frames.

Usage

```

## S3 method for class 'data.frame':
x[i, j, drop = ]
## S3 replacement method for class 'data.frame':
x[i, j] <- value
## S3 method for class 'data.frame':
x[ [..., exact = TRUE]]
## S3 replacement method for class 'data.frame':
x[[i, j]] <- value
## S3 replacement method for class 'data.frame':
x$i <- value

```

Arguments

<code>x</code>	data frame.
<code>i, j, ...</code>	elements to extract or replace. For <code>[</code> and <code>[[</code> , these are numeric or character or, for <code>[</code> only, empty. Numeric values are coerced to integer as if by <code>as.integer</code> . For replacement by <code>[</code> , a logical matrix is allowed. For replacement by <code>\$</code> , <code>i</code> is a name or literal character string.
<code>drop</code>	logical. If <code>TRUE</code> the result is coerced to the lowest possible dimension. The default is to drop if only one column is left, but not to drop if only one row is left.
<code>value</code>	A suitable replacement value: it will be repeated a whole number of times if necessary and it may be coerced: see the Coercion section. If <code>NULL</code> , deletes the column if a single column is selected.
<code>exact</code>	logical: see <code>[</code> , and applies to column names.

Details

Data frames can be indexed in several modes. When `[` and `[[` are used with a single index (`x[i]` or `x[[i]]`), they index the data frame as if it were a list. In this usage a `drop` argument is ignored, with a warning. Using `$` is equivalent to using `[[i, exact = FALSE]]`.

When `[` and `[[` are used with two indices (`x[i, j]` and `x[[i, j]]`) they act like indexing a matrix: `[` can only be used to select one element.

If `[` returns a data frame it will have unique (and non-missing) row names, if necessary transforming the row names using `make.unique`. Similarly, column names will be transformed to be unique if necessary (e.g. if columns are selected more than once, or if more than one column of a given name is selected if the data frame has duplicate columns).

When `drop = TRUE`, this is applied to the subsetting of any matrices contained in the data frame as well as to the data frame itself.

The replacement methods can be used to add whole column(s) by specifying non-existent column(s), in which case the column(s) are added at the right-hand edge of the data frame and numerical indices must be contiguous to existing indices. On the other hand, rows can be added at any row after the current last row, and the columns will be in-filled with missing values. Missing values in the indices are not allowed for replacement.

For `[` the replacement value can be a list: each element of the list is used to replace (part of) one column, recycling the list as necessary. If columns specified by number are created, the names (if any) of the corresponding list elements are used to name the columns. If the replacement is not selecting rows, list values can contain `NULL` elements which will cause the corresponding columns to be deleted. (See the Examples.)

Matrix indexing using `[` is not recommended, and barely supported. For extraction, `x` is first coerced to a matrix. For replacement a logical matrix (only) can be used to select the elements to be replaced in the same way as for a matrix.

Both `[` and `[[` extraction methods partially match row names. By default neither partially match column names, but `[[` will unless `exact=TRUE`. If you want to do exact matching on row names use `match` as in the examples.

Value

For `[` a data frame, list or a single column (the latter two only when dimensions have been dropped). If matrix indexing is used for extraction a matrix results. If the result would be a data frame an error results if undefined columns are selected (as there is no general concept of a 'missing' column in a data frame). Otherwise if a single column is selected and this is undefined the result is `NULL`.

For `[[` a column of the data frame or `NULL` (extraction with one index) or a length-one vector (extraction with two indices).

For `$`, a column of the data frame (or `NULL`).

For `[<-`, `[[<-` and `$<-`, a data frame.

Coercion

The story over when replacement values are coerced is a complicated one, and one that has changed during R's development. This section is a guide only.

When `[` and `[[` are used to add or replace a whole column, no coercion takes place but `value` will be replicated (by calling the generic function `rep`) to the right length if an exact number of repeats can be used.

When `[` is used with a logical matrix, each value is coerced to the type of the column into which it is to be placed.

When `[` and `[[` are used with two indices, the column will be coerced as necessary to accommodate the value.

Note that when the replacement value is an array (including a matrix) it is *not* treated as a series of columns (as `data.frame` and `as.data.frame` do) but inserted as a single column.

Warning

The default behaviour when only one *row* is left is equivalent to specifying `drop = FALSE`. To drop from a data frame to a list, `drop = TRUE` has to be specified explicitly.

See Also

`subset` which is often easier for extraction, `data.frame`, `Extract`.

Examples

```
sw <- swiss[1:5, 1:4] # select a manageable subset

sw[1:3]           # select columns
sw[, 1:3]         # same
sw[4:5, 1:3]     # select rows and columns
sw[1]             # a one-column data frame
sw[, 1, drop = FALSE] # the same
sw[, 1]           # a (unnamed) vector
sw[[1]]          # the same

sw[1,]           # a one-row data frame
sw[1,, drop=TRUE] # a list

sw["C", ] # partially matches
sw[match("C", row.names(sw)), ] # no exact match

swiss[ c(1, 1:2), ] # duplicate row, unique row names are created

sw[sw <= 6] <- 6 # logical matrix indexing
sw

## adding a column
sw["new1"] <- LETTERS[1:5] # adds a character column
sw[["new2"]] <- letters[1:5] # ditto
sw[, "new3"] <- LETTERS[1:5] # ditto
sw$new4 <- 1:5
sapply(sw, class)
sw$new4 <- NULL # delete the column
sw
sw[6:8] <- list(letters[10:14], NULL, aa=1:5)
# delete col7, update 6, append
sw

## matrices in a data frame
A <- data.frame(x=1:3, y=I(matrix(4:6)), z=I(matrix(letters[1:9],3,3)))
A[1:3, "y"] # a matrix
A[1:3, "z"] # a matrix
A[, "y"]    # a matrix
```

Description

Extract or replace subsets of factors.

Usage

```
## S3 method for class 'factor':  
x[... , drop = FALSE]  
## S3 method for class 'factor':  
x[[...]]  
## S3 replacement method for class 'factor':  
x[...] <- value
```

Arguments

x	a factor
...	a specification of indices – see Extract .
drop	logical. If true, unused levels are dropped.
value	character: a set of levels. Factor values are coerced to character.

Details

When unused levels are dropped the ordering of the remaining levels is preserved.

If value is not in levels(x), a missing value is assigned with a warning.

Any [contrasts](#) assigned to the factor are preserved unless drop=TRUE.

The `[[` method supports argument `exact`.

Value

A factor with the same set of levels as x unless drop=TRUE.

See Also

[factor](#), [Extract](#).

Examples

```
## following example(factor)  
(ff <- factor(substring("statistics", 1:10, 1:10), levels=letters))  
ff[, drop=TRUE]  
factor(letters[7:10])[2:3, drop = TRUE]
```

Description

Returns the (parallel) maxima and minima of the input values.

Usage

```
max(..., na.rm = FALSE)
min(..., na.rm = FALSE)

pmax(..., na.rm = FALSE)
pmin(..., na.rm = FALSE)

pmax.int(..., na.rm = FALSE)
pmin.int(..., na.rm = FALSE)
```

Arguments

`...` numeric or character arguments (see Note).
`na.rm` a logical indicating whether missing values should be removed.

Details

`max` and `min` return the maximum or minimum of *all* the values present in their arguments, as [integer](#) if all are logical or integer, as [double](#) if all are numeric, and character otherwise. If `na.rm` is `FALSE` an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

The minimum and maximum of a numeric empty set are `+Inf` and `-Inf` (in this order!) which ensures *transitivity*, e.g., `min(x1, min(x2)) == min(x1, x2)`. For numeric `x` `max(x) == -Inf` and `min(x) == +Inf` whenever `length(x) == 0` (after removing missing values if requested). However, `pmax` and `pmin` return NA if all the parallel elements are NA even for `na.rm = TRUE`.

`pmax` and `pmin` take one or more vectors (or matrices) as arguments and return a single vector giving the ‘parallel’ maxima (or minima) of the vectors. The first element of the result is the maximum (minimum) of the first elements of all the arguments, the second element of the result is the maximum (minimum) of the second elements of all the arguments and so on. Shorter inputs are recycled if necessary. [attributes](#) (such as [names](#) or [dim](#)) are transferred from the first argument (if applicable).

`pmax.int` and `pmin.int` are faster internal versions only used when all arguments are atomic vectors and there are no classes: they drop all attributes. (Note that all versions fail for raw and complex vectors since these have no ordered.)

`max` and `min` are generic functions: methods can be defined for them individually or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

By definition the min/max of any vector containing an `NaN` is `NaN`, except that the min/max of any vector containing an `NA` is `NA` even if it also contains an `NaN`. Note that `max(NA, Inf) == NA` even though the maximum would be `Inf` whatever the missing value actually is.

The `max/min` of an empty character vector is a character `NA`. (One could argue that as "" is the smallest character element, the maximum should be "", but there is no obvious candidate for the minimum.)

Value

For `min` or `max`, a length-one vector. For `pmin` or `pmax`, a vector of length the longest of the input vectors.

The type of the result will be that of the highest of the inputs in the hierarchy `integer < real < character`.

For `min` and `max` if there are only numeric inputs and all are empty (after possible removal of `NA`s), the result is double (`Inf` or `-Inf`).

S4 methods

`max` and `min` are part of the S4 [Summary](#) group generic. Methods for them must use the signature `x, ..., na.rm`.

Note

'Numeric' arguments are vectors of type `integer` and `numeric`, and `logical` (coerced to `integer`). For historical reasons, `NULL` is accepted as equivalent to `integer(0)`.

`pmax` and `pmin` will also work on classed objects with appropriate methods for comparison, `is.na` and `rep` (if recycling of arguments is needed).

See Also

[range](#) (*both* `min` and `max`) and [which.min](#) ([which.max](#)) for the *arg min*, i.e., the location where an extreme value occurs.

'[plotmath](#)' for the use of `min` in plot annotation.

Examples

```
require(stats); require(graphics)
min(5:1, pi) #-> one number
pmin(5:1, pi) #-> 5 numbers

x <- sort(rnorm(100)); cH <- 1.35
pmin(cH, quantile(x)) # no names
pmin(quantile(x), cH) # has names
plot(x, pmin(cH, pmax(-cH, x)), type='b', main= "Huber's function")
```

factor

*Factors***Description**

The function `factor` is used to encode a vector as a factor (the terms ‘category’ and ‘enumerated type’ are also used for factors). If `ordered` is `TRUE`, the factor levels are assumed to be ordered. For compatibility with `S` there is also a function `ordered`.

`is.factor`, `is.ordered`, `as.factor` and `as.ordered` are the membership and coercion functions for these classes.

Usage

```
factor(x = character(),
      levels = sort(unique.default(x), na.last = TRUE),
      labels = levels, exclude = NA, ordered = is.ordered(x))

ordered(x, ...)

is.factor(x)
is.ordered(x)

as.factor(x)
as.ordered(x)

addNA(x, ifany=FALSE)
```

Arguments

<code>x</code>	a vector of data, usually taking a small number of distinct values.
<code>levels</code>	an optional vector of the values that <code>x</code> might have taken. The default is the set of values taken by <code>x</code> , sorted into increasing order.
<code>labels</code>	<i>either</i> an optional vector of labels for the levels (in the same order as <code>levels</code> after removing those in <code>exclude</code>), <i>or</i> a character string of length 1.
<code>exclude</code>	a vector of values to be excluded when forming the set of levels. This should be of the same type as <code>x</code> , and will be coerced if necessary.
<code>ordered</code>	logical flag to determine if the levels should be regarded as ordered (in the order given).
<code>...</code>	(in <code>ordered(.)</code>): any of the above, apart from <code>ordered</code> itself.
<code>ifany</code>	(in <code>addNA</code>): Only add an NA level if it is used, i.e. if <code>any(is.na(x))</code> .

Details

The type of the vector `x` is not restricted.

Ordered factors differ from factors only in their class, but methods and the model-fitting functions treat the two classes quite differently.

The encoding of the vector happens as follows. First all the values in `exclude` are removed from `levels`. If `x[i]` equals `levels[j]`, then the `i`-th element of the result is `j`. If no match is found for `x[i]` in `levels`, then the `i`-th element of the result is set to `NA`.

Normally the ‘levels’ used as an attribute of the result are the reduced set of levels after removing those in `exclude`, but this can be altered by supplying `labels`. This should either be a set of new labels for the levels, or a character string, in which case the levels are that character string with a sequence number appended.

`factor(x, exclude=NULL)` applied to a factor is a no-operation unless there are unused levels: in that case, a factor with the reduced level set is returned. If `exclude` is used it should also be a factor with the same level set as `x` or a set of codes for the levels to be excluded.

The codes of a factor may contain `NA`. For a numeric `x`, set `exclude=NULL` to make `NA` an extra level (prints as `<NA>`); by default, this is the last level.

If `NA` is a level, the way to set a code to be missing (as opposed to the code of the missing level) is to use `is.na` on the left-hand-side of an assignment (as in `is.na(f)[i] <- TRUE`; indexing inside `is.na` does not work). Under those circumstances missing values are currently printed as `<NA>`, i.e., identical to entries of level `NA`.

`is.factor` is generic: you can write methods to handle specific classes of objects, see [Internal-Methods](#).

Value

`factor` returns an object of class `"factor"` which has a set of integer codes the length of `x` with a `"levels"` attribute of mode `character`. If `ordered` is `true` (or `ordered` is used) the result has class `c("ordered", "factor")`.

Applying `factor` to an ordered or unordered factor returns a factor (of the same type) with just the levels which occur: see also [\[.factor\]](#) for a more transparent way to achieve this.

`is.factor` returns `TRUE` or `FALSE` depending on whether its argument is of type `factor` or not. Correspondingly, `is.ordered` returns `TRUE` when its argument is ordered and `FALSE` otherwise.

`as.factor` coerces its argument to a factor. It is an abbreviated form of `factor`.

`as.ordered(x)` returns `x` if this is ordered, and `ordered(x)` otherwise.

`addNA` modifies a factor by turning `NA` into an extra level (so that `NA` values are counted in tables, for instance).

Warning

The interpretation of a factor depends on both the codes and the `"levels"` attribute. Be careful only to compare factors with the same set of levels (in the same order). In particular, `as.numeric` applied to a factor is meaningless, and may happen by implicit coercion. To transform a factor `f` to its original numeric values, `as.numeric(levels(f))[f]` is recommended and slightly more efficient than `as.numeric(as.character(f))`.

The levels of a factor are by default sorted, but the sort order may well depend on the locale at the time of creation, and should not be assumed to be ASCII.

There are some anomalies associated with factors that have `NA` as a level. It is suggested to use them sparingly, e.g., only for tabulation purposes.

Comparison operators and group generic methods

There are `"factor"` and `"ordered"` methods for the [group generic Ops](#), which provide methods for the [Comparison](#) operators. (The rest of the group and the [Math](#) and [Summary](#) groups generate an error as they are not meaningful for factors.)

Only `==` and `!=` can be used for factors: a factor can only be compared to another factor with an identical set of levels (not necessarily in the same ordering) or to a character vector. Ordered factors

are compared in the same way, but the general dispatch mechanism precludes comparing ordered and unordered factors.

All the comparison operators are available for ordered factors. Sorting is done by the levels of the operands: if both operands are ordered factors they must have the same level set.

Note

Storing character data as a factor is more efficient storage if there is even a small proportion of repeats. On a 32-bit machine storing a string of n bytes takes $28 + 8\lceil(n + 1)/8\rceil$ bytes whereas storing a factor code takes 4 bytes. (On a 64-bit machine 28 is replaced by 56 or more.) Only if they were computed from the same values (or in some cases read from a file: see [scan](#)) will identical strings share storage.

[\[.factor\]](#) for subsetting of factors.

[gl](#) for construction of balanced factors and [C](#) for factors with specified contrasts. [levels](#) and [nlevels](#) for accessing the levels, and [unclass](#) to get integer codes.

Examples

```
(ff <- factor(substring("statistics", 1:10, 1:10), levels=letters))
as.integer(ff) # the internal codes
factor(ff)     # drops the levels that do not occur
ff[, drop=TRUE] # the same, more transparently

factor(letters[1:20], labels="letter")

class(ordered(4:1)) # "ordered", inheriting from "factor"

## suppose you want "NA" as a level, and to allow missing values.
(x <- factor(c(1, 2, NA), exclude = NULL))
is.na(x)[2] <- TRUE
x # [1] 1 <NA> <NA>
is.na(x)
# [1] FALSE TRUE FALSE

## Using addNA()
Month <- airquality$Month
table(addNA(Month))
table(addNA(Month, ifany=TRUE))
```

Description

Utility function to access information about files on the user's file systems.

Usage

```
file.access(names, mode = 0)
```

Arguments

names	character vector containing file names.
mode	integer specifying access mode required.

Details

Tilde-expansion is done on names: see [path.expand](#).

The mode value can be the exclusive or of the following values

- 0** test for existence.
- 1** test for execute permission.
- 2** test for write permission.
- 4** test for read permission.

Permission will be computed for real user ID and real group ID (rather than the effective IDs).

Please note that it is not good to use this function to test before trying to open a file. On a multi-tasking system, it is possible that the accessibility of a file will change between the time you call `file.access()` and the time you try to open the file. It is better to wrap file open attempts in [try](#).

Value

An integer vector with values 0 for success and -1 for failure.

Note

This is intended as a replacement for the S-PLUS function `access`, a wrapper for the C function of the same name, which explains the return value encoding. Note that the return value is **false** for **success**.

See Also

[file.info](#), [try](#)

Examples

```
fa <- file.access(dir("."))
table(fa) # count successes & failures
```

`file.choose` *Choose a File Interactively*

Description

Choose a file interactively.

Usage

```
file.choose(new = FALSE)
```

Arguments

`new` Logical: choose the style of dialog box presented to the user: at present only `new = FALSE` is used.

Value

A character vector of length one giving the file path.

See Also

[list.files](#) for non-interactive selection.

`file.info` *Extract File Information*

Description

Utility function to extract information about files on the user's file systems.

Usage

```
file.info(...)
```

Arguments

`...` character vectors containing file paths.

Details

The file paths are tilde-expanded: see [path.expand](#).

What is meant by 'file access' and hence the last access time is system-dependent.

The file 'mode' follows POSIX conventions, giving three octal digits summarizing the permissions for the file owner, the owner's group and for anyone respectively. Each digit is the logical *or* of read (4), write (2) and execute/search (1) permissions.

On most systems symbolic links are followed, so information is given about the file to which the link points rather than about the link.

Value

A data frame with row names the file names and columns

size	double: File size in bytes.
isdir	logical: Is the file a directory?
mode	integer of class "octmode". The file permissions, printed in octal, for example 644.
mtime, ctime, atime	integer of class "POSIXct": file modification, 'last status change' and last access times.
uid	integer: the user ID of the file's owner.
gid	integer: the group ID of the file's group.
uname	character: uid interpreted as a user name.
grname	character: gid interpreted as a group name.

Unknown user and group names will be NA.

Entries for non-existent or non-readable files will be NA. The uid, gid, uname and grname columns may not be supplied on a non-POSIX Unix system.

What is meant by the three file times depends on the OS and file system. On Windows ctime is the creation time.

Note

Some (broken) systems allow files of more than 2Gb to be created but not accessed by the stat system call. Such files will show up as non-readable (and very likely not be readable by any of R's input functions).

See Also

[files](#), [file.access](#), [list.files](#), and [DateTimeClasses](#) for the date formats.

Examples

```
ncol(finfn <- file.info(dir()))# at least six
## Not run: finfn # the whole list
## Those that are more than 100 days old :
finfn[diffftime(Sys.time(), finfn[,"mtime"], units="days") > 100 , 1:4]

file.info("no-such-file-exists")
```

file.path

Construct Path to File

Description

Construct the path to a file from components in a platform-independent way.

Usage

```
file.path(..., fsep = .Platform$file.sep)
```

Arguments

... character vectors.
 fsep the path separator to use.

Value

A character vector of the arguments concatenated term-by-term and separated by `fsep` if all arguments have positive length; otherwise, an empty character vector.

file.show	<i>Display One or More Files</i>
-----------	----------------------------------

Description

Display one or more files.

Usage

```
file.show(..., header = rep("", nfiles),
          title = "R Information",
          delete.file = FALSE, pager = getOption("pager"),
          encoding = "")
```

Arguments

... one or more character vectors containing the names of the files to be displayed. These will be tilde-expanded: see [path.expand](#).
 header character vector (of the same length as the number of files specified in ...) giving a header for each file being displayed. Defaults to empty strings.
 title an overall title for the display. If a single separate window is used for the display, `title` will be used as the window title. If multiple windows are used, their titles should combine the title and the file-specific header.
 delete.file should the files be deleted after display? Used for temporary files.
 pager the pager to be used.
 encoding character string giving the encoding to be assumed for the file(s).

Details

This function provides the core of the R help system, but it can be used for other purposes as well, such as [page](#).

How the pager is implemented is highly system-dependent.

The basic Unix version concatenates the files (using the headers) to a temporary file, and displays it in the pager selected by the `pager` argument, which is a character vector specifying a system command (usually `less`) to run on the set of files.

Most GUI systems will use a separate pager window for each file, and let the user leave it up while R continues running. The selection of such pagers could either be done using special pager names being intercepted by lower-level code (such as `"internal"` and `"console"` on Windows), or by letting `pager` be an R function which will be called with the same first four arguments as `file.show` and take care of interfacing to the GUI.

Not all implementations will honour `delete.file`.

Examples

```
file.show(file.path(R.home("doc"), "COPYRIGHTS"))
```

files

File and Directory Manipulation

Description

These functions provide a low-level interface to the computer's file system.

Usage

```
file.create(..., showWarnings = TRUE)
file.exists(...)
file.remove(...)
file.rename(from, to)
file.append(file1, file2)
file.copy(from, to, overwrite = FALSE)
file.symlink(from, to)
dir.create(path, showWarnings = TRUE, recursive = FALSE,
           mode = "0777")
Sys.chmod(paths, mode = "0777")
Sys.umask(mode = "0000")
```

Arguments

<code>...</code> , <code>file1</code> , <code>file2</code> , <code>from</code> , <code>to</code> , <code>paths</code>	character vectors, containing file names or paths.
<code>path</code>	a character vector containing a single path name.
<code>overwrite</code>	logical; should the destination files be overwritten?
<code>showWarnings</code>	logical; should the warnings on failure be shown?
<code>recursive</code>	logical: should elements of the path other than the last be created? If true, like Unix's <code>mkdir -p</code> .
<code>mode</code>	the file mode to be used on Unix-alikes: it will be coerced by <code>as.octmode</code> .

Details

The `...` arguments are concatenated to form one character string: you can specify the files separately or as one vector. All of these functions expand path names: see [path.expand](#).

`file.create` creates files with the given names if they do not already exist and truncates them if they do. They are created with the maximal permissions allowed by the `umask` setting.

`file.exists` returns a logical vector indicating whether the files named by its argument exist. (Here 'exists' is in the sense of the system's `stat` call: a file will be reported as existing only if you have the permissions needed by `stat`. Existence can also be checked by [file.access](#), which might use different permissions and so obtain a different result. Note that the existence of a file does not imply that it is readable: for that use [file.access](#).)

`file.remove` attempts to remove the files named in its argument. On most platforms 'file' includes *empty* directories, symbolic links, fifos and sockets.

`file.rename` attempts to rename a single file.

`file.append` attempts to append the files named by its second argument to those named by its first. The R subscript recycling rule is used to align names given in vectors of different lengths.

`file.copy` works in a similar way to `file.append` but with the arguments in the natural order for copying. Copying to existing destination files is skipped unless `overwrite = TRUE`. The `to` argument can specify a single existing directory.

`file.symlink` makes symbolic links on those Unix-like platforms which support them. The `to` argument can specify a single existing directory.

`dir.create` creates the last element of the path, unless `recursive = TRUE`. Trailing path separators are removed. The mode will be modified by the `umask` setting in the same way as for the system function `mkdir`. What modes can be set is OS-dependent, and it is unsafe to assume that more than three octal digits will be used. For more details see your OS's documentation on the system call `mkdir` (and not that on the command-line utility of that name).

`Sys.chmod` sets the file permissions of one or more files. It may not be supported (when a warning is issued). See the comments for `dir.create` for how modes are interpreted. Changing mode on a symbolic link is unlikely to work (nor be necessary). For more details see your OS's documentation on the system call `chmod` (and not that on the command-line utility of that name).

`Sys.umask` sets the `umask`. It may not be supported (when a warning is issued and "0000" returned). For more details see your OS's documentation on the system call `umask`.

Value

`dir.create` and `file.rename` return a logical, true for success.

`Sys.umask` returns the previous value of the `umask`, invisibly, as a length-one object of class "octmode".

The remaining functions return a logical vector indicating which operation succeeded for each of the files attempted.

`dir.create` will return failure if the directory already exists.

If `showWarnings = TRUE`, `file.create` and `dir.create` will give a warning for an unexpected failure (e.g. not for a missing value nor for an already existing component for `dir.create(recursive = TRUE)`).

Using a missing value for a file or path name will always be regarded as a failure.

unlink("tmp", recursive=TRUE)
file.remove("A", "B", "C")
```

findInterval

Find Interval Numbers or Indices

Description

Find the indices of `x` in `vec`, where `vec` must be sorted (non-decreasingly); i.e., if `i <- findInterval(x, v)`, we have $v_{i_j} \leq x_j < v_{i_j+1}$ where $v_0 := -\infty$, $v_{N+1} := +\infty$, and $N <- \text{length}(\text{vec})$. At the two boundaries, the returned index may differ by 1, depending on the optional arguments `rightmost.closed` and `all.inside`.

Usage

```
findInterval(x, vec, rightmost.closed = FALSE, all.inside = FALSE)
```

Arguments

<code>x</code>	numeric.
<code>vec</code>	numeric, sorted (weakly) increasingly, of length <code>N</code> , say.
<code>rightmost.closed</code>	logical; if true, the rightmost interval, <code>vec[N-1] .. vec[N]</code> is treated as <i>closed</i> , see below.
<code>all.inside</code>	logical; if true, the returned indices are coerced into $\{1, \dots, N - 1\}$, i.e., 0 is mapped to 1 and <code>N</code> to <code>N - 1</code> .

Details

The function `findInterval` finds the index of one vector `x` in another, `vec`, where the latter must be non-decreasing. Where this is trivial, equivalent to `apply(outer(x, vec, ">="), 1, sum)`, as a matter of fact, the internal algorithm uses interval search ensuring $O(n \log N)$ complexity where $n \leftarrow \text{length}(x)$ (and $N \leftarrow \text{length}(vec)$). For (almost) sorted `x`, it will be even faster, basically $O(n)$.

This is the same computation as for the empirical distribution function, and indeed, `findInterval(t, sort(X))` is *identical* to $nF_n(t; X_1, \dots, X_n)$ where F_n is the empirical distribution function of X_1, \dots, X_n .

When `rightmost.closed = TRUE`, the result for `x[j] = vec[N]` ($= \max(vec)$), is $N - 1$ as for all other values in the last interval.

Value

vector of length `length(x)` with values in $0:N$ (and NA) where $N \leftarrow \text{length}(vec)$, or values coerced to $1:(N-1)$ if and only if `all.inside = TRUE` (equivalently coercing all `x` values *inside* the intervals). Note that NAs are propagated from `x`, and `Inf` values are allowed in both `x` and `vec`.

Author(s)

Martin Maechler

See Also

`approx(*, method = "constant")` which is a generalization of `findInterval()`, `ecdf` for computing the empirical distribution function which is (up to a factor of n) also basically the same as `findInterval(.)`.

Examples

```
N <- 100
X <- sort(round(stats::rt(N, df=2), 2))
tt <- c(-100, seq(-2,2, len=201), +100)
it <- findInterval(tt, X)
tt[it < 1 | it >= N] # only first and last are outside range(X)
```

force

Force Evaluation of an Argument

Description

Forces the evaluation of a function argument.

Usage

```
force(x)
```

Arguments

`x` a formal argument of the enclosing function.

Details

`force` forces the evaluation of a formal argument. This can be useful if the argument will be captured in a closure by the lexical scoping rules and will later be altered by an explicit assignment or an implicit assignment in a loop or an apply function.

Note

This is semantic sugar: just evaluating the symbol will do the same thing (see the examples).

`force` does not force the evaluation of other [promises](#). (It works by forcing the promise that is created when the actual arguments of a call are matched to the formal arguments of a closure, the mechanism which implements *lazy evaluation*.)

Examples

```
f <- function(y) function() y
lf <- vector("list", 5)
for (i in seq(along = lf)) lf[[i]] <- f(i)
lf[[1]]() # returns 5

g <- function(y) { force(y); function() y }
lg <- vector("list", 5)
for (i in seq(along = lg)) lg[[i]] <- g(i)
lg[[1]]() # returns 1

## This is identical to
g <- function(y) { y; function() y }
```

Foreign

Foreign Function Interface

Description

Functions to make calls to compiled code that has been loaded into R.

Usage

```
.C(name, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
.Fortran(name, ..., NAOK = FALSE, DUP = TRUE, PACKAGE, ENCODING)
.External(name, ..., PACKAGE)
.Call(name, ..., PACKAGE)

.External.graphics(name, ..., PACKAGE)
.Call.graphics(name, ..., PACKAGE)
```

Arguments

<code>name</code>	a character string giving the name of a C function or Fortran subroutine, or an object of class " NativeSymbolInfo " or " NativeSymbol " referring to such a name.
<code>...</code>	arguments to be passed to the foreign function.

NAOK	if TRUE then any NA or NaN or Inf values in the arguments are passed on to the foreign function. If FALSE, the presence of NA or NaN or Inf values is regarded as an error.
DUP	if TRUE then arguments are duplicated before their address is passed to C or Fortran.
PACKAGE	if supplied, confine the search for the name to the DLL given by this argument (plus the conventional extension, '.so', '.sl', '.dll', ...). This is intended to add safety for packages, which can ensure by using this argument that no other package can override their external symbols. Use PACKAGE="base" for symbols linked in to R.
ENCODING	optional name for an encoding to be assumed for character vectors. See 'Details'.

Details

The functions `.C` and `.Fortran` can be used to make calls to compiled C and Fortran code.

`.External` and `.External.graphics` can be used to call compiled code that uses R objects in the same way as internal R functions.

`.Call` and `.Call.graphics` can be used to call compiled code which makes use of internal R objects. The arguments are passed to the C code as a sequence of R objects. It is included to provide compatibility with S version 4.

Specifying ENCODING overrides any declared encodings (see `link{Encoding}`) which are otherwise used to translate to the current locale before passing the strings to the compiled code.

For details about how to write code to use with `.Call` and `.External`, see the chapter on "System and foreign language interfaces" in the "Writing R Extensions" manual.

Value

The functions `.C` and `.Fortran` return a list similar to the `...` list of arguments passed in, but reflecting any changes made by the C or Fortran code.

`.External`, `.Call`, `.External.graphics`, and `.Call.graphics` return an R object.

These calls are typically made in conjunction with `dyn.load` which links DLLs to R.

The `.graphics` versions of `.Call` and `.External` are used when calling code which makes low-level graphics calls. They take additional steps to ensure that the device driver display lists are updated correctly.

Argument types

The mapping of the types of R arguments to C or Fortran arguments in `.C` or `.Fortran` is

R	C	Fortran
integer	int *	integer
numeric	double *	double precision
– or –	float *	real
complex	Rcomplex *	double complex
logical	int *	integer
character	char **	[see below]
raw	unsigned char *	not allowed
list	SEXP *	not allowed
other	SEXP	not allowed

Numeric vectors in **R** will be passed as type `double *` to **C** (and as `double` precision to Fortran) unless (i) `.C` or `.Fortran` is used, (ii) `DUP` is true and (iii) the argument has attribute `Csingle` set to `TRUE` (use `as.single` or `single`). This mechanism is only intended to be used to facilitate the interfacing of existing **C** and Fortran code.

The **C** type `Rcomplex` is defined in `'Complex.h'` as a `typedef struct {double r; double i;}`. Fortran type `double complex` is an extension to the Fortran standard, and the availability of a mapping of `complex` to Fortran may be compiler dependent.

Note: The **C** types corresponding to `integer` and `logical` are `int`, not `long` as in **S**. This difference matters on 64-bit platforms.

The first character string of a character vector is passed as a **C** character array to Fortran: that string may be usable as `character*255` if its true length is passed separately. Only up to 255 characters of the string are passed back. (How well this works, or even if it works at all, depends on the **C** and Fortran compilers and the platform.)

Missing (NA) string values are passed to `.C` as the string "NA". As the **C** `char` type can represent all possible bit patterns there appears to be no way to distinguish missing strings from the string "NA". If this distinction is important use `.Call`.

Functions, expressions, environments and other language elements are passed as the internal **R** pointer type `SEXP`. This type is defined in `'Rinternals.h'` or the arguments can be declared as generic pointers, `void *`. Lists are passed as **C** arrays of `SEXP` and can be declared as `void *` or `SEXP *`. Note that you cannot assign values to the elements of the list within the **C** routine. Assigning values to elements of the array corresponding to the list bypasses **R**'s memory management/garbage collection and will cause problems. Essentially, the array corresponding to the list is read-only. If you need to return **S** objects created within the **C** routine, use the `.Call` interface.

R functions can be invoked using `call_S` or `call_R` and can be passed lists or the simple types as arguments.

Warning

DUP=FALSE is dangerous.

There are two dangers with using `DUP=FALSE`.

The first is that if you pass a local variable to `.C/.Fortran` with `DUP=FALSE`, your compiled code can alter the local variable and not just the copy in the return list. Worse, if you pass a local variable that is a formal parameter of the calling function, you may be able to change not only the local variable but the variable one level up. This will be very hard to trace.

The second is that lists are passed as a single **R** `SEXP` with `DUP=FALSE`, not as an array of `SEXP`. This means the accessor macros in `'Rinternals.h'` are needed to get at the list elements and the lists cannot be passed to `call_S/call_R`. New code using **R** objects should be written using `.Call` or `.External`, so this is now only a minor issue.

In addition, character vectors and lists cannot be used with `DUP=FALSE`.

It is safe and useful to set `DUP=FALSE` if you do not change any of the variables that might be affected, e.g.,

```
.C("Cfunction", input=x, output=numeric(10)).
```

In this case the output variable did not exist before the call so it cannot cause trouble. If the input variable is not changed in the **C** code of `Cfunction` you are safe.

Neither `.Call` nor `.External` copy their arguments. You should treat arguments you receive through these interfaces as read-only.

Fortran symbol names

All compilers that can be used with `R` map symbol names to lower case, and so does `.Fortran`.

Symbol names containing underscores are not valid Fortran 77 (although they are valid in Fortran 9x). Many Fortran 77 compilers (including `g77`) will allow them but translate them in a different way to names not containing underscores. Such names will work with `.Fortran`, but portable code should not use Fortran names containing underscores.

Use `.Fortran` with care for compiled Fortran 9x code: it may not work if the Fortran 9x compiler used differs from the Fortran compiler used when configuring `R`, especially if the subroutine name is not lower-case or includes an underscore.

Header files for external code

Writing code for use with `.External` and `.Call` will need to use internal `R` structures. If possible use just those defined in `'Rinternals.h'` and/or the macros in `'Rdefines.h'`, as other header files are not installed and are even more likely to be changed.

[dyn.load](#).

formals

Access to and Manipulation of the Formal Arguments

Description

Get or set the formal arguments of a function.

Usage

```
formals(fun = sys.function(sys.parent()))
formals(fun, envir = environment(fun)) <- value
```

Arguments

<code>fun</code>	a function object, or see 'Details'.
<code>envir</code>	environment in which the function should be defined.
<code>value</code>	a list (or pairlist) of <code>R</code> expressions.

Details

For the first form, `fun` can also be a character string naming the function to be manipulated, which is searched for from the parent environment. If it is not specified, the function calling `formals` is used.

Only *closures* have formals, not primitive functions.

Value

`formals` returns the formal argument list of the function specified, as a [pairlist](#), or `NULL` for a non-function or primitive.

The replacement form sets the formals of a function to the list/pairlist on the right hand side, and (potentially) resets the environment of the function.

See Also

[args](#) for a human-readable version, [alist](#), [body](#), [function](#).

Examples

```
require(stats); require(graphics)
length(formals(lm))      # the number of formal arguments
names(formals(boxplot)) # formal arguments names

f <- function(x) a+b
formals(f) <- alist(a=,b=3) # function(a,b=3)a+b
f(2) # result = 5
```

format

Encode in a Common Format

Description

Format an R object for pretty printing.

Usage

```
format(x, ...)
```

Default S3 method:

```
format(x, trim = FALSE, digits = NULL, nsmall = 0,
       justify = c("left", "right", "centre", "none"),
       width = NULL, na.encode = TRUE, scientific = NA,
       big.mark = "", big.interval = 3,
       small.mark = "", small.interval = 5,
       decimal.mark = ".", zero.print = NULL, drop0trailing = FALSE, ...)
```

S3 method for class 'data.frame':

```
format(x, ..., justify = "none")
```

S3 method for class 'factor':

```
format(x, ...)
```

S3 method for class 'AsIs':

```
format(x, width = 12, ...)
```

Arguments

<code>x</code>	any R object (conceptually); typically numeric.
<code>trim</code>	logical; if <code>FALSE</code> , logical, numeric and complex values are right-justified to a common width: if <code>TRUE</code> the leading blanks for justification are suppressed.
<code>digits</code>	how many significant digits are to be used for numeric and complex <code>x</code> . The default, <code>NULL</code> , uses <code>getOption(digits)</code> . This is a suggestion: enough decimal places will be used so that the smallest (in magnitude) number has this many significant digits, and also to satisfy <code>nsmall</code> . (For the interpretation for complex numbers see signif.)
<code>nsmall</code>	the minimum number of digits to the right of the decimal point in formatting real/complex numbers in non-scientific formats. Allowed values are <code>0 <= nsmall <= 20</code> .
<code>justify</code>	should a <i>character</i> vector be left-justified (the default), right-justified, centred or left alone.
<code>width</code>	default method: the <i>minimum</i> field width or <code>NULL</code> or <code>0</code> for no restriction. <code>AsIs</code> method: the <i>maximum</i> field width for non-character objects. <code>NULL</code> corresponds to the default 12.
<code>na.encode</code>	logical: should NA strings be encoded? Note this only applies to elements of character vectors, not to numerical or logical NAs, which are always encoded as <code>"NA"</code> .
<code>scientific</code>	Either a logical specifying whether elements of a real or complex vector should be encoded in scientific format, or an integer penalty (see options("scipen")). Missing values correspond to the current default penalty.
<code>...</code>	further arguments passed to or from other methods.
<code>big.mark</code> , <code>big.interval</code> , <code>small.mark</code> , <code>small.interval</code> , <code>decimal.mark</code> , <code>zero.print</code> , <code>dr</code>	used for prettying (longish) decimal sequences, passed to prettyNum : that help page explains the details.

Details

`format` is a generic function. Apart from the methods described here there are methods for dates (see [format.Date](#)), date-times (see [format.POSIXct](#)) and for other classes such as `format.octmode` and `format.dist`.

`format.data.frame` formats the data frame column by column, applying the appropriate method of `format` for each column. Methods for columns are often similar to `as.character` but offer more control. Matrix and data-frame columns will be converted to separate columns in the result, and character columns (normally all) will be given class `"AsIs"`.

`format.factor` converts the factor to a character vector and then calls the default method (and so `justify` applies).

`format.AsIs` deals with columns of complicated objects that have been extracted from a data frame. Character objects are passed to the default method (and so `width` does not apply). Otherwise it calls [toString](#) to convert the object to character (if a vector or list, element by element) and then right-justifies the result.

Justification for character vectors (and objects converted to character vectors by their methods) is done on display width (see [nchar](#)), taking double-width characters and the rendering of special characters (as escape sequences, including escaping backslash: see [print.default](#)) into account. Character strings are padded with blanks to the display width of the widest. (If `na.encode`

= FALSE missing character strings are not included in the width computations and are not encoded.)

Numeric vectors are encoded with the minimum number of decimal places needed to display all the elements to at least the `digit` significant digits. However, if all the elements then have trailing zeroes, the number of decimal places is reduced until at least one element has a non-zero final digit; see also the argument documentation for `big.*`, `small.*` etc, above.

Raw vectors are converted to their 2-digit hexadecimal representation by `as.character`.

Value

An object of similar structure to `x` containing character representations of the elements of the first argument `x` in a common format, and in the current locale's encoding.

For character, numeric, complex or factor `x`, `dims` and `dimnames` are preserved on matrices/arrays and names on vectors: no other attributes are copied.

If `x` is a list, the result is a character vector obtained by applying `format.default(x, ...)` to each element of the list (after `unlisting` elements which are themselves lists), and then collapsing the result for each element with `paste(collapse = ", ")`. The defaults in this case are `trim = TRUE`, `justify = "none"` since one does not usually want alignment in the collapsed strings.

See Also

`format.info` indicates how an atomic vector would be formatted.

`formatC`, `paste`, `as.character`, `sprintf`, `print`, `prettyNum`, `toString`, `encodeString`.

Examples

```
format(1:10)
format(1:10, trim = TRUE)

zz <- data.frame("row names" = c("aaaaa", "b"), check.names=FALSE)
format(zz)
format(zz, justify = "left")

## use of nsmall
format(13.7)
format(13.7, nsmall = 3)
format(c(6.0, 13.1), digits = 2)
format(c(6.0, 13.1), digits = 2, nsmall = 1)

## use of scientific
format(2^31-1)
format(2^31-1, scientific = TRUE)

## a list
z <- list(a=letters[1:3], b=(-pi+0i)^((-2:2)/2), c=c(1,10,100,1000),
          d=c("a", "longer", "character", "string"))
```

```
format(z, digits = 2)
format(z, digits = 2, justify = "left", trim = FALSE)
```

format.Date *Date Conversion Functions to and from Character*

Description

Functions to convert between character representations and objects of class "Date" representing calendar dates.

Usage

```
as.Date(x, ...)
## S3 method for class 'character':
as.Date(x, format = "", ...)
## S3 method for class 'numeric':
as.Date(x, origin, ...)

## S3 method for class 'Date':
format(x, ...)

## S3 method for class 'Date':
as.character(x, ...)
```

Arguments

x	An object to be converted.
format	A character string. The default is "%Y-%m-%d". For details see strftime .
origin	a Date object, or something which can be coerced by <code>as.Date(origin, ...)</code> to such an object.
...	Further arguments to be passed from or to other methods, including <code>format</code> for <code>as.character</code> and <code>as.Date</code> methods.

Details

The usual vector re-cycling rules are applied to `x` and `format` so the answer will be of length that of the longer of the vectors.

Locale-specific conversions to and from character strings are used where appropriate and available. This affects the names of the days and months.

The `as.Date` methods accept character strings, factors, logical NA and objects of classes "[POSIXlt](#)" and "[POSIXct](#)". (The last are converted to days by ignoring the time after midnight in the representation of the time in UTC.) Also objects of class "date" (from package [date](#) or [survival](#)) and "dates" (from package [chron](#)). Character strings are processed as far as necessary for the format specified: any trailing characters are ignored.

`as.Date` will accept numeric data (the number of days since an epoch), but *only* if `origin` is supplied.

The `format` and `as.character` methods ignore any fractional part of the date.

Value

The `format` and `as.character` methods return a character vector representing the date. NA dates are returned as `NA_character_`.

The `as.Date` methods return an object of class `"Date"`.

Note

The default formats follow the rules of the ISO 8601 international standard which expresses a day as `"2001-02-03"`.

If the date string does not specify the date completely, the returned answer may be system-specific. The most common behaviour is to assume that a missing year, month or day is the current one. If it specifies a date incorrectly, reliable implementations will give an error and the date is reported as NA. Unfortunately some common implementations (such as `'glibc'`) are unreliable and guess at the intended meaning.

Years before 1CE (aka 1AD) will probably not be handled correctly.

[Date](#) for details of the date class; [locales](#) to query or set a locale.

Your system's help pages on `strftime` and `strptime` to see how to specify their formats.

Examples

```
## locale-specific version of the date
format(Sys.Date(), "%a %b %d")

## read in date info in format 'ddmmyyyy'
## This will give NA(s) in some locales; setting the C locale
## as in the commented lines will overcome this on most systems.
## lct <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "31mar1960", "30jul1960")
z <- as.Date(x, "%d%b%Y")
## Sys.setlocale("LC_TIME", lct)
z

## read in date/time info in format 'm/d/y'
dates <- c("02/27/92", "02/27/92", "01/14/92", "02/28/92", "02/01/92")
as.Date(dates, "%m/%d/%y")

## date given as number of days since 1900-01-01 (a date in 1989)
as.Date(32768, origin="1900-01-01")
```

format.info	<i>format(.) Information</i>
-------------	------------------------------

Description

Information is returned on how `format(x, digits, nsmall)` would be formatted.

Usage

```
format.info(x, digits = NULL, nsmall = 0)
```

Arguments

<code>x</code>	an atomic vector; a potential argument of <code>format(x, ...)</code> .
<code>digits</code>	how many significant digits are to be used for numeric and complex <code>x</code> . The default, <code>NULL</code> , uses <code>getOption(digits)</code> .
<code>nsmall</code>	(see <code>format(..., nsmall)</code>).

Value

An *integer vector* of length 1, 3 or 6, say `r`.

For logical, integer and character vectors a single element, the width which would be used by `format` if `width = NULL`.

For numeric vectors:

<code>r[1]</code>	width (in characters) used by <code>format(x)</code>
<code>r[2]</code>	number of digits after decimal point.
<code>r[3]</code>	in <code>0:2</code> ; if ≥ 1 , <i>exponential</i> representation would be used, with exponent length of <code>r[3]+1</code> .

For a complex vector the first three elements refer to the real parts, and there are three further elements corresponding to the imaginary parts.

See Also

`format`, `formatC`.

Examples

```
dd <- options("digits") ; options(digits = 7) #-- for the following
format.info(123) # 3 0 0
format.info(pi) # 8 6 0
format.info(1e8) # 5 0 1 - exponential "1e+08"
format.info(1e222) # 6 0 2 - exponential "1e+222"

x <- pi*10^c(-10,-2,0:2,8,20)
names(x) <- formatC(x, width=1, digits=3, format="g")
cbind(sapply(x, format))
t(sapply(x, format.info))

## using at least 8 digits right of "."
```

```
t(sapply(x, format.info, nsmall = 8))

# Reset old options:
options(dd)
```

format.pval	<i>Format P Values</i>
-------------	------------------------

Description

format.pval is intended for formatting p-values.

Usage

```
format.pval(pv, digits = max(1, getOption("digits") - 2),
            eps = .Machine$double.eps, na.form = "NA")
```

Arguments

pv	a numeric vector.
digits	how many significant digits are to be used.
eps	a numerical tolerance: see ‘Details’.
na.form	character representation of NAs.

Details

format.pval is mainly an auxiliary function for [print.summary.lm](#) etc., and does separate formatting for fixed, floating point and very small values; those less than eps are formatted as "<[eps]" (where ‘[eps]’ stands for `format(eps, digits)`).

Value

A character vector.

Examples

```
format.pval(c(stats::runif(5), pi^-100, NA))
format.pval(c(0.1, 0.0001, 1e-27))
```

formatC

Formatting Using C-style Formats

Description

Formatting numbers individually and flexibly, using C style format specifications.

Usage

```
formatC(x, digits = NULL, width = NULL,
        format = NULL, flag = "", mode = NULL,
        big.mark = "", big.interval = 3,
        small.mark = "", small.interval = 5,
        decimal.mark = ".", preserve.width = "individual",
        zero.print = NULL, drop0trailing = FALSE)

prettyNum(x, big.mark = "", big.interval = 3,
          small.mark = "", small.interval = 5,
          decimal.mark = ".",
          preserve.width = c("common", "individual", "none"),
          zero.print = NULL, drop0trailing = FALSE, ...)
```

Arguments

x	an atomic numerical or character object, typically a vector of real numbers.
digits	the desired number of digits after the decimal point (<code>format = "f"</code>) or <i>significant</i> digits (<code>format = "g", "e" or "fg"</code>). Default: 2 for integer, 4 for real numbers. If less than 0, the C default of 6 digits is used. If specified as more than 50, 50 will be used with a warning unless <code>format = "f"</code> where it is limited to typically 324. (Not more than 15–21 digits need be accurate, depending on the OS and compiler used. This limit is just a precaution against segfaults in the underlying C runtime.)
width	the total field width; if both <code>digits</code> and <code>width</code> are unspecified, <code>width</code> defaults to 1, otherwise to <code>digits + 1</code> . <code>width = 0</code> will use <code>width = digits</code> , <code>width < 0</code> means left justify the number in this field (equivalent to <code>flag = "-"</code>). If necessary, the result will have more characters than <code>width</code> . For character data this is interpreted in characters (not bytes nor display width).
format	equal to "d" (for integers), "f", "e", "E", "g", "G", "fg" (for reals), or "s" (for strings). Default is "d" for integers, "g" for reals. "f" gives numbers in the usual xxx.xxx format; "e" and "E" give n.ddde+nn or n.dddE+nn (scientific format); "g" and "G" put <code>x[i]</code> into scientific format only if it saves space to do so. "fg" uses fixed format as "f", but <code>digits</code> as the minimum number of <i>significant</i> digits. This can lead to quite long result strings, see examples below. Note that unlike <code>signif</code> this prints large numbers with more significant digits than <code>digits</code> . Trailing zeros are <i>dropped</i> in this format, unless <code>flag</code> contains "#".
flag	For <code>formatC</code> , a character string giving a format modifier as in Kernighan and Ritchie (1988, page 243). "0" pads leading zeros; "-" does left adjustment, others are "+", " ", and "#". There can be more than one of these, in any order.

mode	"double" (or "real"), "integer" or "character". Default: Determined from the storage mode of <code>x</code> .
big.mark	character; if not empty used as mark between every <code>big.interval</code> decimals <i>before</i> (hence <code>big</code>) the decimal point.
big.interval	see <code>big.mark</code> above; defaults to 3.
small.mark	character; if not empty used as mark between every <code>small.interval</code> decimals <i>after</i> (hence <code>small</code>) the decimal point.
small.interval	see <code>small.mark</code> above; defaults to 5.
decimal.mark	the character to be used to indicate the numeric decimal point.
preserve.width	string specifying if the string widths should be preserved where possible in those cases where marks (<code>big.mark</code> or <code>small.mark</code>) are added. "common", the default, corresponds to <code>format</code> -like behavior whereas "individual" is the default in <code>formatC()</code> .
zero.print	logical, character string or NULL specifying if and how <i>zeros</i> should be formatted specially. Useful for pretty printing 'sparse' objects.
drop0trailing	logical, indicating if trailing zeros, i.e., "0" <i>after</i> the decimal mark, should be removed; also drops "e+00" in exponential formats.
...	arguments passed to <code>format</code> .

Details

If you set `format` it overrides the setting of `mode`, so `formatC(123.45, mode="double", format="d")` gives 123.

The rendering of scientific format is platform-dependent: some systems use `n.ddde+nnn` or `n.ddden` rather than `n.ddde+nn`.

`formatC` does not necessarily align the numbers on the decimal point, so `formatC(c(6.11, 13.1), digits=2, format="fg")` gives `c("6.1", " 13")`. If you want common formatting for several numbers, use `format`.

`prettyNum` is the utility function for prettifying `x`. If `x` is not a character, `format(x[i], ...)` is applied to each element, and then it is left unchanged if all the other arguments are at their defaults. Note that `prettyNum(x)` may behave unexpectedly if `x` is a character vector not resulting from something like `format(<number>)`: in particular it assumes that a period is a decimal mark.

Value

A character object of same size and attributes as `x`, in the current locale's encoding. Unlike `format`, each number is formatted individually. Looping over each element of `x`, the C function `sprintf(...)` is called for numeric inputs (inside the C function `str_signif`).

`formatC`: for character `x`, do simple (left or right) padding with white space.

Author(s)

`formatC` was originally written by Bill Dunlap, later much improved by Martin Maechler. It was first adapted for R by Friedrich Leisch.

Examples

```
xx <- pi * 10^(-5:4)
cbind(format(xx, digits=4), formatC(xx))
cbind(formatC(xx, width = 9, flag = "-"))
cbind(formatC(xx, digits = 5, width = 8, format = "f", flag = "0"))
cbind(format(xx, digits=4), formatC(xx, digits = 4, format = "fg"))

formatC( c("a", "Abc", "no way"), width = -7) # <=> flag = "-"
formatC(c((-1:1)/0,c(1,100)*pi), width=8, digits=1)

xx <- c(1e-12,-3.98765e-10,1.45645e-69,1e-70,pi*1e37,3.44e4)
##      1      2      3      4      5      6
formatC(xx)
formatC(xx, format="fg") # special "fixed" format.
formatC(xx[1:4], format="f", digits=75) #>> even longer strings

formatC(c(3.24, 2.3e-6), format="f", digits=11, drop0trailing=TRUE)

r <- c("76491283764.97430", "29.12345678901", "-7.1234", "-100.1", "1123")
## American:
prettyNum(r, big.mark = ",")
## Some Europeans:
prettyNum(r, big.mark = "'", decimal.mark = ",")

(dd <- sapply(1:10, function(i)paste((9:0)[1:i],collapse="")))
prettyNum(dd, big.mark="'")

## examples of 'small.mark'
pN <- stats::pnorm(1:7, lower.tail = FALSE)
cbind(format(pN, small.mark = " ", digits = 15))
cbind(formatC(pN, small.mark = " ", digits = 17, format = "f"))

cbind(ff <- format(1.2345 + 10^(0:5), width = 11, big.mark = "'"))
## all with same width (one more than the specified minimum)

## individual formatting to common width:
fc <- formatC(1.234 + 10^(0:8), format="fg", width=11, big.mark = "'")
cbind(fc)
```

Description

Format vectors of items and their descriptions as 2-column tables or LaTeX-style description lists.

Usage

```
formatDL(x, y, style = c("table", "list"),
         width = 0.9 * getOption("width"), indent = NULL)
```

Arguments

<code>x</code>	a vector giving the items to be described, or a list of length 2 or a matrix with 2 columns giving both items and descriptions.
<code>y</code>	a vector of the same length as <code>x</code> with the corresponding descriptions. Only used if <code>x</code> does not already give the descriptions.
<code>style</code>	a character string specifying the rendering style of the description information. If "table", a two-column table with items and descriptions as columns is produced (similar to Texinfo's <code>@table</code> environment. If "list", a LaTeX-style tagged description list is obtained.
<code>width</code>	a positive integer giving the target column for wrapping lines in the output.
<code>indent</code>	a positive integer specifying the indentation of the second column in table style, and the indentation of continuation lines in list style. Must not be greater than <code>width/2</code> , and defaults to <code>width/3</code> for table style and <code>width/9</code> for list style.

Details

After extracting the vectors of items and corresponding descriptions from the arguments, both are coerced to character vectors.

In table style, items with more than `indent - 3` characters are displayed on a line of their own.

Value

a character vector with the formatted entries.

Examples

```
## Use R to create the 'INDEX' for package 'splines' from its 'CONTENTS'
x <- read.dcf(file = system.file("CONTENTS", package = "splines"),
             fields = c("Entry", "Description"))
x <- as.data.frame(x)
writeLines(formatDL(x$Entry, x$Description))
## or equivalently: writeLines(formatDL(x))
## Same information in tagged description list style:
writeLines(formatDL(x$Entry, x$Description, style = "list"))
## or equivalently: writeLines(formatDL(x, style = "list"))
```

function

*Function Definition***Description**

These functions provide the base mechanisms for defining new functions in the R language.

Usage

```
function( arglist ) expr
return(value)
```

Arguments

arglist	Empty or one or more name or name=expression terms.
value	An expression.

Details

The names in an argument list can be back-quoted non-standard names (see ‘[backquote](#)’).

If `value` is missing, `NULL` is returned. If it is a single expression, the value of the evaluated expression is returned. (The expression is evaluated as soon as `return` is called, in the evaluation frame of the function and before any `on.exit` expression is evaluated.)

If the end of a function is reached without calling `return`, the value of the last evaluated expression is returned.

Warning

Prior to R 1.8.0, `value` could be a series of non-empty expressions separated by commas. In that case the value returned is a list of the evaluated expressions, with names set to the expressions where these are the names of R objects. That is, `a=foo()` names the list component `a` and gives it the value which results from evaluating `foo()`.

This has been deprecated (and a warning is given), as it was never documented in S, and whether or not the list is named differs by S versions. Supply a (named) list `value` instead.

[args](#) and [body](#) for accessing the arguments and body of a function.

[debug](#) for debugging; using [invisible](#) inside `return(.)` for returning *invisibly*.

Examples

```
norm <- function(x) sqrt(x**x)
norm(1:4)

## An anonymous function:
(function(x,y){ z <- x^2 + y^2; x+y+z })(0:7, 1)
```

funprog

Common Higher-Order Functions in Functional Programming Languages

Description

Reduce uses a binary function to successively combine the elements of a given vector and a possibly given initial value. Filter extracts the elements of a vector for which a predicate (logical) function gives true. Find and Position give the first or last such element and its position in the vector, respectively. Map applies a function to the corresponding elements of given vectors. Negate creates the negation of a given function.

Usage

```
Reduce(f, x, init, right = FALSE, accumulate = FALSE)
Filter(f, x)
Find(f, x, right = FALSE, nomatch = NULL)
Map(f, ...)
Negate(f)
Position(f, x, right = FALSE, nomatch = NA_integer_)
```

Arguments

f	a function of the appropriate arity (binary for Reduce, unary for Filter, Find and Position, k -ary for Map if this is called with k arguments). An arbitrary predicate function for Negate.
x	a vector.
init	an R object of the same kind as the elements of x.
right	a logical indicating whether to proceed from left to right (default) or from right to left.
accumulate	a logical indicating whether the successive reduce combinations should be accumulated. By default, only the final combination is used.
nomatch	the value to be returned in the case when “no match” (no element satisfying the predicate) is found.
...	vectors.

Details

If `init` is given, Reduce logically adds it to the start (when proceeding left to right) or the end of `x`, respectively. If this possibly augmented vector v has $n > 1$ elements, Reduce successively applies f to the elements of v from left to right or right to left, respectively. I.e., a left reduce computes $l_1 = f(v_1, v_2)$, $l_2 = f(l_1, v_3)$, etc., and returns $l_{n-1} = f(l_{n-2}, v_n)$, and a right reduce does $r_{n-1} = f(v_{n-1}, v_n)$, $r_{n-2} = f(v_{n-2}, r_{n-1})$ and returns $r_1 = f(v_1, r_2)$. (E.g., if v is the sequence (2, 3, 4) and f is division, left and right reduce give $(2/3)/4 = 1/6$ and $2/(3/4) = 8/3$, respectively.) If v has only a single element, this is returned; if there are no elements, NULL is returned. Thus, it is ensured that `f` is always called with 2 arguments.

The current implementation is non-recursive to ensure stability and scalability.

Reduce is patterned after Common Lisp's `reduce`. A reduce is also known as a fold (e.g., in Haskell) or an accumulate (e.g., in the C++ Standard Template Library). The accumulative version corresponds to Haskell's scan functions.

Filter applies the unary predicate function `f` to each element of `x`, coercing to logical if necessary, and returns the subset of `x` for which this gives true. Note that possible NA values are currently always taken as false; control over NA handling may be added in the future. Filter corresponds to `filter` in Haskell or `remove-if-not` in Common Lisp.

Find and Position are patterned after Common Lisp's `find-if` and `position-if`, respectively. If there is an element for which the predicate function gives true, then the first or last such element or its position is returned depending on whether `right` is false (default) or true, respectively. If there is no such element, the value specified by `nomatch` is returned. The current implementation is not optimized for performance.

Map is a simple wrapper to `mapply` which does not attempt to simplify the result, similar to Common Lisp's `mapcar` (with arguments being recycled, however). Future versions may allow some control of the result type.

Negate corresponds to Common Lisp's `complement`. Given a (predicate) function `f`, it creates a function which returns the logical negation of what `f` returns.

Examples

```
## A general-purpose adder:
add <- function(x) Reduce("+", x)
add(list(1, 2, 3))
## Like sum(), but can also be used for adding matrices etc., as it will
## use the appropriate '+' method in each reduction step.
## More generally, many generics meant to work on arbitrarily many
## arguments can be defined via reduction:
FOO <- function(...) Reduce(FOO2, list(...))
FOO2 <- function(x, y) UseMethod("FOO2")
## FOO() methods can then be provided via FOO2() methods.

## A general-purpose cumulative adder:
cadd <- function(x) Reduce("+", x, accumulate = TRUE)
cadd(seq_len(7))

## A simple function to compute continued fractions:
cfrac <- function(x) Reduce(function(u, v) u + 1 / v, x, right = TRUE)
## Continued fraction approximation for pi:
cfrac(c(3, 7, 15, 1, 292))
## Continued fraction approximation for Euler's number (e):
cfrac(c(2, 1, 2, 1, 1, 4, 1, 1, 6, 1, 1, 8))

## Iterative function application:
Funcall <- function(f, ...) f(...)
## Compute log(exp(acos(cos(0))))
Reduce(Funcall, list(log, exp, acos, cos), 0, right = TRUE)
## n-fold iterate of a function, functional style:
Iterate <- function(f, n = 1)
  function(x) Reduce(Funcall, rep.int(list(f), n), x, right = TRUE)
## Continued fraction approximation to the golden ratio:
Iterate(function(x) 1 + 1 / x, 30)(1)
## which is the same as
cfrac(rep.int(1, 31))
## Computing square root approximations for x as fixed points of the
```

```
## function t |-> (t + x / t) / 2, as a function of the initial value:
asqrt <- function(x, n) Iterate(function(t) (t + x / t) / 2, n)
asqrt(2, 30)(10) # Starting from a positive value => +sqrt(2)
asqrt(2, 30)(-1) # Starting from a negative value => -sqrt(2)

## A list of all functions in the base environment:
funs <- Filter(is.function, sapply(ls(baseenv()), get, baseenv()))
## Functions in base with more than 10 arguments:
names(Filter(function(f) length(formals(args(f))) > 10, funs))
## Number of functions in base with a '...' argument:
length(Filter(function(f)
              any(names(formals(args(f))) %in% "..."),
              funs))

## Find all objects in the base environment which are *not* functions:
Filter(Negate(is.function), sapply(ls(baseenv()), get, baseenv()))
```

gc

*Garbage Collection***Description**

A call of `gc` causes a garbage collection to take place. `gcinfo` sets a flag so that automatic collection is either silent (`verbose=FALSE`) or prints memory usage statistics (`verbose=TRUE`).

Usage

```
gc(verbose = getOption("verbose"), reset=FALSE)
gcinfo(verbose)
```

Arguments

<code>verbose</code>	logical; if <code>TRUE</code> , the garbage collection prints statistics about cons cells and the space allocated for vectors.
<code>reset</code>	logical; if <code>TRUE</code> the values for maximum space used are reset to the current values.

Details

A call of `gc` causes a garbage collection to take place. This will also take place automatically without user intervention, and the primary purpose of calling `gc` is for the report on memory usage.

However, it can be useful to call `gc` after a large object has been removed, as this may prompt R to return memory to the operating system.

R allocates space for vectors in multiples of 8 bytes: hence the report of "Vcells", a relict of an earlier allocator (that used a vector heap).

When `gcinfo(TRUE)` is in force, messages are sent to the message connection at each garbage collection of the form

```
Garbage collection 12 = 10+0+2 (level 0) ...
6.4 Mbytes of cons cells used (58%)
2.0 Mbytes of vectors used (32%)
```

Here the last two lines give the current memory usage rounded up to the next 0.1Mb and as a percentage of the current trigger value. The first line gives a breakdown of the number of garbage collections at various levels (for an explanation see the ‘R Internals’ manual).

Value

gc returns a matrix with rows "Ncells" (*cons cells*), usually 28 bytes each on 32-bit systems and 56 bytes on 64-bit systems, and "Vcells" (*vector cells*, 8 bytes each), and columns "used" and "gc trigger", each also interpreted in megabytes (rounded up to the next 0.1Mb).

If maxima have been set for either "Ncells" or "Vcells", a fifth column is printed giving the current limits in Mb (with NA denoting no limit).

The final two columns show the maximum space used since the last call to gc(reset=TRUE) (or since R started).

gcinfo returns the previous value of the flag.

See Also

The ‘R Internals’ manual.

[Memory](#) on R’s memory management, and [gctorture](#) if you are an R developer.

[reg.finalizer](#) for actions to happen at garbage collection.

Examples

```
gc() #- do it now
gcinfo(TRUE) #-- in the future, show when R does it
x <- integer(100000); for(i in 1:18) x <- c(x,i)
gcinfo(verbose = FALSE) #-- don't show it anymore

gc(TRUE)

gc(reset=TRUE)
```

gc.time

Report Time Spent in Garbage Collection

Description

This function reports the time spent in garbage collection so far in the R session while GC timing was enabled.

Usage

```
gc.time(on = TRUE)
```

Arguments

on logical; if TRUE, GC timing is enabled.

Value

A numerical vector of length 5 giving the user CPU time, the system CPU time, the elapsed time and children's user and system CPU times (normally both zero), of time spent doing garbage collection whilst GC timing was enabled.

Warnings

This is experimental functionality, likely to be removed as soon as the next release.

The timings are rounded up by the sampling interval for timing processes, and so are likely to be over-estimates.

See Also

[gc](#), [proc.time](#) for the timings for the session.

Examples

```
gc.time()
```

gctorture

Torture Garbage Collector

Description

Provokes garbage collection on (nearly) every memory allocation. Intended to ferret out memory protection bugs. Also makes R run *very* slowly, unfortunately.

Usage

```
gctorture(on = TRUE)
```

Arguments

`on` logical; turning it on/off.

Value

Previous value.

Author(s)

Peter Dalgaard

`get`*Return the Value of a Named Object*

Description

Search for an R object with a given name and return it.

Usage

```
get(x, pos = -1, envir = as.environment(pos), mode = "any",
    inherits = TRUE)

mget(x, envir, mode = "any",
     ifnotfound = list(function(x)
       stop(paste("value for '", x, "' not found", sep = "")),
       call. = FALSE)),
     inherits = FALSE)
```

Arguments

<code>x</code>	a variable name (given as a character string).
<code>pos</code>	where to look for the object (see the details section); if omitted, the function will search as if the name of the object appeared unquoted in an expression.
<code>envir</code>	an alternative way to specify an environment to look in; see the ‘Details’ section.
<code>mode</code>	the mode or type of object sought: see the ‘Details’ section.
<code>inherits</code>	should the enclosing frames of the environment be searched?
<code>ifnotfound</code>	A list of values to be used if the item is not found: it will be coerced to list if necessary.

Details

The `pos` argument can specify the environment in which to look for the object in any of several ways: as an integer (the position in the [search](#) list); as the character string name of an element in the search list; or as an [environment](#) (including using `sys.frame` to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

This function looks to see if the name `x` has a value bound to it in the specified environment. If `inherits` is `TRUE` and a value is not found for `x` in the specified environment, the enclosing frames of the environment are searched until the name `x` is encountered. See [environment](#) and the ‘R Language Definition’ manual for details about the structure of environments and their enclosures.

Warning: `inherits = TRUE` is the default behaviour for R but not for S.

If `mode` is specified then only objects of that type are sought. The `mode` may specify one of the collections `"numeric"` and `"function"` (see [mode](#)): any member of the collection will suffice.

Using a `NULL` environment is equivalent to using the current environment.

For `mget` multiple values are returned in a named `list`. This is true even if only one value is requested. The value in `mode` and `ifnotfound` can be either the same length as the number of requested items or of length 1. The argument `ifnotfound` must be a list containing either the

value to use if the requested item is not found or a function of one argument which will be called if the item is not found, with argument the name of the item being requested. The default value for `inherits` is `FALSE`, in contrast to the default behavior for `get`.

`mode` here is a mixture of the meanings of `typeof` and `mode`: "function" covers primitive functions and operators, "numeric", "integer", "real" and "double" all refer to any numeric type, "symbol" and "name" are equivalent *but* "language" must be used.

Value

The object found. (If no object is found an error results.)

Note

The reverse of `a <- get(nam)` is `assign(nam, a)`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

`exists`, `assign`.

Examples

```
get("%o%")

##test mget
e1 <- new.env()
mget(letters, e1, ifnotfound = as.list(LETTERS))
```

getDLLRegisteredRoutines

Reflectance Information for C/Fortran routines in a DLL

Description

This function allows us to query the set of routines in a DLL that are registered with R to enhance dynamic lookup, error handling when calling native routines, and potentially security in the future. This function provides a description of each of the registered routines in the DLL for the different interfaces, i.e. `.C`, `.Call`, `.Fortran` and `.External`.

Usage

```
getDLLRegisteredRoutines(dll, addNames = TRUE)
```

Arguments

dll	<p>a character string or <code>DLLInfo</code> object. The character string specifies the file name of the DLL of interest, and is given without the file name extension (e.g., the <code>.dll</code> or <code>.so</code>) and with no directory/path information. So a file <code>'MyPackage/libs/MyPackage.so'</code> would be specified as <code>'MyPackage'</code>.</p> <p>The <code>DLLInfo</code> objects can be obtained directly in calls to <code>dyn.load</code> and <code>library.dynam</code>, or can be found after the DLL has been loaded using <code>getLoadedDLLs</code>, which returns a list of <code>DLLInfo</code> objects (index-able by DLL file name).</p> <p>The <code>DLLInfo</code> approach avoids any ambiguities related to two DLLs having the same name but corresponding to files in different directories.</p>
addNames	<p>a logical value. If this is <code>TRUE</code>, the elements of the returned lists are named using the names of the routines (as seen by R via registration or raw name). If <code>FALSE</code>, these names are not computed and assigned to the lists. As a result, the call should be quicker. The name information is also available in the <code>NativeSymbolInfo</code> objects in the lists.</p>

Details

This takes the registration information after it has been registered and processed by the R internals. In other words, it uses the extended information

Value

A list with four elements corresponding to the routines registered for the `.C`, `.Call`, `.Fortran` and `.External` interfaces. Each element is a list with as many elements as there were routines registered for that interface. Each element identifies a routine and is an object of class `NativeSymbolInfo`. An object of this class has the following fields:

name	the registered name of the routine (not necessarily the name in the C code).
address	the memory address of the routine as resolved in the loaded DLL. This may be <code>NULL</code> if the symbol has not yet been resolved.
dll	an object of class <code>DLLInfo</code> describing the DLL. This is same for all elements returned.
numParameters	the number of arguments the native routine is to be called with. In the future, we will provide information about the types of the parameters also.

Author(s)

Duncan Temple Lang <duncan@wald.ucdavis.edu>

Examples

```
dlls <- getLoadedDLLs()
getDLLRegisteredRoutines(dlls[["base"]])

getDLLRegisteredRoutines("stats")
```

getLoadedDLLs *Get DLLs Loaded in Current Session*

Description

This function provides a way to get a list of all the DLLs (see [dyn.load](#)) that are currently loaded in the R session.

Usage

```
getLoadedDLLs()
```

Details

This queries the internal table that manages the DLLs.

Value

An object of class "DLLInfoList" which is a list with an element corresponding to each DLL that is currently loaded in the session. Each element is an object of class "DLLInfo" which has the following entries.

name	the abbreviated name.
path	the fully qualified name of the loaded DLL.
dynamicLookup	a logical value indicating whether R uses only the registration information to resolve symbols or whether it searches the entire symbol table of the DLL.
handle	a reference to the C-level data structure that provides access to the contents of the DLL. This is an object of class "DLLHandle".

Note that the class `DLLInfo` has an overloaded method for `$` which can be used to resolve native symbols within that DLL. Therefore, one must access the R-level elements described above using `[, e.g. x[["name"]]` or `x[["handle"]]`.

Note

We are starting to use the `handle` elements in the DLL object to resolve symbols more directly in R.

Author(s)

Duncan Temple Lang (duncan@wald.ucdavis.edu).

Examples

```
getLoadedDLLs ()
```

```
getNativeSymbolInfo
```

Obtain a Description of one or more Native (C/Fortran) Symbols

Description

This finds and returns as comprehensive a description of one or more dynamically loaded or ‘exported’ built-in native symbols. For each name, it returns information about the name of the symbol, the library in which it is located and, if available, the number of arguments it expects and by which interface it should be called (i.e. `.Call`, `.C`, `.Fortran`, or `.External`). Additionally, it returns the address of the symbol and this can be passed to other C routines which can invoke. Specifically, this provides a way to explicitly share symbols between different dynamically loaded package libraries. Also, it provides a way to query where symbols were resolved, and aids diagnosing strange behavior associated with dynamic resolution.

This is vectorized in the `name` argument so can process multiple symbols in a single call. The result is a list that can be indexed by the given symbol names.

Usage

```
getNativeSymbolInfo(name, PACKAGE, unlist = TRUE,
                    withRegistrationInfo = FALSE)
```

Arguments

<code>name</code>	the name(s) of the native symbol(s) as used in a call to <code>is.loaded</code> , etc. Note that Fortran symbols should be supplied as-is, not wrapped in <code>symbol.FOR</code> .
<code>PACKAGE</code>	an optional argument that specifies to which DLL we restrict the search for this symbol. If this is "base", we search in the R executable itself.
<code>unlist</code>	a logical value which controls how the result is returned if the function is called with the name of a single symbol. If <code>unlist</code> is <code>TRUE</code> and the number of symbol names in <code>name</code> is one, then the <code>NativeSymbolInfo</code> object is returned. If it is <code>FALSE</code> , then a list of <code>NativeSymbolInfo</code> objects is returned. This is ignored if the number of symbols passed in <code>name</code> is more than one. To be compatible with earlier versions of this function, this defaults to <code>TRUE</code> .
<code>withRegistrationInfo</code>	a logical value indicating whether, if <code>TRUE</code> , to return information that was registered with R about the symbol and its parameter types if such information is available, or if <code>FALSE</code> to return the address of the symbol.

Details

This uses the same mechanism for resolving symbols as is used in all the native interfaces (`.Call`, etc.). If the symbol has been explicitly registered by the DLL in which it is contained, information about the number of arguments and the interface by which it should be called will be returned. Otherwise, a generic native symbol object is returned.

Value

Generally, a list of `NativeSymbolInfo` elements whose elements can be indexed by the elements of `name` in the call. Each `NativeSymbolInfo` object is a list containing the following elements:

<code>name</code>	the name of the symbol, as given by the <code>name</code> argument.
<code>address</code>	if <code>withRegistrationInfo</code> is <code>FALSE</code> , this is the native memory address of the symbol which can be used to invoke the routine, and also to compare with other symbol addresses. This is an external pointer object and of class <code>NativeSymbol</code> . If <code>withRegistrationInfo</code> is <code>TRUE</code> and registration information is available for the symbol, then this is an object of class <code>RegisteredNativeSymbol</code> and is a reference to an internal data type that has access to the routine pointer and registration information. This too can be used in calls to <code>.Call</code> , <code>.C</code> , <code>.Fortran</code> and <code>.External</code> .
<code>package</code>	a list containing 3 elements: name the short form of the library name which can be used as the value of the <code>PACKAGE</code> argument in the different native interface functions. path the fully qualified name of the DLL. dynamicLookup a logical value indicating whether dynamic resolution is used when looking for symbols in this library, or only registered routines can be located.
<code>numParameters</code>	the number of arguments that should be passed in a call to this routine.

Additionally, the list will have an additional class, being `CRoutine`, `CallRoutine`, `FortranRoutine` or `ExternalRoutine` corresponding to the R interface by which it should be invoked.

If any of the symbols is not found, an error is immediately raised.

If `name` contains only one symbol name and `unlist` is `TRUE`, then the single `NativeSymbolInfo` is returned rather than the list containing that one element.

Note

One motivation for accessing this reflectance information is to be able to pass native routines to C routines as function pointers in C. This allows us to treat native routines and R functions in a similar manner, such as when passing an R function to C code that makes callbacks to that function at different points in its computation (e.g., `nls`). Additionally, we can resolve the symbol just once and avoid resolving it repeatedly or using the internal cache. In the future, one may be able to treat `NativeSymbol` objects directly as callback objects.

library(stats) # normally loaded
getNativeSymbolInfo("dansari")

getNativeSymbolInfo("hcass2") # a Fortran symbol
```

`getNumCConverters` *Management of .C argument conversion list*

Description

These functions provide facilities to manage the extensible list of converters used to translate R objects to C pointers for use in `.C` calls. The number and a description of each element in the list can be retrieved. One can also query and set the activity status of individual elements, temporarily ignoring them. And one can remove individual elements.

Usage

```
getNumCConverters()
getCConverterDescriptions()
getCConverterStatus()
setCConverterStatus(id, status)
removeCConverter(id)
```

Arguments

<code>id</code>	either a number or a string identifying the element of interest in the converter list. A string is matched against the description strings for each element to identify the element. Integers are specified starting at 1 (rather than 0).
<code>status</code>	a logical value specifying whether the element is to be considered active (TRUE) or not (FALSE).

Details

The internal list of converters is potentially used when converting individual arguments in a `.C` call. If an argument has a non-trivial class attribute, we iterate over the list of converters looking for the first that matches. If we find a matching converter, we have it create the C-level pointer corresponding to the R object. When the call to the C routine is complete, we use the same converter for that argument to reverse the conversion and create an R object from the current value in the C pointer. This is done separately for all the arguments.

The functions documented here provide R user-level capabilities for investigating and managing the list of converters. There is currently no mechanism for adding an element to the converter list within the R language. This must be done in C code using the routine `R_addToCConverter()`.

Value

`getNumCConverters` returns an integer giving the number of elements in the list, both active and inactive.

`getCConverterDescriptions` returns a character vector containing the description string of each element of the converter list.

`getCConverterStatus` returns a logical vector with a value for each element in the converter list. Each value indicates whether that converter is active (`TRUE`) or inactive (`FALSE`). The names of the elements are the description strings returned by `getCConverterDescriptions`.

`setCConverterStatus` returns the logical value indicating the activity status of the specified element before the call to change it took effect. This is `TRUE` for active and `FALSE` for inactive.

`removeCConverter` returns `TRUE` if an element in the converter list was identified and removed. In the case that no such element was found, an error occurs.

removeCConverter(getCConverterDescriptions()[1])
## End(Not run)
```

getpid

Get the Process ID of the R Session

Description

Get the process ID of the R Session. It is guaranteed by the operating system that two R sessions running simultaneously will have different IDs, but it is possible that R sessions running at different times will have the same ID.

Usage

```
Sys.getpid()
```

Value

An integer, usually a small integer between 0 and 32767 under Unix-alikes and a much smaller integer under Windows.

Examples

```
Sys.getpid()
```

gettext

Translate Text Messages

Description

If Native Language Support was enabled in this build of R, attempt to translate character vectors or set where the translations are to be found.

Usage

```
gettext(..., domain = NULL)
```

```
ngettext(n, msg1, msg2, domain = NULL)
```

```
bindtextdomain(domain, dirname = NULL)
```

Arguments

...	One or more character vectors.
domain	The 'domain' for the translation.
n	a non-negative integer.
msg1	the message to be used in English for $n = 1$.
msg2	the message to be used in English for $n = 0, 2, 3, \dots$
dirname	The directory in which to find translated message catalogs for the domain.

Details

If `domain` is `NULL` or `"`, a domain is searched for based on the name space which contains the function calling `gettext` or `ngettext`. If a suitable domain can be found, each character string is offered for translation, and replaced by its translation into the current language if one is found.

Conventionally the domain for R warning/error messages in package **pkg** is `"R-pkg"`, and that for C-level messages is `"pkg"`.

For `gettext`, leading and trailing whitespace is ignored when looking for the translation.

`ngettext` is used where the message needs to vary by a single integer. Translating such messages is subject to very specific rules for different languages: see the GNU Gettext Manual. The string will often contain a single instance of `%d` to be used in `sprintf`. If English is used, `msg1` is returned if $n == 1$ and `msg2` in all other cases.

Value

For `gettext`, a character vector, one element per string in If translation is not enabled or no domain is found or no translation is found in that domain, the original strings are returned.

For `ngettext`, a character string.

For `bindtextdomain`, a character string giving the current base directory, or `NULL` if setting it failed.

See Also

[stop](#) and [warning](#) make use of `gettext` to translate messages.

[xgettext](#) for extracting translatable strings from R source files.

Examples

```
bindtextdomain("R") # non-null if and only if NLS is enabled

for(n in 0:3)
  print(sprintf(ngettext(n, "%d variable has missing values",
                        "%d variables have missing values"),
              n))

## Not run:
## for translation, those strings should appear in R-pkg.pot as
msgid      "%d variable has missing values"
msgid_plural "%d variables have missing values"
msgstr[0] ""
msgstr[1] ""
## End(Not run)

miss <- c("one", "or", "another")
cat(ngettext(length(miss), "variable", "variables"),
    paste(sQuote(miss), collapse=", "),
    ngettext(length(miss), "contains", "contain"), "missing values\n")

## better for translators would be to use
cat(sprintf(ngettext(length(miss),
                    "variable %s contains missing values\n",
                    "variables %s contain missing values\n"),
          paste(sQuote(miss), collapse=", ")))
```

getwd

Get or Set Working Directory

Description

`getwd` returns an absolute filename representing the current working directory of the R process; `setwd(dir)` is used to set the working directory to `dir`.

Usage

```
getwd()
setwd(dir)
```

Arguments

`dir` A character string.

Value

`getwd` returns a character vector, or `NULL` if the working directory is not available.

`setwd` returns the current directory before the change, invisibly. It will give an error if it does not succeed.

Note

These functions are not implemented on all platforms.

See Also

`list.files` for the *contents* of a directory.

Examples

```
(WD <- getwd())
if (!is.null(WD)) setwd(WD)
```

gl

Generate Factor Levels

Description

Generate factors by specifying the pattern of their levels.

Usage

```
gl(n, k, length = n*k, labels = 1:n, ordered = FALSE)
```

Arguments

`n` an integer giving the number of levels.
`k` an integer giving the number of replications.
`length` an integer giving the length of the result.
`labels` an optional vector of labels for the resulting factor levels.
`ordered` a logical indicating whether the result should be ordered or not.

Value

The result has levels from 1 to `n` with each value replicated in groups of length `k` out to a total length of `length`.

`gl` is modelled on the *GLIM* function of the same name.

See Also

The underlying `factor()`.

Examples

```
## First control, then treatment:
gl(2, 8, labels = c("Control", "Treat"))
## 20 alternating 1s and 2s
gl(2, 1, 20)
## alternating pairs of 1s and 2s
gl(2, 2, 20)
```

grep

Pattern Matching and Replacement

Description

grep searches for matches to `pattern` (its first argument) within the character vector `x` (second argument). `regexpr` and `gregexpr` do too, but return more detail in a different format.

`sub` and `gsub` perform replacement of matches determined by regular expression matching.

Usage

```
grep(pattern, x, ignore.case = FALSE, extended = TRUE,
      perl = FALSE, value = FALSE, fixed = FALSE, useBytes = FALSE)
```

```
sub(pattern, replacement, x,
     ignore.case = FALSE, extended = TRUE, perl = FALSE,
     fixed = FALSE, useBytes = FALSE)
```

```
gsub(pattern, replacement, x,
      ignore.case = FALSE, extended = TRUE, perl = FALSE,
      fixed = FALSE, useBytes = FALSE)
```

```
regexpr(pattern, text, ignore.case = FALSE, extended = TRUE,
         perl = FALSE, fixed = FALSE, useBytes = FALSE)
```

```
gregexpr(pattern, text, ignore.case = FALSE, extended = TRUE,
          perl = FALSE, fixed = FALSE, useBytes = FALSE)
```

Arguments

<code>pattern</code>	character string containing a regular expression (or character string for <code>fixed = TRUE</code>) to be matched in the given character vector. Coerced by <code>as.character</code> to a character string if possible.
<code>x</code> , <code>text</code>	a character vector where matches are sought, or an object which can be coerced by <code>as.character</code> to a character vector.
<code>ignore.case</code>	if <code>FALSE</code> , the pattern matching is <i>case sensitive</i> and if <code>TRUE</code> , case is ignored during matching.
<code>extended</code>	if <code>TRUE</code> , extended regular expression matching is used, and if <code>FALSE</code> basic regular expressions are used.
<code>perl</code>	logical. Should perl-compatible regexps be used? Has priority over <code>extended</code> .

value	if FALSE, a vector containing the (integer) indices of the matches determined by <code>grep</code> is returned, and if TRUE, a vector containing the matching elements themselves is returned.
fixed	logical. If TRUE, <code>pattern</code> is a string to be matched as is. Overrides all conflicting arguments.
useBytes	logical. If TRUE the matching is done byte-by-byte rather than character-by-character. See 'Details'.
replacement	a replacement for matched pattern in <code>sub</code> and <code>gsub</code> . Coerced to character if possible. For <code>fixed = FALSE</code> this can include backreferences " <code>\1</code> " to " <code>\9</code> " to parenthesized subexpressions of <code>pattern</code> . For <code>perl = TRUE</code> only, it can also contain " <code>\U</code> " or " <code>\L</code> " to convert the rest of the replacement to upper or lower case.

Details

Arguments which should be character strings or character vectors are coerced to character if possible.

The two `*sub` functions differ only in that `sub` replaces only the first occurrence of a `pattern` whereas `gsub` replaces all occurrences.

For `regexpr` it is an error for `pattern` to be NA, otherwise NA is permitted and gives an NA match.

The regular expressions used are those specified by POSIX 1003.2, either extended or basic, depending on the value of the `extended` argument, unless `perl = TRUE` when they are those of PCRE, <http://www.pcre.org/>. (The exact set of patterns supported may depend on the version of PCRE installed on the system in use if R was configured to use the system PCRE.)

`useBytes` is only used if `fixed = TRUE` or `perl = TRUE`. Its main effect is to avoid errors/warnings about invalid inputs and spurious matches, but for `regexpr` it changes the interpretation of the output.

PCRE only supports caseless matching for a non-ASCII pattern in a UTF-8 locale (and not for `useBytes = TRUE` in any locale).

Value

For `grep` a vector giving either the indices of the elements of `x` that yielded a match or, if `value` is TRUE, the matched elements of `x` (after coercion, preserving names but no other attributes).

For `sub` and `gsub` a character vector of the same length and with the same attributes as `x` (after possible coercion). Elements of character vectors `x` which are not substituted will be return unchanged (including any declared encoding). If `useBytes = FALSE`, either `perl = TRUE` or `fixed = TRUE` and any element of `pattern`, `replacement` and `x` is declared to be in UTF-8, the result will be in UTF-8. Otherwise changed elements of the result will be have the encoding declared as that of the current locale (see [Encoding](#) if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8).

For `regexpr` an integer vector of the same length as `text` giving the starting position of the first match, or `-1` if there is none, with attribute "`match.length`" giving the length of the matched text (or `-1` for no match). In a multi-byte locale these quantities are in characters rather than bytes unless `useBytes = TRUE` is used with `fixed = TRUE` or `perl = TRUE`.

For `gregexpr` a list of the same length as `text` each element of which is an integer vector as in `regexpr`, except that the starting positions of every (disjoint) match are given.

If in a multi-byte locale the pattern or replacement is not a valid sequence of bytes, an error is thrown. An invalid string in `x` or `text` is a non-match with a warning for `grep` or `regexpr`, but an error for `sub` or `gsub`.

Warning

The standard regular-expression code has been reported to be very slow when applied to extremely long character strings (tens of thousands of characters or more): the code used when `perl = TRUE` seems much faster and more reliable for such usages.

The standard version of `gsub` does not substitute correctly repeated word-boundaries (e.g. `pattern = "\\b"`). Use `perl = TRUE` for such matches.

The `perl = TRUE` option is only implemented for single-byte and UTF-8 encodings, and will warn if used in a non-UTF-8 multi-byte locale (unless `useBytes = TRUE`).

      gsub("g","#", txt, ignore.case = TRUE)] # the "G" words

regexpr("en", txt)

gregexpr("e", txt)

## trim trailing white space
str <- 'Now is the time '
sub(' +$', '', str) ## spaces only
sub('[:space:]+$', '', str) ## white space, POSIX-style
sub('\\s+$', '', str, perl = TRUE) ## Perl-style white space

## capitalizing
gsub("(\\w)(\\w*)", "\\U\\1\\L\\2", "a test of capitalizing", perl=TRUE)
gsub("\\b(\\w)", "\\U\\1", "a test of capitalizing", perl=TRUE)

```

groupGeneric

S3 Group Generic Functions

Description

Group generic methods can be defined for four pre-specified groups of functions, `Math`, `Ops`, `Summary` and `Complex`. (There are no objects of these names in base R, but there are in the **methods** package.)

A method defined for an individual member of the group takes precedence over a method defined for the group as a whole.

Usage

```

## S3 methods for group generics have prototypes:
Math(x, ...)
Ops(e1, e2)
Complex(z)
Summary(..., na.rm = FALSE)

```

Arguments

`x`, `z`, `e1`, `e2` objects.
`...` further arguments passed to methods.
`na.rm` logical: should missing values be removed?

Details

There are four *groups* for which S3 methods can be written, namely the "Math", "Ops", "Summary" and "Complex" groups. These are not R objects, but methods can be supplied for them and base R contains `factor`, `data.frame` and `difftime` methods for the first three groups. (There is also a `ordered` method for Ops, `POSIXt` and `Date` methods for Math and Ops, `package_version` methods for Ops and Summary, as well as a `ts` method for Ops in package **stats**.)

1. Group "Math":

- abs, sign, sqrt,
 floor, ceiling, trunc,
 round, signif
- exp, log, expm1, log1p,
 cos, sin, tan,
 acos, asin, atan
 cosh, sinh, tanh,
 acosh, asinh, atanh
- lgamma, gamma, digamma, trigamma
- cumsum, cumprod, cummax, cummin

Members of this group dispatch on `x`. Most members accept only one argument, but members `log`, `round` and `signif` accept one or two arguments, and `trunc` accepts one or more.

2. Group "Ops":

- "+", "-", "*", "/", "^", "%%", "%/%"
- "&", "|", "!"
- "==", "!=", "<", "<=", ">=", ">"

This group contains both binary and unary operators (+, - and !): when a unary operator is encountered the `Ops` method is called with one argument and `e2` is missing.

The classes of both arguments are considered in dispatching any member of this group. For each argument its vector of classes is examined to see if there is a matching specific (preferred) or `Ops` method. If a method is found for just one argument or the same method is found for both, it is used. If different methods are found, there is a warning about 'incompatible methods': in that case or if no method is found for either argument the internal method is used.

If the members of this group are called as functions, any argument names are removed to ensure that positional matching is always used.

3. Group "Summary":

- all, any
- sum, prod
- min, max
- range

Members of this group dispatch on the first argument supplied.

4. Group "Complex":

- Arg, Conj, Im, Mod, Re

Members of this group dispatch on `z`.

Note that a method will be used for either one of these groups or one of its members *only* if it corresponds to a "class" attribute, as the internal code dispatches on `oldClass` and not on `class`. This is for efficiency: having to dispatch on, say, `Ops.integer` would be too slow.

The number of arguments supplied for primitive members of the "Math" group generic methods is not checked prior to dispatch.

There is no lazy evaluation of arguments for group-generic functions.

Technical Details

These functions are all primitive and [internal generic](#).

The details of method dispatch and variables such as `.Generic` are discussed in the help for [UseMethod](#). There are a few small differences:

- For the operators of group `Ops`, the object `.Method` is a length-two character vector with elements the methods selected for the left and right arguments respectively. (If no method was selected, the corresponding element is `" "`.)
- Object `.Group` records the group used for dispatch (if a specific method is used this is `" "`).

Examples

```
require(utils)

d.fr <- data.frame(x=1:9, y=stats::rnorm(9))
class(1 + d.fr) == "data.frame" ##-- add to d.f. ...

methods("Math")
methods("Ops")
methods("Summary")
methods("Complex") # none in base R
```

gzcon

(De)compress I/O Through Connections

Description

`gzcon` provides a modified connection that wraps an existing connection, and decompresses reads or compresses writes through that connection. Standard `gzip` headers are assumed.

Usage

```
gzcon(con, level = 6, allowNonCompressed = TRUE)
```

Arguments

`con` a connection.

`level` integer between 0 and 9, the compression level when writing.

`allowNonCompressed` logical. When reading, should non-compressed input be allowed?

Details

If `con` is open then the modified connection is opened. Closing the wrapper connection will also close the underlying connection.

Reading from a connection which does not supply a `gzip` magic header is equivalent to reading from the original connection if `allowNonCompressed` is true, otherwise an error.

The original connection becomes unusable: any object pointing to it will now refer to the modified connection.

When the connection is opened for reading, the input is expected to start with the `gzip` magic header. If it does not and if `allowNonCompressed = TRUE` (the default) the input is read as-is.

Value

An object inheriting from class `"connection"`. This is the same connection *number* as supplied, but with a modified internal structure. It has binary mode.

See Also

[gzfile](#)

Examples

```
## Uncompress a data file from a URL
z <- gzcon(url("http://www.stats.ox.ac.uk/pub/datasets/csb/ch12.dat.gz"))
# read.table can only read from a text-mode connection.
raw <- textConnection(readLines(z))
close(z)
dat <- read.table(raw)
close(raw)
dat[1:4, ]

## gzfile and gzcon can inter-work.
## Of course here one would used gzfile, but file() can be replaced by
## any other connection generator.
zz <- gzfile("ex.gz", "w")
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzcon(file("ex.gz", "rb")))
close(zz)
unlink("ex.gz")

zz <- gzcon(file("ex2.gz", "wb"))
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file = zz, sep = "\n")
close(zz)
readLines(zz <- gzfile("ex2.gz"))
close(zz)
unlink("ex2.gz")
```

`hexmode`*Display Numbers in Hexadecimal*

Description

Convert or print integers in hexadecimal format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

Usage

```
as.hexmode(x)

## S3 method for class 'hexmode':
as.character(x, upper.case = FALSE, ...)

## S3 method for class 'hexmode':
format(x, upper.case = FALSE, ...)

## S3 method for class 'hexmode':
print(x, ...)
```

Arguments

<code>x</code>	An object, for the methods inheriting from class "hexmode".
<code>upper.case</code>	a logical indicating whether to use upper-case letters or lower-case letters (default).
<code>...</code>	further arguments passed to or from other methods.

Details

Class "hexmode" consists of integer vectors with that class attribute, used merely to ensure that they are printed in hex.

See Also

[octmode](#)

`Hyperbolic`*Hyperbolic Functions*

Description

These functions give the obvious hyperbolic functions. They respectively compute the hyperbolic cosine, sine, tangent, and their inverses, arc-cosine, arc-sine, arc-tangent (or 'area cosine', etc).

Usage

```
cosh(x)
sinh(x)
tanh(x)
acosh(x)
asinh(x)
atanh(x)
```

Arguments

`x` a numeric or complex vector

Details

These are generic functions: methods can be defined for them individually or via the `Math` group generic.

Branch cuts are consistent with the inverse trigonometric functions `asin()` et seq, and agree with those defined in Abramowitz and Stegun, figure 4.7, page 86.

S4 methods

All are S4 generic functions: methods can be defined for them individually or via the `Math` group generic.

References

See Also

The trigonometric functions, `cos`, `sin`, `tan`, and their inverses `acos`, `asin`, `atan`.

The logistic distribution function `plogis` is a shifted version of `tanh()` for numeric `x`.

`iconv`*Convert Character Vector between Encodings*

Description

This uses system facilities to convert a character vector between encodings: the 'i' stands for 'internationalization'.

Usage

```
iconv(x, from = "", to = "", sub = NA)

iconvlist()
```

Arguments

<code>x</code>	A character vector, or an object to be converted to a character vector by as.character .
<code>from</code>	A character string describing the current encoding.
<code>to</code>	A character string describing the target encoding.
<code>sub</code>	character string. If not <code>NA</code> it is used to replace any non-convertible bytes in the input. (This would normally be a single character, but can be more.) If <code>"byte"</code> , the indication is <code>"<xx>"</code> with the hex code of the byte.

Details

The names of encodings and which ones are available (and indeed, if any are) is platform-dependent. On all systems that support `iconv` you can use `" "` for the encoding of the current locale, as well as `"latin1"` and `"UTF-8"`.

On many platforms `iconvlist` provides an alphabetical list of the supported encodings. On others, the information is on the man page for `iconv(5)` or elsewhere in the man pages (and beware that the system command `iconv` may not support the same set of encodings as the C functions R calls). Unfortunately, the names are rarely common across platforms.

Elements of `x` which cannot be converted (perhaps because they are invalid or because they cannot be represented in the target encoding) will be returned as `NA` unless `sub` is specified.

Most versions of `iconv` will allow transliteration by appending `//TRANSLIT` to the `to` encoding: see the examples.

Any encoding bits (see [Encoding](#)) on elements of `x` are ignored: they will always be translated as if from `from` even if declared otherwise.

As from R 2.7.0 `"UTF8"` will be accepted as meaning the (more correct) `"UTF-8"`.

Value

A character vector of the same length and the same attributes as `x` (after conversion).

The elements of the result have a declared encoding if `from` is `"latin1"` or `"UTF-8"`, or if `from = ""` and the current locale's encoding is detected as Latin-1 or UTF-8.

Note

Not all platforms support these functions, although almost all support `iconv`. See also [capabilities\("iconv"\)](#).

See Also

[localeToCharset](#), [file](#).

Examples

```
utils::head(iconvlist(), n = 50)

## Not run:
## convert from Latin-2 to UTF-8: two of the glibc iconv variants.
iconv(x, "ISO_8859-2", "UTF-8")
iconv(x, "LATIN2", "UTF-8")
## End(Not run)
```

```
## Both x below are in latin1 and will only display correctly in a
## locale that can represent and display latin1.
x <- "fa\xE7ile"
Encoding(x) <- "latin1"
x
charToRaw(xx <- iconv(x, "latin1", "UTF-8"))
xx

iconv(x, "latin1", "ASCII")          # NA
iconv(x, "latin1", "ASCII", "?")    # "fa?ile"
iconv(x, "latin1", "ASCII", "")     # "faile"
iconv(x, "latin1", "ASCII", "byte") # "fa<e7>ile"

# Extracts from R help files
x <- c("Ekstr\xf8m", "J\xf6reskog", "bi\xdfchen Z\xfccher")
Encoding(x) <- "latin1"
x
try(iconv(x, "latin1", "ASCII//TRANSLIT")) # platform-dependent
iconv(x, "latin1", "ASCII", sub="byte")
```

icuSetCollate *Setup Collation by ICU*

Description

Controls the way collation is done by ICU (an optional part of the R build).

Usage

```
icuSetCollate(...)
```

Arguments

... Named arguments, see ‘Details’.

Details

Optionally, R can be built to collate character strings by ICU (<http://www.icu-project.org>). For such systems, `icuSetCollate` can be used to tune the way collation is done. On other builds calling this function does nothing, with a warning.

Possible arguments are

locale: A character string such as "da_DK" giving the country whose collation rules are to be used. If present, this should be the first argument.

case_first: "upper", "lower" or "default", asking for upper- or lower-case characters to be sorted first. The default is usually lower-case first, but not in all languages (see the Danish example).

alternate_handling: Controls the handling of ‘variable’ characters (mainly punctuation and symbols). Possible values are "non_ignorable" (primary strength) and "shifted" (quaternary strength).

strength: Which components should be used? Possible values "primary", "secondary", "tertiary" (default), "quaternary" and "identical".

french_collation: In a French locale the way accents affect collation is from right to left, whereas in most other locales it is from left to right. Possible values "on", "off" and "default".

normalization: Should strings be normalized? Possible values "on" and "off" (default). This affects the collation of composite characters.

case_level: An additional level between secondary and tertiary, used to distinguish large and small Japanese Kana characters. Possible values "on" and "off" (default).

hiragana_quaternary: Possible values "on" (sort Hiragana first at quaternary level) and "off".

Only the first three are likely to be of interest except to those with a detailed understanding of collation and specialized requirements.

Some examples are `case_level="on"`, `strength="primary"` to ignore accent differences, `alternate_handling="shifted"` to ignore space and punctuation characters.

See Also

[Comparison, sort](#)

The ICU user guide chapter on collation (http://www.icu-project.org/userguide/Collate_Intro.html).

Examples

```
x <- c("Aarhus", "aarhus", "safe", "test", "Zoo")
sort(x)
icuSetCollate(case_first="upper"); sort(x)
icuSetCollate(case_first="lower"); sort(x)

icuSetCollate(locale="da_DK", case_first="default"); sort(x)
icuSetCollate(locale="et_EE"); sort(x)
```

identical

Test Objects for Exact Equality

Description

The safe and reliable way to test two objects for being *exactly* equal. It returns TRUE in this case, FALSE in every other case.

Usage

```
identical(x, y)
```

Arguments

`x`, `y` any R objects.

Details

A call to `identical` is the way to test exact equality in `if` and `while` statements, as well as in logical expressions that use `&&` or `||`. In all these applications you need to be assured of getting a single logical value.

Users often use the comparison operators, such as `==` or `!=`, in these situations. It looks natural, but it is not what these operators are designed to do in R. They return an object like the arguments. If you expected `x` and `y` to be of length 1, but it happened that one of them wasn't, you will *not* get a single `FALSE`. Similarly, if one of the arguments is `NA`, the result is also `NA`. In either case, the expression `if(x == y) . . .` won't work as expected.

The function `all.equal` is also sometimes used to test equality this way, but was intended for something different: it allows for small differences in numeric results.

The computations in `identical` are also reliable and usually fast. There should never be an error. The only known way to kill `identical` is by having an invalid pointer at the C level, generating a memory fault. It will usually find inequality quickly. Checking equality for two large, complicated objects can take longer if the objects are identical or nearly so, but represent completely independent copies. For most applications, however, the computational cost should be negligible.

`identical` sees `NaN` as different from `NA_real_`, but all `NaN`s are equal (and all `NA` of the same type are equal).

Comparison of attributes view them as a set (and not a vector, so order is not tested).

Value

A single logical value, `TRUE` or `FALSE`, never `NA` and never anything other than a single value.

Author(s)

John Chambers and R Core

References

Chambers, J. M. (1998) *Programming with Data. A Guide to the S Language*. Springer.

See Also

[all.equal](#) for descriptions of how two objects differ; [Comparison](#) for operators that generate elementwise comparisons. `isTRUE` is a simple wrapper based on `identical`.

Examples

```
identical(1, NULL) ## FALSE -- don't try this with ==
identical(1, 1.)  ## TRUE in R (both are stored as doubles)
identical(1, as.integer(1)) ## FALSE, stored as different types

x <- 1.0; y <- 0.999999999999
## how to test for object equality allowing for numeric fuzz :
(E <- all.equal(x,y))
isTRUE(E) # which is simply defined to just use
identical(TRUE, E)
## If all.equal thinks the objects are different, it returns a
## character string, and the above expression evaluates to FALSE

# even for unusual R objects :
identical(.GlobalEnv, environment())
```

<code>identity</code>	<i>Identity function</i>
-----------------------	--------------------------

Description

A trivial identity function returning its argument.

Usage

```
identity(x)
```

Arguments

<code>x</code>	an R object.
----------------	--------------

<code>ifelse</code>	<i>Conditional Element Selection</i>
---------------------	--------------------------------------

Description

`ifelse` returns a value with the same shape as `test` which is filled with elements selected from either `yes` or `no` depending on whether the element of `test` is TRUE or FALSE.

Usage

```
ifelse(test, yes, no)
```

Arguments

<code>test</code>	an object which can be coerced to logical mode.
<code>yes</code>	return values for true elements of <code>test</code> .
<code>no</code>	return values for false elements of <code>test</code> .

Details

If `yes` or `no` are too short, their elements are recycled. `yes` will be evaluated if and only if any element of `test` is true, and analogously for `no`.

Missing values in `test` give missing values in the result.

Value

A vector of the same length and attributes (including class) as `test` and data values from the values of `yes` or `no`. The mode of the answer will be coerced from logical to accommodate first any values taken from `yes` and then any values taken from `no`.

Warning

The mode of the result may depend on the value of `test`, and the class attribute of the result is taken from `test` and may be inappropriate for the values selected from `yes` and `no`.

Sometimes it is better to use a construction such as `(tmp <- yes; tmp[!test] <- no[!test]; tmp)`, possibly extended to handle missing values in `test`.

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[if](#).

Examples

```
x <- c(6:-4)
sqrt(x)#- gives warning
sqrt(iffelse(x >= 0, x, NA))# no warning

## Note: the following also gives the warning !
iffelse(x >= 0, sqrt(x), NA)

## example of different return modes:
yes <- 1:3
no <- pi^(0:3)
typeof(iffelse(NA, yes, no)) # logical
typeof(iffelse(TRUE, yes, no)) # integer
typeof(iffelse(FALSE, yes, no))# double
```

integer

Integer Vectors

Description

Creates or tests for objects of type "integer".

Usage

```
integer(length = 0)
as.integer(x, ...)
is.integer(x)
```

Arguments

length	desired length.
x	object to be coerced or tested.
...	further arguments passed to or from other methods.

Details

Integer vectors exist so that data can be passed to C or Fortran code which expects them, and so that small integer data can be represented exactly and compactly.

Note that on almost all implementations of R the range of representable integers is restricted to about $\pm 2 \times 10^9$: [doubles](#) can hold much larger integers exactly.

Value

`integer` creates a integer vector of the specified length. Each element of the vector is equal to 0. `as.integer` attempts to coerce its argument to be of integer type. The answer will be NA unless the coercion succeeds. Real values larger in modulus than the largest integer are coerced to NA (unlike S which gives the most extreme integer of the same sign). Non-integral numeric values are truncated towards zero (i.e., `as.integer(x)` equals `trunc(x)` there), and imaginary parts of complex numbers are discarded (with a warning). Character strings containing either a decimal representation or a hexadecimal representation (starting with 0x or 0X) can be converted, as well as any allowed by the platform for real numbers. Like `as.vector` it strips attributes including names. (To ensure that an object is of integer type without stripping attributes, use `storage.mode`.)

`is.integer` returns TRUE or FALSE depending on whether its argument is of integer [type](#) or not, unless it is a factor when it returns FALSE.

x <- pi * c(-1:1,10)
as.integer(x)
```

interaction

Compute Factor Interactions

Description

`interaction` computes a factor which represents the interaction of the given factors. The result of `interaction` is always unordered.

Usage

```
interaction(..., drop = FALSE, sep = ".", lex.order = FALSE)
```

Arguments

<code>...</code>	the factors for which <code>interaction</code> is to be computed, or a single list giving those factors.
<code>drop</code>	if <code>drop</code> is TRUE, unused factor levels are dropped from the result. The default is to retain all factor levels.
<code>sep</code>	string to construct the new level labels by joining the constituent ones.
<code>lex.order</code>	logical indicating if the order of factor concatenation should be lexically ordered.

Value

A factor which represents the interaction of the given factors. The levels are labelled as the levels of the individual factors joined by `sep` which is `.` by default.

By default, when `lex.order = FALSE`, the levels are ordered so the level of the first factor varies fastest, then the second and so on. This is the reverse of lexicographic ordering (which you can get by `lex.order = TRUE`), and differs from `:.:` (It is done this way for compatibility with S.)

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

`factor`; `:` where `f:g` is similar to `interaction(f, g, sep=":")` when `f` and `g` are factors.

Examples

```
a <- gl(2, 4, 8)
b <- gl(2, 2, 8, labels = c("ctrl", "treat"))
s <- gl(2, 1, 8, labels = c("M", "F"))
interaction(a, b)
interaction(a, b, s, sep = ":")
stopifnot(identical(a:s,
                    interaction(a, s, sep = ":", lex.order = TRUE)),
          identical(a:s:b,
                    interaction(a, s, b, sep = ":", lex.order = TRUE)))
```

 interactive

Is R Running Interactively?

Description

Return `TRUE` when `R` is being used interactively and `FALSE` otherwise.

Usage

```
interactive()
```

See Also

`source`, `.First`

Examples

```
.First <- function() if(interactive()) x11()
```

Internal

*Call an Internal Function***Description**

`.Internal` performs a call to an internal code which is built in to the R interpreter. Only true R wizards should even consider using this function, and only R developers can add to the list of internal functions.

Usage

```
.Internal(call)
```

Arguments

`call` a call expression

See Also

[.Primitive](#), [.External](#) (the nearest equivalent available to users).

InternalMethods

*Internal Generic Functions***Description**

Many R-internal functions are *generic* and allow methods to be written for.

Details

The following primitive and internal functions are *generic*, i.e., you can write [methods](#) for them:

```
[, [[, $, [<-, [[<-, $<-,
length, length<-, dimnames, dimnames<-, dim, dim<-, names, names<-,
levels<-,
c, unlist, cbind, rbind,
as.character, as.complex, as.double, as.integer, as.logical, as.raw,
as.vector, is.array, is.matrix, is.na, is.nan, is.numeric, rep and seq.int
(which dispatches methods for "seq").
```

In addition, `is.name` is a synonym for `is.symbol` and dispatches methods for the latter.

Note that all of the [group generic](#) functions are also internal/primitive and allow methods to be written for them.

`.S3PrimitiveGenerics` is a character vector listing the primitives which are internal generic and not [group generic](#). Currently `as.vector`, `cbind`, `rbind` and `unlist` are the internal non-primitive functions which are internally generic.

For efficiency, internal dispatch only occurs on *objects*, that is those for which `is.object` returns true.

See Also

[methods](#) for the methods which are available.

`invisible`*Change the Print Mode to Invisible*

Description

Return a (temporarily) invisible copy of an object.

Usage

```
invisible(x)
```

Arguments

`x` an arbitrary R object.

Details

This function can be useful when it is desired to have functions return values which can be assigned, but which do not print when they are not assigned.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[withVisible](#), [return](#), [function](#).

Examples

```
# These functions both return their argument
f1 <- function(x) x
f2 <- function(x) invisible(x)
f1(1) # prints
f2(1) # does not
```

`is.finite`*Finite, Infinite and NaN Numbers*

Description

`is.finite` and `is.infinite` return a vector of the same length as `x`, indicating which elements are finite (not infinite and not missing).

`Inf` and `-Inf` are positive and negative infinity whereas `NaN` means 'Not a Number'. (These apply to numeric values and real and imaginary parts of complex values but not to values of integer vectors.) All are [reserved](#) words in the R language.

Usage

```
is.finite(x)
is.infinite(x)
Inf
NaN
is.nan(x)
```

Arguments

`x` (numerical) object to be tested.

Details

`is.finite` returns a vector of the same length as `x` the `j`th element of which is TRUE if `x[j]` is finite (i.e., it is not one of the values NA, NaN, Inf or -Inf). All elements of types other than logical, integer, numeric and complex vectors are false. Complex numbers are finite if both the real and imaginary parts are.

`is.infinite` returns a vector of the same length as `x` the `j`th element of which is TRUE if `x[j]` is infinite (i.e., equal to one of Inf or -Inf). This will be false unless `x` is numeric or complex. Complex numbers are infinite if either the real and imaginary part is.

`is.nan` tests if a numeric value is NaN. Do not test equality to NaN, or even use `identical`, since systems typically have many different NaN values. One of these is used for the numeric missing value NA, and `is.nan` is false for that value. A complex number is regarded as NaN if either the real or imaginary part is NaN but not NA.

All three functions are generic: you can write methods to handle specific classes of objects, see [InternalMethods](#). The default methods handle real and complex vectors.

Note

In R, basically all mathematical functions (including basic [Arithmetic](#)), are supposed to work properly with +/- Inf and NaN as input or output.

The basic rule should be that calls and relations with Infs really are statements with a proper mathematical *limit*.

The C99 function `isfinite` is used for `is.finite` if available.

See Also

NA, ‘Not Available’ which is not a number as well, however usually used for missing values and applies to many modes, not just numeric.

Examples

```

pi / 0 ## = Inf a non-zero number divided by zero creates infinity
0 / 0 ## = NaN

1/0 + 1/0# Inf
1/0 - 1/0# NaN

stopifnot(
  1/0 == Inf,
  1/Inf == 0
)
sin(Inf)
cos(Inf)
tan(Inf)

```

is.function	<i>Is an Object of Type (Primitive) Function?</i>
-------------	---

Description

Checks whether its argument is a (primitive) function.

Usage

```

is.function(x)
is.primitive(x)

```

Arguments

`x` an R object.

Details

`is.primitive(x)` tests if `x` is a primitive function (either a "builtin" or "special" as described for [typeof](#))?

Value

TRUE if `x` is a (primitive) function, and FALSE otherwise.

Examples

```

is.function(1) # FALSE
is.function(is.primitive) # TRUE: it is a function, but ..
is.primitive(is.primitive) # FALSE:it's not a primitive one, whereas
is.primitive(is.function) # TRUE: that one *is*

```

`is.language`*Is an Object a Language Object?*

Description

`is.language` returns TRUE if `x` is a variable [name](#), a [call](#), or an [expression](#).

Usage

```
is.language(x)
```

Arguments

`x` object to be tested.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

Examples

```
ll <- list(a = expression(x^2 - 2*x + 1), b = as.name("Jim"),
          c = as.expression(exp(1)), d = call("sin", pi))
sapply(ll, typeof)
sapply(ll, mode)
stopifnot(sapply(ll, is.language))
```

`is.object`*Is an Object "internally classed"?*

Description

A function rather for internal use. It returns TRUE if the object `x` has the R internal OBJECT bit set, and FALSE otherwise. The OBJECT bit is set when a "class" attribute is added and removed when that attribute is removed, so this is a very efficient way to check if an object has a class attribute. (S4 objects always should.)

Usage

```
is.object(x)
```

Arguments

`x` object to be tested.

See Also

[class](#), and [methods](#).

[isS4](#).

Examples

```
is.object(1) # FALSE
is.object(as.factor(1:3)) # TRUE
```

```
is.R
```

Are we using R, rather than S?

Description

Test if running under R.

Usage

```
is.R()
```

Details

The function has been written such as to correctly run in all versions of R, S and S-PLUS. In order for code to be runnable in both R and S dialects previous to S-PLUS 8.0, your code must either define `is.R` or use it as

```
if (exists("is.R") && is.function(is.R) && is.R()) {
  ## R-specific code
} else {
  ## S-version of code
}
```

Value

`is.R` returns TRUE if we are using R and FALSE otherwise.

See Also

[R.version](#), [system](#).

Examples

```
x <- stats::runif(20); small <- x < 0.4
## In the early years of R, 'which()' only existed in R:
if(is.R()) which(small) else seq(along=small)[small]
```

is.recursive *Is an Object Atomic or Recursive?*

Description

`is.atomic` returns TRUE if `x` is an atomic vector (or NULL) and FALSE otherwise.

`is.recursive` returns TRUE if `x` has a recursive (list-like) structure and FALSE otherwise.

Usage

```
is.atomic(x)
is.recursive(x)
```

Arguments

`x` object to be tested.

Details

`is.atomic` is true for the atomic vector types ("logical", "integer", "numeric", "complex", "character" and "raw") and NULL.

Most types of language objects are regarded as recursive: those which are not are the atomic vector types, NULL and symbols (as given by `as.name`).

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`is.list`, `is.language`, etc, and the demo("is.things").

Examples

```
require(stats)

is.a.r <- function(x) c(is.atomic(x), is.recursive(x))

is.a.r(c(a=1,b=3))            # TRUE FALSE
is.a.r(list())                # FALSE TRUE ??
is.a.r(list(2))              # FALSE TRUE
is.a.r(lm)                    # FALSE TRUE
is.a.r(y ~ x)                # FALSE TRUE
is.a.r(expression(x+1))     # FALSE TRUE (not in 0.62.3!)
```

`is.single`*Is an Object of Single Precision Type?*

Description

`is.single` reports an error. There are no single precision values in R.

Usage

```
is.single(x)
```

Arguments

`x` object to be tested.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

`is.unsorted`*Test if an Object is Not Sorted*

Description

Test if an object is not sorted, without the cost of sorting it.

Usage

```
is.unsorted(x, na.rm = FALSE, strictly = FALSE)
```

Arguments

`x` an R object with a class or a numeric, complex, character or logical vector.
`na.rm` logical. Should missing values be removed before checking?
`strictly` logical indicating if the check should be for *strictly* increasing values.

Value

A length-one logical value. All objects of length 0 or 1 are sorted: the result will be `NA` for objects of length 2 or more except for atomic vectors and objects with a class (where the `>=` or `>` method is used).

See Also

[sort](#), [order](#).

`isS4`*Test for an S4 object*

Description

Tests whether the object is an instance of an S4 class.

Usage

```
isS4(object)

asS4(object, value = TRUE)
```

Arguments

<code>object</code>	Any R object.
<code>value</code>	A single logical value; not NA.

Details

Note that `isS4` does not rely on the **methods** package, so in particular it can be used to detect the need to [require](#) that package. (But `asS4` does depend on **methods**.)

You should not set the flag directly unless you really know why. As from R 2.6.0, S4 methods are restricted to S4 objects for primitive functions; `asS4` allows method dispatch of S4 methods on primitives for S3 classes. For all other purposes, an object will satisfy `isS4(x)` if and only if it should.

Note that S4 methods can only be set on those primitives which are ‘[internal generic](#)’ and `%*%`.

Value

`isS4` always returns `TRUE` or `FALSE` according to whether the internal flag marking an S4 object has been turned on for this object.

`asS4` will turn this flag on or off. But see the details.

See Also

[is.object](#)

Examples

```
isS4(pi) # FALSE
isS4(getClass("MethodDefinition")) # TRUE
```

isSymmetric	<i>Test if a Matrix or other Object is Symmetric</i>
-------------	--

Description

Generic function to test if `object` is symmetric or not. Currently only a matrix method is implemented.

Usage

```
isSymmetric(object, ...)  
## S3 method for class 'matrix':  
isSymmetric(object, tol = 100 * .Machine$double.eps, ...)
```

Arguments

<code>object</code>	any R object; a <code>matrix</code> for the matrix method.
<code>tol</code>	numeric scalar ≥ 0 . Smaller differences are not considered, see all.equal.numeric .
<code>...</code>	further arguments passed to methods; the matrix method passes these to all.equal .

Details

The `matrix` method is used inside `eigen` by default to test symmetry of matrices *up to rounding error*, using [all.equal](#). It might not be appropriate in all situations.

Value

logical indicating if `object` is symmetric or not.

See Also

[eigen](#) which calls `isSymmetric` when its `symmetric` argument is missing, as per default.

Examples

```
isSymmetric(D3 <- diag(3)) # -> TRUE  
  
D3[2,1] <- 1e-100  
D3  
isSymmetric(D3) # TRUE  
isSymmetric(D3, tol = 0) # FALSE for zero-tolerance
```

jitter

Add 'Jitter' (Noise) to Numbers

Description

Add a small amount of noise to a numeric vector.

Usage

```
jitter(x, factor=1, amount = NULL)
```

Arguments

<code>x</code>	numeric vector to which <i>jitter</i> should be added.
<code>factor</code>	numeric
<code>amount</code>	numeric; if positive, used as <i>amount</i> (see below), otherwise, if = 0 the default is <code>factor * z/50</code> . Default (NULL): <code>factor * d/5</code> where <i>d</i> is about the smallest difference between <i>x</i> values.

Details

The result, say *r*, is `r <- x + runif(n, -a, a)` where `n <- length(x)` and *a* is the `amount` argument (if specified).

Let `z <- max(x) - min(x)` (assuming the usual case). The amount *a* to be added is either provided as *positive* argument `amount` or otherwise computed from *z*, as follows:

If `amount == 0`, we set `a <- factor * z/50` (same as *S*).

If `amount` is NULL (*default*), we set `a <- factor * d/5` where *d* is the smallest difference between adjacent unique (apart from fuzz) *x* values.

Value

`jitter(x, ...)` returns a numeric of the same length as *x*, but with an amount of noise added in order to break ties.

[rug](#) which you may want to combine with `jitter`.

Examples

```
round(jitter(c(rep(1,3), rep(1.2, 4), rep(3,3))), 3)
## These two 'fail' with S-plus 3.x:
jitter(rep(0, 7))
jitter(rep(10000,5))
```

kappa

*Compute or Estimate the Condition Number of a Matrix***Description**

The condition number of a regular (square) matrix is the product of the *norm* of the matrix and the norm of its inverse (or pseudo-inverse), and hence depends on the kind of matrix-norm.

`kappa()` computes an estimate of the 2-norm condition number of a matrix or of the R matrix of a QR decomposition, perhaps of a linear fit. The 2-norm condition number can be shown to be the ratio of the largest to the smallest *non-zero* singular value of the matrix.

Usage

```
kappa(z, ...)
## Default S3 method:
kappa(z, exact = FALSE,
      norm = NULL, method = c("qr", "direct"), ...)
## S3 method for class 'lm':
kappa(z, ...)
## S3 method for class 'qr':
kappa(z, ...)

kappa.tri(z, exact = FALSE, LINPACK = TRUE, norm=NULL, ...)

rcond(x, norm = c("O", "I", "1"), triangular = FALSE, ...)
```

Arguments

<code>z, x</code>	A matrix or a the result of <code>qr</code> or a fit from a class inheriting from "lm".
<code>exact</code>	logical. Should the result be exact?
<code>norm</code>	character string, specifying the matrix norm wrt to which the condition number is to be computed. "O", the default, means the O ne- or 1-norm. The (currently only) other possible value is "I" for the infinity norm.
<code>method</code>	character string, specifying the method to be used; "qr" is default for back-compatibility, mainly.
<code>triangular</code>	logical. If true, the matrix used is just the lower triangular part of <code>z</code> .
<code>LINPACK</code>	logical. If true and <code>z</code> is not complex, the Linpack routine <code>dtcco()</code> is called; otherwise the relevant Lapack routine is.
<code>...</code>	further arguments passed to or from other methods.

Details

For `kappa()`, if `exact = FALSE` (the default) the 2-norm condition number is estimated by a cheap approximation. Following `S`, by default, this uses the LINPACK routine `dtrco()`. However, in `R` (or `S`) the exact calculation (via `svd`) is also likely to be quick enough.

Note that the 1- and Inf-norm condition numbers are much faster to calculate, and `rcond()` computes these *reciprocal* condition numbers, also for complex matrices, using standard Lapack routines.

`kappa.tri` is an internal function called by `kappa.qr`.

Value

The condition number, *kappa*, or an approximation if `exact = FALSE`.

Author(s)

The design was inspired by (but differs considerably from) the `S` function of the same name described in Chambers (1992).

See Also

`svd` for the singular value decomposition and `qr` for the *QR* one.

Examples

```
kappa(x1 <- cbind(1, 1:10))# 15.71
kappa(x1, exact = TRUE)    # 13.68
kappa(x2 <- cbind(x1, 2:11))# high! [x2 is singular!]

hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
sv9 <- svd(h9 <- hilbert(9))$ d
kappa(h9)# pretty high!
kappa(h9, exact = TRUE) == max(sv9) / min(sv9)
kappa(h9, exact = TRUE) / kappa(h9) # .677 (i.e., rel.error = 32%)
```

kronecker

Kronecker products on arrays

Description

Computes the generalised kronecker product of two arrays, `X` and `Y`. `kronecker(X, Y)` returns an array `A` with dimensions `dim(X) * dim(Y)`.

Usage

```
kronecker(X, Y, FUN = "*", make.dimnames = FALSE, ...)
X %x% Y
```

Arguments

X	A vector or array.
Y	A vector or array.
FUN	a function; it may be a quoted string.
make.dimnames	Provide dimnames that are the product of the dimnames of X and Y.
...	optional arguments to be passed to FUN.

Details

If X and Y do not have the same number of dimensions, the smaller array is padded with dimensions of size one. The returned array comprises submatrices constructed by taking X one term at a time and expanding that term as FUN(x, Y, ...).

%x% is an alias for kronecker (where FUN is hardwired to "*").

# simple scalar multiplication
( M <- matrix(1:6, ncol=2) )
kronecker(4, M)
# Block diagonal matrix:
kronecker(diag(1, 3), M)

# ask for dimnames

fred <- matrix(1:12, 3, 4, dimnames=list(LETTERS[1:3], LETTERS[4:7]))
bill <- c("happy" = 100, "sad" = 1000)
kronecker(fred, bill, make.dimnames = TRUE)

bill <- outer(bill, c("cat"=3, "dog"=4))
kronecker(fred, bill, make.dimnames = TRUE)
```

l10n_info	<i>Localization Information</i>
-----------	---------------------------------

Description

Report on localization information.

Usage

```
l10n_info()
```

Value

A list with three logical components:

MBCS	If a multi-byte character set in use?
UTF-8	Is this a UTF-8 locale?
Latin-1	Is this a Latin-1 locale?

See Also

[Sys.getlocale](#), [localeconv](#)

Examples

```
l10n_info()
```

labels	<i>Find Labels from Object</i>
--------	--------------------------------

Description

Find a suitable set of labels from an object for use in printing or plotting, for example. A generic function.

Usage

```
labels(object, ...)
```

Arguments

object	Any R object: the function is generic.
...	further arguments passed to or from other methods.

Value

A character vector or list of such vectors. For a vector the results is the names or `seq(along=x)` and for a data frame or array it is the `dimnames` (with `NULL` expanded to `seq(len=d[i])`).

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

lapply

*Apply a Function over a List or Vector***Description**

`lapply` returns a list of the same length as `X`, each element of which is the result of applying `FUN` to the corresponding element of `X`.

`sapply` is a user-friendly version of `lapply` by default returning a vector or matrix if appropriate.

`replicate` is a wrapper for the common use of `sapply` for repeated evaluation of an expression (which will usually involve random number generation).

Usage

```
lapply(X, FUN, ...)
```

```
sapply(X, FUN, ..., simplify = TRUE, USE.NAMES = TRUE)
```

```
replicate(n, expr, simplify = TRUE)
```

Arguments

<code>X</code>	a vector (atomic or list) or an expressions vector. Other objects (including classed objects) will be coerced by <code>as.list</code> .
<code>FUN</code>	the function to be applied to each element of <code>X</code> : see ‘Details’. In the case of functions like <code>+</code> , <code>%*%</code> , etc., the function name must be backquoted or quoted.
<code>...</code>	optional arguments to <code>FUN</code> .
<code>simplify</code>	logical; should the result be simplified to a vector or matrix if possible?
<code>USE.NAMES</code>	logical; if <code>TRUE</code> and if <code>X</code> is character, use <code>X</code> as <code>names</code> for the result unless it had names already.
<code>n</code>	number of replications.
<code>expr</code>	expression (language object, usually a call) to evaluate repeatedly.

Details

`FUN` is found by a call to `match.fun` and typically is specified as a function or a symbol (e.g. a backquoted name) or a character string specifying a function to be searched for from the environment of the call to `lapply`.

Function `FUN` must be able to accept as input any of the elements of `X`. If the latter is an atomic vector, `FUN` will always be passed a length-one vector of the same type as `X`.

Simplification in `sapply` is only attempted if `X` has length greater than zero and if the return values from all elements of `X` are all of the same (positive) length. If the common length is one the result is a vector, and if greater than one is a matrix with a column corresponding to each element of `X`.

Users of S4 classes should pass a list to `lapply`: the internal coercion is done by the system `as.list` in the base namespace and not one defined by a user (e.g. by setting S4 methods on the system function).

Value

For `lapply` and `sapply(simplify=FALSE)`, a list.

For `sapply(simplify=TRUE)` and `replicate`: if `X` has length zero or `n = 0`, an empty list. Otherwise an atomic vector or matrix or list of the same length as `X` (of length `n` for `replicate`). If simplification occurs, the output type is determined from the highest type of the return values in the hierarchy `NULL < raw < logical < integer < real < complex < character < list < expression`, after coercion of pairlists to lists.

Note

`sapply(*, simplify = FALSE, USE.NAMES = FALSE)` is equivalent to `lapply(*)`.

For historical reasons, the calls created by `lapply` are unevaluated, and code has been written (e.g. `bquote`) that relies on this. This means that the recorded call is always of the form `FUN(X[[0L]], ...)`, with `0L` replaced by the current integer index. This is not normally a problem, but it can be if `FUN` uses `sys.call` or `match.call` or if it is a primitive function that makes use of the call. This means that it is often safer to call primitive functions with a wrapper, so that e.g. `lapply(l1, function(x) is.numeric(x))` is required in R 2.7.1 to ensure that method dispatch for `is.numeric` occurs correctly.

If `expr` is a function call, be aware of assumptions about where it is evaluated, and in particular what `...` might refer to. You can pass additional named arguments to a function call as additional named arguments to `replicate`: see ‘Examples’.

See Also

`apply`, `tapply`, `mapply` for applying a function to multiple arguments, and `rapply` for a recursive version of `lapply()`, `eapply` for applying a function to each entry in an environment.

Examples

```
require(stats); require(graphics)

x <- list(a = 1:10, beta = exp(-3:3), logic = c(TRUE,FALSE,FALSE,TRUE))
# compute the list mean for each list element
lapply(x,mean)
# median and quartiles for each list element
lapply(x, quantile, probs = 1:3/4)
sapply(x, quantile)
i39 <- sapply(3:9, seq) # list of vectors
sapply(i39, fivenum)

hist(replicate(100, mean(rexp(10))))

## use of replicate() with parameters:
foo <- function(x=1, y=2) c(x,y)
# does not work: bar <- function(n, ...) replicate(n, foo(...))
bar <- function(n, x) replicate(n, foo(x=x))
bar(5, x=3)
```

Last.value	<i>Value of Last Evaluated Expression</i>
------------	---

Description

The value of the internal evaluation of a top-level R expression is always assigned to `.Last.value` (in `package:base`) before further processing (e.g., printing).

Usage

```
.Last.value
```

Details

The value of a top-level assignment *is* put in `.Last.value`, unlike S.

Do not assign to `.Last.value` in the workspace, because this will always mask the object of the same name in `package:base`.

See Also

[eval](#)

Examples

```
## These will not work correctly from example(),
## but they will in make check or if pasted in,
## as example() does not run them at the top level
gamma(1:15)      # think of some intensive calculation...
fac14 <- .Last.value # keep them

library("splines") # returns invisibly
.Last.value      # shows what library(.) above returned
```

length	<i>Length of an Object</i>
--------	----------------------------

Description

Get or set the length of vectors (including lists) and factors, and of any other R object for which a method has been defined.

Usage

```
length(x)
length(x) <- value
```

Arguments

<code>x</code>	an R object. For replacement, a vector or factor.
<code>value</code>	an integer.

Details

Both functions are generic: you can write methods to handle specific classes of objects, see [InternalMethods](#). `length<-` has a "factor" method.

The replacement form can be used to reset the length of a vector. If a vector is shortened, extra values are discarded and when a vector is lengthened, it is padded out to its new length with `NA`s (`nul` for raw vectors).

Value

The default method currently returns an `integer` of length 1. Since this may change in the future and may differ for other methods, programmers should not rely on it. (Should the length exceed the maximum representable integer, it is returned as `NA`.)

For vectors (including lists) and factors the length is the number of elements. For an environment it is the number of objects in the environment, and `NULL` has length 0. For expressions and pairlists (including language objects and dotlists) it is the length of the pairlist chain. All other objects (including functions) have length one: note that for functions this differs from `S`.

The replacement form removes all the attributes of `x` except its names.

See Also

`nchar` for counting the number of characters in character vectors.

Examples

```
length(diag(4))# = 16 (4 x 4)
length(options())# 12 or more
length(y ~ x1 + x2 + x3)# 3
length(expression(x, {y <- x^2; y+2}, x^y)) # 3

## from example(warpbreaks)
require(stats)

fm1 <- lm(breaks ~ wool * tension, data = warpbreaks)
length(fm1$call) # 3, lm() and two arguments.
length(formula(fm1)) # 3, ~ lhs rhs
```

levels

Levels Attributes

Description

`levels` provides access to the levels attribute of a variable. The first form returns the value of the levels of its argument and the second sets the attribute.

Usage

```
levels(x)
levels(x) <- value
```

Arguments

x	an object, for example a factor.
value	A valid value for <code>levels(x)</code> . For the default method, <code>NULL</code> or a character vector. For the <code>factor</code> method, a vector of character strings with length at least the number of levels of <code>x</code> , or a named list specifying how to rename the levels.

Details

Both the extractor and replacement forms are generic and new methods can be written for them. The most important method for the replacement function is that for [factors](#).

For the factor replacement method, a `NA` in `value` causes that level to be removed from the levels and the elements formerly with that level to be replaced by `NA`.

Note that for a factor, replacing the levels via `levels(x) <- value` is not the same as (and is preferred to) `attr(x, "levels") <- value`.

f <- factor(c("a","b"))
levels(f) <- list(C="C", A="a", B="b")
f
```

libPaths

*Search Paths for Packages***Description**

`.libPaths` gets/sets the library trees within which packages are looked for.

Usage

```
.libPaths(new)

.Library
.Library.site
```

Arguments

`new` a character vector with the locations of R library trees. Tilde expansion (`path.expand`) is done, and if any element contains one of `*?[]`, globbing is done where supported by the platform: see `Sys.glob`.

Details

`.Library` is a character string giving the location of the default library, the ‘library’ subdirectory of `R_HOME`.

`.Library.site` is a (possibly empty) character vector giving the locations of the site libraries, by default the ‘site-library’ subdirectory of `R_HOME` (which may not exist).

`.libPaths` is used for getting or setting the library trees that R knows about (and hence uses when looking for packages). If called with argument `new`, the library search path is set to the existing directories in `unique(c(new, .Library.site, .Library))` and this is returned. If given no argument, a character vector with the currently active library trees is returned.

The library search path is initialized at startup from the environment variable `R_LIBS` (which should be a colon-separated list of directories at which R library trees are rooted) followed by those in environment variable `R_LIBS_USER`. Only directories which exist at the time will be included.

By default `R_LIBS` is unset, and `R_LIBS_USER` is set to directory ‘`R/R.version$platform-library/x.y`’ of the home directory (or ‘`Library/R/x.y/library`’ for Mac OS X AQUA builds), for R `x.y.z`.

`.Library.site` can be set via the environment variable `R_LIBS_SITE` (as a colon-separated list of library trees).

Both `R_LIBS_USER` and `R_LIBS_SITE` feature possible expansion of specifiers for R version specific information as part of the startup process. The possible conversion specifiers all start with a ‘`%`’ and are followed by a single letter (use ‘`%%`’ to obtain ‘`%`’), with currently available conversion specifications as follows:

%V R version number including the patchlevel (e.g., '2.5.0').

%v R version number excluding the patchlevel (e.g., '2.5').

%p the platform for which R was built.

%o the underlying operating system.

%a the architecture (CPU) R was built on/for.

(See [version](#) for details on R version information.)

Function `.libPaths` always uses the values of `.Library` and `.Library.site` in the base name space. `.Library.site` can be set by the site in 'Rprofile.site', which should be followed by a call to `.libPaths(.libPaths())` to make use of the updated value.

Value

A character vector of file paths.

Examples

```
.libPaths()                # all library trees R knows about
```

library	<i>Loading and Listing of Packages</i>
---------	--

Description

`library` and `require` load add-on packages.

`.First.lib` is called when a package is loaded; `.Last.lib` is called when a package is detached.

Usage

```
library(package, help, pos = 2, lib.loc = NULL,
         character.only = FALSE, logical.return = FALSE,
         warn.conflicts = TRUE,
         keep.source = getOption("keep.source.pkgs"),
         verbose = getOption("verbose"),
         version)
```

```
require(package, lib.loc = NULL, quietly = FALSE,
         warn.conflicts = TRUE,
         keep.source = getOption("keep.source.pkgs"),
         character.only = FALSE, version, save = TRUE)
```

```
.First.lib(libname, pkgname)
```

```
.Last.lib(libpath)
```

Arguments

<code>package, help</code>	the name of a package, given as a name or literal character string, or a character string, depending on whether <code>character.only</code> is <code>FALSE</code> (default) or <code>TRUE</code>).
<code>pos</code>	the position on the search list at which to attach the loaded package. Note that <code>.First.lib</code> may attach other packages, and <code>pos</code> is computed <i>after</i> <code>.First.lib</code> has been run. Can also be the name of a position on the current search list as given by <code>search()</code> .
<code>lib.loc</code>	a character vector describing the location of R library trees to search through, or <code>NULL</code> . The default value of <code>NULL</code> corresponds to all libraries currently known. Non-existent library trees are silently ignored.
<code>character.only</code>	a logical indicating whether <code>package</code> or <code>help</code> can be assumed to be character strings.
<code>version</code>	A character string denoting a version number of the package to be loaded, for use with <i>versioned installs</i> : see the section later in this document.
<code>logical.return</code>	logical. If it is <code>TRUE</code> , <code>FALSE</code> or <code>TRUE</code> is returned to indicate success.
<code>warn.conflicts</code>	logical. If <code>TRUE</code> , warnings are printed about conflicts from attaching the new package, unless that package contains an object <code>.conflicts.OK</code> . A conflict is a function masking a function, or a non-function masking a non-function.
<code>keep.source</code>	logical. If <code>TRUE</code> , functions ‘keep their source’ including comments, see argument <code>keep.source</code> to options . This applies only to the named package, and not to any packages or name spaces which might be loaded to satisfy dependencies or imports. This argument does not apply to packages using lazy-loading. Whether they have kept source is determined when they are installed (and is most likely false).
<code>verbose</code>	a logical. If <code>TRUE</code> , additional diagnostics are printed.
<code>quietly</code>	a logical. If <code>TRUE</code> , no message confirming package loading is printed.
<code>save</code>	logical or environment. If <code>TRUE</code> , a call to <code>require</code> from the source for a package will save the name of the required package in the variable <code>".required"</code> , allowing function detach to warn if a required package is detached. See section ‘Packages that require other packages’ below.
<code>libname</code>	a character string giving the library directory where the package was found.
<code>pkgname</code>	a character string giving the name of the package, including the version number if the package was installed with <code>--with-package-versions</code> (deprecated).
<code>libpath</code>	a character string giving the complete path to the package.

Details

`library(package)` and `require(package)` both load the package with name `package`. `require` is designed for use inside other functions; it returns `FALSE` and gives a warning (rather than an error as `library()` does by default) if the package does not exist. Both functions check and update the list of currently loaded packages and do not reload a package which is already loaded. (Furthermore, if the package has a name space and a name space of that name is already

loaded, they work from the existing name space rather than reloading from the file system. If you want to reload a package, call `detach` or `unloadNamespace` first.)

To suppress messages during the loading of packages use `suppressPackageStartupMessages`: this will suppress all messages from R itself but not necessarily all those from package authors.

If `library` is called with no package or `help` argument, it lists all available packages in the libraries specified by `lib.loc`, and returns the corresponding information in an object of class `"libraryIQR"`. The structure of this class may change in future versions. In earlier versions of R, only the names of all available packages were returned; use `.packages(all = TRUE)` for obtaining these. Note that `installed.packages()` returns even more information.

`library(help = somename)` computes basic information about the package `somename`, and returns this in an object of class `"packageInfo"`. The structure of this class may change in future versions. When used with the default value (NULL) for `lib.loc`, the loaded packages are searched before the libraries.

`.First.lib` is called when a package without a name space is loaded by `library`. (For packages with name spaces see `.onLoad`.) It is called with two arguments, the name of the library directory where the package was found (i.e., the corresponding element of `lib.loc`), and the name of the package (in that order, and with the package name including the version for a versioned install, e.g. `tree_1.0-16`). It is a good place to put calls to `library.dynam` which are needed when loading a package into this function (don't call `library.dynam` directly, as this will not work if the package is not installed in a standard location). `.First.lib` is invoked after the search path interrogated by `search()` has been updated, so `as.environment(match("package:name", search()))` will return the environment in which the package is stored. If calling `.First.lib` gives an error the loading of the package is abandoned, and the package will be unavailable. Similarly, if the option `".First.lib"` has a list element with the package's name, this element is called in the same manner as `.First.lib` when the package is loaded. This mechanism allows the user to set package 'load hooks' in addition to startup code as provided by the package maintainers, but `setHook` is preferred.

`.Last.lib` is called when a package is detached. Beware that it might be called if `.First.lib` has failed, so it should be written defensively. (It is called within `try`, so errors will not stop the package being detached.)

Value

`library` returns the list of loaded (or available) packages (or TRUE if `logical.return` is TRUE). `require` returns a logical indicating whether the required package is available, invisibly

Packages that require other packages

NB: This mechanism has been almost entirely superseded by using the `Depends:` field in the 'DESCRIPTION' file of a package.

The source code for a package that requires one or more other packages should have a call to `require`, preferably near the beginning of the source, and of course before any code that uses functions, classes or methods from the other package. The default for argument `save` will save the names of all required packages in the environment of the new package. The saved package names are used by `detach` when a package is detached to warn if other packages still require the to-be-detached package. Also, if a package is installed with saved image (see `INSTALL`), the saved package names are used to require these packages when the new package is attached.

Formal methods

`library` takes some further actions when package **methods** is attached (as it is by default). Packages may define formal generic functions as well as re-defining functions in other packages (notably **base**) to be generic, and this information is cached whenever such a package is loaded after **methods** and re-defined functions (**implicit generics**) are excluded from the list of conflicts. The caching and check for conflicts require looking for a pattern of objects; the search may be avoided by defining an object `.noGenerics` (with any value) in the package. Naturally, if the package *does* have any such methods, this will prevent them from being used.

Versioned installs

Packages can be installed with version information by R CMD `INSTALL --with-package-versions` or `install.packages(installWithVers = TRUE)`. This allows more than one version of a package to be installed in a library directory, using package directory names like `foo_1.5-1`. When such packages are loaded, it is this *versioned* name that `search()` returns. Some utility functions require the versioned name and some the unversioned name (here `foo`).

If *version is not* specified, `library` looks first for a packages of that name, and then for versioned installs of the package, selecting the one with the latest version number. If *version is* specified, a versioned install with an exactly matching version is looked for.

If *version is not* specified, `require` will accept any version that is already loaded, whereas `library` will look for an unversioned install even if a versioned install is already loaded.

Loading more than one version of a package into an R session is not currently supported. Support for versioned installs is patchy.

Note

`library` and `require` can only load an *installed* package, and this is detected by having a ‘DESCRIPTION’ file containing a `Built:` field.

Under Unix-alikes, the code checks that the package was installed under a similar operating system as given by `R.version$platform` (the canonical name of the platform under which R was compiled), provided it contains compiled code. Packages which do not contain compiled code can be shared between Unix-alikes, but not to other OSes because of potential problems with line endings and OS-specific help files. If sub-architectures are used, the OS similarity is not checked since the OS used to build may differ (e.g. `i386-pc-linux-gnu` code can be built on an `x86_64-unknown-linux-gnu` OS).

The package name given to `library` and `require` must match the name given in the package’s ‘DESCRIPTION’ file exactly, even on case-insensitive file systems such as MS Windows.

library(help = splines) # documentation on package 'splines'
library(splines) # load package 'splines'
require(splines) # the same
search() # "splines", too
detach("package:splines")

# if the package name is in a character vector, use
pkg <- "splines"
library(pkg, character.only = TRUE)
detach(pos = match(paste("package", pkg, sep=":"), search()))

require(pkg, character.only = TRUE)
detach(pos = match(paste("package", pkg, sep=":"), search()))

require(nonexistent) # FALSE
## Not run:
## Suppose a package needs to call a DLL named 'fooEXT',
## where 'EXT' is the system-specific extension. Then you should use
.First.lib <- function(lib, pkg)
  library.dynam("foo", pkg, lib)

## if you want to mask as little as possible, use
library(mypkg, pos = "package:base")
## End(Not run)

```

library.dynam	<i>Loading DLLs from Packages</i>
---------------	-----------------------------------

Description

Load the specified file of compiled code if it has not been loaded already, or unloads it.

Usage

```

library.dynam(chname, package = NULL, lib.loc = NULL,
              verbose = getOption("verbose"),
              file.ext = .Platform$dynlib.ext, ...)

library.dynam.unload(chname, libpath,
                     verbose = getOption("verbose"),
                     file.ext = .Platform$dynlib.ext)

.dynLibs(new)

```

Arguments

chname	a character string naming a DLL (also known as a dynamic shared object or library) to load.
package	a character vector with the names of packages to search through, or NULL. By default, all packages in the search path are used.

<code>lib.loc</code>	a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.
<code>libpath</code>	the path to the loaded package whose DLL is to be unloaded.
<code>verbose</code>	a logical value indicating whether an announcement is printed on the console before loading the DLL. The default value is taken from the <code>verbose</code> entry in the system options.
<code>file.ext</code>	the extension to append to the file name to specify the library to be loaded. This defaults to the appropriate value for the operating system.
<code>...</code>	additional arguments needed by some libraries that are passed to the call to <code>dyn.load</code> to control how the library is loaded.
<code>new</code>	a list of "DLLInfo" objects corresponding to the DLLs loaded by packages. Can be missing.

Details

See `dyn.load` for what sort of objects these functions handle.

`library.dynam` is designed to be used inside a package rather than at the command line, and should really only be used inside `.First.lib` or `.onLoad`. The system-specific extension for DLLs (e.g., `.so` or `.sl` on Unix systems, `.so` on Mac OS X, `.dll` on Windows) should not be added. Note that to allow for versioned installs, the `chname` argument should not be set to the `pkgname` argument of `.First.lib` or `.onLoad`.

If `...` does not include a named argument `Dllpath`, `dyn.load` is called with `DLLpath` set to the package's `'libs'` directory. (Currently only used under Windows.)

`library.dynam.unload` is designed for use in `.Last.lib` or `.onUnload`: it unloads the DLL and updates the value of `.dynLibs()`

`.dynLibs` is used for getting (with no argument) or setting the DLLs which are currently loaded by packages (using `library.dynam`).

Value

If `chname` is not specified, `library.dynam` returns an object of class "DLLInfoList" corresponding to the DLLs loaded by packages.

If `chname` is specified, an object of class "DLLInfo" that identifies the DLL and can be used in future calls is returned invisibly. For packages that have name spaces, a list of these objects is stored in the name space's environment for use at run-time.

Note that the class `DLLInfo` has an overloaded method for `$` which can be used to resolve native symbols within that DLL.

`library.dynam.unload` invisibly returns an object of class "DLLInfo" identifying the DLL successfully unloaded.

`.dynLibs` returns an object of class "DLLInfoList" corresponding corresponding to its current value.

Warning

Do not use `dyn.unload` on a DLL loaded by `library.dynam`: use `library.dynam.unload` to ensure that `.dynLibs` gets updated. Otherwise a subsequent call to `library.dynam` will be told the object is already loaded.

list

Lists – Generic and Dotted Pairs

Description

Functions to construct, coerce and check for both kinds of R lists.

Usage

```
list(...)
pairlist(...)

as.list(x, ...)
## S3 method for class 'environment':
as.list(x, all.names = FALSE, ...)
as.pairlist(x)

is.list(x)
is.pairlist(x)

alist(...)
```

Arguments

<code>...</code>	objects, possibly named.
<code>x</code>	object to be coerced or tested.
<code>all.names</code>	a logical indicating whether to copy all values or (default) only those whose names do not begin with a dot.

Details

Most lists in R internally are *Generic Vectors*, whereas traditional *dotted pair* lists (as in LISP) are available but rarely seen by users (except as `formals` of functions).

The arguments to `list` or `pairlist` are of the form `value` or `tag=value`. The functions return a list or dotted pair list composed of its arguments with each value either tagged or untagged, depending on how the argument was specified.

`alist` handles its arguments as if they described function arguments. So the values are not evaluated, and tagged arguments with no value are allowed whereas `list` simply ignores them. `alist` is most often used in conjunction with `formals`.

`as.list` attempts to coerce its argument to a list. For functions, this returns the concatenation of the list of formal arguments and the function body. For expressions, the list of constituent elements is returned. `as.list` is generic, and as the default method calls `as.vector(mode="list")` methods for `as.vector` may be invoked. `as.list` turns a factor into a list of one-element factors. All attributes will be dropped unless the argument already is a list. (This is inconsistent with functions such as `as.character`, and is for efficiency since lists can be expensive to copy.)

`is.list` returns TRUE if and only if its argument is a list *or* a pairlist of length > 0. `is.pairlist` returns TRUE if and only if the argument is a pairlist or NULL (see below).

The `"environment"` method for `as.list` copies the name-value pairs (for names not beginning with a dot) from an environment to a named list. The user can request that all named objects are copied. The list is in no particular order (the order depends on the order of creation of objects and whether the environment is hashed). No parent environments are searched. (Objects copied are duplicated so this can be an expensive operation.)

An empty pairlist, `pairlist()` is the same as NULL. This is different from `list()`.

`as.pairlist` is implemented as `as.vector(x, "pairlist")`, and hence will dispatch methods for the generic function `as.vector`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`vector("list", length)` for creation of a list with empty components; `c`, for concatenation; `formals.unlist` is an approximate inverse to `as.list()`.
`'plotmath'` for the use of `list` in plot annotation.

Examples

```
require(graphics)

# create a plotting structure
pts <- list(x=cars[,1], y=cars[,2])
plot(pts)

is.pairlist(.Options) # a user-level pairlist

## "pre-allocate" an empty list of length 5
vector("list", 5)

# Argument lists
f <- function() x
# Note the specification of a "..." argument:
formals(f) <- al <- alist(x=, y=2+3, ...=)
f
al

## environment->list coercion

e1 <- new.env()
e1$a <- 10
e1$b <- 20
as.list(e1)
```

list.files

List the Files in a Directory/Folder

Description

These functions produce a character vector of the names of files in the named directory.

Usage

```
list.files(path = ".", pattern = NULL, all.files = FALSE,
           full.names = FALSE, recursive = FALSE,
           ignore.case = FALSE)

dir(path = ".", pattern = NULL, all.files = FALSE,
    full.names = FALSE, recursive = FALSE,
    ignore.case = FALSE)
```

Arguments

<code>path</code>	a character vector of full path names; the default corresponds to the working directory <code>getwd()</code> . Missing values will be ignored.
<code>pattern</code>	an optional regular expression . Only file names which match the regular expression will be returned.
<code>all.files</code>	a logical value. If <code>FALSE</code> , only the names of visible files are returned. If <code>TRUE</code> , all file names will be returned.
<code>full.names</code>	a logical value. If <code>TRUE</code> , the directory path is prepended to the file names. If <code>FALSE</code> , only the file names are returned.
<code>recursive</code>	logical. Should the listing recurse into directories?
<code>ignore.case</code>	logical. Should pattern-matching be case-insensitive?

Value

A character vector containing the names of the files in the specified directories, or "" if there were no files. If a path does not exist or is not a directory or is unreadable it is skipped, with a warning.

The files are sorted in alphabetical order, on the full path if `full.names = TRUE`. Directories are included only if `recursive = FALSE`.

Note

File naming conventions are platform dependent.

`recursive = TRUE` is not supported on all platforms and may be ignored (with a warning).

Author(s)

Ross Ihaka, Brian Ripley

See Also

[file.info](#), [file.access](#) and [files](#) for many more file handling functions and [file.choose](#) for interactive selection.

[glob2rx](#) to convert wildcards (as used by system file commands and shells) to regular expressions.

[Sys.glob](#) for wildcard expansion on file paths.

Examples

```
list.files(R.home())
## Only files starting with a-l or r
## Note that a-l is locale-dependent, but using case-insensitive
## matching makes it unambiguous in English locales
dir("../..", pattern = "[a-lr]", full.names=TRUE, ignore.case = TRUE)
```

load *Reload Saved Datasets*

Description

Reload datasets written with the function `save`.

Usage

```
load(file, envir = parent.frame())
```

Arguments

<code>file</code>	a (readable binary) connection or a character string giving the name of the file to load.
<code>envir</code>	the environment where the data should be loaded.

Details

`load` can load R objects saved in the current or any earlier format. It can read a compressed file (see [save](#)) directly from a file or from a suitable connection (including a call to [url](#)).

Only R objects saved in the current format (used since R 1.4.0) can be read from a connection. If no input is available on a connection a warning will be given, but any input not in the current format will result in an error.

Loading from an earlier version will give a warning about the ‘magic number’: magic numbers 1971:1977 are from R < 0.99.0, and R [ADX] 1 from R 0.99.0 to R 1.3.1.

Value

A character vector of the names of objects created, invisibly.

Warning

Saved R objects are binary files, even those saved with `ascii = TRUE`, so ensure that they are transferred without conversion of end of line markers. `load` tries to detect this case and give an informative error message.

See Also

[save](#), [download.file](#).

Examples

```
## save all data
xx <- pi # to ensure there is some data
save(list = ls(all=TRUE), file= "all.Rdata")
rm(xx)

## restore the saved values to the current environment
local({
  load("all.Rdata")
  ls()
})
```

```

}))
## restore the saved values to the user's workspace
load("all.Rdata", .GlobalEnv)

unlink("all.Rdata")

## Not run:
con <- url("http://some.where.net/R/data/example.rda")
## print the value to see what objects were created.
print(load(con))
close(con) # url() always opens the connection
## End(Not run)

```

localeconv	<i>Find Details of the Numerical and Monetary Representations in the Current Locale</i>
------------	---

Description

Get details of the numerical and monetary representations in the current locale.

Usage

```
Sys.localeconv()
```

Details

These settings are usually controlled by the environment variables `LC_NUMERIC` and `LC_MONETARY` and if not set the values of `LC_ALL` or `LANG`.

Normally `R` is run without looking at the value of `LC_NUMERIC`, so the decimal point remains `'.'`. So the first three of these values will not be useful unless you have set `LC_NUMERIC` in the current `R` session.

Value

A character vector with 18 named components. See your ISO C documentation for details of the meaning.

It is possible to compile `R` without support for locales, in which case the value will be `NULL`.

See Also

[Sys.setlocale](#) for ways to set locales.

Examples

```

Sys.localeconv()
## The results in the C locale are
##   decimal_point  thousands_sep      grouping  int_curr_symbol
##   "."           ""                ""        ""
##   currency_symbol mon_decimal_point mon_thousands_sep  mon_grouping
##   ""            ""                ""            ""
##   positive_sign   negative_sign   int_frac_digits  frac_digits
##   ""             ""                "127"          "127"

```

```
##      p_cs_precedes    p_sep_by_space    n_cs_precedes    n_sep_by_space
##      "127"           "127"           "127"           "127"
##      p_sign_posn     n_sign_posn
##      "127"           "127"

## Now try your default locale (which might be "C").
## Not run:
old <- Sys.getlocale()
Sys.setlocale(locale = "")
Sys.localeconv()
Sys.setlocale(locale = old)
## End(Not run)

## Not run: read.table("foo", dec=Sys.localeconv()["decimal_point"])
```

locales

Query or Set Aspects of the Locale

Description

Get details of or set aspects of the locale for the R process.

Usage

```
Sys.getlocale(category = "LC_ALL")
Sys.setlocale(category = "LC_ALL", locale = "")
```

Arguments

category	character string. The following categories should always be supported: "LC_ALL", "LC_COLLATE", "LC_CTYPE", "LC_MONETARY", "LC_NUMERIC" and "LC_TIME". Some systems will also support "LC_MESSAGES", "LC_PAPER" and "LC_MEASUREMENT".
locale	character string. A valid locale name on the system in use. Normally "" (the default) will pick up the default locale for the system.

Details

The locale describes aspects of the internationalization of a program. Initially most aspects of the locale of R are set to "C" (which is the default for the C language and reflects North-American usage). R sets "LC_CTYPE" and "LC_COLLATE", which allow the use of a different character set and alphabetic comparisons in that character set (including the use of `sort`), "LC_MONETARY" (for use by `Sys.localeconv`) and "LC_TIME" may affect the behaviour of `as.POSIXlt` and `strptime` and functions which use them (but not `date`).

R can be built with no support for locales, but it is normally available on Unix and is available on Windows.

The first seven categories described here are those specified by POSIX. "LC_MESSAGES" will be "C" on systems that do not support message translation, and is not supported on Windows. Trying to use an unsupported category is an error for `Sys.setlocale`.

Note that setting "LC_ALL" sets only "LC_COLLATE", "LC_CTYPE", "LC_MONETARY" and "LC_TIME".

Attempts to set an invalid locale are ignored. There may or may not be a warning, depending on the OS.

Attempts to change the character set (by `Sys.setlocale("LC_TYPE",)`, if that implies a different character set) during a session may not work and are likely to lead to some confusion.

Value

A character string of length one describing the locale in use (after setting for `Sys.setlocale`), or an empty character string if the current locale settings are invalid or `NULL` if locale information is unavailable.

For `category = "LC_ALL"` the details of the string are system-specific: it might be a single locale name or a set of locale names separated by `" / "` (Solaris, Mac OS X) or `" ; "` (Windows, Linux). For portability, it is best to query categories individually: it is not necessarily the case that the result of `foo <- Sys.getlocale()` can be used in `Sys.setlocale("LC_ALL", locale = foo)`.

Warning

Setting `"LC_NUMERIC"` may cause R to function anomalously, so gives a warning. As from R 2.7.0 input conversions in R itself are unaffected, but the reading and writing of ASCII `save` files will be, as may packages. Setting it temporarily to produce graphical or text output may work well enough, but `options(OutDec)` is often preferable.

See Also

`strptime` for uses of `category = "LC_TIME"`. `Sys.localeconv` for details of numerical and monetary representations.

`l10n_info` gives some summary facts about the locale and its encoding.

Examples

```
Sys.getlocale()
Sys.getlocale("LC_TIME")
## Not run:
Sys.setlocale("LC_TIME", "de")      # Solaris 7: details are OS-dependent
Sys.setlocale("LC_TIME", "de_DE.utf8") # Modern Linux etc.
Sys.setlocale("LC_TIME", "German") # Windows
## End(Not run)
Sys.getlocale("LC_PAPER")          # may or may not be set

Sys.setlocale("LC_COLLATE", "C")   # turn off locale-specific sorting
```

log

Logarithms and Exponentials

Description

`log` computes logarithms, by default natural logarithms, `log10` computes common (i.e., base 10) logarithms, and `log2` computes binary (i.e., base 2) logarithms. The general form `log(x, base)` computes logarithms with base `base`.

`log1p(x)` computes $\log(1 + x)$ accurately also for $|x| \ll 1$ (and less accurately when $x \approx -1$).

`exp` computes the exponential function.

`expm1(x)` computes $\exp(x) - 1$ accurately also for $|x| \ll 1$.

Usage

```
log(x, base = exp(1))
logb(x, base = exp(1))
log10(x)
log2(x)

log1p(x)

exp(x)
expm1(x)
```

Arguments

<code>x</code>	a numeric or complex vector.
<code>base</code>	a positive or complex number: the base with respect to which logarithms are computed. Defaults to $e = \exp(1)$.

Details

All except `logb` are generic functions: methods can be defined for them individually or via the [Math](#) group generic.

`log10` and `log2` are only convenience wrappers, but logs to bases 10 and 2 (whether computed *via* `log` or the wrappers) will be computed more efficiently and accurately where supported by the OS. Methods can be set for them individually (and otherwise methods for `log` will be used).

`logb` is a wrapper for `log` for compatibility with S. If (S3 or S4) methods are set for `log` they will be dispatched. Do not set S4 methods on `logb` itself.

Value

A vector of the same length as `x` containing the transformed values. `log(0)` gives `-Inf`, and negative values give `NaN`.

S4 methods

`exp`, `expm1`, `log`, `log10`, `log2` and `log1p` are S4 generic and are members of the [Math](#) group generic.

Note that this means that the S4 generic for `log` has a signature with only one argument, `x`, but that `base` can be passed to methods (but will not be used for method selection). On the other hand, if you only set a method for the [Math](#) group generic then `base` argument of `log` will be ignored for your class.

Note

`log` and `logb` are the same thing in R, but `logb` is preferred if `base` is specified, for S-PLUS compatibility.

Source

`log1p` and `expm1` may be taken from the operating system, but if not available there are based on the Fortran subroutine `dlnrel` by W. Fullerton of Los Alamos Scientific Laboratory (see <http://www.netlib.org/slatec/fnlib/dlnrel.f> and (for small x) a single Newton step for the solution of $\log_{1p}(y) = x$ respectively.

[Trig](#), [sqrt](#), [Arithmetic](#).

Examples

```
log(exp(3))
log10(1e7) # = 7

x <- 10^-(1+2*1:9)
cbind(x, log(1+x), log1p(x), exp(x)-1, expm1(x))
```

Logic

Logical Operators

Description

These operators act on logical vectors.

Usage

```
! x
x & y
x && y
x | y
x || y
xor(x, y)

isTRUE(x)
```

Arguments

`x`, `y` logical vectors, or objects which can be coerced to such or for which methods have been written.

Details

`!` indicates logical negation (NOT).

`&` and `&&` indicate logical AND and `|` and `||` indicate logical OR. The shorter form performs elementwise comparisons in much the same way as arithmetic operators. The longer form evaluates left to right examining only the first element of each vector. Evaluation proceeds only until the result is determined. The longer form is appropriate for programming control-flow and typically preferred in `if` clauses.

`xor` indicates elementwise exclusive OR.

`isTRUE(x)` is an abbreviation of `identical(TRUE, x)`, and so is true if and only if `x` is a length-one logical vector with no attributes (not even names).

Numeric and complex vectors will be coerced to logical values, with zero being false and all non-zero values being true. Raw vectors are handled without any coercion for `!`, `&` and `|`, with these operators being applied bitwise (so `!` is the 1-complement).

The operators `!`, `&` and `|` are generic functions: methods can be written for them individually or via the `Ops` (or `S4 Logic`, see below) group generic function. (See `Ops` for how dispatch is computed.)

`NA` is a valid logical object. Where a component of `x` or `y` is `NA`, the result will be `NA` if the outcome is ambiguous. In other words `NA & TRUE` evaluates to `NA`, but `NA & FALSE` evaluates to `FALSE`. See the examples below.

See `Syntax` for the precedence of these operators: unlike many other languages (including `S`) the AND and OR operators do not have the same precedence (the AND operators are higher than the OR operators).

Value

For `!`, a logical or raw vector of the same length as `x`.

For `|`, `&` and `xor` a logical or raw vector. The elements of shorter vectors are recycled as necessary (with a `warning` when they are recycled only *fractionally*). The rules for determining the attributes of the result are rather complicated. Most attributes are taken from the longer argument, the first if they are of the same length. Names will be copied from the first if it is the same length as the answer, otherwise from the second if that is. For time series, these operations are allowed only if the series are compatible, when the class and `tsp` attribute of whichever is a time series (the same, if both are) are used. For arrays (and an array result) the dimensions and `dimnames` are taken from first argument if it is an array, otherwise the second.

For `||`, `&&` and `isTRUE`, a length-one logical vector.

S4 methods

`!`, `&` and `|` are S4 generics, the latter two part of the `Logic` group generic (and hence methods need argument names `e1`, `e2`).

Prior to R 2.6.0 S4 methods for `!` needed argument name `e1`, but now `x` is correct.

See Also

[TRUE](#) or [logical](#).

[any](#) and [all](#) for OR and AND on many scalar arguments.

[Syntax](#) for operator precedence.

Examples

```
y <- 1 + (x <- stats::rpois(50, lambda=1.5) / 4 - 1)
x[(x > 0) & (x < 1)] # all x values between 0 and 1
if (any(x == 0) || any(y == 0)) "zero encountered"

## construct truth tables :

x <- c(NA, FALSE, TRUE)
names(x) <- as.character(x)
outer(x, x, "&") ## AND table
outer(x, x, "|") ## OR table
```

logical

Logical Vectors

Description

Create or test for objects of type "logical", and the basic logical constants.

Usage

```
TRUE
FALSE
T; F

logical(length = 0)
as.logical(x, ...)
is.logical(x)
```

Arguments

length	desired length.
x	object to be coerced or tested.
...	further arguments passed to or from other methods.

Details

TRUE and FALSE are [reserved](#) words denoting logical constants in the R language, whereas T and F are global variables whose initial values set to these. All four are `logical(1)` vectors.

Value

`logical` creates a logical vector of the specified length. Each element of the vector is equal to `FALSE`.

`as.logical` attempts to coerce its argument to be of logical type. For `factors`, this uses the `levels` (labels). Like `as.vector` it strips attributes including names.

`is.logical` returns `TRUE` or `FALSE` depending on whether its argument is of logical type or not.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`NA`, the other logical constant.

`lower.tri`*Lower and Upper Triangular Part of a Matrix*

Description

Returns a matrix of logicals the same size of a given matrix with entries `TRUE` in the lower or upper triangle.

Usage

```
lower.tri(x, diag = FALSE)
upper.tri(x, diag = FALSE)
```

Arguments

<code>x</code>	a matrix.
<code>diag</code>	logical. Should the diagonal be included?

See Also

`diag, matrix`.

Examples

```
(m2 <- matrix(1:20, 4, 5))
lower.tri(m2)
m2[lower.tri(m2)] <- NA
m2
```

ls *List Objects*

Description

`ls` and `objects` return a vector of character strings giving the names of the objects in the specified environment. When invoked with no argument at the top level prompt, `ls` shows what data sets and functions a user has defined. When invoked with no argument inside a function, `ls` returns the names of the functions local variables. This is useful in conjunction with `browser`.

Usage

```
ls(name, pos = -1, envir = as.environment(pos),
   all.names = FALSE, pattern)
objects(name, pos = -1, envir = as.environment(pos),
        all.names = FALSE, pattern)
```

Arguments

<code>name</code>	which environment to use in listing the available objects. Defaults to the <i>current</i> environment. Although called <code>name</code> for back compatibility, in fact this argument can specify the environment in any form; see the details section.
<code>pos</code>	an alternative argument to <code>name</code> for specifying the environment as a position in the search list. Mostly there for back compatibility.
<code>envir</code>	an alternative argument to <code>name</code> for specifying the environment evaluation environment. Mostly there for back compatibility.
<code>all.names</code>	a logical value. If <code>TRUE</code> , all object names are returned. If <code>FALSE</code> , names which begin with a <code>'.'</code> are omitted.
<code>pattern</code>	an optional regular expression . Only names matching <code>pattern</code> are returned. <code>glob2rx</code> can be used to convert wildcard patterns to regular expressions.

Details

The `name` argument can specify the environment from which object names are taken in one of several forms: as an integer (the position in the [search](#) list); as the character string name of an element in the search list; or as an explicit [environment](#) (including using `sys.frame` to access the currently active function calls). By default, the environment of the call to `ls` or `objects` is used. The `pos` and `envir` arguments are an alternative way to specify an environment, but are primarily there for back compatibility.

Note that the *order* of the resulting strings is locale dependent, see [Sys.getlocale](#).

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[glob2rx](#) for converting wildcard patterns to regular expressions.

[ls.str](#) for a long listing based on [str](#). [apropos](#) (or [find](#)) for finding objects in the whole search path; [grep](#) for more details on ‘regular expressions’; [class](#), [methods](#), etc., for object-oriented programming.

Examples

```
.Ob <- 1
ls(pattern = "O")
ls(pattern= " O", all.names = TRUE)      # also shows ".[foo]"

# shows an empty list because inside myfunc no variables are defined
myfunc <- function() {ls()}
myfunc()

# define a local variable inside myfunc
myfunc <- function() {y <- 1; ls()}
myfunc()          # shows "y"
```

make.names

Make Syntactically Valid Names

Description

Make syntactically valid names out of character vectors.

Usage

```
make.names(names, unique = FALSE, allow_ = TRUE)
```

Arguments

names	character vector to be coerced to syntactically valid names. This is coerced to character if necessary.
unique	logical; if TRUE, the resulting elements are unique. This may be desired for, e.g., column names.
allow_	logical. For compatibility with R prior to 1.9.0.

Details

A syntactically valid name consists of letters, numbers and the dot or underline characters and starts with a letter or the dot not followed by a number. Names such as ".2way" are not valid, and neither are the [reserved](#) words.

The definition of a *letter* depends on the current locale, but only ASCII digits are considered to be digits.

The character "X" is prepended if necessary. All invalid characters are translated to ".". A missing value is translated to "NA". Names which match R keywords have a dot appended to them. Duplicated values are altered by [make.unique](#).

Value

A character vector of same length as `names` with each changed to a syntactically valid name, in the current locale's encoding.

Note

Prior to R version 1.9.0, underscores were not valid in variable names, and code that relies on them being converted to dots will no longer work. Use `allow_ = FALSE` for back-compatibility.

`allow_ = FALSE` is also useful when creating names for export to applications which do not allow underline in names (for example, S-PLUS and some DBMSs).

See Also

`make.unique`, `names`, `character`, `data.frame`.

Examples

```
make.names(c("a and b", "a-and-b"), unique=TRUE)
# "a.and.b" "a.and.b.1"
make.names(c("a and b", "a_and_b"), unique=TRUE)
# "a.and.b" "a_and_b"
make.names(c("a and b", "a_and_b"), unique=TRUE, allow_=FALSE)
# "a.and.b" "a.and.b.1"

state.name[make.names(state.name) != state.name] # those 10 with a space
```

`make.unique`

Make Character Strings Unique

Description

Makes the elements of a character vector unique by appending sequence numbers to duplicates.

Usage

```
make.unique(names, sep = ".")
```

Arguments

<code>names</code>	a character vector
<code>sep</code>	a character string used to separate a duplicate name from its sequence number.

Details

The algorithm used by `make.unique` has the property that `make.unique(c(A, B)) == make.unique(c(make.unique(A), B))`.

In other words, you can append one string at a time to a vector, making it unique each time, and get the same result as applying `make.unique` to all of the strings at once.

If character vector `A` is already unique, then `make.unique(c(A, B))` preserves `A`.

Value

A character vector of same length as `names` with duplicates changed, in the current locale's encoding.

Author(s)

Thomas P. Minka

Examples

```
make.unique(c("a", "a", "a"))
make.unique(c(make.unique(c("a", "a")), "a"))

make.unique(c("a", "a", "a.2", "a"))
make.unique(c(make.unique(c("a", "a")), "a.2", "a"))

rbind(data.frame(x=1), data.frame(x=2), data.frame(x=3))
rbind(rbind(data.frame(x=1), data.frame(x=2)), data.frame(x=3))
```

manglePackageName *Mangle the Package Name*

Description

This function takes the package name and the package version number and pastes them together with a separating underscore.

Usage

```
manglePackageName(pkgName, pkgVersion)
```

Arguments

`pkgName` The package name, as a character string.
`pkgVersion` The package version, as a character string.

Value

A character string with the two inputs pasted together.

Examples

```
manglePackageName("foo", "1.2.3")
```

mapply

Apply a function to multiple list or vector arguments

Description

mapply is a multivariate version of [sapply](#). mapply applies FUN to the first elements of each ... argument, the second elements, the third elements, and so on. Arguments are recycled if necessary.

Vectorize returns a new function that acts as if mapply was called.

Usage

```
mapply(FUN, ..., MoreArgs = NULL, SIMPLIFY = TRUE,
       USE.NAMES = TRUE)
```

```
Vectorize(FUN, vectorize.args = arg.names, SIMPLIFY = TRUE,
         USE.NAMES = TRUE)
```

Arguments

FUN	function to apply, found via match.fun .
...	arguments to vectorize over (list or vector).
MoreArgs	a list of other arguments to FUN.
SIMPLIFY	logical; attempt to reduce the result to a vector or matrix?
USE.NAMES	logical; use names if the first ... argument has names, or if it is a character vector, use that character vector as the names.
vectorize.args	a character vector of arguments which should be vectorized. Defaults to all arguments to FUN.

Details

The arguments named in the `vectorize.args` argument to `Vectorize` correspond to the arguments passed in the ... list to `mapply`. However, only those that are actually passed will be vectorized; default values will not. See the example below.

`Vectorize` cannot be used with primitive functions as they have no formal list.

Value

mapply returns a list, vector, or matrix.

Vectorize returns a function with the same arguments as FUN, but wrapping a call to mapply.

See Also

[sapply](#), [outer](#)

Examples

```

require(graphics)

mapply(rep, 1:4, 4:1)

mapply(rep, times=1:4, x=4:1)

mapply(rep, times=1:4, MoreArgs=list(x=42))

# Repeat the same using Vectorize: use rep.int as rep is primitive
vrep <- Vectorize(rep.int)
vrep(1:4, 4:1)
vrep(times=1:4, x=4:1)

vrep <- Vectorize(rep.int, "times")
vrep(times=1:4, x=42)

mapply(function(x,y) seq_len(x) + y,
        c(a= 1, b=2, c= 3), # names from first
        c(A=10, B=0, C=-10))

word <- function(C,k) paste(rep.int(C,k), collapse='')
utils::str(mapply(word, LETTERS[1:6], 6:1, SIMPLIFY = FALSE))

f <- function(x=1:3, y) c(x,y)
vf <- Vectorize(f, SIMPLIFY = FALSE)
f(1:3,1:3)
vf(1:3,1:3)
vf(y=1:3) # Only vectorizes y, not x

# Nonlinear regression contour plot, based on nls() example

SS <- function(Vm, K, resp, conc) {
  pred <- (Vm * conc)/(K + conc)
  sum((resp - pred)^2 / pred)
}
vSS <- Vectorize(SS, c("Vm", "K"))
Treated <- subset(Puromycin, state == "treated")

Vm <- seq(140, 310, len=50)
K <- seq(0, 0.15, len=40)
SSvals <- outer(Vm, K, vSS, Treated$rate, Treated$conc)
contour(Vm, K, SSvals, levels=(1:10)^2, xlab="Vm", ylab="K")

```

margin.table

*Compute table margin***Description**

For a contingency table in array form, compute the sum of table entries for a given index.

Usage

```
margin.table(x, margin=NULL)
```

Arguments

`x` an array
`margin` index number (1 for rows, etc.)

Details

This is really just `apply(x, margin, sum)` packaged up for newbies, except that if `margin` has length zero you get `sum(x)`.

Value

The relevant marginal table. The class of `x` is copied to the output table, except in the summation case.

Author(s)

Peter Dalgaard

See Also

[prop.table](#) and [addmargins](#).

Examples

```
m <- matrix(1:4, 2)
margin.table(m, 1)
margin.table(m, 2)
```

mat.or.vec

Create a Matrix or a Vector

Description

`mat.or.vec` creates an `nr` by `nc` zero matrix if `nc` is greater than 1, and a zero vector of length `nr` if `nc` equals 1.

Usage

```
mat.or.vec(nr, nc)
```

Arguments

`nr`, `nc` numbers of rows and columns.

Examples

```
mat.or.vec(3, 1)
mat.or.vec(3, 2)
```

match	<i>Value Matching</i>
-------	-----------------------

Description

`match` returns a vector of the positions of (first) matches of its first argument in its second.

`%in%` is a more intuitive interface as a binary operator, which returns a logical vector indicating if there is a match or not for its left operand.

Usage

```
match(x, table, nomatch = NA_integer_, incomparables = NULL)
```

```
x %in% table
```

Arguments

<code>x</code>	vector or <code>NULL</code> : the values to be matched.
<code>table</code>	vector or <code>NULL</code> : the values to be matched against.
<code>nomatch</code>	the value to be returned in the case when no match is found. Note that it is coerced to <code>integer</code> .
<code>incomparables</code>	a vector of values that cannot be matched. Any value in <code>x</code> matching a value in this vector is assigned the <code>nomatch</code> value. For historical reasons, <code>FALSE</code> is equivalent to <code>NULL</code> .

Details

`%in%` is currently defined as

```
"%in%" <- function(x, table) match(x, table, nomatch = 0) > 0
```

Factors, raw vectors and lists are converted to character vectors, and then `x` and `table` are coerced to a common type (the later of the two types in R's ordering, `logical < integer < numeric < complex < character`) before matching. If `incomparables` has positive length it is coerced to the common type.

Matching for lists is potentially very slow and best avoided except in simple cases.

Exactly what matches what is to some extent a matter of definition. For all types, `NA` matches `NA` and no other value. For real and complex values, `NaN` values are regarded as matching any other `NaN` value, but not matching `NA`.

Value

A vector of the same length as `x`.

`match`: An integer vector giving the position in `table` of the first match if there is a match, otherwise `nomatch`.

If `x[i]` is found to equal `table[j]` then the value returned in the `i`-th position of the return value is `j`, for the smallest possible `j`. If no match is found, the value is `nomatch`.

`%in%`: A logical vector, indicating if a match was located for each element of `x`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[pmatch](#) and [charmatch](#) for (*partial*) string matching, [match.arg](#), etc for function argument matching. [findInterval](#) similarly returns a vector of positions, but finds numbers within intervals, rather than exact matches.

[is.element](#) for an S-compatible equivalent of `%in%`.

Examples

```
## The intersection of two sets can be defined via match():
## Simple version: intersect <- function(x, y) y[match(x, y, nomatch = 0)]
intersect # the R function in base, slightly more careful
intersect(1:10, 7:20)

1:10 %in% c(1,3,5,9)
sstr <- c("c", "ab", "B", "bba", "c", "@", "bla", "a", "Ba", "%")
sstr[sstr %in% c(letters, LETTERS)]

"%w/o%" <- function(x,y) x[!x %in% y] #-- x without y
(1:10) %w/o% c(3,7,12)
```

match.arg

Argument Verification Using Partial Matching

Description

`match.arg` matches `arg` against a table of candidate values as specified by `choices`, where `NULL` means to take the first one.

Usage

```
match.arg(arg, choices, several.ok = FALSE)
```

Arguments

<code>arg</code>	a character vector (of length one unless <code>several.ok</code> is <code>TRUE</code>) or <code>NULL</code> .
<code>choices</code>	a character vector of candidate values
<code>several.ok</code>	logical specifying if <code>arg</code> should be allowed to have more than one element.

Details

In the one-argument form `match.arg(arg)`, the `choices` are obtained from a default setting for the formal argument `arg` of the function from which `match.arg` was called. (Since default argument matching will set `arg` to `choices`, this is allowed as an exception to the ‘length one unless `several.ok` is `TRUE`’ rule, and returns the first element.)

Matching is done using [pmatch](#), so `arg` may be abbreviated.

Value

The unabbreviated version of the exact or unique partial match if there is one; otherwise, an error is signalled if `several.ok` is false, as per default. When `several.ok` is true and more than one element of `arg` has a match, all unabbreviated versions of matches are returned.

See Also

[pmatch](#), [match.fun](#), [match.call](#).

Examples

```
require(stats)
## Extends the example for 'switch'
center <- function(x, type = c("mean", "median", "trimmed")) {
  type <- match.arg(type)
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
center(x, "t")      # Works
center(x, "med")    # Works
try(center(x, "m")) # Error
stopifnot(identical(center(x),      center(x, "mean")),
           identical(center(x, NULL), center(x, "mean")))

## Allowing more than one match:
match.arg(c("gauss", "rect", "ep"),
          c("gaussian", "epanechnikov", "rectangular", "triangular"),
          several.ok = TRUE)
```

match.call

Argument Matching

Description

`match.call` returns a call in which all of the specified arguments are specified by their full names.

Usage

```
match.call(definition = NULL, call = sys.call(sys.parent()),
           expand.dots = TRUE)
```

Arguments

<code>definition</code>	a function, by default the function from which <code>match.call</code> is called. See details.
<code>call</code>	an unevaluated call to the function specified by <code>definition</code> , as generated by call .
<code>expand.dots</code>	logical. Should arguments matching <code>...</code> in the call be included or left as a <code>...</code> argument?

Details

‘function’ on this help page means an interpreted function (also known as a ‘closure’): `match.call` does not support primitive functions (where argument matching is normally positional).

`match.call` is most commonly used in two circumstances:

- To record the call for later re-use: for example most model-fitting functions record the call as element `call` of the list they return. Here the default `expand.dots = TRUE` is appropriate.
- To pass most of the call to another function, often `model.frame`. Here the common idiom is that `expand.dots = FALSE` is used, and the `...` element of the matched call is removed. An alternative is to explicitly select the arguments to be passed on, as is done in `lm`.

Calling `match.call` outside a function without specifying `definition` is an error.

Value

An object of class `call`.

References

Chambers, J. M. (1998) *Programming with Data. A Guide to the S Language*. Springer.

See Also

`sys.call()` is similar, but does *not* expand the argument names; `call`, `pmatch`, `match.arg`, `match.fun`.

Examples

```
match.call(get, call("get", "abc", i = FALSE, p = 3))
## -> get(x = "abc", pos = 3, inherits = FALSE)
fun <- function(x, lower = 0, upper = 1) {
  structure((x - lower) / (upper - lower), CALL = match.call())
}
fun(4 * atan(1), u = pi)
```

match.fun

Function Verification for “Function Variables”

Description

When called inside functions that take a function as argument, extract the desired function object while avoiding undesired matching to objects of other types.

Usage

```
match.fun(FUN, descend = TRUE)
```

Arguments

<code>FUN</code>	item to match as function: a function, symbol or character string. See ‘Details’.
<code>descend</code>	logical; control whether to search past non-function objects.

Details

`match.fun` is not intended to be used at the top level since it will perform matching in the *parent* of the caller.

If `FUN` is a function, it is returned. If it is a symbol (for example, enclosed in backquotes) or a character vector of length one, it will be looked up using `get` in the environment of the parent of the caller. If it is of any other mode, it is attempted first to get the argument to the caller as a symbol (using `substitute` twice), and if that fails, an error is declared.

If `descend = TRUE`, `match.fun` will look past non-function objects with the given name; otherwise if `FUN` points to a non-function object then an error is generated.

This is used in base functions such as `apply`, `lapply`, `outer`, and `sweep`.

Value

A function matching `FUN` or an error is generated.

Bugs

The `descend` argument is a bit of misnomer and probably not actually needed by anything. It may go away in the future.

It is impossible to fully foolproof this. If one attaches a list or data frame containing a length-one character vector with the same name as a function, it may be used (although name spaces will help).

Author(s)

Peter Dalgaard and Robert Gentleman, based on an earlier version by Jonathan Rougier.

See Also

`match.arg`, `get`

Examples

```
# Same as get("*"):
match.fun("*")
# Overwrite outer with a vector
outer <- 1:5
## Not run:
match.fun(outer, descend = FALSE) #-> Error: not a function
## End(Not run)
match.fun(outer) # finds it anyway
is.function(match.fun("outer")) # as well
```

Description

These functions compute miscellaneous mathematical functions. The naming follows the standard for computer languages such as C or Fortran.

Usage

```
abs(x)
sqrt(x)
```

Arguments

`x` a numeric or [complex](#) vector or array.

Details

These are generic functions: methods can be defined for them individually or via the [Math](#) group generic. For complex arguments (and the default method), `z`, `abs(z) == Mod(z)` and `sqrt(z) == z^0.5`.

`abs(x)` returns an [integer](#) vector when `x` is `integer` or `logical`.

S4 methods

Both are S4 generic and members of the [Math](#) group generic.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[Arithmetic](#) for simple, [log](#) for logarithmic, [sin](#) for trigonometric, and [Special](#) for special mathematical functions.

'[plotmath](#)' for the use of `sqrt` in plot annotation.

Examples

```
require(stats) # for spline
require(graphics)
xx <- -9:9
plot(xx, sqrt(abs(xx)), col = "red")
lines(spline(xx, sqrt(abs(xx)), n=101), col = "pink")
```

matmult

Matrix Multiplication

Description

Multiplies two matrices, if they are conformable. If one argument is a vector, it will be promoted to either a row or column matrix to make the two arguments conformable. If both are vectors it will return the inner product (as a matrix).

Usage

```
x %*% y
```

Arguments

`x`, `y` numeric or complex matrices or vectors.

Details

When a vector is promoted to a matrix, its names are not promoted to row or column names, unlike `as.matrix`.

This operator is S4 generic but not S3 generic. S4 methods need to be written for a function of two arguments named `x` and `y`.

Value

A double or complex matrix product. Use `drop` to remove dimensions which have only one level.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`matrix`, `Arithmetic`, `diag`.

Examples

```
x <- 1:4
(z <- x %*% x)      # scalar ("inner") product (1 x 1 matrix)
drop(z)            # as scalar

y <- diag(x)
z <- matrix(1:12, ncol = 3, nrow = 4)
y %*% z
y %*% x
x %*% z
```

matrix

Matrices

Description

`matrix` creates a matrix from the given set of values.

`as.matrix` attempts to turn its argument into a matrix.

`is.matrix` tests if its argument is a (strict) matrix.

Usage

```
matrix(data = NA, nrow = 1, ncol = 1, byrow = FALSE,
        dimnames = NULL)

as.matrix(x, ...)
## S3 method for class 'data.frame':
as.matrix(x, rownames.force = NA, ...)

is.matrix(x)
```

Arguments

<code>data</code>	an optional data vector.
<code>nrow</code>	the desired number of rows.
<code>ncol</code>	the desired number of columns.
<code>byrow</code>	logical. If <code>FALSE</code> (the default) the matrix is filled by columns, otherwise the matrix is filled by rows.
<code>dimnames</code>	A <code>dimnames</code> attribute for the matrix: <code>NULL</code> or a list of length 2 giving the row and column names respectively. An empty list is treated as <code>NULL</code> , and a list of length one as row names. The list can be named, and the list names will be used as names for the dimensions.
<code>x</code>	an R object.
<code>...</code>	additional arguments to be passed to or from methods.
<code>rownames.force</code>	logical indicating if the resulting matrix should have character (rather than <code>NULL</code>) <code>rownames</code> . The default, <code>NA</code> , uses <code>NULL</code> <code>rownames</code> if the data frame has ‘automatic’ <code>row.names</code> or for a zero-row data frame.

Details

If one of `nrow` or `ncol` is not given, an attempt is made to infer it from the length of `data` and the other parameter. If neither is given, a one-column matrix is returned.

If there are too few elements in `data` to fill the array, then the elements in `data` are recycled. If `data` has length zero, `NA` of an appropriate type is used for atomic vectors (0 for raw vectors) and `NULL` for lists.

`is.matrix` returns `TRUE` if `x` is a matrix and has a `dim` attribute of length 2) and `FALSE` otherwise. Note that a `data.frame` is **not** a matrix by this test. It is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#).

`as.matrix` is a generic function. The method for data frames will return a character matrix if there is any non-(numeric/logical/complex) column, applying `format` to non-character columns. Otherwise, the usual coercion hierarchy (logical < integer < double < complex) will be used, e.g., all-logical data frames will be coerced to a logical matrix, mixed logical-integer will give a integer matrix, etc.

When coercing a vector, it produces a one-column matrix, and promotes the names (if any) of the vector to the `rownames` of the matrix.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`data.matrix`, which attempts to convert to a numeric matrix.

Examples

```
is.matrix(as.matrix(1:10))
!is.matrix(warpbreaks) # data.frame, NOT matrix!
warpbreaks[1:10,]
as.matrix(warpbreaks[1:10,]) #using as.matrix.data.frame(.) method

# Example of setting row and column names
mdat <- matrix(c(1,2,3, 11,12,13), nrow = 2, ncol=3, byrow=TRUE,
               dimnames = list(c("row1", "row2"),
                               c("C.1", "C.2", "C.3")))
mdat
```

maxCol

Find Maximum Position in Matrix

Description

Find the maximum position for each row of a matrix, breaking ties at random.

Usage

```
max.col(m, ties.method=c("random", "first", "last"))
```

Arguments

<code>m</code>	numerical matrix
<code>ties.method</code>	a character string specifying how ties are handled, "random" by default; can be abbreviated; see 'Details'.

Details

When `ties.method = "random"`, as per default, ties are broken at random. In this case, the determination of a tie assumes that the entries are probabilities: there is a relative tolerance of 10^{-5} , relative to the largest (in magnitude, omitting infinity) entry in the row.

If `ties.method = "first"`, `max.col` returns the column number of the *first* of several maxima in every row, the same as `unname(unname(m, 1, unname))`.

Correspondingly, `ties.method = "last"` returns the *last* of possibly several indices.

Value

index of a maximal value for each row, an integer vector of length `nrow(m)`.

`which.max` for vectors.

Examples

```
table(mc <- max.col(swiss))# mostly "1" and "5", 5 x "2" and once "4"
swiss[unique(print(mr <- max.col(t(swiss)))) , ] # 3 33 45 45 33 6

set.seed(1)# reproducible example:
(mm <- rbind(x = round(2*stats::runif(12)),
            y = round(5*stats::runif(12)),
            z = round(8*stats::runif(12))))

## Not run:
  [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10] [,11] [,12]
x    1    1    1    2    0    2    2    1    1    0    0    0
y    3    2    4    2    4    5    2    4    5    1    3    1
z    2    3    0    3    7    3    4    5    4    1    7    5
## End(Not run)
## column indices of all row maxima :
utils::str(lapply(1:3, function(i) which(mm[i,] == max(mm[i,]))))
max.col(mm) ; max.col(mm) # "random"
max.col(mm, "first")# -> 4 6 5
max.col(mm, "last") # -> 7 9 11
```

mean

Arithmetic Mean

Description

Generic function for the (trimmed) arithmetic mean.

Usage

```
mean(x, ...)

## Default S3 method:
mean(x, trim = 0, na.rm = FALSE, ...)
```

Arguments

<code>x</code>	An R object. Currently there are methods for numeric data frames, numeric vectors and dates. A complex vector is allowed for <code>trim = 0</code> , only.
<code>trim</code>	the fraction (0 to 0.5) of observations to be trimmed from each end of <code>x</code> before the mean is computed. Values of <code>trim</code> outside that range are taken as the nearest endpoint.
<code>na.rm</code>	a logical value indicating whether NA values should be stripped before the computation proceeds.
<code>...</code>	further arguments passed to or from other methods.

Value

For a data frame, a named vector with the appropriate method being applied column by column.

If `trim` is zero (the default), the arithmetic mean of the values in `x` is computed, as a numeric or complex vector of length one. If `x` is not logical (coerced to numeric), integer, numeric or complex, NA is returned, with a warning.

If `trim` is non-zero, a symmetrically trimmed mean is computed with a fraction of `trim` observations deleted from each end before the mean is computed.

See Also

[weighted.mean](#), [mean.POSIXct](#), [colMeans](#) for row and column means.

Examples

```
x <- c(0:10, 50)
xm <- mean(x)
c(xm, mean(x, trim = 0.10))

mean(USArrests, trim = 0.2)
```

Memory

Memory Available for Data Storage

Description

Use command line options to control the memory available for R.

Usage

```
R --min-vsize=v1 --max-vsize=vu --min-nsiz=nl --max-nsiz=nu --max-ppsize=N

mem.limits(nsize = NA, vsize = NA)
```

Arguments

```
v1, vu, vsize      Heap memory in bytes.
nl, nu, nsize      Number of cons cells.
N                  Number of nested PROTECT calls.
```

Details

R has a variable-sized workspace. There is much less need to set memory options than prior to R 1.2.0, and most users will never need to set these. They are provided both as a way to control the overall memory usage (which can also be done by operating-system facilities such as `limit` on Unix), and since setting larger values of the minima will make R slightly more efficient on large tasks.

To understand the options, one needs to know that R maintains separate areas for fixed and variable sized objects. The first of these is allocated as an array of *cons cells* (Lisp programmers will know what they are, others may think of them as the building blocks of the language itself, parse trees, etc.), and the second are thrown on a *heap* of ‘Vcells’ of 8 bytes each. Effectively, the inputs `v1` and `vu` are rounded up to the next multiple of 8.

Each cons cell occupies 28 bytes on a 32-bit machine, (usually) 56 bytes on a 64-bit machine.

The ‘`--*-nsize`’ options can be used to specify the number of cons cells and the ‘`--*-vsize`’ options specify the size of the vector heap in bytes. Both options must be integers or integers followed by G, M, K, or k meaning Giga ($2^{30} = 1073741824$) Mega ($2^{20} = 1048576$), (computer) Kilo ($2^{10} = 1024$), or regular kilo (1000).

The ‘`--min-*`’ options set the minimal sizes for the number of cons cells and for the vector heap. These values are also the initial values, but thereafter R will grow or shrink the areas depending on usage, but never exceeding the limits set by the ‘`--max-*`’ options nor decreasing below the initial values.

The default values are currently minima of 350k cons cells, 6Mb of vector heap and no maxima (other than machine resources). The maxima can be changed during an R session by calling `mem.limits`. (If this is called with the default values, it reports the current settings.)

You can find out the current memory consumption (the heap and cons cells used as numbers and megabytes) by typing `gc()` at the R prompt. Note that following `gcinfo(TRUE)`, automatic garbage collection always prints memory use statistics. Maxima will never be reduced below the current values for triggering garbage collection, and attempts to do so will be silently ignored.

The command-line option ‘`--max-ppsize`’ controls the maximum size of the pointer protection stack. This defaults to 50000, but can be increased to allow deep recursion or large and complicated calculations to be done. *Note* that parts of the garbage collection process goes through the full reserved pointer protection stack and hence becomes slower when the size is increased. Currently the maximum value accepted is 500000.

Value

`mem.limits()` returns an integer vector giving the current settings of the maxima, possibly NA.

An Introduction to R for more command-line options

[Memory-limits](#) for the design limitations.

`gc` for information on the garbage collector and total memory usage, `object.size(a)` for the (approximate) size of R object `a`. [memory.profile](#) for profiling the usage of cons cells.

Examples

```
# Start R with 10MB of heap memory and 500k cons cells, limit to
# 100Mb and 1M cells
## Not run:
## Unix
```

```
R --min-vsize=10M --max-vsize=100M --min-nsize=500k --max-nsize=1M
## End(Not run)
```

Memory-limits

Memory Limits in R

Description

R holds objects it is using in memory. This help file documents the current design limitations on large objects: these differ between 32-bit and 64-bit builds of R.

Details

R holds all objects in memory, and there are limits based on the amount of memory that can be used by all objects:

- There may be limits on the size of the heap and the number of cons cells allowed – see [Memory](#) – but these are usually not imposed.
- There is a limit on the address space of a single process such as the R executable. This is system-specific, but 32-bit OSes imposes a limit of no more than 4Gb: it is often 3Gb or less.
- The environment may impose limitations on the resources available to a single process – see the OS/shell’s help on commands such as `limit` or `ulimit`.

Error messages beginning `cannot allocate vector of size` indicate a failure to obtain memory, either because the size exceeded the address-space limit for a process or, more likely, because the system was unable to provide the memory. Note that on a 32-bit OS there may well be enough free memory available, but not a large enough contiguous block of address space into which to map it.

There are also limits on individual objects. On all versions of R, the maximum length (number of elements) of a vector is $2^{31} - 1 \approx 2 \cdot 10^9$, as lengths are stored as signed integers. In addition, the storage space cannot exceed the address limit, and if you try to exceed that limit, the error message begins `cannot allocate vector of length`. The number of characters in a character string is in theory only limited by the address space.

See Also

`object.size(a)` for the (approximate) size of R object `a`.

memory.profile

Profile the Usage of Cons Cells

Description

Lists the usage of the cons cells by SEXPREC type.

Usage

```
memory.profile()
```

Details

The current types and their uses are listed in the include file ‘Rinternals.h’.

Value

A vector of counts, named by the types. See [typeof](#) for an explanation of types.

See Also

[gc](#) for the overall usage of cons cells. [Rprofmem](#) and [tracemem](#) allow memory profiling of specific code or objects, but need to be enabled at compile time.

Examples

```
memory.profile()
```

merge	<i>Merge Two Data Frames</i>
-------	------------------------------

Description

Merge two data frames by common columns or row names, or do other versions of database *join* operations.

Usage

```
merge(x, y, ...)

## Default S3 method:
merge(x, y, ...)

## S3 method for class 'data.frame':
merge(x, y, by = intersect(names(x), names(y)),
      by.x = by, by.y = by, all = FALSE, all.x = all, all.y = all,
      sort = TRUE, suffixes = c(".x", ".y"), incomparables = NULL, ...)
```

Arguments

<code>x, y</code>	data frames, or objects to be coerced to one.
<code>by, by.x, by.y</code>	specifications of the common columns. See ‘Details’.
<code>all</code>	logical; <code>all = L</code> is shorthand for <code>all.x = L</code> and <code>all.y = L</code> .
<code>all.x</code>	logical; if <code>TRUE</code> , then extra rows will be added to the output, one for each row in <code>x</code> that has no matching row in <code>y</code> . These rows will have <code>NA</code> s in those columns that are usually filled with values from <code>y</code> . The default is <code>FALSE</code> , so that only rows with data from both <code>x</code> and <code>y</code> are included in the output.
<code>all.y</code>	logical; analogous to <code>all.x</code> above.
<code>sort</code>	logical. Should the results be sorted on the <code>by</code> columns?
<code>suffixes</code>	character(2) specifying the suffixes to be used for making non-by names() unique.

`incomparables`
 values which cannot be matched. See [match](#).
`...` arguments to be passed to or from methods.

Details

By default the data frames are merged on the columns with names they both have, but separate specifications of the columns can be given by `by.x` and `by.y`. Columns can be specified by name, number or by a logical vector: the name `"row.names"` or the number 0 specifies the row names. The rows in the two data frames that match on the specified columns are extracted, and joined together. If there is more than one match, all possible matches contribute one row each. For the precise meaning of ‘match’, see [match](#).

If `by` or both `by.x` and `by.y` are of length 0 (a length zero vector or `NULL`), the result, `r`, is the *Cartesian product* of `x` and `y`, i.e., $\text{dim}(r) = c(\text{nrow}(x) * \text{nrow}(y), \text{ncol}(x) + \text{ncol}(y))$.

If `all.x` is true, all the non matching cases of `x` are appended to the result as well, with `NA` filled in the corresponding columns of `y`; analogously for `all.y`.

If the remaining columns in the data frames have any common names, these have suffixes (`".x"` and `".y"` by default) appended to make the names of the result unique.

The complexity of the algorithm used is proportional to the length of the answer.

In SQL database terminology, the default value of `all = FALSE` gives a *natural join*, a special case of an *inner join*. Specifying `all.x = TRUE` gives a *left (outer) join*, `all.y = TRUE` a *right (outer) join*, and both (`all=TRUE`) a *(full) outer join*. DBMSes do not match `NULL` records, equivalent to `incomparables = NA` in `R`.

Value

A data frame. The rows are by default lexicographically sorted on the common columns, but for `sort = FALSE` are in an unspecified order. The columns are the common columns followed by the remaining columns in `x` and then those in `y`. If the matching involved row names, an extra character column called `Row.names` is added at the left, and in all cases the result has ‘automatic’ row names.

See Also

[data.frame](#), [by](#), [cbind](#)

Examples

```
## use character columns of names to get sensible sort order
authors <- data.frame(
  surname = I(c("Tukey", "Venables", "Tierney", "Ripley", "McNeil")),
  nationality = c("US", "Australia", "US", "UK", "Australia"),
  deceased = c("yes", rep("no", 4)))
books <- data.frame(
  name = I(c("Tukey", "Venables", "Tierney",
            "Ripley", "Ripley", "McNeil", "R Core")),
  title = c("Exploratory Data Analysis",
            "Modern Applied Statistics ...",
            "LISP-STAT",
            "Spatial Statistics", "Stochastic Simulation",
            "Interactive Data Analysis",
            "An Introduction to R"),
```

```

other.author = c(NA, "Ripley", NA, NA, NA, NA,
                 "Venables & Smith"))

(m1 <- merge(authors, books, by.x = "surname", by.y = "name"))
(m2 <- merge(books, authors, by.x = "name", by.y = "surname"))
stopifnot(as.character(m1[,1]) == as.character(m2[,1]),
          all.equal(m1[, -1], m2[, -1][ names(m1)[-1] ]),
          dim(merge(m1, m2, by = integer(0))) == c(36, 10))

## "R core" is missing from authors and appears only here :
merge(authors, books, by.x = "surname", by.y = "name", all = TRUE)

## example of using 'incomparables'
x <- data.frame(k1=c(NA,NA,3,4,5), k2=c(1,NA,NA,4,5), data=1:5)
y <- data.frame(k1=c(NA,2,NA,4,5), k2=c(NA,NA,3,4,5), data=1:5)
merge(x, y, by=c("k1","k2")) # NA's match
merge(x, y, by=c("k1","k2"), incomparables=NA)
merge(x, y, by="k1") # NA's match, so 6 rows
merge(x, y, by="k2", incomparables=NA) # 2 rows

```

message

Diagnostic Messages

Description

Generate a diagnostic message from its arguments.

Usage

```

message(..., domain = NULL, appendLF = TRUE)
suppressMessages(expr)

packageStartupMessage(..., domain = NULL, appendLF = TRUE)
suppressPackageStartupMessages(expr)

.makeMessage(..., domain = NULL, appendLF = FALSE)

```

Arguments

...	zero or more objects which can be coerced to character (and which are pasted together with no separator) or (for <code>message</code> only) a single condition object.
domain	see gettext . If NA, messages will not be translated.
appendLF	logical: should messages given as a character string have a newline appended?
expr	expression to evaluate.

Details

`message` is used for generating ‘simple’ diagnostic messages which are neither warnings nor errors, but nevertheless represented as conditions. Unlike warnings and errors, a final newline is regarded as part of the message, and is optional. The default handler sends the message to the `stderr()` connection.

If a condition object is supplied to `message` it should be the only argument, and further arguments will be ignored, with a warning.

While the message is being processed, a `muffleMessage` restart is available.

`suppressMessages` evaluates its expression in a context that ignores all ‘simple’ diagnostic messages.

`packageStartupMessage` is a variant whose messages can be suppressed separately by `suppressPackageStartupMessages`. (They are still messages, so can be suppressed by `suppressMessages`.)

`.makeMessage` is a utility used by `message`, `warning` and `stop` to generate a text message from the ... arguments by possible translation (see [gettext](#)) and concatenation (with no separator).

See Also

[warning](#) and [stop](#) for generating warnings and errors; [conditions](#) for condition handling and recovery.

[gettext](#) for the mechanisms for the automated translation of text.

Examples

```
message("ABC", "DEF")
suppressMessages(message("ABC"))

testit <- function() {
  message("testing package startup messages")
  packageStartupMessage("initializing ...", appendLF = FALSE)
  Sys.sleep(1)
  packageStartupMessage(" done")
}

testit()
suppressPackageStartupMessages(testit())
suppressMessages(testit())
```

missing

Does a Formal Argument have a Value?

Description

`missing` can be used to test whether a value was specified as an argument to a function.

Usage

```
missing(x)
```

Arguments

`x` a formal argument.

Details

`missing(x)` is only reliable if `x` has not been altered since entering the function: in particular it will *always* be false after `x <- match.arg(x)`.

The example shows how a plotting function can be written to work with either a pair of vectors giving `x` and `y` coordinates of points to be plotted or a single vector giving `y` values to be plotted against their indexes.

Currently `missing` can only be used in the immediate body of the function that defines the argument, not in the body of a nested function or a `local` call. This may change in the future.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

Chambers, J. M. (1998) *Programming with Data. A Guide to the S Language*. Springer.

See Also

[substitute](#) for argument expression; [NA](#) for missing values in data.

Examples

```
myplot <- function(x,y) {
  if(missing(y)) {
    y <- x
    x <- 1:length(y)
  }
  plot(x,y)
}
```

mode

The (Storage) Mode of an Object

Description

Get or set the type or storage mode of an object.

Usage

```
mode(x)
mode(x) <- value
storage.mode(x)
storage.mode(x) <- value
```

Arguments

`x` any R object.
`value` a character string giving the desired mode or ‘storage mode’ (type) of the object.

Details

Both `mode` and `storage.mode` return a character string giving the (storage) mode of the object — often the same — both relying on the output of `typeof(x)`, see the example below.

`mode(x) <- "newmode"` changes the mode of object `x` to `newmode`. This is only supported if there is an appropriate `as.newmode` function, for example "logical", "integer", "double", "complex", "raw", "character", "list", "expression", "name", "symbol" and "function". Attributes are preserved (but see below).

`storage.mode(x) <- "newmode"` is a more efficient internal version of `mode<-`, which works for "newmode" which is one of the internal types (see `typeof`), but not for "single". Attributes are preserved.

As storage mode "single" is only a pseudo-mode in R, it will not be reported by `mode` or `storage.mode`: use `attr(object, "Csingle")` to examine this. However, `mode<-` can be used to set the mode to "single", which sets the real mode to "double" and the "Csingle" attribute to TRUE. Setting any other mode will remove this attribute.

Note (in the examples below) that some `calls` have mode " (" which is S compatible.

Mode names

Modes have the same set of names as types (see `typeof`) except that

- types "integer" and "double" are returned as "numeric".
- types "special" and "builtin" are returned as "function".
- type "symbol" is called mode "name".
- type "language" is returned as " (" or "call".

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`typeof` for the R-internal 'mode', `attributes`.

Examples

```
require(stats)

sapply(options(),mode)

cex3 <- c("NULL","1","1:1","1i","list(1)","data.frame(x=1)",
  "pairlist(pi)", "c", "lm", "formals(lm)[[1]]", "formals(lm)[[2]]",
  "y~x", "expression(1)[[1]]", "(y~x)[[1]]",
  "expression(x <- pi)[[1]][[1]]")
lex3 <- sapply(cex3, function(x) eval(parse(text=x)))
mex3 <- t(sapply(lex3,
  function(x) c(typeof(x), storage.mode(x), mode(x))))
dimnames(mex3) <- list(cex3, c("typeof(.)", "storage.mode(.)", "mode(.)))
mex3

## This also makes a local copy of 'pi':
storage.mode(pi) <- "complex"
```

```
storage.mode(pi)
rm(pi)
```

NA

Not Available / "Missing" Values

Description

NA is a logical constant of length 1 which contains a missing value indicator. NA can be freely coerced to any other vector type except raw. There are also constants `NA_integer_`, `NA_real_`, `NA_complex_` and `NA_character_` of the other atomic vector types which support missing values: all of these are [reserved](#) words in the R language.

The generic function `is.na` indicates which elements are missing.

The generic function `is.na<-` sets elements to NA.

Usage

```
NA
is.na(x)
## S3 method for class 'data.frame':
is.na(x)

is.na(x) <- value
```

Arguments

`x` an R object to be tested.

`value` a suitable index vector for use with `x`.

Details

The NA of character type is distinct from the string "NA". Programmers who need to specify an explicit string NA should use `NA_character_` rather than "NA", or set elements to NA using `is.na<-`.

`is.na(x)` works elementwise when `x` is a [list](#). It is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#). A complex value is regarded as NA if either its real or imaginary part is NA or NaN.

Function `is.na<-` may provide a safer way to set missingness. It behaves differently for factors, for example.

Value

The default method for `is.na` returns a logical vector of the same length as its argument `x`, containing TRUE for those elements marked NA or NaN (!) and FALSE otherwise. `dim`, `dimnames` and `names` attributes are preserved.

The method `is.na.data.frame` returns a logical matrix with the same dimensions as the data frame, and with `dimnames` taken from the row and column names of the data frame.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

Chambers, J. M. (1998) *Programming with Data. A Guide to the S Language*. Springer.

See Also

`NaN`, `is.nan`, etc., and the utility function `complete.cases`.

`na.action`, `na.omit`, `na.fail` on how methods can be tuned to deal with missing values.

Examples

```
is.na(c(1, NA))           #> FALSE TRUE
is.na(paste(c(1, NA)))   #> FALSE FALSE

(xx <- c(0:4))
is.na(xx) <- c(2, 4)
xx                #> 0 NA 2 NA 4
```

name

Names and Symbols

Description

A ‘name’ (also known as a ‘symbol’) is a way to refer to R objects by name (rather than the value of the object, if any, bound to that name).

`as.name` and `as.symbol` are identical: they attempt to coerce the argument to a name.

`is.symbol` and the identical `is.name` return TRUE or FALSE depending on whether the argument is a name or not.

Usage

```
as.symbol(x)
is.symbol(x)
```

```
as.name(x)
is.name(x)
```

Arguments

`x` object to be coerced or tested.

Details

`as.name` first coerces its argument internally to a character vector (so methods for `as.character` are not used). It then takes the first element and provided it is not "", returns a symbol of that name (and if the element is `NA_character_`, the name is `'NA'`).

`as.name` is implemented as `as.vector(x, "symbol")`, and hence will dispatch methods for the generic function `as.vector`.

Value

For `as.name` and `as.symbol`, an R object of type "symbol" (see `typeof`).

For `is.name` and `is.symbol`, a length-one logical vector with value TRUE or FALSE.

Note

The term ‘symbol’ is from the LISP background of R, whereas ‘name’ has been the standard S term for this.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`call`, `is.language`. For the internal object mode, `typeof`.

`plotmath` for another use of ‘symbol’.

Examples

```
an <- as.name("arrg")
is.name(an) # TRUE
mode(an)    # name
typeof(an)  # symbol
```

names

The Names of an Object

Description

Functions to get or set the names of an object.

Usage

```
names(x)
names(x) <- value
```

Arguments

`x` an R object.

`value` a character vector of up to the same length as `x`, or NULL.

Details

`names` is a generic accessor function, and `names<-` is a generic replacement function. The default methods get and set the "names" attribute of a vector (including a list) or pairlist.

If `value` is shorter than `x`, it is extended by character NAs to the length of `x`.

It is possible to update just part of the names attribute via the general rules: see the examples. This works because the expression there is evaluated as `z <- "names<-"(z, "[<-"(names(z), 3, "c2")))`.

The name "" is special: it is used to indicate that there is no name associated with an element of a (atomic or generic) vector. Subscripting by "" will match nothing (not even elements which have no name).

A name can be character NA, but such a name will never be matched and is likely to lead to confusion.

Value

For `names`, NULL or a character vector of the same length as `x`. (NULL is given if the object has no names, including for objects of types which cannot have names.)

For `names<-`, the updated object. (Note that the value of `names(x) <- value` is that of the assignment, `value`, not the return value from the left-hand side.)

Note

For vectors, the names are one of the [attributes](#) with restrictions on the possible values. For pairlists, the names are the tags and converted to and from a character vector.

For a one-dimensional array the names attribute really is `dimnames[[1]]`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

Examples

```
# print the names attribute of the islands data set
names(islands)

# remove the names attribute
names(islands) <- NULL
islands
rm(islands) # remove the copy made

z <- list(a=1, b="c", c=1:3)
names(z)
# change just the name of the third element.
names(z)[3] <- "c2"
z

z <- 1:3
names(z)
## assign just one name
names(z)[2] <- "b"
z
```

`nargs`*The Number of Arguments to a Function*

Description

When used inside a function body, `nargs` returns the number of arguments supplied to that function, *including* positional arguments left blank.

Usage

```
nargs()
```

Details

The count includes empty (missing) arguments, so that `foo(x, , z)` will be considered to have three arguments (see ‘Examples’). This can occur in rather indirect ways, so for example `x[]` might dispatch a call to ``.some_method`(x,)`` which is considered to have two arguments.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[args](#), [formals](#) and [sys.call](#).

Examples

```
tst <- function(a, b = 3, ...) {nargs()}
tst() # 0
tst(clicketyclack) # 1 (even non-existing)
tst(c1, a2, rr3) # 3

foo <- function(x, y, z, w) {
  cat("call was", deparse(match.call()), "\n")
  nargs()
}
foo() # 0
foo(, , 3) # 3
foo(z=3) # 1, even though this is the same call

nargs() # not really meaningful
```

nchar	<i>Count the Number of Characters (or Bytes or Width)</i>
-------	---

Description

`nchar` takes a character vector as an argument and returns a vector whose elements contain the sizes of the corresponding elements of `x`.

`nzchar` is a fast way to find out if elements of a character vector are non-empty strings.

Usage

```
nchar(x, type = "chars", allowNA = FALSE)
```

```
nzchar(x)
```

Arguments

<code>x</code>	character vector, or a vector to be coerced to a character vector.
<code>type</code>	character string: partial matching to one of <code>c("bytes", "chars", "width")</code> . See ‘Details’.
<code>allowNA</code>	logical: show NA be returned for invalid multibyte strings (rather than throwing an error)?

Details

The ‘size’ of a character string can be measured in one of three ways

bytes The number of bytes needed to store the string (plus in C a final terminator which is not counted).

chars The number of human-readable characters.

width The number of columns `cat` will use to print the string in a monospaced font. The same as `chars` if this cannot be calculated.

These will often be the same, and almost always will be in single-byte locales. There will be differences between the first two with multibyte character sequences, e.g. in UTF-8 locales.

The internal equivalent of the default method of `as.character` is performed on `x` (so there is no method dispatch). If you want to operate on non-vector objects passing them through `deparse` first will be required.

Value

For `nchar`, an integer vector giving the sizes of each element, currently always 2 for missing values (for NA).

If `allowNA = TRUE` and an element is invalid in a multi-byte character set such as UTF-8, its number of characters and the width will be NA. Otherwise the number of characters will be non-negative, so `!is.na(nchar(x, "chars", TRUE))` is a test of validity.

Names, dims and dimnames are copied from the input.

For `nzchar`, a logical vector of the same length as `x`, true if and only if the element has non-zero length.

Note

This does **not** by default give the number of characters that will be used to `print()` the string. Use `encodeString` to find the characters used to print the string. Where character strings have been marked as UTF-8, the number of characters and widths will be computed in UTF-8, even though printing may use escapes such as `<U+2642>` in a non-UTF-8 locale.

See Also

`strwidth` giving width of strings for plotting; `paste`, `substr`, `strsplit`

Examples

```
x <- c("asfef", "qwerty", "yuiop[", "b", "stuff.blah.yech")
nchar(x)
# 5 6 6 1 15

nchar(deparse(mean))
# 18 17
```

nlevels

The Number of Levels of a Factor

Description

Return the number of levels which its argument has.

Usage

```
nlevels(x)
```

Arguments

`x` an object, usually a factor.

Details

This is usually applied to a factor, but other objects can have levels.

The actual factor levels (if they exist) can be obtained with the `levels` function.

Value

The length of `levels(x)`, which is zero if `x` has no levels.

See Also

`levels`, `factor`.

Examples

```
nlevels(gl(3,7)) # = 3
```

noquote

Class for “no quote” Printing of Character Strings

Description

Print character strings without quotes.

Usage

```
noquote(obj)

## S3 method for class 'noquote':
print(x, ...)

## S3 method for class 'noquote':
c(..., recursive = FALSE)
```

Arguments

<code>obj</code>	any R object, typically a vector of character strings.
<code>x</code>	an object of class "noquote".
<code>...</code>	further options passed to next methods, such as print .
<code>recursive</code>	for compatibility with the generic c function.

Details

`noquote` returns its argument as an object of class "noquote". There is a method for `c()` and subscript method (`"[.noquote"`) which ensures that the class is not lost by subsetting. The `print` method (`print.noquote`) prints character strings *without* quotes (`"..."`).

These functions exist both as utilities and as an example of using (S3) [class](#) and object orientation.

Martin Maechler <maechler@stat.math.ethz.ch>

See Also

[methods](#), [class](#), [print](#).

Examples

```
letters
nql <- noquote(letters)
nql
nql[1:4] <- "oh"
nql[1:12]

cmp.logical <- function(log.v)
```

```
{
  ## Purpose: compact printing of logicals
  log.v <- as.logical(log.v)
  noquote(if(length(log.v)==0) "()" else c(".", "|")[1+log.v])
}
cmp.logical(stats::runif(20) > 0.8)
```

 NotYet

Not Yet Implemented Functions and Unused Arguments

Description

In order to pinpoint missing functionality, the R core team uses these functions for missing R functions and not yet used arguments of existing R functions (which are typically there for compatibility purposes).

You are very welcome to contribute your code ...

Usage

```
.NotYetImplemented()
.NotYetUsed(arg, error = TRUE)
```

Arguments

<code>arg</code>	an argument of a function that is not yet used.
<code>error</code>	a logical. If TRUE, an error is signalled; if FALSE, only a warning is given.

See Also

the contrary, [Deprecated](#) and [Defunct](#) for outdated code.

Examples

```
require(graphics)
require(stats)
plot.mlm          # to see how the "NotYetImplemented"
                  # reference is made automatically
try(plot.mlm())

barplot(1:5, inside = TRUE) # 'inside' is not yet used
```

`nrow`*The Number of Rows/Columns of an Array*

Description

`nrow` and `ncol` return the number of rows or columns present in `x`. `NCOL` and `NROW` do the same treating a vector as 1-column matrix.

Usage

```
nrow(x)
ncol(x)
NCOL(x)
NROW(x)
```

Arguments

`x` a vector, array or data frame

Value

an [integer](#) of length 1 or `NULL`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole (`ncol` and `nrow`.)

See Also

[dim](#) which returns *all* dimensions; [array](#), [matrix](#).

Examples

```
ma <- matrix(1:12, 3, 4)
nrow(ma) # 3
ncol(ma) # 4

ncol(array(1:24, dim = 2:4)) # 3, the second dimension
NCOL(1:12) # 1
NROW(1:12) # 12
```

`ns-dblcolon`*Double Colon and Triple Colon Operators*

Description

Accessing exported and internal variables in a name space.

Usage

```
pkg::name  
pkg>:::name
```

Arguments

<code>pkg</code>	package name symbol or literal character string.
<code>name</code>	variable name symbol or literal character string.

Details

The expression `pkg::name` returns the value of the exported variable `name` in package `pkg` if the package has a name space. The expression `pkg>:::name` returns the value of the internal variable `name` in package `pkg` if the package has a name space. The package will be loaded if it was not loaded already before the call. Assignment into name spaces is not supported.

Note that it is typically a design mistake to use `:::` in your code since the corresponding object has probably been kept namespace-internal for a good reason. Consider contacting the package maintainer if you feel the need to access the object for anything but mere inspection.

If the package `pkg` does not have a name space but is on the search path then `pkg::name` returns the value of `name` in the package environment.

See Also

[get](#) to access an object masked by another of the same name.

Examples

```
base::log  
base::"+"  
  
## Beware -- use '::::' at your own risk! (see "Details")  
stats:::coef.default
```

 ns-hooks

Hooks for Name Space events

Description

Packages with name spaces can supply functions to be called when loaded, attached or unloaded.

Usage

```
.onLoad(libname, pkgname)
.onAttach(libname, pkgname)
.onUnload(libpath)
```

Arguments

libname	a character string giving the library directory where the package defining the namespace was found.
pkgname	a character string giving the name of the package, including the version number if the package was installed with <code>--with-package-versions</code> (deprecated).
libpath	a character string giving the complete path to the package.

Details

These functions apply only to packages with name spaces.

After loading, `loadNamespace` looks for a hook function named `.onLoad` and runs it before sealing the namespace and processing exports.

If a name space is unloaded (via `unloadNamespace`), a hook function `.onUnload` is run before final unloading.

Note that the code in `.onLoad` and `.onUnload` is run without the package being on the search path, but (unless circumvented) lexical scope will make objects in the namespace and its imports visible. (Do not use the double colon operator in `.onLoad` as exports have not been processed at the point it is run.)

When the package is attached (via `library`), the hook function `.onAttach` is looked for and if found is called after the exported functions are attached and before the package environment is sealed. This is less likely to be useful than `.onLoad`, which should be seen as the analogue of `.First.lib` (which is only used for packages without a name space).

`.onLoad`, `.onUnload` and `.onAttach` are looked for as internal variables in the name space and should not be exported.

If a function `.Last.lib` is visible in the package, it will be called when the package is detached: this does need to be exported.

Anything needed for the functioning of the name space should be handled at load/unload times by the `.onLoad` and `.onUnload` hooks. For example, DLLs can be loaded (unless done by a `useDynLib` directive in the 'NAMESPACE' file) and initialized in `.onLoad` and unloaded in `.onUnload`. Use `.onAttach` only for actions that are needed only when the package becomes visible to the user, for example a start-up message.

If a package was installed with `--with-package-versions`, the `pkgname` supplied will be something like `tree_1.0-16`.

See Also

[setHook](#) shows how users can set hooks on the same events.

 ns-load

Loading and Unloading Name Spaces

Description

Functions to load and unload namespaces.

Usage

```
attachNamespace(ns, pos = 2, dataPath = NULL)
loadNamespace(package, lib.loc = NULL,
              keep.source = getOption("keep.source.pkgs"),
              partial = FALSE, declarativeOnly = FALSE)
loadedNamespaces()
unloadNamespace(ns)
```

Arguments

ns	string or namespace object.
pos	integer specifying position to attach.
dataPath	path to directory containing a database of datasets to be lazy-loaded into the attached environment.
package	string naming the package/name space to load.
lib.loc	character vector specifying library search path.
keep.source	logical specifying whether to retain source. This applies only to the specified name space, and not to other name spaces which might be loaded to satisfy imports. For more details see this argument to library .
partial	logical; if true, stop just after loading code.
declarativeOnly	logical; disables <code>.Import</code> , etc, if true.

Details

The functions `loadNamespace` and `attachNamespace` are usually called implicitly when `library` is used to load a name space and any imports needed. However it may be useful to call these functions directly at times.

`loadNamespace` loads the specified name space and registers it in an internal data base. A request to load a name space that is already loaded has no effect. The arguments have the same meaning as the corresponding arguments to `library`, whose help page explains the details of how a particular installed package comes to be chosen. After loading, `loadNamespace` looks for a hook function named `.onLoad` as an internal variable in the name space (it should not be exported). This function is called with the same arguments as `.First.lib`. Partial loading is used to support installation with the `'--save'` and `'--lazy'` options.

`loadNamespace` does not attach the name space it loads to the search path. `attachNamespace` can be used to attach a frame containing the exported values of a name space to the search path. The hook function `.onAttach` is run after the name space exports are attached.

`loadedNamespaces` returns a character vector of the names of the loaded name spaces.

`unloadNamespace` can be used to force a name space to be unloaded. An error is signaled if the name space is imported by other loaded name spaces. If defined, a hook function `.onUnload` is run before removing the name space from the internal registry. `unloadNamespace` will first `detach` a package of the same name if one is on the path, thereby running a `.Last.lib` function in the package if one is exported.

ns-topenv

Top Level Environment

Description

Finding the top level environment.

Usage

```
topenv(envir = parent.frame(),
       matchThisEnv = getOption("topLevelEnvironment"))
```

Arguments

`envir` environment.

`matchThisEnv` return this environment, if it matches before any other criterion is satisfied. The default, the option ‘topLevelEnvironment’, is set by `sys.source`, which treats a specific environment as the top level environment. Supplying the argument as `NULL` means it will never match.

Details

`topenv` returns the first top level environment found when searching `envir` and its parent environments. An environment is considered top level if it is the internal environment of a name space, a package environment in the search path, or `.GlobalEnv`.

Examples

```
topenv(.GlobalEnv)
topenv(new.env())
```

NULL

The Null Object

Description

NULL represents the null object in R: it is a [reserved](#) word. NULL is often returned by expressions and functions whose value is undefined: it is also used as the empty [pairlist](#).

`as.null` ignores its argument and returns the value NULL.

`is.null` returns TRUE if its argument is NULL and FALSE otherwise.

Usage

```
NULL
as.null(x, ... )
is.null(x)
```

Arguments

<code>x</code>	an object to be tested or coerced.
<code>...</code>	ignored.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

Examples

```
is.null(list())      # FALSE (on purpose!)
is.null(integer(0)) # F
is.null(logical(0)) # F
as.null(list(a=1,b='c'))
```

numeric

Numeric Vectors

Description

Creates or coerces objects of type "numeric". `is.numeric` is a more general test of an object being interpretable as numbers.

Usage

```
numeric(length = 0)
as.numeric(x, ... )
is.numeric(x)
```

Arguments

<code>length</code>	desired length.
<code>x</code>	object to be coerced or tested.
<code>...</code>	further arguments passed to or from other methods.

Details

`numeric` is identical to `double` (and `real`). It creates a double-precision vector of the specified length with each element equal to 0.

`as.numeric` is a generic function, but S3 methods must be written for `as.double`. It is identical to `as.double` (and `as.real`).

`is.numeric` is generic: you can write methods to handle specific classes of objects, see [Internal-Methods](#). It is **not** the same as `is.double`. Factors are handled by the default method, and there are methods for classes `"Date"` and `"POSIXt"` (in all three cases the result is false). Methods for `is.numeric` should only return true if the base type of the class is `double` or `integer` and values can reasonably be regarded as numeric (e.g. arithmetic on them makes sense).

Value

for `numeric` and `as.numeric` see [double](#).

The default method for `is.numeric` returns TRUE if its argument is of `mode` `"numeric"` (`type` `"double"` or `type` `"integer"`) and not a factor, and FALSE otherwise. That is, `is.integer(x) || is.double(x)`, or `(mode(x) == "numeric") && !is.factor(x)`.

S4 methods

`as.numeric` and `is.numeric` are internally S4 generic and so methods can be set for them *via* `setMethod`.

To ensure that `as.numeric`, `as.double` and `as.real` remain identical, S4 methods can only be set for `as.numeric`.

Note on names

It is a historical anomaly that R has three names for its floating-point vectors, `double`, `numeric` and `real`.

`double` is the name of the `type`. `numeric` is the name of the `mode` and also of the implicit `class`. As an S4 formal class, use `"numeric"` (there was a formal class `"double"` prior to R 2.7.0).

`real` is deprecated and should not be used in new code.

The potential confusion is that R has used `mode` `"numeric"` to mean ‘double or integer’, which conflicts with the S4 usage. Thus `is.numeric` tests the mode, not the class, but `as.numeric` (which is identical to `as.double`) coerces to the class.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[double](#), [integer](#), [storage.mode](#).

Examples

```
as.numeric(c("-.1", " 2.7 ", "B")) # (-0.1, 2.7, NA) + warning
as.numeric(factor(5:10))
```

NumericConstants *Numeric Constants*

Description

How R parses numeric constants.

Details

R parses numeric constants in its input in a very similar way to C99 floating-point constants.

`Inf` and `NaN` are numeric constants (with `typeof(.)` "double"). These are recognized ignoring case, as is `infinity` as an alternative to `Inf`. `NA_real_` and `NA_integer_` are constants of types "double" and "integer" representing missing values. All other numeric constants start with a digit or period and are either a decimal or hexadecimal constant optionally followed by `L`.

Hexadecimal constants start with `0x` or `0X` followed by a nonempty sequence from `0-9 a-f A-F .` which is interpreted as a hexadecimal number, optionally followed by a binary exponent. A binary exponent consists of an `P` or `p` followed by an optional plus or minus sign followed by a non-empty sequence of (decimal) digits, and indicates multiplication by a power of two. Thus `0x123p456` is 291×2^{456} .

Decimal constants consist of a nonempty sequence of digits possibly containing a period (the decimal point), optionally followed by a decimal exponent. A decimal exponent consists of an `E` or `e` followed by an optional plus or minus sign followed by a non-empty sequence of digits, and indicates multiplication by a power of ten.

Values which are too large or too small to be representable will overflow to `Inf` or underflow to `0.0`.

A numeric constant immediately followed by `i` is regarded as an imaginary **complex** number.

An numeric constant immediately followed by `L` is regarded as an **integer** number when possible (and with a warning if it contains a `" . "`).

Only the ASCII digits `0-9` are recognized as digits, even in languages which have other representations of digits. The 'decimal separator' is always a period and never a comma.

Note that a leading plus or minus is not regarded by the parser as part of a numeric constant but as a unary operator applied to the constant.

See Also

[Syntax](#).

[Quotes](#) for the parsing of character constants,

Examples

```

2.1
typeof(2)
sqrt(1i) # remember elementary math?
utils::str(0xA0)
identical(1L, as.integer(1))

## You can combine the "0x" prefix with the "L" suffix :
identical(0xFL, as.integer(15)) # (with a regard to Fritz :-)
```

numeric_version *Numeric Versions*

Description

A simple S3 class for representing numeric versions including package versions, and associated methods.

Usage

```

numeric_version(x, strict = TRUE)
package_version(x, strict = TRUE)
R_system_version(x, strict = TRUE)
getRversion()
```

Arguments

<code>x</code>	a character vector with suitable numeric version strings (see ‘Details’); for <code>package_version</code> , alternatively an R version object as obtained by R.version .
<code>strict</code>	a logical indicating whether invalid numeric versions should results in an error (default) or not.

Details

Numeric versions are sequences of one or more non-negative integers, usually (e.g., in package ‘DESCRIPTION’ files) represented as character strings with the elements of the sequence concatenated and separated by single ‘.’ or ‘-’ characters. R package versions consist of at least two such integers, an R system version of exactly three (major, minor and patchlevel).

Functions `numeric_version`, `package_version` and `R_system_version` create a representation from such strings (if suitable) which allows for coercion and testing, combination, comparison, summaries (min/max), inclusion in data frames, subscripting, and printing. The classes can hold a vector of such representations.

`getRversion` returns the version of the running R as an R system version object.

The `[]` operator extracts or replaces a single version. To access the integers of a version use two indices: see the examples.

See Also

[compareVersion](#)

Examples

```
x <- package_version(c("1.2-4", "1.2-3", "2.1"))
x < "1.4-2.3"
c(min(x), max(x))
x[2, 2]
x$major
x$minor

if(getRversion() <= "2.5.0") { ## work around missing feature
  cat("Your version of R, ", as.character(getRversion()),
      ", is outdated.\n",
      "Now trying to work around that ... \n", sep = "")
}

x[[c(1,3)]] # '4' as a numeric vector, same as x[1, 3]
x[1, 3]     # 4 as an integer
x[[2, 3]] <- 0 # zero the patchlevel
x[[c(2,3)]] <- 0 # same
x
x[[3]] <- "2.2.3"; x
```

 octmode

Display Numbers in Octal

Description

Convert or print integers in octal format, with as many digits as are needed to display the largest, using leading zeroes as necessary.

Usage

```
as.octmode(x)

## S3 method for class 'octmode':
as.character(x, ...)

## S3 method for class 'octmode':
format(x, ...)

## S3 method for class 'octmode':
print(x, ...)
```

Arguments

`x` An object, for the methods inheriting from class "octmode".
`...` further arguments passed to or from other methods.

Details

Class "octmode" consists of integer vectors with that class attribute, used merely to ensure that they are printed in octal notation, specifically for Unix-like file permissions such as 755. Subsetting (`[]`) works too.

as.octmode can convert integers (of type "integer" or "double") and character strings to class "octmode"

See Also

These are auxiliary functions for [file.info](#).

[hexmode](#)

Examples

```
(on <- structure(c(16,32, 127:129), class = "octmode")) #-> print.*()
##-> "020" "040" "177" "200" "201"
unclass(on[3:4]) # subsetting
```

on.exit

Function Exit Code

Description

on.exit records the expression given as its argument as needing to be executed when the current function exits (either naturally or as the result of an error). This is useful for resetting graphical parameters or performing other cleanup actions.

If no expression is provided, i.e., the call is on.exit(), then the current on.exit code is removed.

on.exit is a primitive function so positional matching is used and names of supplied arguments are ignored.

Usage

```
on.exit(expr, add = FALSE)
```

Arguments

expr	an expression to be executed.
add	if TRUE, add expr to be executed after any previously set expressions; otherwise (the default) expr will overwrite any previously set expressions.

Details

Where expr was evaluated changed in R 2.8.0, and the following applies only to that and later versions.

The expr argument passed to on.exit is recorded without evaluation. If it is not subsequently removed/replaced by another on.exit call in the same function, it is evaluated in the evaluation frame of the function when it exits (including during standard error handling). Thus any functions or variables in the expression will be looked for in the function and its environment at the time of exit: to capture the current value in expr use [substitute](#) or similar.

Value

Invisible NULL.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`sys.on.exit` which returns the expression stored for use by `on.exit()` in the function in which `sys.on.exit()` is evaluated.

Examples

```
require(graphics)

opar <- par(mai = c(1,1,1,1))
on.exit(par(opar))
```

Ops.Date

Operators on the Date Class

Description

Operators for the "Date" class.

There is an `Ops` method and specific methods for `+` and `-` for the `Date` class.

Usage

```
date + x
date - x
date1 lop date2
```

Arguments

<code>date</code>	date objects
<code>date1, date2</code>	date objects or character vectors. (Character vectors are converted by <code>as.Date</code> .)
<code>x</code>	a numeric vector (in days) <i>or</i> an object of class "difftime".
<code>lop</code>	One of <code>==</code> , <code>!=</code> , <code><</code> , <code><=</code> , <code>></code> or <code>>=</code> .

Examples

```
(z <- Sys.Date())
z + 10
z < c("2006-06-01", "2007-01-01", "2010-01-01")
```

options

*Options Settings***Description**

Allow the user to set and examine a variety of global *options* which affect the way in which R computes and displays its results.

Usage

```
options(...)
```

```
getOption(x)
```

```
.Options
```

Arguments

`...` any options can be defined, using `name = value` or by passing a list of such tagged values. However, only the ones below are used in base R. Further, `options('name') == options()['name']`, see the example.

`x` a character string holding an option name.

Details

Invoking `options()` with no arguments returns a list with the current values of the options. Note that not all options listed below are set initially. To access the value of a single option, one should use `getOption("width")`, e.g., rather than `options("width")` which is a *list* of length one.

`.Options` also always contains the `options()` list (as a pairlist, unsorted), for S compatibility. Assigning to it will make a local copy and not change the original.

Value

For `getOption`, the current value set for option `x`, or `NULL` if the option is unset.

For `options()`, a list of all set options sorted by name. For `options(name)`, a list of length one containing the set value, or `NULL` if it is unset. For uses setting one or more options, a list with the previous values of the options changed (returned invisibly).

Options used in base R

add.smooth: typically logical, defaulting to `TRUE`. Could also be set to an integer for specifying how many (simulated) smooths should be added. This is currently only used by `plot.lm`.

check.bounds: logical, defaulting to `FALSE`. If true, a **warning** is produced whenever a vector (atomic or `list`) is extended, by something like `x <- 1:3; x[5] <- 6`.

continue: a non-empty string setting the prompt used for lines which continue over one line.

defaultPackages: the packages that are attached by default when R starts up. Initially set from value of the environment variable `R_DEFAULT_PACKAGES`, or if that is unset to `c("datasets", "utils", "grDevices", "graphics", "stats",`

"methods"). (Set `R_DEFAULT_PACKAGES` to `NULL` or a comma-separated list of package names.) A call to `options` should be in your `.Rprofile` file to ensure that the change takes effect before the base package is initialized (see [Startup](#)).

deparse.max.lines: controls the number of lines used when deparsing in [traceback](#) and [browser](#). Initially unset, and only used if set to a positive integer.

digits: controls the number of digits to print when printing numeric values. It is a suggestion only. Valid values are 1...22 with default 7. See the warning in [print.default](#) about values greater than 15.

digits.secs: controls the maximum number of digits to print when formatting time values in seconds. Valid values are 0...6 with default 0. See [strftime](#).

download.file.method: Method to be used for `download.file`. Currently download methods "internal", "wget" and "lynx" are available. There is no default for this option, when `method = "auto"` is chosen: see [download.file](#).

echo: logical. Only used in non-interactive mode, when it controls whether input is echoed. Command-line option `-slave` sets this to `FALSE`, but otherwise it starts the session as `TRUE`.

encoding: The name of an encoding, default "native.enc"). See [connections](#).

error: either a function or an expression governing the handling of non-catastrophic errors such as those generated by [stop](#) as well as by signals and internally detected errors. If the option is a function, a call to that function, with no arguments, is generated as the expression. The default value is `NULL`: see [stop](#) for the behaviour in that case. The functions [dump.frames](#) and [recover](#) provide alternatives that allow post-mortem debugging. Note that these need to be specified as e.g. `options=utils::recover` in startup files such as `.Rprofile`.

expressions: sets a limit on the number of nested expressions that will be evaluated. Valid values are 25...500000 with default 5000. If you increase it, you may also want to start R with a larger protection stack; see `-max-ppsize` in [Memory](#). Note too that you may cause a segfault from overflow of the C stack, and on OSes where it is possible you may want to increase that.

keep.source: When `TRUE`, the source code for functions (newly defined or loaded) is stored in their "source" attribute (see [attr](#)) allowing comments to be kept in the right places.

The default is `interactive()`, i.e., `TRUE` for interactive use.

keep.source.pkgs: As for `keep.source`, for functions in packages loaded by [library](#) or [require](#). Defaults to `FALSE` unless the environment variable `R_KEEP_PKG_SOURCE` is set to `yes`.

Note this does not apply to packages using lazy-loading or saved images. Whether they have kept source is determined when they are installed (and is almost certainly false).

mailer: default mailer used by [bug.report\(\)](#). Can be "none".

max.contour.segments: positive integer, defaulting to 250000 and usually not set. A limit on the number of segments in a single contour line in [contour](#) or [contourLines](#).

max.print: integer, defaulting to 99999. [print](#) or [show](#) methods can make use of this option, to limit the amount of information that is printed, to something in the order of (and typically slightly less than) `max.print.entries`.

OutDec: one-character string. The character to be used as the decimal point in output conversions, that is in printing, plotting and `as.character` but not deparsing.

pager: the command used for displaying text files by [file.show](#). Defaults to `'R_HOME/bin/pager'`, which selects a pager via the `PAGER` environment variable (and that usually defaults to `less`). Can be a character string or an R function, in which case it needs to accept the same first four arguments as [file.show](#).

- papersize:** the default paper format used by `postscript`; set by environment variable `R_PAPERSIZE` when `R` is started: if that is unset or invalid it defaults to a value derived from the locale category `LC_PAPER`, or if that is unavailable to a default set when `R` was built.
- printcmd:** the command used by `postscript` for printing; set by environment variable `R_PRINTCMD` when `R` is started. This should be a command that expects either input to be piped to `'stdin'` or to be given a single filename argument.
- prompt:** a non-empty string to be used for `R`'s prompt; should usually end in a blank (`" "`).
- rl_word_breaks:** Used for the readline-based terminal interface. Default value `"\t\n\"\\' '><=%;,|&{ () }"`. This is the set of characters use to break the input line up into tokens for object- and file-name completion. Those who do not use spaces around operators may prefer `"\t\n\"\\' '><=+-*%;,|&{ () }"`. which was the default in `R` 2.5.0. (The default in pre-2.5.0 versions of `R` was `"\t\n\"\\' '@$><=;|&{ (.)"`)
- save.defaults, save.image.defaults:** see `save`.
- scipen:** integer. A penalty to be applied when deciding to print numeric values in fixed or exponential notation. Positive values bias towards fixed and negative towards scientific notation: fixed notation will be preferred unless it is more than `scipen` digits wider.
- showWarnCalls, showErrorCalls:** a logical. Should warning and error messages show a summary of the call stack? By default error calls are shown in non-interactive sessions.
- showNCalls:** a integer. Controls how long the sequence of calls must be (in bytes) before ellipses are used. Defaults to 40 and should be at least 30 and no more than 500.
- show.error.messages:** a logical. Should error messages be printed? Intended for use with `try` or a user-installed error handler.
- stringsAsFactors:** The default setting for arguments of `data.frame` and `read.table`.
- texi2dvi:** used by function `texi2dvi` in package `tools`.
- timeout:** integer. The timeout for some Internet operations, in seconds. Default 60 seconds. See `download.file` and `connections`.
- topLevelEnvironment:** see `topenv` and `sys.source`.
- useFancyQuotes:** see `sQuote`.
- verbose:** logical. Should `R` report extra information on progress? Set to `TRUE` by the command-line option `'-verbose'`.
- warn:** sets the handling of warning messages. If `warn` is negative all warnings are ignored. If `warn` is zero (the default) warnings are stored until the top-level function returns. If fewer than 10 warnings were signalled they will be printed otherwise a message saying how many (max 50) were signalled. An object called `last.warning` is created and can be printed through the function `warnings`. If `warn` is one, warnings are printed as they occur. If `warn` is two or larger all warnings are turned into errors.
- warnEscapes:** logical. If true (the default) the parser warns on unrecognized (backslash) escape sequences and there is a truncation warning on any attempt to create a character string containing an embedded nul.
- warnPartialMatchArgs:** logical. If true, warns if partial matching is used in argument matching.
- warnPartialMatchAttr:** logical. If true, warns if partial matching is used in extracting attributes via `attr`.
- warnPartialMatchDollar:** logical. If true, warns if partial matching is used for extraction by `$`.

warning.expression: an R code expression to be called if a warning is generated, replacing the standard message. If non-null it is called irrespective of the value of option `warn`.

warning.length: sets the truncation limit for error and warning messages. A non-negative integer, with allowed values 100...8170, default 1000.

width: controls the maximum number of columns on a line used in printing vectors, matrices and arrays, and when filling by `cat`.

Columns are normally the same as characters except in CJK languages.

You may want to change this if you re-size the window that R is running in. Valid values are 10...10000 with default normally 80. (The limits on valid values are in file 'Print.h' and can be changed by re-compiling R.) Some R consoles automatically change the value when they are resized.

The 'factory-fresh' default settings of some of these options are

```

add.smooth          TRUE
check.bounds        FALSE
continue            "+ "
digits              7
echo                TRUE
encoding            "native.enc"
error               NULL
expressions         5000
keep.source         interactive()
keep.source.pkgs    FALSE
max.print           99999
OutDec              "."
prompt              "> "
scipen              0
show.error.messages TRUE
timeout             60
verbose             FALSE
warn                0
warnings.length     1000
width               80

```

Others are set from environment variables or are platform-dependent.

Options set in package `grDevices`

These will be set when package `grDevices` (or its name space) is loaded if not already set.

device: a character string giving the name of a function, or the function object itself, which when called creates a new graphics device of the default type for that session. The value of this option defaults to the normal screen device (e.g., X11, windows or quartz) for an interactive session, and `pdf` in batch use or if a screen is not available. If set to the name of a device, the device is looked for first from the global environment (that is down the usual search path) and then in the `grDevices` namespace.

The default values in interactive and non-interactive sessions are configurable via environment variables `R_INTERACTIVE_DEVICE` and `R_DEFAULT_DEVICE` respectively.

locatorBell: logical. Should selection in `locator` and `identify` be confirmed by a bell? Default TRUE. Honoured at least on X11 and windows devices.

device.ask.default: logical. The default for `devAskNewPage("ask")` when a device is opened.

bitmapType: character. The default type for the bitmap devices such as `png`. Defaults to "cairo" on systems where that is available, or to "quartz" on Mac OS X where that is available.

Options set in package stats

These will be set when package `stats` (or its name space) is loaded if not already set.

contrasts: the default `contrasts` used in model fitting such as with `ao` or `lm`. A character vector of length two, the first giving the function to be used with unordered factors and the second the function to be used with ordered factors. By default the elements are named `c("unordered", "ordered")`, but the names are unused.

na.action: the name of a function for treating missing values (NA's) for certain situations.

show.coef.Pvalues: logical, affecting whether P values are printed in summary tables of coefficients. See `printCoefmat`.

show.signif.stars: logical, should stars be printed on summary tables of coefficients? See `printCoefmat`.

ts.eps: the relative tolerance for certain time series (`ts`) computations. Default $1e-05$.

ts.S.compat: logical. Used to select S compatibility for plotting time-series spectra. See the description of argument `log` in `plot.spec`.

Options set in package utils

These will be set when package `utils` (or its name space) is loaded if not already set.

browser: default HTML browser used by `help.start()` and `browseURL` on UNIX, or a non-default browser on Windows. Alternatively, an R function that is called with a URL as its argument.

de.cellwidth: integer: the cell widths (number of characters) to be used in the data editor `dataentry`. If this is unset (the default), 0, negative or NA, variable cell widths are used.

editor: a non-empty string, or a function that is called with a file path as argument. Sets the default text editor, e.g., for `edit`. Set from the environment variable `VISUAL` on UNIX.

example.ask: default for the `ask` argument of `example`.

help.try.all.packages: default for an argument of `help`.

HTTPUserAgent: string used as the user agent in HTTP requests. If NULL, HTTP requests will be made without a user agent header. The default is `R (<version> <platform> <arch> <os>)`

internet.info: The minimum level of information to be printed on URL downloads etc. Default is 2, for failure causes. Set to 1 or 0 to get more information.

menu.graphics: Logical: should graphical menus be used if available?. Defaults to TRUE. Currently applies to `chooseCRANmirror`, `setRepositories` and to select from multiple help files in `help`.

pkgType: The default type of packages to be downloaded and installed – see `install.packages`. Possible values are "source" (the default except under the CRAN Mac OS X build) and "mac.binary". The latter can have a suffix if supported by a special build, such as "mac.binary.leopard" to access the "leopard" tree of repositories instead of the default "universal".

repos: URLs of the repositories for use by `update.packages`. Defaults to `c(CRAN="@CRAN@")`, a value that causes some utilities to prompt for a CRAN mirror. To avoid this do set the CRAN mirror, by something like `local({r <- getOption("repos"); r["CRAN"] <- "http://my.local.cran"; options(repos=r)})`.

Note that you can add more repositories (Bioconductor and Omegahat, notably) using `setRepositories()`.

SweaveHooks, SweaveSyntax: see `Sweave`.

unzip: a character string, the path of the command used for unzipping help files, or "internal". Defaults to the value of `R_UNZIPCMD`, which is set in 'etc/Renviron' if an unzip command was found during configuration.

Options used on Unix only

These will be "" if no suitable path is known.

latexcmd, dvipscmd: character strings giving commands to be used in off-line printing of help pages.

pdfviewer: default PDF viewer. Set from the environment variable `R_PDFVIEWER`.

options(error = quote({dump.frames(to.file=TRUE); q()}))
## End(Not run)

```

order

Ordering Permutation

Description

`order` returns a permutation which rearranges its first argument into ascending or descending order, breaking ties by further arguments. `sort.list` is the same, using only one argument. See the examples for how to use these functions to sort data frames, etc.

Usage

```

order(..., na.last = TRUE, decreasing = FALSE)

sort.list(x, partial = NULL, na.last = TRUE, decreasing = FALSE,
          method = c("shell", "quick", "radix"))

```

Arguments

<code>...</code>	a sequence of numeric, complex, character or logical vectors, all of the same length.
<code>x</code>	a vector.
<code>partial</code>	vector of indices for partial sorting. (Non-NULL values are not implemented.)
<code>decreasing</code>	logical. Should the sort order be increasing or decreasing?
<code>na.last</code>	for controlling the treatment of NAs. If <code>TRUE</code> , missing values in the data are put last; if <code>FALSE</code> , they are put first; if <code>NA</code> , they are removed.
<code>method</code>	the method to be used: partial matches are allowed.

Details

In the case of ties in the first vector, values in the second are used to break the ties. If the values are still tied, values in the later arguments are used to break the tie (see the first example). The sort used is *stable* (except for `method = "quick"`), so any unresolved ties will be left in their original ordering.

Complex values are sorted first by the real part, then the imaginary part.

The sort order for character vectors will depend on the collating sequence of the locale in use: see [Comparison](#).

The default method for `sort.list` is a good compromise. Method "quick" is only supported for numeric `x` with `na.last=NA`, and is not stable, but will be faster for long vectors. Method "radix" is only implemented for integer `x` with a range of less than 100,000. For such `x` it is very fast (and stable), and hence is ideal for sorting factors.

`partial` is supplied for compatibility with other implementations of `S`, but no other values are accepted and ordering is always complete.

Note that these functions are only defined for vectors, so any class of the object supplied is ignored: this means factors are sorted on their internal codes and not their printed representation.

Note

`sort.list` can get called by mistake as a method for `sort` with a list argument, and gives a suitable error message for list `x`.

system.time(o <- sort.list(x, method="radix")) # 0.02 sec
stopifnot(!is.unsorted(x[o]))
xx <- sample(1:26, 1e7, replace=TRUE)
system.time(o <- sort.list(xx, method="radix")) # 0.2 sec
xx <- sample(1:100000, 1e7, replace=TRUE)
system.time(o <- sort.list(xx, method="radix")) # 0.8 sec
system.time(o <- sort.list(xx, method="quick", na.last=NA)) # 1.4 sec
## End(Not run)

```

outer

Outer Product of Arrays

Description

The outer product of the arrays X and Y is the array A with dimension $c(\dim(X), \dim(Y))$ where element $A[c(\text{arrayindex.x}, \text{arrayindex.y})] = \text{FUN}(X[\text{arrayindex.x}], Y[\text{arrayindex.y}], \dots)$.

Usage

```

outer(X, Y, FUN="*", ...)
X %o% Y

```

Arguments

X, Y	First and second arguments for function <code>FUN</code> . Typically a vector or array.
<code>FUN</code>	a function to use on the outer products, found <i>via</i> <code>match.fun</code> (except for the special case <code>"*"</code>).
<code>...</code>	optional arguments to be passed to <code>FUN</code> .

Details

X and Y must be suitable arguments for FUN. Each will be extended by `rep` to length the products of the lengths of X and Y before FUN is called.

FUN is called with these two extended vectors as arguments. Therefore, it must be a vectorized function (or the name of one), expecting at least two arguments.

Where they exist, the [dim]names of X and Y will be copied to the answer, and a dimension assigned which is the concatenation of the dimensions of X and Y (or lengths if dimensions do not exist).

FUN = "*" is handled internally as a special case, *via* `as.vector(X) %*% t(as.vector(Y))`, and is intended only for numeric vectors and arrays.

`%o%` is binary operator providing a wrapper for `outer(x, y, "*")`.

See Also

`%*%` for usual (*inner*) matrix vector multiplication; `kronecker` which is based on `outer`; `Vectorize` for vectorizing a non-vectorized function.

Examples

```
x <- 1:9; names(x) <- x
# Multiplication & Power Tables
x %o% x
y <- 2:8; names(y) <- paste(y, ":", sep="")
outer(y, x, "^")

outer(month.abb, 1999:2003, FUN = "paste")

## three way multiplication table:
x %o% x %o% y[1:3]
```

 Paren

Parentheses and Braces

Description

Open parenthesis, (, and open brace, {, are `.Primitive` functions in R.

Effectively, (is semantically equivalent to the identity function `function(x) x`, whereas { is slightly more interesting, see examples.

Usage

```
( ... )
```

```
{ ... }
```

Value

For `()`, the result of evaluating the argument. This has visibility set, so will auto-print if used at top-level.

For `{}`, the result of the last expression evaluated. This has the visibility of the last evaluation.

(invisible(2+3))
{invisible(2+3)}
```

parse

Parse Expressions

Description

`parse` returns the parsed but unevaluated expressions in a list.

Usage

```
parse(file = "", n = NULL, text = NULL, prompt = "?", srcfile,
      encoding = "unknown")
```

Arguments

<code>file</code>	a connection, or a character string giving the name of a file or a URL to read the expressions from. If <code>file</code> is "" and <code>text</code> is missing or NULL then input is taken from the console.
<code>n</code>	integer (or coerced to integer). The maximum number of expressions to parse. If <code>n</code> is NULL or negative or NA the input is parsed in its entirety.
<code>text</code>	character vector. The text to parse. Elements are treated as if they were lines of a file. Other R objects will be coerced to character (without method dispatch) if possible.

prompt	the prompt to print when parsing from the keyboard. NULL means to use R's prompt, <code>getOption("prompt")</code> .
srcfile	NULL, or a <code>srcfile</code> object. See the 'Details' section.
encoding	encoding to be assumed for input strings. If the value is "latin1" or "UTF-8" it is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input. To do the latter, specify the encoding as part of the connection <code>con</code> or <i>via</i> <code>options(encoding=)</code> : see the example under <code>file</code> .

Details

If `text` has length greater than zero (after coercion) it is used in preference to `file`.

All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CRLF (as used on DOS/Windows) or CR (as used on classic MacOS). The final line can be incomplete, that is missing the final EOL marker.

See `source` for the limits on the size of functions that can be parsed (by default).

When input is taken from the console, `n = NULL` is equivalent to `n = 1`, and `n < 0` will read until an EOF character is read.

The default for `srcfile` is set as follows. If `options("keep.source")` is FALSE, `srcfile` defaults to NULL. Otherwise, if `text` is used, `srcfile` will be set to a `srcfilecopy` containing the text. If a character string is used for `file`, a `srcfile` object referring to that file will be used.

Value

An object of type "expression", with up to `n` elements if specified as a non-negative integer.

When `srcfile` is non-NULL, a "srcref" attribute will be attached to the result containing a list of `srcref` records corresponding to each element, and a "srcfile" attribute will be attached containing a copy of `srcfile`.

A syntax error (including an incomplete expression) will throw an error.

Character strings in the result will have a declared encoding if `encoding` is "latin1" or "UTF-8".

See Also

`scan`, `source`, `eval`, `deparse`.

Examples

```
cat("x <- c(1,4)\n x ^ 3 -10 ; outer(1:7,5:9)\n", file="xyz.Rdmped")
# parse 3 statements from the file "xyz.Rdmped"
parse(file = "xyz.Rdmped", n = 3)
unlink("xyz.Rdmped")
```

paste	<i>Concatenate Strings</i>
-------	----------------------------

Description

Concatenate vectors after converting to character.

Usage

```
paste(..., sep = " ", collapse = NULL)
```

Arguments

...	one or more R objects, to be converted to character vectors.
sep	a character string to separate the terms. Not NA_character_ .
collapse	an optional character string to separate the results. Not NA_character_ .

Details

`paste` converts its arguments (*via* [as.character](#)) to character strings, and concatenates them (separating them by the string given by `sep`). If the arguments are vectors, they are concatenated term-by-term to give a character vector result. Vector arguments are recycled as needed, with zero-length arguments being recycled to "".

Note that `paste()` coerces [NA_character_](#), the character missing value, to "NA" which may seem undesirable, e.g., when pasting two character vectors, or very desirable, e.g. in `paste("the value of p is ", p)`.

If a value is specified for `collapse`, the values in the result are then concatenated into a single string, with the elements being separated by the value of `collapse`.

Value

A character vector of the concatenated values. This will be of length zero if all the objects are, unless `collapse` is non-NULL in which case it is a single empty string.

If any input into an element of the result is in UTF-8, that element will be in UTF-8, otherwise in the current encoding in which case the encoding of an element of the element is declared if the current locale is either Latin-1 or UTF-8, at least one of the corresponding inputs (including separators) had a declared encoding and all inputs were either ASCII or declared.

[‘plotmath’](#) for the use of `paste` in plot annotation.

Examples

```
paste(1:12) # same as as.character(1:12)
paste("A", 1:6, sep = "")
paste("Today is", date())
```

path.expand	<i>Expand File Paths</i>
-------------	--------------------------

Description

Expand a path name, for example by replacing a leading tilde by the user's home directory (if defined on that platform).

Usage

```
path.expand(path)
```

Arguments

path character vector containing one or more path names.

Details

On *some* Unix versions, a leading `~user` will expand to the home directory of `user`, but not on Unix versions without `readline` installed, nor if `R` is invoked with `'--no-readline'`.

[basename](#)

Examples

```
path.expand("~/foo")
```

pmatch	<i>Partial String Matching</i>
--------	--------------------------------

Description

`pmatch` seeks matches for the elements of its first argument among those of its second.

Usage

```
pmatch(x, table, nomatch = NA_integer_, duplicates.ok = FALSE)
```

Arguments

<code>x</code>	the values to be matched: converted to a character vector by <code>as.character</code> .
<code>table</code>	the values to be matched against: converted to a character vector.
<code>nomatch</code>	the value to be returned at non-matching or multiply partially matching positions. Note that it is coerced to <code>integer</code> .
<code>duplicates.ok</code>	should elements be in <code>table</code> be used more than once?

Details

The behaviour differs by the value of `duplicates.ok`. Consider first the case if this is true. First exact matches are considered, and the positions of the first exact matches are recorded. Then unique partial matches are considered, and if found recorded. (A partial match occurs if the whole of the element of `x` matches the beginning of the element of `table`.) Finally, all remaining elements of `x` are regarded as unmatched. In addition, an empty string can match nothing, not even an exact match to an empty string. This is the appropriate behaviour for partial matching of character indices, for example.

If `duplicates.ok` is FALSE, values of `table` once matched are excluded from the search for subsequent matches. This behaviour is equivalent to the R algorithm for argument matching, except for the consideration of empty strings (which in argument matching are matched after exact and partial matching to any remaining arguments).

`charmatch` is similar to `pmatch` with `duplicates.ok` true, the differences being that it differentiates between no match and an ambiguous partial match, it does match empty strings, and it does not allow multiple exact matches.

NA values are treated as if they were the string constant "NA".

Value

An integer vector (possibly including NA if `nomatch = NA`) of the same length as `x`, giving the indices of the elements in `table` which matched, or `nomatch`.

See Also

`match`, `charmatch` and `match.arg`, `match.fun`, `match.call`, for function argument matching etc., `grep` etc for more general (regex) matching of strings.

Examples

```
pmatch("", "") # returns NA
pmatch("m", c("mean", "median", "mode")) # returns NA
pmatch("med", c("mean", "median", "mode")) # returns 2

pmatch(c("", "ab", "ab"), c("abc", "ab"), dup=FALSE)
pmatch(c("", "ab", "ab"), c("abc", "ab"), dup=TRUE)
## compare
charmatch(c("", "ab", "ab"), c("abc", "ab"))
```

 polyroot

Find Zeros of a Real or Complex Polynomial

Description

Find zeros of a real or complex polynomial.

Usage

```
polyroot(z)
```

Arguments

`z` the vector of polynomial coefficients in increasing order.

Details

A polynomial of degree $n - 1$,

$$p(x) = z_1 + z_2x + \dots + z_nx^{n-1}$$

is given by its coefficient vector `z[1:n]`. `polyroot` returns the $n - 1$ complex zeros of $p(x)$ using the Jenkins-Traub algorithm.

If the coefficient vector `z` has zeroes for the highest powers, these are discarded.

As from R 2.8.0 there is no maximum degree, but numerical stability may be an issue for all but low-degree polynomials.

Value

A complex vector of length $n - 1$, where n is the position of the largest non-zero element of `z`.

References

Jenkins and Traub (1972) TOMS Algorithm 419. *Comm. ACM*, **15**, 97–99.

See Also

`uniroot` for numerical root finding of arbitrary functions; `complex` and the `zero` example in the demos directory.

Examples

```
polyroot(c(1, 2, 1))
round(polyroot(choose(8, 0:8)), 11) # guess what!
for (n1 in 1:4) print(polyroot(1:n1), digits = 4)
polyroot(c(1, 2, 1, 0, 0)) # same as the first
```

 pos.to.env

Convert Positions in the Search Path to Environments

Description

Returns the environment at a specified position in the search path.

Usage

```
pos.to.env(x)
```

Arguments

`x` an integer between 1 and `length(search())`, the length of the search path.

Details

Several R functions for manipulating objects in environments (such as `get` and `ls`) allow specifying environments via corresponding positions in the search path. `pos.to.env` is a convenience function for programmers which converts these positions to corresponding environments; users will typically have no need for it.

Examples

```
pos.to.env(1) # R_GlobalEnv
# the next returns the base environment
pos.to.env(length(search()))
```

 pretty

Pretty Breakpoints

Description

Compute a sequence of about `n+1` equally spaced ‘round’ values which cover the range of the values in `x`. The values are chosen so that they are 1, 2 or 5 times a power of 10.

Usage

```
pretty(x, n = 5, min.n = n %/% 3, shrink.sml = 0.75,
       high.u.bias = 1.5, u5.bias = .5 + 1.5*high.u.bias,
       eps.correct = 0)
```

Arguments

`x` an object coercible to numeric by `as.numeric`.

`n` integer giving the *desired* number of intervals. Non-integer values are rounded down.

`min.n` nonnegative integer giving the *minimal* number of intervals. If `min.n == 0`, `pretty(.)` may return a single value.

<code>shrink.sml</code>	positive numeric by which a default scale is shrunk in the case when <code>range(x)</code> is very small (usually 0).
<code>high.u.bias</code>	non-negative numeric, typically > 1 . The interval unit is determined as $\{1,2,5,10\}$ times <code>b</code> , a power of 10. Larger <code>high.u.bias</code> values favor larger units.
<code>u5.bias</code>	non-negative numeric multiplier favoring factor 5 over 2. Default and ‘optimal’: <code>u5.bias = .5 + 1.5*high.u.bias</code> .
<code>eps.correct</code>	integer code, one of $\{0,1,2\}$. If non-0, an <i>epsilon correction</i> is made at the boundaries such that the result boundaries will be outside <code>range(x)</code> ; in the ‘small’ case, the correction is only done if <code>eps.correct</code> ≥ 2 .

Details

`pretty` ignores non-finite values in `x`.

Let $d \leftarrow \max(x) - \min(x) \geq 0$. If d is not (very close) to 0, we let $c \leftarrow d/n$, otherwise more or less $c \leftarrow \max(\text{abs}(\text{range}(x))) * \text{shrink.sml} / \text{min.n}$. Then, the 10 base b is $10^{\lfloor \log_{10}(c) \rfloor}$ such that $b \leq c < 10b$.

Now determine the basic *unit* u as one of $\{1,2,5,10\}b$, depending on $c/b \in [1,10)$ and the two ‘bias’ coefficients, $h = \text{high.u.bias}$ and $f = \text{u5.bias}$.

utils::str(lapply(add.names(0:20), pretty, min.n = 0))
sapply(  add.names(0:20), pretty, min.n = 4)

pretty(1.234e100)
pretty(1001.1001)
```

```
pretty(1001.1001, shrink = .2)
for(k in -7:3)
  cat("shrink=", formatC(2^k, width=9), ":",
      formatC(pretty(1001.1001, shrink.sml = 2^k), width=6), "\n")
```

 Primitive

Call a “Primitive” Internal Function

Description

`.Primitive` returns an entry point to a ‘primitive’ (internally implemented) function.

Usage

```
.Primitive(name)
```

Arguments

name name of the R function.

Details

The advantage of `.Primitive` over `.Internal` functions is the potential efficiency of argument passing. However, this is done by ignoring argument names and using positional matching of arguments (unless arranged differently for specific primitives such as `rep`), so this is discouraged for functions of more than one argument.

All primitive functions are in the base name space.

See Also

[.Internal](#).

Examples

```
mysqrt <- .Primitive("sqrt")
c
.Internal # this one *must* be primitive!
get("if") # just 'if' or 'print(if)' are not syntactically ok.
```

 print

Print Values

Description

`print` prints its argument and returns it *invisibly* (via `invisible(x)`). It is a generic function which means that new printing methods can be easily added for new `classes`.

Usage

```
print(x, ...)

## S3 method for class 'factor':
print(x, quote = FALSE, max.levels = NULL,
      width = getOption("width"), ...)

## S3 method for class 'table':
print(x, digits = getOption("digits"), quote = FALSE,
      na.print = "", zero.print = "0", justify = "none", ...)
```

Arguments

x	an object used to select a method.
...	further arguments passed to or from other methods.
quote	logical, indicating whether or not strings should be printed with surrounding quotes.
max.levels	integer, indicating how many levels should be printed for a factor; if 0, no extra "Levels" line will be printed. The default, NULL, entails choosing max.levels such that the levels print on one line of width width.
width	only used when max.levels is NULL, see above.
digits	minimal number of <i>significant</i> digits, see print.default .
na.print	character string (or NULL) indicating NA values in printed output, see print.default .
zero.print	character specifying how zeros (0) should be printed; for sparse tables, using ". ." can produce stronger results.
justify	character indicating if strings should left- or right-justified or left alone, passed to format .

Details

The default method, [print.default](#) has its own help page. Use `methods("print")` to get all the methods for the `print` generic.

`print.factor` allows some customization and is used for printing [ordered](#) factors as well.

`print.table` for printing [tables](#) allows other customization.

See [noquote](#) as an example of a class whose main purpose is a specific `print` method.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

See Also

The default method [print.default](#), and help for the methods above; further [options](#), [noquote](#).

For more customizable (but cumbersome) printing, see [cat](#), [format](#) or also [write](#).

Examples

```
require(stats)

ts(1:20)#-- print is the "Default function" --> print.ts(.) is called
rr <- for(i in 1:3) print(1:i)
rr

## Printing of factors
attenu$station ## 117 levels -> 'max.levels' depending on width

## ordered factors: levels "l1 < l2 < .."
esoph$agegp[1:12]
esoph$alcgp[1:12]

## Printing of sparse (contingency) tables
set.seed(521)
t1 <- round(abs(rt(200, df=1.8)))
t2 <- round(abs(rt(200, df=1.4)))
table(t1,t2) # simple
print(table(t1,t2), zero.print = ".")# nicer to read
```

print.data.frame *Printing Data Frames*

Description

Print a data frame.

Usage

```
## S3 method for class 'data.frame':
print(x, ..., digits = NULL,
      quote = FALSE, right = TRUE, row.names = TRUE)
```

Arguments

x	object of class <code>data.frame</code> .
...	optional arguments to <code>print</code> or <code>plot</code> methods.
digits	the minimum number of significant digits to be used: see print.default .
quote	logical, indicating whether or not entries should be printed with surrounding quotes.
right	logical, indicating whether or not strings should be right-aligned. The default is right-alignment.
row.names	logical (or character vector), indicating whether (or what) row names should be printed.

Details

This calls `format` which formats the data frame column-by-column, then converts to a character matrix and dispatches to the `print` method for matrices.

When `quote = TRUE` only the entries are quoted not the row names nor the column names.

See Also

[data.frame.](#)

Examples

```
(dd <- data.frame(x=1:8, f=g1(2,4), ch=I(letters[1:8])))
# print() with defaults
print(dd, quote = TRUE, row.names = FALSE)
# suppresses row.names and quotes all entries
```

print.default

Default Printing

Description

`print.default` is the *default* method of the generic `print` function which prints its argument.

Usage

```
## Default S3 method:
print(x, digits = NULL, quote = TRUE,
      na.print = NULL, print.gap = NULL, right = FALSE,
      max = NULL, useSource = TRUE, ...)
```

Arguments

<code>x</code>	the object to be printed.
<code>digits</code>	a non-null value for <code>digits</code> specifies the minimum number of significant digits to be printed in values. The default, <code>NULL</code> , uses <code>getOption(digits)</code> . (For the interpretation for complex numbers see <code>signif</code> .) Non-integer values will be rounded down, and only values greater than or equal to 1 and no greater than 22 are accepted.
<code>quote</code>	logical, indicating whether or not strings (<code>characters</code>) should be printed with surrounding quotes.
<code>na.print</code>	a character string which is used to indicate <code>NA</code> values in printed output, or <code>NULL</code> (see ‘Details’).
<code>print.gap</code>	a non-negative integer ≤ 1024 , or <code>NULL</code> (meaning 1), giving the spacing between adjacent columns in printed vectors, matrices and arrays.
<code>right</code>	logical, indicating whether or not strings should be right aligned. The default is left alignment.
<code>max</code>	a non-null value for <code>max</code> specifies the approximate maximum number of entries to be printed. The default, <code>NULL</code> , uses <code>getOption(max.print)</code> ; see that help page for more details.
<code>useSource</code>	logical, indicating whether to use source references or copies rather than deparsing language objects. The default is to use the original source if it is available.
<code>...</code>	further arguments to be passed to or from other methods. They are ignored in this function.

Details

The default for printing NAs is to print NA (without quotes) unless this is a character NA *and* `quote = FALSE`, when `<NA>` is printed.

The same number of decimal places is used throughout a vector. This means that `digits` specifies the minimum number of significant digits to be used, and that at least one entry will be encoded with that minimum number. However, if all the encoded elements then have trailing zeroes, the number of decimal places is reduced until at least one element has a non-zero final digit. Decimal points are only included if at least one decimal place is selected.

Attributes are printed respecting their class(es), using the values of `digits` to `print.default`, but using the default values (for the methods called) of the other arguments.

When the **methods** package is attached, `print` will call `show` for R objects with formal classes if called with no optional arguments.

Warning

Using too large a value of `digits` may lead to representation errors in the calculation of the number of significant digits and the decimal representation: these are likely for `digits >= 16`, and these possible errors are taken into account in assessing the number of significant digits to be printed in that case.

Whereas earlier versions of R might have printed further digits for `digits >= 16` on some platforms, they were not necessarily reliable.

Single-byte locales

If a non-printable character is encountered during output, it is represented as one of the ANSI escape sequences (`\a`, `\b`, `\f`, `\n`, `\r`, `\t`, `\v`, `\` and `\0`: see [Quotes](#)), or failing that as a 3-digit octal code: for example the UK currency pound sign in the C locale (if implemented correctly) is printed as `\243`. Which characters are non-printable depends on the locale.

Unicode and other multi-byte locales

In all locales, the characters in the ASCII range (`0x00` to `0x7f`) are printed in the same way, as-is if printable, otherwise via ANSI escape sequences or 3-digit octal escapes as described for single-byte locales.

Multi-byte non-printing characters are printed as an escape sequence of the form `\uxxxx` or `\Uxxxxxxxx` (in hexadecimal). This is the internal code for the wide-character representation of the character. If this is not known to be the Unicode point, a warning is issued. The only known exceptions are certain Japanese ISO2022 locales on commercial Unixes, which use a concatenation of the bytes: it is unlikely that R compiles on such a system.

It is possible to have a character string in a character vector that is not valid in the current locale. If a byte is encountered that is not part of a valid character it is printed in hex in the form `\xab` and this is repeated until the start of a valid character. (This will rapidly recover from minor errors in UTF-8.)

See Also

The generic `print`, `options`. The `"noquote"` class and `print` method.

`encodeString`, which encodes a character vector the way it would be printed.

Examples

```

pi
print(pi, digits = 16)
LETTERS[1:16]
print(LETTERS, quote = FALSE)

M <- cbind(I = 1, matrix(1:10000, ncol = 10,
                        dimnames = list(NULL, LETTERS[1:10])))
utils::head(M) # makes more sense than
print(M, max = 1000) # prints 90 rows and a message about omitting 910

```

prmatrix

*Print Matrices, Old-style***Description**

An earlier method for printing matrices, provided for S compatibility.

Usage

```

prmatrix(x, rowlab =, collab =,
         quote = TRUE, right = FALSE, na.print = NULL, ...)

```

Arguments

<code>x</code>	numeric or character matrix.
<code>rowlab, collab</code>	(optional) character vectors giving row or column names respectively. By default, these are taken from <code>dimnames(x)</code> .
<code>quote</code>	logical; if TRUE and <code>x</code> is of mode "character", <i>quotes</i> (") are used.
<code>right</code>	if TRUE and <code>x</code> is of mode "character", the output columns are <i>right-justified</i> .
<code>na.print</code>	how NAs are printed. If this is non-null, its value is used to represent NA.
<code>...</code>	arguments for <code>print</code> methods.

Details

`prmatrix` is an earlier form of `print.matrix`, and is very similar to the S function of the same name.

Value

Invisibly returns its argument, `x`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

`print.default`, and other `print` methods.

Examples

```
prmatrix(m6 <- diag(6), rowlab = rep("",6), collab =rep("",6))

chm <- matrix(scan(system.file("help", "AnIndex", package = "splines"),
                          what = ""), , 2, byrow = TRUE)
chm # uses print.matrix()
prmatrix(chm, collab = paste("Column",1:3), right=TRUE, quote=FALSE)
```

proc.time

Running Time of R

Description

`proc.time` determines how much real and CPU time (in seconds) the currently running R process has already taken.

Usage

```
proc.time()
```

Details

`proc.time` returns five elements for backwards compatibility, but its `print` method prints a named vector of length 3. The first two entries are the total user and system CPU times of the current R process and any child processes on which it has waited, and the third entry is the ‘real’ elapsed time since the process was started.

Value

An object of class "proc_time" which is a numeric vector of length 5, containing the user, system, and total elapsed times for the currently running R process, and the cumulative sum of user and system times of any child processes spawned by it on which it has waited. (The `print` method combines the child times with those of the main process.)

The definition of ‘user’ and ‘system’ times is from your OS. Typically it is something like

The ‘user time’ is the CPU time charged for the execution of user instructions of the calling process. The ‘system time’ is the CPU time charged for execution by the system on behalf of the calling process.

The resolution of the times will be system-specific and on Unix-alikes times are rounded to the nearest 1ms. On modern systems they will be that accurate, but on older systems they might be accurate to 1/100 or 1/60 sec.

Note

It is possible to compile R without support for `proc.time`, when the function will throw an error.

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`system.time` for timing a valid R expression, `gc.time` for how much of the time was spent in garbage collection.

Examples

```
## Not run:
## a way to time an R expression: system.time is preferred
ptm <- proc.time()
for (i in 1:50) mad(stats::runif(500))
proc.time() - ptm
## End(Not run)
```

 prod

Product of Vector Elements

Description

`prod` returns the product of all the values present in its arguments.

Usage

```
prod(..., na.rm = FALSE)
```

Arguments

`...` numeric or complex or logical vectors.
`na.rm` logical. Should missing values be removed?

Details

If `na.rm` is `FALSE` an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

This is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

Logical true values are regarded as one, false values as zero. For historical reasons, NULL is accepted and treated as if it were `numeric(0)`.

Value

The product, a numeric (of type "double") or complex vector of length one. **NB:** the product of an empty set is one, by definition.

S4 methods

This is part of the S4 [Summary](#) group generic. Methods for it must use the signature `x, ..., na.rm`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[sum](#), [cumprod](#), [cumsum](#).

Examples

```
print(prod(1:7)) == print(gamma(8))
```

prop.table

Express Table Entries as Fraction of Marginal Table

Description

This is really `sweep(x, margin, margin.table(x, margin), "/")` for newbies, except that if `margin` has length zero, then one gets `x/sum(x)`.

Usage

```
prop.table(x, margin=NULL)
```

Arguments

<code>x</code>	table
<code>margin</code>	index, or vector of indices to generate margin for

Value

Table like `x` expressed relative to `margin`

Author(s)

Peter Dalgaard

See Also

[margin.table](#)

Examples

```
m <- matrix(1:4,2)
m
prop.table(m,1)
```

`pushBack`*Push Text Back on to a Connection*

Description

Functions to push back text lines onto a connection, and to enquire how many lines are currently pushed back.

Usage

```
pushBack(data, connection, newLine = TRUE)
pushBackLength(connection)
```

Arguments

<code>data</code>	a character vector.
<code>connection</code>	A connection.
<code>newLine</code>	logical. If true, a newline is appended to each string pushed back.

Details

Several character strings can be pushed back on one or more occasions. The occasions form a stack, so the first line to be retrieved will be the first string from the last call to `pushBack`. Lines which are pushed back are read prior to the normal input from the connection, by the normal text-reading functions such as `readLines` and `scan`.

Pushback is only allowed for readable connections in text mode.

Not all uses of connections respect pushbacks, in particular the input connection is still wired directly, so for example parsing commands from the console and `scan("")` ignore pushbacks on `stdin`.

Value

`pushBack` returns nothing.

`pushBackLength` returns number of lines currently pushed back.

See Also

[connections](#), [readLines](#).

Examples

```
zz <- textConnection(LETTERS)
readLines(zz, 2)
pushBack(c("aa", "bb"), zz)
pushBackLength(zz)
readLines(zz, 1)
pushBackLength(zz)
readLines(zz, 1)
readLines(zz, 1)
close(zz)
```

Description

qr computes the QR decomposition of a matrix. It provides an interface to the techniques used in the LINPACK routine DQRDC or the LAPACK routines DGEQP3 and (for complex matrices) ZGEQP3.

Usage

```
qr(x, ...)
## Default S3 method:
qr(x, tol = 1e-07 , LAPACK = FALSE, ...)

qr.coef(qr, y)
qr.qy(qr, y)
qr.qty(qr, y)
qr.resid(qr, y)
qr.fitted(qr, y, k = qr$rank)
qr.solve(a, b, tol = 1e-7)
## S3 method for class 'qr':
solve(a, b, ...)

is.qr(x)
as.qr(x)
```

Arguments

x	a matrix whose QR decomposition is to be computed.
tol	the tolerance for detecting linear dependencies in the columns of x. Only used if LAPACK is false and x is real.
qr	a QR decomposition of the type computed by qr.
y, b	a vector or matrix of right-hand sides of equations.
a	A QR decomposition or (qr.solve only) a rectangular matrix.
k	effective rank.
LAPACK	logical. For real x, if true use LAPACK otherwise use LINPACK.
...	further arguments passed to or from other methods

Details

The QR decomposition plays an important role in many statistical techniques. In particular it can be used to solve the equation $Ax = b$ for given matrix A , and vector b . It is useful for computing regression coefficients and in applying the Newton-Raphson algorithm.

The functions `qr.coef`, `qr.resid`, and `qr.fitted` return the coefficients, residuals and fitted values obtained when fitting y to the matrix with QR decomposition `qr`. (If pivoting is used, some of the coefficients will be NA.) `qr.qy` and `qr.qty` return $Q \%*\% y$ and $t(Q) \%*\% y$, where Q is the (complete) Q matrix.

All the above functions keep `dimnames` (and `names`) of `x` and `y` if there are.

`solve.qr` is the method for `solve` for `qr` objects. `qr.solve` solves systems of equations via the QR decomposition: if `a` is a QR decomposition it is the same as `solve.qr`, but if `a` is a rectangular matrix the QR decomposition is computed first. Either will handle over- and under-determined systems, providing a least-squares fit if appropriate.

`is.qr` returns TRUE if `x` is a `list` with components named `qr`, `rank` and `qraux` and FALSE otherwise.

It is not possible to coerce objects to mode "qr". Objects either are QR decompositions or they are not.

Value

The QR decomposition of the matrix as computed by LINPACK or LAPACK. The components in the returned value correspond directly to the values returned by DQRDC/DGGEQP3/ZGGEQP3.

<code>qr</code>	a matrix with the same dimensions as <code>x</code> . The upper triangle contains the R of the decomposition and the lower triangle contains information on the Q of the decomposition (stored in compact form). Note that the storage used by DQRDC and DGGEQP3 differs.
<code>qraux</code>	a vector of length <code>ncol(x)</code> which contains additional information on Q .
<code>rank</code>	the rank of <code>x</code> as computed by the decomposition: always full rank in the LAPACK case.
<code>pivot</code>	information on the pivoting strategy used during the decomposition.

Non-complex QR objects computed by LAPACK have the attribute "useLAPACK" with value TRUE.

Note

To compute the determinant of a matrix (do you *really* need it?), the QR decomposition is much more efficient than using Eigen values (`eigen`). See `det`.

Using LAPACK (including in the complex case) uses column pivoting and does not attempt to detect rank-deficient matrices.

`det` (using `qr`) to compute the determinant of a matrix.

Examples

```

hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
h9 <- hilbert(9); h9
qr(h9)$rank          #--> only 7
qrh9 <- qr(h9, tol = 1e-10)
qrh9$rank            #--> 9
##-- Solve linear equation system H %*% x = y :
y <- 1:9/10
x <- qr.solve(h9, y, tol = 1e-10) # or equivalently :
x <- qr.coef(qrh9, y) #-- is == but much better than
                        #-- solve(h9) %*% y
h9 %*% x              # = y

## overdetermined system
A <- matrix(runif(12), 4)
b <- 1:4
qr.solve(A, b) # or solve(qr(A), b)
solve(qr(A, LAPACK=TRUE), b)
# this is a least-squares solution, cf. lm(b ~ 0 + A)

## underdetermined system
A <- matrix(runif(12), 3)
b <- 1:3
qr.solve(A, b)
solve(qr(A, LAPACK=TRUE), b)
# solutions will have one zero, not necessarily the same one

```

QR.Auxiliaries

*Reconstruct the Q, R, or X Matrices from a QR Object***Description**

Returns the original matrix from which the object was constructed or the components of the decomposition.

Usage

```

qr.X(qr, complete = FALSE, ncol =)
qr.Q(qr, complete = FALSE, Dvec =)
qr.R(qr, complete = FALSE)

```

Arguments

<code>qr</code>	object representing a QR decomposition. This will typically have come from a previous call to <code>qr</code> or <code>lsfit</code> .
<code>complete</code>	logical expression of length 1. Indicates whether an arbitrary orthogonal completion of the Q or X matrices is to be made, or whether the R matrix is to be completed by binding zero-value rows beneath the square upper triangle.
<code>ncol</code>	integer in the range $1:nrow(qr\$qr)$. The number of columns to be in the reconstructed X . The default when <code>complete</code> is <code>FALSE</code> is the first $\min(ncol(X), nrow(X))$ columns of the original X from which the <code>qr</code>

object was constructed. The default when `complete` is `TRUE` is a square matrix with the original X in the first `ncol(X)` columns and an arbitrary orthogonal completion (unitary completion in the complex case) in the remaining columns.

`Dvec` vector (not matrix) of diagonal values. Each column of the returned Q will be multiplied by the corresponding diagonal value. Defaults to all 1s.

Value

`qr.X` returns X , the original matrix from which the `qr` object was constructed, provided `ncol(X) <= nrow(X)`. If `complete` is `TRUE` or the argument `ncol` is greater than `ncol(X)`, additional columns from an arbitrary orthogonal (unitary) completion of X are returned.

`qr.Q` returns part or all of Q , the order-`nrow(X)` orthogonal (unitary) transformation represented by `qr`. If `complete` is `TRUE`, Q has `nrow(X)` columns. If `complete` is `FALSE`, Q has `ncol(X)` columns. When `Dvec` is specified, each column of Q is multiplied by the corresponding value in `Dvec`.

`qr.R` returns R . The number of rows of R is either `nrow(X)` or `ncol(X)` (and may depend on whether `complete` is `TRUE` or `FALSE`).

[qr](#), [qr.qy](#).

Examples

```
p <- ncol(x <- LifeCycleSavings[,-1]) # not the 'sr'
qrstr <- qr(x) # dim(x) == c(n,p)
qrstr $ rank # = 4 = p
Q <- qr.Q(qrstr) # dim(Q) == dim(x)
R <- qr.R(qrstr) # dim(R) == ncol(x)
X <- qr.X(qrstr) # X == x
range(X - as.matrix(x)) # ~ < 6e-12
## X == Q %*% R if there has been no pivoting, as here.
Q %*% R
```

quit

Terminate an R Session

Description

The function `quit` or its alias `q` terminate the current `R` session.

Usage

```
quit(save = "default", status = 0, runLast = TRUE)
  q(save = "default", status = 0, runLast = TRUE)
.Last <- function(x) { ..... }
```

Arguments

save	a character string indicating whether the environment (workspace) should be saved, one of "no", "yes", "ask" or "default".
status	the (numerical) error status to be returned to the operating system, where relevant. Conventionally 0 indicates successful completion.
runLast	should <code>.Last()</code> be executed?

Details

save must be one of "no", "yes", "ask" or "default". In the first case the workspace is not saved, in the second it is saved and in the third the user is prompted and can also decide *not* to quit. The default is to ask in interactive use but may be overridden by command-line arguments (which must be supplied in non-interactive use).

Immediately *before* terminating, the function `.Last()` is executed if it exists and `runLast` is true. If in interactive use there are errors in the `.Last` function, control will be returned to the command prompt, so do test the function thoroughly. There is a system analogue, `.Last.sys()`, which is run after `.Last()` if `runLast` is true.

Some error statuses are used by R itself. The default error handler for non-interactive use effectively calls `q("no", 1, FALSE)` and returns error code 1. Error status 2 is used for R 'suicide', that is a catastrophic failure, and other small numbers are used by specific ports for initialization failures. It is recommended that users choose statuses of 10 or more.

Valid values of `status` are system-dependent, but 0:255 are normally valid. (Many OSes will report the last byte of the value, that is report the number modulo 256. But not all.)

`.First` for setting things on startup.

Examples

```
## Not run:
## Unix-flavour example
.Last <- function() {
  cat("Now sending PostScript graphics to the printer:\n")
  system("lpr Rplots.ps")
  cat("bye bye...\n")
}
quit("yes")
## End(Not run)
```

 Quotes

*Quotes***Description**

Descriptions of the various uses of quoting in R.

Details

Three types of quote are part of the syntax of R: single and double quotation marks and the back-tick (or back quote, ```). In addition, backslash is used for quoting the following characters inside character constants.

Character constants

Single and double quotes delimit character constants. They can be used interchangeably but double quotes are preferred (and character constants are printed using double quotes), so single quotes are normally only used to delimit character constants containing double quotes.

Backslash is used to start an escape sequence inside character constants. Unless specified in the following table, an escaped character is interpreted as the character itself. (Note that the parser will warn about most such uses, as they are most often erroneous, e.g. using `\.` where `\\.` was intended.)

Single quotes need to be escaped by backslash in single-quoted strings, and double quotes in double-quoted strings.

<code>\n</code>	newline
<code>\r</code>	carriage return
<code>\t</code>	tab
<code>\b</code>	backspace
<code>\a</code>	alert (bell)
<code>\f</code>	form feed
<code>\v</code>	vertical tab
<code>\\</code>	backslash <code>\</code>
<code>\nnn</code>	character with given octal code (1, 2 or 3 digits)
<code>\xnn</code>	character with given hex code (1 or 2 hex digits)
<code>\unnnn</code>	Unicode character with given code (1–4 hex digits)
<code>\Unnnnnnnn</code>	Unicode character with given code (1–8 hex digits)

The last two are only supported on versions of R built with MBCS support: they are an error on other versions. Alternative forms are `\u{nnnn}` and `\U{nnnnnnnn}`. All except the Unicode escape sequences are also supported when reading character strings by `scan` and `read.table` if `allowEscapes = TRUE`.

These forms will also be used by `print.default` when outputting non-printable characters (including backslash).

Note that as from R 2.8.0 embedded nuls are not allowed in character strings, so using escapes (such as `\0`) for a nul will result in the string being truncated at that point (usually with a warning).

Names and Identifiers

Identifiers consist of a sequence of letters, digits, the period (.) and the underscore. They must not start with a digit nor underscore, nor with a period followed by a digit. [Reserved](#) words are not valid identifiers.

The definition of a *letter* depends on the current locale, but only ASCII digits are considered to be digits.

Such identifiers are also known as *syntactic names* and may be used directly in R code. Almost always, other names can be used provided they are quoted. The preferred quote is the backtick (`), and [deparse](#) will normally use it, but under many circumstances single or double quotes can be used (as a character constant will often be converted to a name). One place where backticks may be essential is to delimit variable names in formulae: see [formula](#).

See Also

[Syntax](#) for other aspects of the syntax.

[sQuote](#) for quoting English text.

[shQuote](#) for quoting OS commands.

The *R Language Definition* manual.

R.Version

Version Information

Description

`R.Version()` provides detailed information about the version of R running.

`R.version` is a variable (a [list](#)) holding this information (and `version` is a copy of it for S compatibility).

Usage

```
R.Version()
R.version
R.version.string
version
```

Value

`R.Version` returns a list with character-string components

<code>platform</code>	the platform for which R was built. A triplet of the form CPU-VENDOR-OS, as determined by the configure script. E.g. "i586-unknown-linux" or "i386-pc-mingw32".
<code>arch</code>	the architecture (CPU) R was built on/for.
<code>os</code>	the underlying operating system
<code>system</code>	CPU and OS, separated by a comma.
<code>status</code>	the status of the version (e.g., "Alpha")
<code>major</code>	the major version number

minor	the minor version number, including the patchlevel
year	the year the version was released
month	the month the version was released
day	the day the version was released
svn rev	the Subversion revision number, which should be either "unknown" or a single number. (A range of numbers or a number with 'M' or 'S' appended indicates inconsistencies in the sources used to build this version of R.)
language	always "R".
version.string	a character string concatenating some of the info above, useful for plotting, etc.

`R.version` and `version` are lists of class "simple.list" which has a `print` method.

Note

Do *not* use `R.version$os` to test the platform the code is running on: use `.Platform$OS.type` instead. Slightly different versions of the OS may report different values of `R.version$os`, as may different versions of R.

`R.version.string` is a copy of `R.version$version.string` for simplicity and backwards compatibility.

See Also

[sessionInfo](#) which provides additional information; [getRversion](#) typically used inside R code, [.Platform](#).

Examples

```
require(graphics)

R.version$os # to check how lucky you are ...
plot(0) # any plot
mtext(R.version.string, side=1,line=4,adj=1) # a useful bottom-right note
```

Description

`.Random.seed` is an integer vector, containing the random number generator (RNG) **state** for random number generation in R. It can be saved and restored, but should not be altered by the user.

`RNGkind` is a more friendly interface to query or set the kind of RNG in use.

`RNGversion` can be used to set the random generators as they were in an earlier R version (for reproducibility).

`set.seed` is the recommended way to specify seeds.

Usage

```
.Random.seed <- c(rng.kind, n1, n2, ...)
save.seed <- .Random.seed

RNGkind(kind = NULL, normal.kind = NULL)
RNGversion(vstr)
set.seed(seed, kind = NULL, normal.kind = NULL)
```

Arguments

<code>kind</code>	character or NULL. If <code>kind</code> is a character string, set R's RNG to the kind desired. Use "default" to return to the R default. See 'Details' for the interpretation of NULL.
<code>normal.kind</code>	character string or NULL. If it is a character string, set the method of Normal generation. Use "default" to return to the R default. NULL makes no change.
<code>seed</code>	a single value, interpreted as an integer.
<code>vstr</code>	a character string containing a version number, e.g., "1.6.2"
<code>rng.kind</code>	integer code in 0:k for the above kind.
<code>n1, n2, ...</code>	integers. See the details for how many are required (which depends on <code>rng.kind</code>).

Details

The currently available RNG kinds are given below. `kind` is partially matched to this list. The default is "Mersenne-Twister".

"Wichmann-Hill" The seed, `.Random.seed[-1] == r[1:3]` is an integer vector of length 3, where each `r[i]` is in $1:(p[i] - 1)$, where `p` is the length 3 vector of primes, `p = (30269, 30307, 30323)`. The Wichmann-Hill generator has a cycle length of 6.9536×10^{12} ($= \text{prod}(p-1) / 4$, see *Applied Statistics* (1984) **33**, 123 which corrects the original article).

"Marsaglia-Multicarry": A *multiply-with-carry* RNG is used, as recommended by George Marsaglia in his post to the mailing list 'sci.stat.math'. It has a period of more than 2^{60} and has passed all tests (according to Marsaglia). The seed is two integers (all values allowed).

"Super-Duper": Marsaglia's famous Super-Duper from the 70's. This is the original version which does *not* pass the MTUPLE test of the Diehard battery. It has a period of $\approx 4.6 \times 10^{18}$ for most initial seeds. The seed is two integers (all values allowed for the first seed: the second must be odd).

We use the implementation by Reeds et al. (1982-84).

The two seeds are the Tausworthe and congruence long integers, respectively. A one-to-one mapping to S's `.Random.seed[1:12]` is possible but we will not publish one, not least as this generator is **not** exactly the same as that in recent versions of S-PLUS.

"Mersenne-Twister": From Matsumoto and Nishimura (1998). A twisted GFSR with period $2^{19937} - 1$ and equidistribution in 623 consecutive dimensions (over the whole period). The 'seed' is a 624-dimensional set of 32-bit integers plus a current position in that set.

"Knuth-TAOCP-2002": A 32-bit integer GFSR using lagged Fibonacci sequences with subtraction. That is, the recurrence used is

$$X_j = (X_{j-100} - X_{j-37}) \bmod 2^{30}$$

and the 'seed' is the set of the 100 last numbers (actually recorded as 101 numbers, the last being a cyclic shift of the buffer). The period is around 2^{129} .

"Knuth-TAOCP": An earlier version from Knuth (1997).

The 2002 version was not backwards compatible with the earlier version: the initialization of the GFSR from the seed was altered. R did not allow you to choose consecutive seeds, the reported 'weakness', and already scrambled the seeds.

Initialization of this generator is done in interpreted R code and so takes a short but noticeable time.

"user-supplied": Use a user-supplied generator. See `Random.user` for details.

`normal.kind` can be "Kinderman-Ramage", "Buggy Kinderman-Ramage" (not for `set.seed`), "Ahrens-Dieter", "Box-Muller", "Inversion" (the default), or "user-supplied". (For inversion, see the reference in `qnorm`.) The Kinderman-Ramage generator used in versions prior to 1.7.1 (now called "Buggy" had several approximation errors and should only be used for reproduction of older results. The "Box-Muller" generator is stateful as pairs of normals are generated and returned sequentially. The state is reset whenever it is selected (even if it is the current normal generator) and when `kind` is changed.

`set.seed` uses its single integer argument to set as many seeds as are required. It is intended as a simple way to get quite different seeds by specifying small integer arguments, and also as a way to get valid seed sets for the more complicated methods (especially "Mersenne-Twister" and "Knuth-TAOCP").

The use of `kind=NULL` or `normal.kind=NULL` in `RNGkind` or `set.seed` selects the currently-used generator (including as from R 2.8.0 that used in the previous session if the workspace has been restored): if no generator has been used it selects "default".

Value

`.Random.seed` is an `integer` vector whose first element *codes* the kind of RNG and normal generator. The lowest two decimal digits are in $0:(k-1)$ where k is the number of available RNGs. The hundreds represent the type of normal generator (starting at 0).

In the underlying C, `.Random.seed[-1]` is unsigned; therefore in R `.Random.seed[-1]` can be negative, due to the representation of an unsigned integer by a signed integer.

`RNGkind` returns a two-element character vector of the RNG and normal kinds selected *before* the call, invisibly if either argument is not NULL. A type starts a session as the default, and is selected either by a call to `RNGkind` or by setting `.Random.seed` in the workspace.

`RNGversion` returns the same information as `RNGkind` about the defaults in a specific R version.

`set.seed` returns NULL, invisibly.

Note

Initially, there is no seed; a new one is created from the current time when one is required. Hence, different sessions started at (sufficiently) different times will give different simulation results, by default. However, the seed might be restored from a previous session if a previously saved workspace is restored.

`.Random.seed` saves the seed set for the uniform random-number generator, at least for the system generators. It does not necessarily save the state of other generators, and in particular does not save the state of the Box-Muller normal generator. If you want to reproduce work later, call `set.seed` (preferably with explicit values for `kind` and `normal.kind`) rather than `set.Random.seed`.

The object `.Random.seed` is only looked for in the user's workspace.

Do not rely on randomness of low-order bits from RNGs. Most of the supplied uniform generators return 32-bit integer values that are converted to doubles, so they take at most 2^{32} distinct values and long runs will return duplicated values (Wichmann-Hill is the exception, and all give at least 30 varying bits.)

## Reset:
RNGkind(ok[1])

## ----
sum(duplicated(runif(1e6))) # around 110 for default generator
## and we would expect about almost sure duplicates beyond about
qbirthday(1-1e-6, classes=2e9) # 235,000

```

Random.user

User-supplied Random Number Generation

Description

Function `RNGkind` allows user-coded uniform and normal random number generators to be supplied. The details are given here.

Details

A user-specified uniform RNG is called from entry points in dynamically-loaded compiled code. The user must supply the entry point `user_unif_rand`, which takes no arguments and returns a *pointer to a double*. The example below will show the general pattern.

Optionally, the user can supply the entry point `user_unif_init`, which is called with an unsigned int argument when `RNGkind` (or `set.seed`) is called, and is intended to be used to initialize the user's RNG code. The argument is intended to be used to set the 'seeds'; it is the seed argument to `set.seed` or an essentially random seed if `RNGkind` is called.

If only these functions are supplied, no information about the generator's state is recorded in `.Random.seed`. Optionally, functions `user_unif_nseed` and `user_unif_seedloc` can

be supplied which are called with no arguments and should return pointers to the number of seeds and to an integer array of seeds. Calls to `GetRNGstate` and `PutRNGstate` will then copy this array to and from `.Random.seed`.

A user-specified normal RNG is specified by a single entry point `user_norm_rand`, which takes no arguments and returns a *pointer to a double*.

Warning

As with all compiled code, mis-specifying these functions can crash R. Do include the `'R_ext/Random.h'` header file for type checking.

Examples

```
## Not run:
## Marsaglia's congruential PRNG
#include <R_ext/Random.h>

static Int32 seed;
static double res;
static int nseed = 1;

double * user_unif_rand()
{
    seed = 69069 * seed + 1;
    res = seed * 2.32830643653869e-10;
    return &res;
}

void user_unif_init(Int32 seed_in) { seed = seed_in; }
int * user_unif_nseed() { return &nseed; }
int * user_unif_seedloc() { return (int *) &seed; }

/* ratio-of-uniforms for normal */
#include <math.h>
static double x;

double * user_norm_rand()
{
    double u, v, z;
    do {
        u = unif_rand();
        v = 0.857764 * (2. * unif_rand() - 1);
        x = v/u; z = 0.25 * x * x;
        if (z < 1. - u) break;
        if (z > 0.259/u + 0.35) continue;
    } while (z > -log(u));
    return &x;
}

## Use under Unix:
R CMD SHLIB urand.c
R
> dyn.load("urand.so")
> RNGkind("user")
> runif(10)
> .Random.seed
```

```

> RNGkind(, "user")
> rnorm(10)
> RNGkind()
[1] "user-supplied" "user-supplied"
## End(Not run)

```

range

Range of Values

Description

`range` returns a vector containing the minimum and maximum of all the given arguments.

Usage

```

range(..., na.rm = FALSE)

## Default S3 method:
range(..., na.rm = FALSE, finite = FALSE)

```

Arguments

`...` any [numeric](#) or character objects.

`na.rm` logical, indicating if `NA`'s should be omitted.

`finite` logical, indicating if all non-finite elements should be omitted.

Details

`range` is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and dispatch is on the first argument.

If `na.rm` is `FALSE`, `NA` and `NaN` values in any of the arguments will cause `NA` values to be returned, otherwise `NA` values are ignored.

If `finite` is `TRUE`, the minimum and maximum of all finite values is computed, i.e., `finite=TRUE` *includes* `na.rm=TRUE`.

A special situation occurs when there is no (after omission of `NA`s) nonempty argument left, see [min](#).

S4 methods

This is part of the S4 [Summary](#) group generic. Methods for it must use the signature `x, ..., na.rm`.

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

The [extendrange\(\)](#) utility; [min](#), [max](#), [Methods](#).

Examples

```

(r.x <- range(stats::rnorm(100)))
diff(r.x) # the SAMPLE range

x <- c(NA, 1:3, -1:1/0); x
range(x)
range(x, na.rm = TRUE)
range(x, finite = TRUE)

```

rank	<i>Sample Ranks</i>
------	---------------------

Description

Returns the sample ranks of the values in a vector. Ties (i.e., equal values) and missing values can be handled in several ways.

Usage

```

rank(x, na.last = TRUE,
      ties.method = c("average", "first", "random", "max", "min"))

```

Arguments

<code>x</code>	a numeric, complex, character or logical vector.
<code>na.last</code>	for controlling the treatment of NAs. If TRUE, missing values in the data are put last; if FALSE, they are put first; if NA, they are removed; if "keep" they are kept with rank NA.
<code>ties.method</code>	a character string specifying how ties are treated, see 'Details'; can be abbreviated.

Details

If all components are different (and no NAs), the ranks are well defined, with values in `seq_len(x)`. With some values equal (called 'ties'), the argument `ties.method` determines the result at the corresponding indices. The "first" method results in a permutation with increasing values at each index set of ties. The "random" method puts these in random order whereas the default, "average", replaces them by their mean, and "max" and "min" replaces them by their maximum and minimum respectively, the latter being the typical sports ranking.

NA values are never considered to be equal: for `na.last = TRUE` and `na.last = FALSE` they are given distinct ranks in the order in which they occur in `x`.

NB: `rank` is not itself generic but `xtfrm` is, and `rank(xtfrm(x), ...)` will have the desired result if there is a `xtfrm` method. Otherwise, `rank` will make use of `==`, `>` and `is.na` methods for classed objects, possibly rather slowly.

Value

A numeric vector of the same length as `x` with names copied from `x` (unless `na.last = NA`, when missing values are removed). The vector is of integer type unless `ties.method = "average"` when it is of double type (whether or not there are any ties).

[order](#) and [sort](#).

Examples

```
(r1 <- rank(x1 <- c(3, 1, 4, 15, 92)))
x2 <- c(3, 1, 4, 1, 5, 9, 2, 6, 5, 3, 5)
names(x2) <- letters[1:11]
(r2 <- rank(x2)) # ties are averaged

## rank() is "idempotent": rank(rank(x)) == rank(x) :
stopifnot(rank(r1) == r1, rank(r2) == r2)

## ranks without averaging
rank(x2, ties.method= "first") # first occurrence wins
rank(x2, ties.method= "random") # ties broken at random
rank(x2, ties.method= "random") # and again

## keep ties ties, no average
(rma <- rank(x2, ties.method= "max")) # as used classically
(rmi <- rank(x2, ties.method= "min")) # as in Sports
stopifnot(rma + rmi == round(r2 + r2))
```

rapply

Recursively Apply a Function to a List

Description

rapply is a recursive version of [lapply](#).

Usage

```
rapply(object, f, classes = "ANY", deflt = NULL,
       how = c("unlist", "replace", "list"), ...)
```

Arguments

object	A list.
f	A function of a single argument.
classes	A character vector of class names, or "ANY" to match any class.
deflt	The default result (not used if how = "replace").
how	A character string matching the three possibilities given: see ‘Details’.
...	additional arguments passed to the call to f.

Details

This function has two basic modes. If `how = "replace"`, each element of the list which is not itself a list and has a class included in `classes` is replaced by the result of applying `f` to the element.

If the mode is `how = "list"` or `how = "unlist"`, the list is copied, all non-list elements which have a class included in `classes` are replaced by the result of applying `f` to the element and all others are replaced by `deflt`. Finally, if `how = "unlist"`, `unlist(recursive = TRUE)` is called on the result.

The semantics differ in detail from `lapply`: in particular the arguments are evaluated before calling the C code.

Value

If `how = "unlist"`, a vector, otherwise a list of similar structure to `object`.

References

Chambers, J. A. (1998) *Programming with Data*. Springer.
(`rapply` is only described briefly there.)

See Also

`lapply`, `dendraply`.

Examples

```
X <- list(list(a=pi, b=list(c=1:1)), d="a test")
rapply(X, function(x) x, how="replace")
rapply(X, sqrt, classes="numeric", how="replace")
rapply(X, nchar, classes="character",
       deflt = as.integer(NA), how="list")
rapply(X, nchar, classes="character",
       deflt = as.integer(NA), how="unlist")
rapply(X, nchar, classes="character", how="unlist")
rapply(X, log, classes="numeric", how="replace", base=2)
```

raw

Raw Vectors

Description

Creates or tests for objects of type "raw".

Usage

```
raw(length = 0)
as.raw(x)
is.raw(x)
```

Arguments

length	desired length.
x	object to be coerced.

Details

The raw type is intended to hold raw bytes. It is possible to extract subsequences of bytes, and to replace elements (but only by elements of a raw vector). The relational operators (see [Comparison](#)) work, as do the logical operators (see [Logic](#)) with a bitwise interpretation.

A raw vector is printed with each byte separately represented as a pair of hex digits. If you want to see a character representation (with escape sequences for non-printing characters) use [rawToChar](#).

Coercion to raw treats the input values as representing a small (decimal) integers, so the input is first coerced to integer, and then values which are outside the range [0 . . . 255] or are NA are set to 0 (the nul byte).

Value

`raw` creates a raw vector of the specified length. Each element of the vector is equal to 0. Raw vectors are used to store fixed-length sequences of bytes.

`as.raw` attempts to coerce its argument to be of raw type. The (elementwise) answer will be 0 unless the coercion succeeds.

`is.raw` returns true if and only if `typeof(x) == "raw"`.

See Also

[charToRaw](#), [rawShift](#), etc.

Examples

```
xx <- raw(2)
xx[1] <- as.raw(40)      # NB, not just 40.
xx[2] <- charToRaw("A")
xx

x <- "A test string"
(y <- charToRaw(x))
is.vector(y) # TRUE
rawToChar(y)
is.raw(x)
is.raw(y)

isASCII <- function(txt) all(charToRaw(txt) <= as.raw(127))
isASCII(x) # true
isASCII("\x9c25.63") # false (in Latin-1, this is an amount in UK pounds)
```

rawConnection	<i>Raw Connections</i>
---------------	------------------------

Description

Input and output raw connections.

Usage

```
rawConnection(object, open = "r")  
  
rawConnectionValue(con)
```

Arguments

object	character or raw vector. A description of the connection. For an input this is an R raw vector object, and for an output connection the name for the connection.
open	character. Any of the standard connection open modes.
con	An output raw connection.

Details

An input raw connection is opened and the raw vector is copied at the time the connection object is created, and `close` destroys the copy.

An output raw connection is opened and creates an R raw vector internally. The raw vector can be retrieved *via* `rawConnectionValue`.

If a connection is open for both input and output the initial raw vector supplied is copied when the connections is open

Value

For `rawConnection`, a connection object of class `"rawConnection"` which inherits from class `"connection"`.

For `rawConnectionValue`, a raw vector.

Note

As output raw connections keep the internal raw vector up to date call-by-call, they are relatively expensive to use (although over-allocation is used), and it may be better to use an anonymous `file()` connection to collect output.

On (rare) platforms where `vsprintf` does not return the needed length of output there is a 100,000 character limit on the length of line for output connections: longer lines will be truncated with a warning.

See Also

[connections](#), [showConnections](#).

Examples

```
zz <- rawConnection(raw(0), "r+") # start with empty raw vector
writeBin(LETTERS, zz)
seek(zz, 0)
readLines(zz) # raw vector has embedded nuls
seek(zz, 0)
writeBin(letters[1:3], zz)
rawConnectionValue(zz)
close(zz)
```

rawConversion	<i>Convert to or from Raw Vectors</i>
---------------	---------------------------------------

Description

Conversion and manipulation of objects of type "raw".

Usage

```
charToRaw(x)
rawToChar(x, multiple = FALSE)

rawShift(x, n)

rawToBits(x)
intToBits(x)
packBits(x, type = c("raw", "integer"))
```

Arguments

x	object to be converted or shifted.
multiple	logical: should the conversion be to a single character string or multiple individual characters?
n	the number of bits to shift. Positive numbers shift right and negative numbers shift left: allowed values are $-8 \dots 8$.
type	the result type.

Details

packBits accepts raw, integer or logical inputs, the last two without any NAs.

Note that 'bytes' are not necessarily the same as characters, e.g. in UTF-8 domains.

Value

charToRaw converts a length-one character string to raw bytes. It does so without taking into account any declared encoding (see [Encoding](#)).

rawToChar converts raw bytes either to a single character string or a character vector of single bytes (with "" for 0). (Note that a single character string could contain embedded nuls, in which case it will be truncated at the first nul with a warning.) In either case it is possible to create a result which is invalid in a multibyte locale, e.g. one using UTF-8.

`rawToBits` returns a raw vector of 8 times the length of a raw vector with entries 0 or 1. `intToBits` returns a raw vector of 32 times the length of an integer vector with entries 0 or 1. (Non-integral numeric values are truncated to integers.) In both cases the unpacking is least-significant bit first.

`packBits` packs its input (using only the lowest bit for raw or integer vectors) least-significant bit first to a raw or integer vector.

Examples

```
x <- "A test string"
(y <- charToRaw(x))
is.vector(y) # TRUE

rawToChar(y)
rawToChar(y, multiple = TRUE)
(xx <- c(y, as.raw(0), charToRaw("more")))
rawToChar(xx)
xxx <- xx
xxx[length(y)+1] <- charToRaw("&")
xxx
rawToChar(xxx)

rawShift(y, 1)
rawShift(y, -2)

rawToBits(y)
```

Description

Utilities for converting files in R documentation (Rd) format to other formats or create indices from them, and for converting documentation in other formats to Rd format.

Usage

```
R CMD Rdconv [options] file
R CMD Rd2dvi [options] files
R CMD Rd2txt [options] file
R CMD Sd2Rd [options] file
```

Arguments

<code>file</code>	the path to a file to be processed.
<code>files</code>	a list of file names specifying the R documentation sources to use, by either giving the paths to the files, or the path to a directory with the sources of a package.
<code>options</code>	further options to control the processing, or for obtaining information about usage and version of the utility.

Details

`Rdconv` converts Rd format to other formats. Currently, plain text, HTML, LaTeX, S version 3 (Sd), and S version 4 (.sgml) formats are supported. It can also extract the examples for run-time testing.

`Rd2dvi` and `Rd2txt` are user-level programs for producing DVI/PDF output or pretty text output from Rd sources. `Rd2dvi` will make use of environment variables `R_PAPERSIZE` (set by `R CMD`, with a default set when `R` was installed) and `xdvi` (the DVI previewer, default `xdvi`), and `R_PDFVIEWER` (the PDF previewer). (Valid values for `R_PAPERSIZE` are `a4`, `letter`, `legal` and `executive`.)

`Sd2Rd` converts S (version 3 or 4) documentation formats to Rd format.

Use `R CMD foo --help` to obtain usage information on utility `foo`.

Note

Conversion to S version 3/4 formats is rough: there are some ‘.Rd’ constructs for which there is no natural analogue. They are intended as a starting point for hand-tuning.

See Also

The chapter “Processing Rd format” in the “Writing R Extensions” manual.

readBin

Transfer Binary Data To and From Connections

Description

Read binary data from a connection, or write binary data to a connection.

Usage

```
readBin(con, what, n = 1, size = NA_integer_, signed = TRUE,
        endian = .Platform$endian)
```

```
writeBin(object, con, size = NA_integer_,
         endian = .Platform$endian)
```

Arguments

<code>con</code>	A connection object or a character string naming a file or a raw vector.
<code>what</code>	Either an object whose mode will give the mode of the vector to be read, or a character vector of length one describing the mode: one of "numeric", "double", "integer", "int", "logical", "complex", "character", "raw".
<code>n</code>	integer. The (maximal) number of records to be read. You can use an over-estimate here, but not too large as storage is reserved for <code>n</code> items.
<code>size</code>	integer. The number of bytes per element in the byte stream. The default, <code>NA_integer_</code> , uses the natural size. Size changing is not supported for raw and complex vectors.

signed	logical. Only used for integers of sizes 1 and 2, when it determines if the quantity on file should be regarded as a signed or unsigned integer.
endian	The endian-ness ("big" or "little" of the target system for the file. Using "swap" will force swapping endian-ness.
object	An R object to be written to the connection.

Details

If `con` is a character string, the functions call `file` to obtain an file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call in an appropriate mode (binary read or write) and then closed again. An open connection must be in binary mode.

If `readBin` is called with `con` a raw vector, the data in the vector is used as input. If `writeBin` is called with `con` a raw vector, it is just an indication that a raw vector should be returned.

If `size` is specified and not the natural size of the object, each element of the vector is coerced to an appropriate type before being written or as it is read. Possible sizes are 1, 2, 4 and possibly 8 for integer or logical vectors, and 4, 8 and possibly 12/16 for numeric vectors. (Note that coercion occurs as signed types except if `signed = FALSE` when reading integers of sizes 1 and 2.) Changing sizes is unlikely to preserve NAs, and the extended precision sizes are unlikely to be portable across platforms.

`readBin` and `writeBin` read and write C-style zero-terminated character strings. Input strings are limited to 10000 characters. `readChar` and `writeChar` can be used to read and write fixed-length strings. No check is made that the string is valid in the current locale.

Handling R's missing and special (`Inf`, `-Inf` and `NaN`) values is discussed in the *R Data Import/Export* manual.

Value

For `readBin`, a vector of appropriate mode and length the number of items read (which might be less than `n`).

For `writeBin`, a raw vector (if `con` is a raw vector) or invisibly `NULL`.

Note

Integer read/writes of size 8 will be available if either C type `long` is of size 8 bytes or C type `long long` exists and is of size 8 bytes.

Real read/writes of size `sizeof(long double)` (usually 12 or 16 bytes) will be available only if that type is available and different from `double`.

If `readBin(what = character())` is used incorrectly on a file which does not contain C-style character strings, warnings (usually many) are given. From a file or connection, the input will be broken into pieces of length 10000 with any final part being discarded.

See Also

The *R Data Import/Export* manual.

`readChar` to read/write fixed-length strings.

`connections`, `readLines`, `writeLines`.

`.Machine` for the sizes of `long`, `long long` and `long double`.

Examples

```

zz <- file("testbin", "wb")
writeBin(1:10, zz)
writeBin(pi, zz, endian="swap")
writeBin(pi, zz, size=4)
writeBin(pi^2, zz, size=4, endian="swap")
writeBin(pi+3i, zz)
writeBin("A test of a connection", zz)
z <- paste("A very long string", 1:100, collapse=" + ")
writeBin(z, zz)
if(.Machine$sizeof.long == 8 || .Machine$sizeof.longlong == 8)
  writeBin(as.integer(5^(1:10)), zz, size = 8)
if((s <- .Machine$sizeof.longdouble) > 8)
  writeBin((pi/3)^(1:10), zz, size = s)
close(zz)

zz <- file("testbin", "rb")
readBin(zz, integer(), 4)
readBin(zz, integer(), 6)
readBin(zz, numeric(), 1, endian="swap")
readBin(zz, numeric(), size=4)
readBin(zz, numeric(), size=4, endian="swap")
readBin(zz, complex(), 1)
readBin(zz, character(), 1)
z2 <- readBin(zz, character(), 1)
if(.Machine$sizeof.long == 8 || .Machine$sizeof.longlong == 8)
  readBin(zz, integer(), 10, size = 8)
if((s <- .Machine$sizeof.longdouble) > 8)
  readBin(zz, numeric(), 10, size = s)
close(zz)
unlink("testbin")
stopifnot(z2 == z)

## signed vs unsigned ints
zz <- file("testbin", "wb")
x <- as.integer(seq(0, 255, 32))
writeBin(x, zz, size=1)
writeBin(x, zz, size=1)
x <- as.integer(seq(0, 60000, 10000))
writeBin(x, zz, size=2)
writeBin(x, zz, size=2)
close(zz)
zz <- file("testbin", "rb")
readBin(zz, integer(), 8, size=1)
readBin(zz, integer(), 8, size=1, signed=FALSE)
readBin(zz, integer(), 7, size=2)
readBin(zz, integer(), 7, size=2, signed=FALSE)
close(zz)
unlink("testbin")

## use of raw
z <- writeBin(pi^{1:5}, raw(), size = 4)
readBin(z, numeric(), 5, size = 4)
z <- writeBin(c("a", "test", "of", "character"), raw())
rawToChar(z)
readBin(z, character(), 4)

```

readChar

Transfer Character Strings To and From Connections

Description

Transfer character strings to and from connections, without assuming they are null-terminated on the connection.

Usage

```
readChar(con, nchars, useBytes = FALSE)

writeChar(object, con,
          nchars = nchar(object, type="chars"), eos = "")
```

Arguments

con	A connection object, or a character string naming a file, or a raw vector.
nchars	integer, giving the lengths in characters of (unterminated) character strings to be read or written. Must be ≥ 0 and not missing.
useBytes	logical: should <code>nchars</code> be regarded as a number of bytes not characters in a multi-byte locale?
object	A character vector to be written to the connection, at least as long as <code>nchars</code> .
eos	'end of string': character string . The terminator to be written after each string, followed by an ASCII <code>nul</code> ; use <code>NULL</code> for no terminator at all.

Details

These functions complement `readBin` and `writeBin` which read and write C-style zero-terminated character strings. They are for strings of known length, and can optionally write an end-of-string mark. They are intended only for character strings valid in the current locale.

If `con` is a character string, the functions call `file` to obtain an file connection which is opened for the duration of the function call.

If the connection is open it is read/written from its current position. If it is not open, it is opened for the duration of the call in an appropriate mode (binary read or write) and then closed again. An open connection must be in binary mode.

If `readChar` is called with `con` a raw vector, the data in the vector is used as input. If `writeChar` is called with `con` a raw vector, it is just an indication that a raw vector should be returned.

Character strings containing ASCII `nul`(s) will be read correctly by `readChar` but truncated at the first `nul` with a warning.

If the character length requested for `readChar` is longer than the data available on the connection, what is available is returned. For `writeChar` if too many characters are requested the output is zero-padded, with a warning.

Missing strings are written as NA.

Value

For `readChar`, a character vector of length the number of items read (which might be less than `length(nchars)`).

For `writeChar`, a raw vector (if `con` is a raw vector) or invisibly `NULL`.

Note

Earlier versions of R allowed embedded nul bytes within character strings, but not R \geq 2.8.0. `readChar` was commonly used to read fixed-size zero-padded byte fields for which `readBin` was unsuitable. `readChar` can still be used for such fields if there are no embedded nuls: otherwise `readBin(what="raw")` provides an alternative.

`nchars` will be interpreted in bytes not characters in a non-UTF-8 multi-byte locale, with a warning.

There is little validity checking of UTF-8 reads.

See Also

The *R Data Import/Export* manual.

[connections](#), [readLines](#), [writeLines](#), [readBin](#)

Examples

```
## test fixed-length strings
zz <- file("testchar", "wb")
x <- c("a", "this will be truncated", "abc")
nc <- c(3, 10, 3)
writeChar(x, zz, nc, eos=NULL)
writeChar(x, zz, eos="\r\n")
close(zz)

zz <- file("testchar", "rb")
readChar(zz, nc)
readChar(zz, nchar(x)+3) # need to read the terminator explicitly
close(zz)
unlink("testchar")
```

readline

Read a Line from the Terminal

Description

`readline` reads a line from the terminal

Usage

```
readline(prompt = "")
```

Arguments

`prompt` the string printed when prompting the user for input. Should usually end with a space " ".

Details

The prompt string will be truncated to a maximum allowed length, normally 256 chars (but can be changed in the source code).

Value

A character vector of length one.

See Also

[readLines](#) for reading text lines of connections, including files.

Examples

```
fun <- function() {
  ANSWER <- readline("Are you a satisfied R user? ")
  if (substr(ANSWER, 1, 1) == "n")
    cat("This is impossible. YOU LIED!\n")
  else
    cat("I knew it.\n")
}
fun()
```

readLines

Read Text Lines from a Connection

Description

Read some or all text lines from a connection.

Usage

```
readLines(con = stdin(), n = -1, ok = TRUE, warn = TRUE,
          encoding = "unknown")
```

Arguments

con	a connection object or a character string.
n	integer. The (maximal) number of lines to read. Negative values indicate that one should read up to the end of the connection.
ok	logical. Is it OK to reach the end of the connection before $n > 0$ lines are read? If not, an error will be generated.
warn	logical. Warn if a text file is missing a final EOL.
encoding	encoding to be assumed for input strings. It is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input. To do the latter, specify the encoding as part of the connection <code>con</code> or via <code>options(encoding=)</code> : see the example under file .

Details

If the `con` is a character string, the function calls `file` to obtain a file connection which is opened for the duration of the function call.

If the connection is open it is read from its current position. If it is not open, it is opened in "rt" mode for the duration of the call and then closed again.

If the final line is incomplete (no final EOL marker) the behaviour depends on whether the connection is blocking or not. For a non-blocking text-mode connection the incomplete line is pushed back, silently. For all other connections the line will be accepted, with a warning.

Whatever mode the connection is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line.

Value

A character vector of length the number of lines read.

The elements of the result have a declared encoding if `encoding` is "latin1" or "UTF-8",

Note

The default connection, `stdin`, may be different from `con = "stdin"`: see `file`.

See Also

`connections`, `writeLines`, `readBin`, `scan`

Examples

```
cat("TITLE extra line", "2 3 5 7", "", "11 13 17", file="ex.data",
    sep="\n")
readLines("ex.data", n=-1)
unlink("ex.data") # tidy up

## difference in blocking
cat("123\nabc", file = "test1")
readLines("test1") # line with a warning

con <- file("test1", "r", blocking = FALSE)
readLines(con) # empty
cat(" def\n", file = "test1", append = TRUE)
readLines(con) # gets both
close(con)

unlink("test1") # tidy up
```

Description

These functions are the same as their `double` equivalents and are provided for backwards compatibility only.

Usage

```
real(length = 0)
as.real(x, ...)
is.real(x)
```

Arguments

length	desired length.
x	object to be coerced or tested.
...	further arguments passed to or from other methods.

Details

`as.real` is a generic function, but S3 methods must be written for `as.double`.

 Recall

Recursive Calling

Description

`Recall` is used as a placeholder for the name of the function in which it is called. It allows the definition of recursive functions which still work after being renamed, see example below.

Usage

```
Recall(...)
```

Arguments

...	all the arguments to be passed.
-----	---------------------------------

Note

`Recall` will not work correctly when passed as a function argument, e.g. to the `apply` family of functions.

See Also

[do.call](#) and [call](#).

[local](#) for another way to write anonymous recursive functions.

Examples

```
## A trivial (but inefficient!) example:
fib <- function(n)
  if(n<=2) { if(n>=0) 1 else 0 } else Recall(n-1) + Recall(n-2)
fibonacci <- fib; rm(fib)
## renaming wouldn't work without Recall
fibonacci(10) # 55
```

reg.finalizer	<i>Finalization of Objects</i>
---------------	--------------------------------

Description

Registers an R function to be called upon garbage collection of object or (optionally) at the end of an R session.

Usage

```
reg.finalizer(e, f, onexit = FALSE)
```

Arguments

e	Object to finalize. Must be environment or external pointer.
f	Function to call on finalization. Must accept a single argument, which will be the object to finalize.
onexit	logical: should the finalizer be run if the object is still uncollected at the end of the R session?

Value

NULL.

Note

The purpose of this function is mainly to allow objects that refer to external items (a temporary file, say) to perform cleanup actions when they are no longer referenced from within R. This only makes sense for objects that are never copied on assignment, hence the restriction to environments and external pointers.

See Also

[gc](#) and [Memory](#) for garbage collection and memory management.

Examples

```
f <- function(e) print("cleaning...")
g <- function(x){ e <- environment(); reg.finalizer(e,f) }
g()
invisible(gc()) # trigger cleanup
```

Description

This help page documents the regular expression patterns supported by `grep` and related functions `regexpr`, `gregexpr`, `sub` and `gsub`, as well as by `strsplit`.

Details

A ‘regular expression’ is a pattern that describes a set of strings. Three types of regular expressions are used in R, *extended* regular expressions, used by `grep(extended = TRUE)` (its default), *basic* regular expressions, as used by `grep(extended = FALSE)`, and *Perl-like* regular expressions used by `grep(perl = TRUE)`.

Other functions which use regular expressions (often via the use of `grep`) include `apropos`, `browseEnv`, `help.search`, `list.files`, `ls` and `strsplit`. These will all use *extended* regular expressions, unless `strsplit` is called with argument `extended = FALSE` or `perl = TRUE`.

Patterns are described here as they would be printed by `cat`: *do remember that backslashes need to be doubled when entering R character strings*, e.g. from the keyboard.

Extended Regular Expressions

This section covers the regular expressions allowed if `extended = TRUE` in `grep`, `regexpr`, `gregexpr`, `sub`, `gsub` and `strsplit`. They use the `glibc 2.7` implementation of the POSIX 1003.2 standard.

Regular expressions are constructed analogously to arithmetic expressions, by using various operators to combine smaller expressions.

The fundamental building blocks are the regular expressions that match a single character. Most characters, including all letters and digits, are regular expressions that match themselves. Any metacharacter with special meaning may be quoted by preceding it with a backslash. (Escaping other characters with a backslash is undefined in POSIX but gives the character in the R implementation.) The metacharacters in EREs are `.` `\` `|` `(` `)` `[` `{` `^` `$` `*` `+` `?`, but note that whether these have a special meaning depends on the context.

A *character class* is a list of characters enclosed between `[` and `]` which matches any single character in that list; unless the first character of the list is the caret `^`, when it matches any character *not* in the list. For example, the regular expression `[0123456789]` matches any single digit, and `[^abc]` matches anything except the characters `a`, `b` or `c`. A range of characters may be specified by giving the first and last characters, separated by a hyphen. (Because their interpretation is so locale-dependent, they are best avoided.)

The precise way character ranges are interpreted depends on the values of `perl` and `ignore.case`. For basic and extended regular expressions the collation order is taken from the OS’s implementation of the setting of the locale category `LC_COLLATE`, so `[W-Z]` may include `x` and if it does may or may not include `w`. (In most English locales the collation order is `wWxXyYzZ`.) For caseless matching the characters in a range are interpreted as if in lower case, so in an English locale `[W-z]` matches `WXYZwxyz`. The only portable way to specify all ASCII letters is to list them all as character class, `[ABCDEFGHIJKLMNOPQRSTUVWXYZabcdefghijklmnopqrstuvwxyz]`.

For Perl regexps, the ranges are interpreted in the numerical order of the characters, either as bytes in a single-byte locale or as Unicode points in a UTF-8 locale. So in either case `[A-Za-z]` specifies the set of ASCII letters.

Certain named classes of characters are predefined. Their interpretation depends on the *locale* (see [locales](#)); the interpretation below is that of the POSIX locale.

- [:alnum:]** Alphanumeric characters: `[:alpha:]` and `[:digit:]`.
- [:alpha:]** Alphabetic characters: `[:lower:]` and `[:upper:]`.
- [:blank:]** Blank characters: space and tab.
- [:cntrl:]** Control characters. In ASCII, these characters have octal codes 000 through 037, and 177 (DEL). In another character set, these are the equivalent characters, if any.
- [:digit:]** Digits: 0 1 2 3 4 5 6 7 8 9.
- [:graph:]** Graphical characters: `[:alnum:]` and `[:punct:]`.
- [:lower:]** Lower-case letters in the current locale.
- [:print:]** Printable characters: `[:alnum:]`, `[:punct:]` and space.
- [:punct:]** Punctuation characters: ! " # \$ % & ' () * + , - . / : ; < = > ? @ [\] ^ _ ` { | } ~.
- [:space:]** Space characters: tab, newline, vertical tab, form feed, carriage return, and space.
- [:upper:]** Upper-case letters in the current locale.
- [:xdigit:]** Hexadecimal digits: 0 1 2 3 4 5 6 7 8 9 A B C D E F a b c d e f.

For example, `[[:alnum:]]` means `[0-9A-Za-z]`, except the latter depends upon the locale and the character encoding, whereas the former is independent of locale and character set. (Note that the brackets in these class names are part of the symbolic names, and must be included in addition to the brackets delimiting the bracket list.) Most metacharacters lose their special meaning inside lists. To include a literal `]`, place it first in the list. Similarly, to include a literal `^`, place it anywhere but first. Finally, to include a literal `-`, place it first or last (or, for `perl = TRUE` only, precede it by a backslash.). (Only these and `\` remain special inside character classes.)

The period `.` matches any single character. The symbol `\w` is documented to be synonym for `[[:alnum:]]` and `\W` is its negation. However, `\w` also matches underscore in the GNU `grep` code used in `R`.

The caret `^` and the dollar sign `$` are metacharacters that respectively match the empty string at the beginning and end of a line. The symbols `\<` and `\>` respectively match the empty string at the beginning and end of a word. The symbol `\b` matches the empty string at either edge of a word, and `\B` matches the empty string provided it is not at an edge of a word.

A regular expression may be followed by one of several repetition quantifiers:

- ?** The preceding item is optional and will be matched at most once.
- *** The preceding item will be matched zero or more times.
- +** The preceding item will be matched one or more times.
- {n}** The preceding item is matched exactly *n* times.
- {n, }** The preceding item is matched *n* or more times.
- {n, m}** The preceding item is matched at least *n* times, but not more than *m* times.

Repetition is greedy, so the maximal possible number of repeats is used.

Two regular expressions may be concatenated; the resulting regular expression matches any string formed by concatenating two substrings that respectively match the concatenated subexpressions.

Two regular expressions may be joined by the infix operator `|`; the resulting regular expression matches any string matching either subexpression. For example, `abba|cde` matches either the string `abba` or the string `cde`. Note that alternation does not work inside character classes, where `|` has its literal meaning.

Repetition takes precedence over concatenation, which in turn takes precedence over alternation. A whole subexpression may be enclosed in parentheses to override these precedence rules.

The backreference `\N`, where `N` is a single digit, matches the substring previously matched by the `N`th parenthesized subexpression of the regular expression.

Basic Regular Expressions

This section covers the regular expressions allowed if `extended = FALSE` in `grep`, `regexpr`, `gregexpr`, `sub`, `gsub` and `strsplit`.

In basic regular expressions the metacharacters `?`, `+`, `{`, `|`, `(`, and `)` lose their special meaning; instead use the backslashed versions `\?`, `\+`, `\{`, `\|`, `\(`, and `\)`. Thus the metacharacters are `.\[\^$*`.

Perl Regular Expressions

The `perl = TRUE` argument to `grep`, `regexpr`, `gregexpr`, `sub`, `gsub` and `strsplit` switches to the PCRE library that ‘implements regular expression pattern matching using the same syntax and semantics as Perl 5.6 or later, with just a few differences’. It adds some features from Perl 5.10.

For complete details please consult the man pages for PCRE, especially `man pcrepattern` and `man pcreapi`, on your system or from the sources at <http://www.pcre.org>. If PCRE support was compiled from the sources within `R`, the PCRE version is 7.7 as described here (version ≥ 7.6 is required if `R` is configured to use the system’s PCRE library).

Perl regular expressions are computed byte-by-byte rather than character-by-character except in UTF-8 locales. Since the only non-UTF-8 multibyte locales in common use are those for CJK languages, they should be used with care in non-UTF-8 CJK locales.

All the regular expressions described for extended regular expressions are accepted except `\<` and `\>`: in Perl all backslashed metacharacters are alphanumeric and backslashed symbols always are interpreted as a literal character. `{` is not special if it would be the start of an invalid interval specification. There can be more than 9 backreferences. In a UTF-8 locale the named character classes only match ASCII characters: see `\p` below for an alternative.

The construct `(? . . .)` is used for Perl extensions in a variety of ways depending on what immediately follows the `?`.

Perl-like matching can work in several modes, set by the options `(?i)` (caseless, equivalent to Perl’s `/i`), `(?m)` (multiline, equivalent to Perl’s `/m`), `(?s)` (single line, so a dot matches all characters, even new lines: equivalent to Perl’s `/s`) and `(?x)` (extended, whitespace data characters are ignored unless escaped and comments are allowed: equivalent to Perl’s `/x`). These can be concatenated, so for example, `(?im)` sets caseless multiline matching. It is also possible to unset these options by preceding the letter with a hyphen, and to combine setting and unsetting such as `(?im-sx)`. These settings can be applied within patterns, and then apply to the remainder of the pattern. Additional options not in Perl include `(?U)` to set ‘ungreedy’ mode (so matching is minimal unless `?` is used, when it is greedy). Initially none of these options are set.

If you want to remove the special meaning from a sequence of characters, you can do so by putting them between `\Q` and `\E`. This is different from Perl in that `$` and `@` are handled as literals in `\Q . . . \E` sequences in PCRE, whereas in Perl, `$` and `@` cause variable interpolation.

The escape sequences `\d`, `\s` and `\w` represent any decimal digit, space character and ‘word’ character (letter, digit or underscore in the current locale, except that in a UTF-8 locale only ASCII letters are considered) respectively, and their upper-case versions represent their negation. Unlike POSIX and earlier versions of Perl and PCRE, vertical tab is not regarded as a whitespace character.

Escape sequence `\a` is BEL, `\e` is ESC, `\f` is FF, `\n` is LF, `\r` is CR and `\t` is TAB. In addition `\cx` is `cntrl-x` for any `x`, `\ddd` is the octal character `ddd` (for up to three digits unless interpretable as a backreference, as `\1` to `\7` always are), and `\xhh` specifies a character in hex. In a UTF-8 locale, `\x{h . . . }` specifies a Unicode point by one or more hex digits.

Outside a character class, `\b` matches a word boundary, `\B` is its negation, `\A` matches at start of a subject (even in multiline mode, unlike `^`), `\Z` matches at end of a subject or before newline at end, `\z` matches at end of a subject. and `\G` matches at first matching position in a subject (which is subtly different from Perl’s end of the previous match). `\C` matches a single byte. including a newline. In a UTF-8 locale, `\R` matches any Unicode newline character (not just CR), and `\X` matches any number of Unicode characters that form an extended Unicode sequence.

In a UTF-8 locale, some Unicode properties are supported via `\p{xx}` and `\P{xx}` which match characters with and without property `xx` respectively. For a list of supported properties see the PCRE documentation, but for example `Lu` is ‘upper case letter’ and `Sc` is ‘currency symbol’.

The same repetition quantifiers as extended POSIX are supported. However, if a quantifier is followed by `?`, the match is ‘ungreedy’, that is as short as possible rather than as long as possible (unless the meanings are reversed by the `(?U)` option.)

The sequence `(?#` marks the start of a comment which continues up to the next closing parenthesis. Nested parentheses are not permitted. The characters that make up a comment play no part at all in the pattern matching.

If the extended option is set, an unescaped `#` character outside a character class introduces a comment that continues up to the next newline character in the pattern.

The pattern `(?: . . .)` groups characters just as parentheses do but does not make a backreference.

Patterns `(?= . . .)` and `(?! . . .)` are zero-width positive and negative lookahead *assertions*: they match if an attempt to match the `. . .` forward from the current position would succeed (or not), but use up no characters in the string being processed. Patterns `(?<= . . .)` and `(?<! . . .)` are the lookbehind equivalents: they do not allow repetition quantifiers nor `\C` in `. . . .`

Named subpatterns, atomic grouping, possessive qualifiers and conditional and recursive patterns are not covered here.

remove *Remove Objects from a Specified Environment*

Description

`remove` and `rm` can be used to remove objects. These can be specified successively as character strings, or in the character vector `list`, or through a combination of both. All objects thus specified will be removed.

If `envir` is `NULL` then the currently active environment is searched first.

If `inherits` is `TRUE` then parents of the supplied directory are searched until a variable with the given name is encountered. A warning is printed for each variable that is not found.

Usage

```
remove(..., list = character(0), pos = -1,
        envir = as.environment(pos), inherits = FALSE)

rm      (... , list = character(0), pos = -1,
        envir = as.environment(pos), inherits = FALSE)
```

Arguments

<code>...</code>	the objects to be removed, as names (unquoted) or character strings (quoted).
<code>list</code>	a character vector naming objects to be removed.
<code>pos</code>	where to do the removal. By default, uses the current environment. See the details for other possibilities.
<code>envir</code>	the environment to use. See the details section.
<code>inherits</code>	should the enclosing frames of the environment be inspected?

Details

The `pos` argument can specify the environment from which to remove the objects in any of several ways: as an integer (the position in the [search](#) list); as the character string name of an element in the search list; or as an [environment](#) (including using `sys.frame` to access the currently active function calls). The `envir` argument is an alternative way to specify an environment, but is primarily there for back compatibility.

It is not allowed to remove variables from the base environment and base name space, nor from any environment which is locked (see [lockEnvironment](#)).

Earlier versions of R incorrectly claimed that supplying a character vector in `...` removed the objects named in the character vector, but it removed the character vector. Use the `list` argument to specify objects *via* a character vector.

Examples

```

tmp <- 1:4
## work with tmp and cleanup
rm(tmp)

## Not run:
## remove (almost) everything in the working environment.
## You will get no warning, so don't do this unless you are really sure.
rm(list = ls())
## End(Not run)

```

rep

Replicate Elements of Vectors and Lists

Description

rep replicates the values in *x*. It is a generic function, and the (internal) default method is described here.

rep.int is a faster simplified version for the most common case.

Usage

```

rep(x, ...)

rep.int(x, times)

```

Arguments

<i>x</i>	a vector (of any mode including a list) or a pairlist or a factor or (except for rep.int) a POSIXct or POSIXlt or date object.
...	further arguments to be passed to or from other methods. For the internal default method these can include: <ul style="list-style-type: none"> times A vector giving the number of times to repeat each element if of length length(<i>x</i>), or to repeat the whole vector if of length 1. length.out non-negative integer. The desired length of the output vector. Ignored if NA or invalid. each non-negative integer. Each element of <i>x</i> is repeated each times. Treated as 1 if NA or invalid.
times	see

Details

The default behaviour is as if the call was rep(*x*, times=1, length.out=NA, each=1). Normally just one of the additional arguments is specified, but if each is specified with either of the other two, its replication is performed first, and then that implied by times or length.out.

If times consists of a single integer, the result consists of the whole input repeated this many times. If times is a vector of the same length as *x* (after replication by each), the result consists of *x*[1] repeated times[1] times, *x*[2] repeated times[2] times and so on.

`length.out` may be given in place of `times`, in which case `x` is repeated as many times as is necessary to create a vector of this length. If both are given, `length.out` takes priority and `times` is ignored.

Non-integer values of `times` will be truncated towards zero. If `times` is a computed quantity it is prudent to add a small fuzz.

If `x` has length zero and `length.out` is supplied and is positive, the values are filled in using the extraction rules, that is by an NA of the appropriate class for an atomic vector (0 for raw vectors) and NULL for a list.

Value

An object of the same type as `x` (except that `rep` will coerce pairlists to vector lists).

`rep.int` returns no attributes.

The default method of `rep` gives the result names (which will almost always contain duplicates) if `x` had names, but retains no other attributes except for factors.

Note

Function `rep.int` is a simple case handled by internal code, and provided as a separate function purely for S compatibility.

Function `rep` is a primitive, but (partial) matching of argument names is performed as for normal functions. You can no longer pass a missing argument to. e.g. `length.out`.

Examples

```
rep(1:4, 2)
rep(1:4, each = 2)      # not the same.
rep(1:4, c(2,2,2,2))   # same as second.
rep(1:4, c(2,1,2,1))
rep(1:4, each = 2, len = 4)  # first 4 only.
rep(1:4, each = 2, len = 10) # 8 integers plus two recycled 1's.
rep(1:4, each = 2, times = 3) # length 24, 3 complete replications

rep(1, 40*(1-.8)) # length 7 on most platforms
rep(1, 40*(1-.8)+1e-7) # better

## replicate a list
fred <- list(happy = 1:10, name = "squash")
rep(fred, 5)

# date-time objects
x <- .leap.seconds[1:3]
rep(x, 2)
rep(as.POSIXlt(x), rep(2, 3))
```

```
## named factor
x <- factor(LETTERS[1:4]); names(x) <- letters[1:4]
x
rep(x, 2)
rep(x, each=2)
rep.int(x, 2) # no names
```

 replace

Replace Values in a Vector

Description

`replace` replaces the values in `x` with indexes given in `list` by those given in `values`. If necessary, the values in `values` are recycled.

Usage

```
replace(x, list, values)
```

Arguments

<code>x</code>	vector
<code>list</code>	an index vector
<code>values</code>	replacement values

Value

A vector with the values replaced.

Note

`x` is unchanged: remember to assign the result.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

 Reserved

Reserved Words in R

Description

The reserved words in R's parser are

```
if else repeat while function for in next break
```

```
TRUE FALSE NULL Inf NaN NA NA_integer_ NA_real_ NA_complex_
NA_character_
```

... and `..1`, `..2` etc, which are used to refer to arguments passed down from an enclosing function.

Details

Reserved words outside [quotes](#) are always parsed to be references to the objects linked to in the 'Description', and hence they are not allowed as syntactic names (see [make.names](#)). They **are** allowed as non-syntactic names, e.g. inside [backtick](#) quotes.

rev

Reverse Elements

Description

`rev` provides a reversed version of its argument. It is generic function with a default method for vectors and one for [dendrograms](#).

Note that this is no longer needed (nor efficient) for obtaining vectors sorted into descending order, since that is now rather more directly achievable by `sort(x, decreasing = TRUE)`.

Usage

```
rev(x)
```

Arguments

`x` a vector or another object for which reversal is defined.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[seq](#), [sort](#).

Examples

```
x <- c(1:5, 5:3)
## sort into descending order; first more efficiently:
stopifnot(sort(x, decreasing = TRUE) == rev(sort(x)))
stopifnot(rev(1:7) == 7:1) #- don't need 'rev' here
```

Rhome	<i>Return the R Home Directory</i>
-------	------------------------------------

Description

Return the R home directory.

Usage

```
R.home(component="home")
```

Arguments

component	As well as "home" which gives the R home directory, other known values are "bin", "doc", "etc" and "share" giving the paths to the corresponding parts of an R installation.
-----------	--

Details

The R home directory is the top-level directory of the R installation being run.

The R home directory is often referred to as *R_HOME*, and is the value of an environment variable of that name in an R session. It can be found outside an R session by R [RHOME](#).

Value

A character string giving the R home directory or path to a particular component. Normally the components are all subdirectories of the R home directory, but this may not be the case in a Unix-like installation.

rle	<i>Run Length Encoding</i>
-----	----------------------------

Description

Compute the lengths and values of runs of equal values in a vector – or the reverse operation.

Usage

```
rle(x)
inverse.rle(x, ...)
```

Arguments

x	an atomic vector for <code>rle()</code> ; an object of class "rle" for <code>inverse.rle()</code> .
...	further arguments which are ignored in R.

Details

Missing values are regarded as unequal to the previous value, even if that is also missing.

`inverse.rle()` is the inverse function of `rle()`, reconstructing `x` from the runs.

Value

`rle()` returns an object of class "rle" which is a list with components:

`lengths` an integer vector containing the length of each run.

`values` a vector of the same length as `lengths` with the corresponding values.

`inverse.rle()` returns an atomic vector.

Examples

```
x <- rev(rep(6:10, 1:5))
rle(x)
## lengths [1:5]  5 4 3 2 1
## values  [1:5] 10 9 8 7 6

z <- c(TRUE, TRUE, FALSE, FALSE, TRUE, FALSE, TRUE, TRUE, TRUE)
rle(z)
rle(as.character(z))

stopifnot(x == inverse.rle(rle(x)),
          z == inverse.rle(rle(z)))
```

Round

Rounding of Numbers

Description

`ceiling` takes a single numeric argument `x` and returns a numeric vector containing the smallest integers not less than the corresponding elements of `x`.

`floor` takes a single numeric argument `x` and returns a numeric vector containing the largest integers not greater than the corresponding elements of `x`.

`trunc` takes a single numeric argument `x` and returns a numeric vector containing the integers formed by truncating the values in `x` toward 0.

`round` rounds the values in its first argument to the specified number of decimal places (default 0).

`signif` rounds the values in its first argument to the specified number of significant digits.

`zapsmall` determines a `digits` argument `dr` for calling `round(x, digits = dr)` such that values close to zero (compared with the maximal absolute value) are 'zapped', i.e., treated as 0.

Usage

```
ceiling(x)
floor(x)
trunc(x, ...)

round(x, digits = 0)
signif(x, digits = 6)
zapsmall(x, digits = getOption("digits"))
```

Arguments

<code>x</code>	a numeric vector. A complex vector is allowed for <code>round</code> , <code>signif</code> and <code>zapsmall</code> .
<code>digits</code>	integer indicating the precision to be used.
<code>...</code>	arguments to be passed to methods.

Details

All but `zapsmall` are generic functions: methods can be defined for them individually or via the [Math](#) group generic.

Note that for rounding off a 5, the IEC 60559 standard is expected to be used, ‘*go to the even digit*’. Therefore `round(0.5)` is 0 and `round(-1.5)` is -2. However, this is dependent on OS services and on representation error (since e.g. 0.15 is not represented exactly, the rounding rule applies to the represented number and not to the printed number, and so `round(0.15, 1)` could be either 0.1 or 0.2).

For `signif` the recognized values of `digits` are 1...22. Complex numbers are rounded to retain the specified number of digits in the larger of the components. Each element of the vector is rounded individually, unlike printing.

All except `zapsmall` are primitive, but as from R 2.7.0 arguments are matched by name in `round` and `signif` (whereas the default method for `ceiling`, `floor` and `trunc` ignore argument names).

S4 methods

`ceiling`, `floor` and `trunc` are S4 generic and members of the [Math](#) group generic. As an S4 generic, `trunc` has only one argument.

`round` and `signif` are S4 generic and members of the [Math2](#) group generic.

round(.5 + -2:4) # IEEE rounding: -2 0 0 2 2 4 4
( x1 <- seq(-2, 4, by = .5) )
round(x1) #-- IEEE rounding !
x1[trunc(x1) != floor(x1)]
x1[round(x1) != floor(x1 + .5)]
(non.int <- ceiling(x1) != floor(x1))

x2 <- pi * 100^(-1:3)
round(x2, 3)
signif(x2, 3)
```

```
print (x2 / 1000, digits=4)
zapsmall(x2 / 1000, digits=4)
zapsmall(exp(1i*0:4*pi/2))
```

round.POSIXt	<i>Round / Truncate Data-Time Objects</i>
--------------	---

Description

Round or truncate date-time objects.

Usage

```
## S3 method for class 'POSIXt':
round(x, units = c("secs", "mins", "hours", "days"))
## S3 method for class 'POSIXt':
trunc(x, units = c("secs", "mins", "hours", "days"), ...)

## S3 method for class 'Date':
round(x, ...)
## S3 method for class 'Date':
trunc(x, ...)
```

Arguments

x	an object inheriting from "POSIXt" or "Date".
units	one of the units listed. Can be abbreviated.
...	arguments to be passed to or from other methods, notably <code>digits</code> for <code>round</code> .

Details

The time is rounded or truncated to the second, minute, hour or day. Timezones are only relevant to days, when midnight in the current timezone is used.

The methods for class "Date" are of little use except to remove fractional days.

Value

An object of class "POSIXlt" or "Date".

See Also

[round](#) for the generic function and default methods.
[DateTimeClasses](#), [Date](#)

Examples

```
round(.leap.seconds + 1000, "hour")
trunc(Sys.time(), "day")
```

`row`*Row Indexes*

Description

Returns a matrix of integers indicating their row number in a matrix-like object, or a factor indicating the row labels.

Usage

```
row(x, as.factor = FALSE)
```

Arguments

<code>x</code>	a matrix-like object, that is one with a two-dimensional <code>dim</code> .
<code>as.factor</code>	a logical value indicating whether the value should be returned as a factor of row labels (created if necessary) rather than as numbers.

Value

An integer (or factor) matrix with the same dimensions as `x` and whose i -th element is equal to i (or the i -th row label).

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

# extract the diagonal of a matrix
dx <- x[row(x) == col(x)]
dx

# create an identity 5-by-5 matrix
x <- matrix(0, nrow = 5, ncol = 5)
x[row(x) == col(x)] <- 1
x
```

`row.names`*Get and Set Row Names for Data Frames*

Description

All data frames have a row names attribute, a character vector of length the number of rows with no duplicates nor missing values.

For convenience, these are generic functions for which users can write other methods, and there are default methods for arrays. The description here is for the `data.frame` method.

Usage

```
row.names(x)
row.names(x) <- value
```

Arguments

<code>x</code>	object of class "data.frame", or any other class for which a method has been defined.
<code>value</code>	an object to be coerced to character unless an integer vector. It should have (after coercion) the same length as the number of rows of <code>x</code> with no duplicated nor missing values. <code>NULL</code> is also allowed: see 'Details'.

Details

A data frame has (by definition) a vector of *row names* which has length the number of rows in the data frame, and contains neither missing nor duplicated values. Where a row names sequence has been added by the software to meet this requirement, they are regarded as 'automatic'.

Row names were character are allowed to be integer or character, but for backwards compatibility (with R <= 2.4.0) `row.names` will always return a character vector. (Use `attr(x, "row.names")` if you need an integer value.)

Using `NULL` for the value resets the row names to `seq_len(nrow(x))`, regarded as 'automatic'.

Value

`row.names` returns a character vector.

`row.names<-` returns a data frame with the row names changed.

Note

`row.names` is similar to `rownames` for arrays, and it has a method that calls `rownames` for an array argument.

Row names of the form `1:n` for `n > 2` are stored internally in a compact form, which might be seen from C code or by deparsing but never via `row.names` or `attr(x, "row.names")`. Additionally, some names of this sort are marked as 'automatic' and handled differently by `as.matrix` and `data.matrix` (and potentially other functions). (All zero-row data frames are regarded as having automatic row.names.)

References

Chambers, J. M. (1992) *Data for models*. Chapter 3 of *Statistical Models in S* eds J. M. Chambers and T. J. Hastie, Wadsworth & Brooks/Cole.

See Also

[data.frame](#), [rownames](#), [names](#).
[.row_names_info](#) for the internal representations.

row/colnames	<i>Row and Column Names</i>
--------------	-----------------------------

Description

Retrieve or set the row or column names of a matrix-like object.

Usage

```
rownames(x, do.NULL = TRUE, prefix = "row")
rownames(x) <- value

colnames(x, do.NULL = TRUE, prefix = "col")
colnames(x) <- value
```

Arguments

<code>x</code>	a matrix-like R object, with at least two dimensions for <code>colnames</code> .
<code>do.NULL</code>	logical. Should this create names if they are NULL?
<code>prefix</code>	for created names.
<code>value</code>	a valid value for that component of <code>dimnames(x)</code> . For a matrix or array this is either NULL or a character vector of non-zero length equal to the appropriate dimension.

Details

The extractor functions try to do something sensible for any matrix-like object `x`. If the object has `dimnames` the first component is used as the row names, and the second component (if any) is used for the column names. For a data frame, `rownames` and `colnames` eventually call `row.names` and `names` respectively, but the latter are preferred.

If `do.NULL` is FALSE, a character vector (of length `NROW(x)` or `NCOL(x)`) is returned in any case, prepending `prefix` to simple numbers, if there are no `dimnames` or the corresponding component of the `dimnames` is NULL.

The replacement methods for arrays/matrices coerce vector and factor values of `value` to character, but do not dispatch methods for `as.character`.

For a data frame, `value` for `rownames` should be a character vector of non-duplicated and non-missing names (this is enforced), and for `colnames` a character vector of (preferably) unique syntactically-valid names. In both cases, `value` will be coerced by `as.character`, and setting `colnames` will convert the row names to character.

Examples

```
m0 <- matrix(NA, 4, 0)
rownames(m0)

m2 <- cbind(1,1:4)
colnames(m2, do.NULL = FALSE)
colnames(m2) <- c("x", "Y")
rownames(m2) <- rownames(m2, do.NULL = FALSE, prefix = "Obs.")
m2
```

rowsum	<i>Give column sums of a matrix or data frame, based on a grouping variable</i>
--------	---

Description

Compute column sums across rows of a matrix-like object for each level of a grouping variable. `rowsum` is generic, with a method for data frames and a default method for vectors and matrices.

Usage

```
rowsum(x, group, reorder = TRUE, ...)

## S3 method for class 'data.frame':
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)

## Default S3 method:
rowsum(x, group, reorder = TRUE, na.rm = FALSE, ...)
```

Arguments

<code>x</code>	a matrix, data frame or vector of numeric data. Missing values are allowed. A numeric vector will be treated as a column vector.
<code>group</code>	a vector or factor giving the grouping, with one element per row of <code>x</code> . Missing values will be treated as another group and a warning will be given.
<code>reorder</code>	if <code>TRUE</code> , then the result will be in order of <code>sort(unique(group))</code> , if <code>FALSE</code> , it will be in the order that groups were encountered.
<code>na.rm</code>	logical (<code>TRUE</code> or <code>FALSE</code>). Should NA values be discarded?
<code>...</code>	other arguments to be passed to or from methods

Details

The default is to reorder the rows to agree with `tapply` as in the example below. Reordering should not add noticeably to the time except when there are very many distinct values of `group` and `x` has few columns.

The original function was written by Terry Therneau, but this is a new implementation using hashing that is much faster for large matrices.

To sum over all the rows of a matrix (ie, a single group) use `colSums`, which should be even faster.

Value

A matrix or data frame containing the sums. There will be one row per unique value of `group`.

See Also

`tapply`, `aggregate`, `rowSums`

Examples

```
require(stats)

x <- matrix(runif(100), ncol=5)
group <- sample(1:8, 20, TRUE)
(xsum <- rowsum(x, group))
## Slower versions
tapply(x, list(group[row(x)]), col(x)), sum)
t(sapply(split(as.data.frame(x), group), colSums))
aggregate(x, list(group), sum)[-1]
```

sample

Random Samples and Permutations

Description

`sample` takes a sample of the specified size from the elements of `x` using either with or without replacement.

Usage

```
sample(x, size, replace = FALSE, prob = NULL)
```

Arguments

<code>x</code>	Either a (numeric, complex, character or logical) vector of more than one element from which to choose, or a positive integer.
<code>size</code>	non-negative integer giving the number of items to choose.
<code>replace</code>	Should sampling be with replacement?
<code>prob</code>	A vector of probability weights for obtaining the elements of the vector being sampled.

Details

If `x` has length 1, is numeric (in the sense of `is.numeric`) and `x >= 1`, sampling takes place from `1:x`. *Note* that this convenience feature may lead to undesired behaviour when `x` is of varying length `sample(x)`. See the `resample()` example below.

By default `size` is equal to `length(x)` so that `sample(x)` generates a random permutation of the elements of `x` (or `1:x`).

The optional `prob` argument can be used to give a vector of weights for obtaining the elements of the vector being sampled. They need not sum to one, but they should be nonnegative and not all zero. If `replace` is true, Walker's alias method (Ripley, 1987) is used when there are more than 250 reasonably probable values: this gives results incompatible with those from R < 2.2.0, and there will be a warning the first time this happens in a session.

If `replace` is false, these probabilities are applied sequentially, that is the probability of choosing the next item is proportional to the weights amongst the remaining items. The number of nonzero weights must be at least `size` in this case.

See Also

Package **sampling** for other methods of weighted sampling without replacement.

Examples

```
x <- 1:12
# a random permutation
sample(x)
# bootstrap sampling -- only if length(x) > 1 !
sample(x, replace=TRUE)

# 100 Bernoulli trials
sample(c(0,1), 100, replace = TRUE)

## More careful bootstrapping -- Consider this when using sample()
## programmatically (i.e., in your function or simulation)!

# sample()'s surprise -- example
x <- 1:10
  sample(x[x > 8]) # length 2
  sample(x[x > 9]) # oops -- length 10!
try(sample(x[x > 10]))# error!

## This is safer, but only for sampling without replacement
resample <- function(x, size, ...)
  if(length(x) <= 1) { if(!missing(size) && size == 0) x[FALSE] else x
  } else sample(x, size, ...)

resample(x[x > 8])# length 2
resample(x[x > 9])# length 1
resample(x[x > 10])# length 0
```

Description

`save` writes an external representation of R objects to the specified file. The objects can be read back from the file at a later date by using the function `load` (or `data` in some cases).

`save.image()` is just a short-cut for ‘save my current workspace’, i.e., `save(list = ls(all=TRUE), file = ".RData")`. It is also what happens with `q("yes")`.

Usage

```
save(..., list = character(0),
      file = stop("'file' must be specified"),
      ascii = FALSE, version = NULL, envir = parent.frame(),
      compress = !ascii, eval.promises = TRUE, precheck = TRUE)

save.image(file = ".RData", version = NULL, ascii = FALSE,
           compress = !ascii, safe = TRUE)
```

Arguments

<code>...</code>	the names of the objects to be saved (as symbols or character strings).
<code>list</code>	A character vector containing the names of objects to be saved.
<code>file</code>	a connection or the name of the file where the data will be saved. Must be a file name for workspace format version 1.
<code>ascii</code>	if <code>TRUE</code> , an ASCII representation of the data is written. The default value of <code>ascii</code> is <code>FALSE</code> which leads to a more compact binary file being written.
<code>version</code>	the workspace format version to use. <code>NULL</code> specifies the current default format. The version used from R 0.99.0 to R 1.3.1 was version 1. The default format as from R 1.4.0 is version 2.
<code>envir</code>	environment to search for objects to be saved.
<code>compress</code>	logical specifying whether saving to a named file is to use compression. Ignored when <code>file</code> is a connection and for workspace format version 1.
<code>eval.promises</code>	logical: should objects which are promises be forced before saving?
<code>precheck</code>	logical: should the existence of the objects be checked before starting to save (and in particular before opening the file/connection)? Does not apply to version 1 saves.
<code>safe</code>	logical. If <code>TRUE</code> , a temporary file is used for creating the saved workspace. The temporary file is renamed to <code>file</code> if the save succeeds. This preserves an existing workspace <code>file</code> if the save fails, but at the cost of using extra disk space during the save.

Details

The names of the objects specified either as symbols (or character strings) in `...` or as a character vector in `list` are used to look up the objects from environment `envir`. By default `promises` are evaluated, but if `eval.promises = FALSE` promises are saved (together with their evaluation environments). (Promises embedded in objects are always saved unevaluated.)

All R platforms use the XDR (bigendian) representation of C ints and doubles in binary save-d files, and these are portable across all R platforms. (ASCII saves used to be useful for moving data between platforms but are now mainly of historical interest.)

Default values for the `ascii`, `compress`, `safe` and `version` arguments can be modified with the `save.defaults` option (used both by `save` and `save.image`), see also the example section below. If a `save.image.defaults` option is set it overrides `save.defaults` for function `save.image` (which allows this to have different defaults).

It is possible to compress later (with `gzip`) a file saved with `compress = FALSE`: the effect is the same as saving with `compress = TRUE`.

Warnings

The `...` arguments only give the *names* of the objects to be saved: they are searched for in the environment given by the `envir` argument, and the actual objects given as arguments need not be those found.

Saved R objects are binary files, even those saved with `ascii = TRUE`, so ensure that they are transferred without conversion of end of line markers and of 8-bit characters. The lines are delimited by LF on all platforms.

Although the default version has not changed since R 1.4.0, this does not mean that saved files are necessarily backwards compatible. You will be able to load a saved image into an earlier version of R unless use is made of later additions (for example, raw vectors or external pointers).

Note

The most common reason for failure is lack of write permission in the current directory. For `save.image` and for saving at the end of a session this will shown by messages like

```
Error in gzfile(file, "wb") : unable to open connection
In addition: Warning message:
In gzfile(file, "wb") :
  cannot open compressed file '.RDataTmp',
  probable reason 'Permission denied'
```

The defaults were changed to use compressed saves for `save` in 2.3.0 and for `save.image` in 2.4.0. Any recent version of R can read compressed save files, and a compressed file can be uncompressed (by `gzip -d`) for use with very old versions of R.

Examples

```
x <- stats::runif(20)
y <- list(a = 1, b = TRUE, c = "oops")
save(x, y, file = "xy.Rdata")
save.image()
unlink("xy.Rdata")
unlink(".RData")

# set save defaults using option:
options(save.defaults=list(ascii=TRUE, safe=FALSE))
save.image()
unlink(".RData")
```

 scale

Scaling and Centering of Matrix-like Objects

Description

`scale` is generic function whose default method centers and/or scales the columns of a numeric matrix.

Usage

```
scale(x, center = TRUE, scale = TRUE)
```

Arguments

<code>x</code>	a numeric matrix(like object).
<code>center</code>	either a logical value or a numeric vector of length equal to the number of columns of <code>x</code> .
<code>scale</code>	either a logical value or a numeric vector of length equal to the number of columns of <code>x</code> .

Details

The value of `center` determines how column centering is performed. If `center` is a numeric vector with length equal to the number of columns of `x`, then each column of `x` has the corresponding value from `center` subtracted from it. If `center` is `TRUE` then centering is done by subtracting the column means (omitting NAs) of `x` from their corresponding columns, and if `center` is `FALSE`, no centering is done.

The value of `scale` determines how column scaling is performed (after centering). If `scale` is a numeric vector with length equal to the number of columns of `x`, then each column of `x` is divided by the corresponding value from `scale`. If `scale` is `TRUE` then scaling is done by dividing the (centered) columns of `x` by their root-mean-square, and if `scale` is `FALSE`, no scaling is done.

The root-mean-square for a column is obtained by computing the square-root of the sum-of-squares of the non-missing values in the column divided by the number of non-missing values minus one.

Value

For `scale.default`, the centered, scaled matrix. The numeric centering and scalings used (if any) are returned as attributes `"scaled:center"` and `"scaled:scale"`

[sweep](#) which allows centering (and scaling) with arbitrary statistics.

For working with the scale of a plot, see [par](#).

Examples

```
require(stats)
x <- matrix(1:10, ncol=2)
(centered.x <- scale(x, scale=FALSE))
cov(centered.scaled.x <- scale(x))# all 1
```

 scan

Read Data Values

Description

Read data into a vector or list from the console or file.

Usage

```
scan(file = "", what = double(0), nmax = -1, n = -1, sep = "",
      quote = if(identical(sep, "\n")) "" else "'\"'", dec = ".",
      skip = 0, nlines = 0, na.strings = "NA",
      flush = FALSE, fill = FALSE, strip.white = FALSE,
      quiet = FALSE, blank.lines.skip = TRUE, multi.line = TRUE,
      comment.char = "", allowEscapes = FALSE,
      encoding = "unknown")
```

Arguments

- | | |
|------|--|
| file | <p>the name of a file to read data values from. If the specified file is "", then input is taken from the keyboard (or whatever <code>stdin()</code> reads if input is redirected or R is embedded). (In this case input can be terminated by a blank line or an EOF signal, <code>Ctrl-D</code> on Unix and <code>Ctrl-Z</code> on Windows.)</p> <p>Otherwise, the file name is interpreted <i>relative</i> to the current working directory (given by <code>getwd()</code>), unless it specifies an <i>absolute</i> path. Tilde-expansion is performed where supported. When running R from a script, <code>file="stdin"</code> can be used to refer to the process's <code>stdin</code> file stream.</p> <p>Alternatively, <code>file</code> can be a <i>connection</i>, which will be opened if necessary, and if so closed at the end of the function call. Whatever mode the connection is opened in, any of LF, CRLF or CR will be accepted as the EOL marker for a line and so will match <code>sep = "\n"</code>.</p> <p><code>file</code> can also be a complete URL.</p> <p>To read a data file not in the current encoding (for example a Latin-1 file in a UTF-8 locale or conversely) use a <i>file</i> connection setting the <code>encoding</code> argument.</p> |
| what | <p>the type of what gives the type of data to be read. The supported types are <code>logical</code>, <code>integer</code>, <code>numeric</code>, <code>complex</code>, <code>character</code>, <code>raw</code> and <code>list</code>. If <code>what</code> is a list, it is assumed that the lines of the data file are records each containing <code>length(what)</code> items ('fields') and the list components should have elements which are one of the first six types listed or <code>NULL</code>, see section 'Details' below.</p> |
| nmax | <p><code>integer</code>: the maximum number of data values to be read, or if <code>what</code> is a list, the maximum number of records to be read. If omitted or not positive or an invalid value for an integer (and <code>nlines</code> is not set to a positive value), <code>scan</code> will read to the end of <code>file</code>.</p> |

<code>n</code>	integer: the maximum number of data values to be read, defaulting to no limit. Invalid values will be ignored.
<code>sep</code>	by default, <code>scan</code> expects to read white-space delimited input fields. Alternatively, <code>sep</code> can be used to specify a character which delimits fields. A field is always delimited by an end-of-line marker unless it is quoted. If specified this should be the empty character string (the default) or <code>NULL</code> or a character string containing just one single-byte character.
<code>quote</code>	the set of quoting characters as a single character string or <code>NULL</code> . In a multibyte locale the quoting characters must be ASCII (single-byte).
<code>dec</code>	decimal point character. This should be a character string containing just one single-byte character. (<code>NULL</code> and a zero-length character vector are also accepted, and taken as the default.)
<code>skip</code>	the number of lines of the input file to skip before beginning to read data values.
<code>nlines</code>	if positive, the maximum number of lines of data to be read.
<code>na.strings</code>	character vector. Elements of this vector are to be interpreted as missing (<code>NA</code>) values. Blank fields are also considered to be missing values in logical, integer, numeric and complex fields.
<code>flush</code>	logical: if <code>TRUE</code> , <code>scan</code> will flush to the end of the line after reading the last of the fields requested. This allows putting comments after the last field, but precludes putting more than one record on a line.
<code>fill</code>	logical: if <code>TRUE</code> , <code>scan</code> will implicitly add empty fields to any lines with fewer fields than implied by <code>what</code> .
<code>strip.white</code>	vector of logical value(s) corresponding to items in the <code>what</code> argument. It is used only when <code>sep</code> has been specified, and allows the stripping of leading and trailing white space from character fields (numeric fields are always stripped). If <code>strip.white</code> is of length 1, it applies to all fields; otherwise, if <code>strip.white[i]</code> is <code>TRUE</code> and the <i>i</i> -th field is of mode character (because <code>what[i]</code> is) then the leading and trailing white space from field <i>i</i> is stripped.
<code>quiet</code>	logical: if <code>FALSE</code> (default), <code>scan()</code> will print a line, saying how many items have been read.
<code>blank.lines.skip</code>	logical: if <code>TRUE</code> blank lines in the input are ignored, except when counting <code>skip</code> and <code>nlines</code> .
<code>multi.line</code>	logical. Only used if <code>what</code> is a list. If <code>FALSE</code> , all of a record must appear on one line (but more than one record can appear on a single line). Note that using <code>fill = TRUE</code> implies that a record will terminated at the end of a line.
<code>comment.char</code>	character: a character vector of length one containing a single character or an empty string. Use <code>" "</code> to turn off the interpretation of comments altogether (the default).
<code>allowEscapes</code>	logical. Should C-style escapes such as <code>\n</code> be processed (the default) or read verbatim? Note that if not within quotes these could be interpreted as a delimiter (but not as a comment character). The escapes which are interpreted are the control characters <code>\a</code> , <code>\b</code> , <code>\f</code> , <code>\n</code> , <code>\r</code> , <code>\t</code> , <code>\v</code> and octal and hexadecimal representations like <code>\040</code> and <code>\0x2A</code> . Any other escaped character is treated as itself, including backslash.

encoding encoding to be assumed for input strings. If the value is "latin1" or "UTF-8" it is used to mark character strings as known to be in Latin-1 or UTF-8: it is not used to re-encode the input. To do the latter, specify the encoding as part of the connection `con` or via `options(encoding=)`: see the example under [file](#).

Details

The value of `what` can be a list of types, in which case `scan` returns a list of vectors with the types given by the types of the elements in `what`. This provides a way of reading columnar data. If any of the types is `NULL`, the corresponding field is skipped (but a `NULL` component appears in the result).

The type of `what` or its components can be one of the six atomic vector types or `NULL` (see [is.atomic](#)).

‘White space’ is defined for the purposes of this function as one or more contiguous characters from the set space, horizontal tab, carriage return and line feed. It does not include form feed or vertical tab, but in Latin-1 and Windows 8-bit locales ‘space’ includes non-breaking space.

Empty numeric fields are always regarded as missing values. Empty character fields are scanned as empty character vectors, unless `na.strings` contains "" when they are regarded as missing values.

The allowed input for a numeric field is optional whitespace followed either `NA` or an optional sign followed by a decimal or hexadecimal constant (see [NumericConstants](#)), or `NaN`, `Inf` or `infinity` (ignoring case). Out-of-range values are recorded as `Inf`, `-Inf` or `0`.

For an integer field the allowed input is optional whitespace, followed by either `NA` or an optional sign and one or more digits (0–9): all out-of-range values are converted to `NA_integer_`.

If `sep` is the default (" "), the character \ in a quoted string escapes the following character, so quotes may be included in the string by escaping them.

If `sep` is non-default, the fields may be quoted in the style of ‘.CSV’ files where separators inside quotes (" or ") are ignored and quotes may be put inside strings by doubling them. However, if `sep = "\n"` it is assumed by default that one wants to read entire lines verbatim.

Quoting is only interpreted in character fields and in `NULL` fields (which might be skipping character fields).

Note that since `sep` is a separator and not a terminator, reading a file by `scan("foo", sep="\n", blank.lines.skip=FALSE)` will give an empty final line if the file ends in a linefeed and not if it does not. This might not be what you expected; see also [readLines](#).

If `comment.char` occurs (except inside a quoted character field), it signals that the rest of the line should be regarded as a comment and be discarded. Lines beginning with a comment character (possibly after white space with the default separator) are treated as blank lines.

There is a check for a user interrupt every 1000 lines if `what` is a list, otherwise every 10000 items.

Value

if `what` is a list, a list of the same length and same names (as any) as `what`.

Otherwise, a vector of the type of `what`.

Character strings in the result will have a declared encoding if `encoding` is "latin1" or "UTF-8".

Note

The default for `multi.line` differs from `S`. To read one record per line, use `flush = TRUE` and `multi.line = FALSE`. (Note that quoted character strings can still include embedded new-lines.)

If number of items is not specified, the internal mechanism re-allocates memory in powers of two and so could use up to three times as much memory as needed. (It needs both old and new copies.) If you can, specify either `n` or `nmax` whenever inputting a large vector, and `nmax` or `nlines` when inputting a large list.

Using `scan` on an open connection to read partial lines can lose chars: use an explicit separator to avoid this.

Having nul bytes in fields (including `\0` if `allowEscapes = TRUE`) may lead to interpretation of the field being terminated at the nul. They not normally present in text files – see `readBin`.

See Also

`read.table` for more user-friendly reading of data matrices; `readLines` to read a file a line at a time. `write`.

Quotes for the details of C-style escape sequences.

`readChar` and `readBin` to read fixed or variable length character strings or binary representations of numbers a few at a time from a connection.

Examples

```
cat("TITLE extra line", "2 3 5 7", "11 13 17", file="ex.data", sep="\n")
pp <- scan("ex.data", skip = 1, quiet= TRUE)
scan("ex.data", skip = 1)
scan("ex.data", skip = 1, nlines=1) # only 1 line after the skipped one
scan("ex.data", what = list("", "", "")) # flush is F -> read "7"
scan("ex.data", what = list("", "", ""), flush = TRUE)
unlink("ex.data") # tidy up
```

search

Give Search Path for R Objects

Description

Gives a list of *attached packages* (see `library`), and `R` objects, usually `data.frames`.

Usage

```
search()
searchpaths()
```

Value

A character vector, starting with `".GlobalEnv"`, and ending with `"package:base"` which is R's **base** package required always.

`searchpaths` gives a similar character vector, with the entries for packages being the path to the package used to load the code.

References

[attach](#) and [detach](#) to change the search path, [objects](#) to find R objects in there.

Examples

```
search()
searchpaths()
```

 seek

Functions to Reposition Connections

Description

Functions to re-position connections.

Usage

```
seek(con, ...)
## S3 method for class 'connection':
seek(con, where = NA, origin = "start", rw = "", ...)

isSeekable(con)

truncate(con, ...)
```

Arguments

<code>con</code>	a connection.
<code>where</code>	numeric. A file position (relative to the origin specified by <code>origin</code>), or <code>NA</code> .
<code>rw</code>	character. Empty or <code>"read"</code> or <code>"write"</code> , partial matches allowed.
<code>origin</code>	character. One of <code>"start"</code> , <code>"current"</code> , <code>"end"</code> : see ‘Details’.
<code>...</code>	further arguments passed to or from other methods.

Details

`seek` with `where = NA` returns the current byte offset of a connection (from the beginning), and with a non-missing `where` argument the connection is re-positioned (if possible) to the specified position. `isSeekable` returns whether the connection in principle supports `seek`: currently only (possibly gz-compressed) file connections do. `gzfile` connections do not support `origin = "end"`; the file position they use is that of the uncompressed file.

`where` is stored as a real but should represent an integer: non-integer values are likely to be truncated. Note that the possible values can exceed the largest representable number in an R integer on 64-bit OSes, and on some 32-bit OSes.

File connections can be open for both writing/appending, in which case R keeps separate positions for reading and writing. Which `seek` refers to can be set by its `rw` argument: the default is the last mode (reading or writing) which was used. Most files are only opened for reading or writing and so default to that state. If a file is open for both reading and writing but has not been used, the default is to give the reading position (0).

The initial file position for reading is always at the beginning. The initial position for writing is at the beginning of the file for modes `"r+"` and `"r+b"`, otherwise at the end of the file. Some platforms only allow writing at the end of the file in the append modes. (The reported write position for a file opened in an append mode will typically be unreliable until the file has been written to.)

If `seek` is called with a non-NA value of `where`, any pushback on a text-mode connection is discarded.

`truncate` truncates a file opened for writing at its current position. It works only for file connections, and is not implemented on all platforms: on others (including Windows) it will not work for large (> 2Gb) files.

Value

`seek` returns the current position (before any move), as a (numeric) byte offset from the origin, if relevant, or 0 if not. Note that the position can exceed the largest representable number in an R integer on 64-bit OSes, and on some 32-bit OSes.

`truncate` returns `NULL`: it stops with an error if it fails (or is not implemented).

`isSeekable` returns a logical value, whether the connection supports `seek`.

[connections](#)

seq

Sequence Generation

Description

Generate regular sequences. `seq` is a standard generic with a default method. `seq.int` is an internal generic which can be much faster but has a few restrictions. `seq_along` and `seq_len` are very fast primitives for two common cases.

Usage

```
seq(...)

## Default S3 method:
seq(from = 1, to = 1, by = ((to - from)/(length.out - 1)),
     length.out = NULL, along.with = NULL, ...)

seq.int(from, to, by, length.out, along.with, ...)

seq_along(along.with)
seq_len(length.out)
```

Arguments

<code>...</code>	arguments passed to or from methods.
<code>from, to</code>	the starting and (maximal) end value of the sequence.
<code>by</code>	number: increment of the sequence.
<code>length.out</code>	desired length of the sequence. A non-negative number, which for <code>seq</code> and <code>seq.int</code> will be rounded up if fractional.
<code>along.with</code>	take the length from the length of this argument.

Details

The interpretation of the unnamed arguments of `seq` and `seq.int` is *not* standard, and it is recommended always to name the arguments when programming.

Both `seq` and `seq.int` are generic, and only the default method is described here. Typical usages are

```
seq(from, to)
seq(from, to, by= )
seq(from, to, length.out= )
seq(along.with= )
seq(from)
seq(length.out= )
```

The first form generates the sequence `from, from+/-1, ..., to` (identical to `from:to`).

The second form generates `from, from+by, ..., up to the sequence value less than or equal to to`. Specifying `to - from` and `by` of opposite signs is an error. Note that the final value can go just beyond `to` to allow for rounding error.

The third generates a sequence of `length.out` equally spaced values from `from` to `to`. (`length.out` is usually abbreviated to `length` or `len`, and `seq_len` is much faster.)

The fourth form generates the sequence `1, 2, ..., length(along.with)`. (`along.with` is usually abbreviated to `along`, and `seq_along` is much faster.)

The fifth form generates the sequence `1, 2, ..., length(from)` (as if argument `along.with` had been specified), *unless* the argument is numeric of length 1 when it is interpreted as `1:from` (even for `seq(0)` for compatibility with S).

The final form generates `1, 2, ..., length.out` unless `length.out = 0`, when it generates `integer(0)`.

Very small sequences (with `from` - `to` of the order of 10^{-14} times the larger of the ends) will return `from`.

For `seq(only)`, up to two of `from`, `to` and `by` can be supplied as complex values provided `length.out` or `along.with` is specified.

Value

Currently, the default method returns a result of type "integer" if `from` is (numerically equal to an) integer and, e.g., only `to` is specified, or also if only `length` or only `along.with` is specified. **Note:** this may change in the future and programmers should not rely on it.

The methods `seq.Date` and `seq.POSIXt`.
`;`, `rep`, `sequence`, `row`, `col`.

Examples

```
seq(0, 1, length.out=11)
seq(stats::rnorm(20))
seq(1, 9, by = 2) # match
seq(1, 9, by = pi)# stay below
seq(1, 6, by = 3)
seq(1.575, 5.125, by=0.05)
seq(17) # same as 1:17
```

seq.Date

Generate Regular Sequences of Dates

Description

The method for `seq` for objects of class class "Date" representing calendar dates.

Usage

```
## S3 method for class 'Date':
seq(from, to, by, length.out = NULL, along.with = NULL, ...)
```

Arguments

<code>from</code>	starting date. Required
<code>to</code>	end date. Optional.
<code>by</code>	increment of the sequence. Optional. See 'Details'.
<code>length.out</code>	integer, optional. desired length of the sequence.
<code>along.with</code>	take the length from the length of this argument.
<code>...</code>	arguments passed to or from other methods.

Details

by can be specified in several ways.

- A number, taken to be in days.
- A object of class `diffftime`
- A character string, containing one of "day", "week", "month" or "year". This can optionally be preceded by a (positive or negative) integer and a space, or followed by "s". See `seq.POSIXt` for the details of "month".

Value

A vector of class "Date".

See Also

`Date`

Examples

```
## first days of years
seq(as.Date("1910/1/1"), as.Date("1999/1/1"), "years")
## by month
seq(as.Date("2000/1/1"), by="month", length.out=12)
## quarters
seq(as.Date("2000/1/1"), as.Date("2003/1/1"), by="3 months")

## find all 7th of the month between two dates, the last being a 7th.
st <- as.Date("1998-12-17")
en <- as.Date("2000-1-7")
ll <- seq(en, st, by="-1 month")
rev(ll[ll > st & ll < en])
```

seq.POSIXt

Generate Regular Sequences of Dates

Description

The method for `seq` for date-time classes.

Usage

```
## S3 method for class 'POSIXt':
seq(from, to, by, length.out = NULL, along.with = NULL, ...)
```

Arguments

from	starting date. Required.
to	end date. Optional.
by	increment of the sequence. Optional. See 'Details'.
length.out	integer, optional. desired length of the sequence.
along.with	take the length from the length of this argument.
...	arguments passed to or from other methods.

Details

by can be specified in several ways.

- A number, taken to be in seconds.
- A object of class `difftime`
- A character string, containing one of "sec", "min", "hour", "day", "DSTday", "week", "month" or "year". This can optionally be preceded by a (positive or negative) integer and a space, or followed by "s".

The difference between "day" and "DSTday" is that the former ignores changes to/from daylight savings time and the latter takes the same clock time each day. ("week" ignores DST (it is a period of 144 hours), but "7 DSTdays") can be used as an alternative. "month" and "year" allow for DST.)

The timezone of the result is taken from `from`: remember that GMT does not have daylight savings time.

Using "month" first advances the month without changing the day: if this results in an invalid day of the month, it is counted forward into the next month: see the examples.

Value

A vector of class "POSIXct".

See Also

[DateTimeClasses](#)

Examples

```
## first days of years
seq(ISOdate(1910,1,1), ISOdate(1999,1,1), "years")
## by month
seq(ISOdate(2000,1,1), by = "month", length.out = 12)
seq(ISOdate(2000,1,31), by = "month", length.out = 4)
## quarters
seq(ISOdate(1990,1,1), ISOdate(2000,1,1), by = "3 months")
## days vs DSTdays: use c() to lose the timezone.
seq(c(ISOdate(2000,3,20)), by = "day", length.out = 10)
seq(c(ISOdate(2000,3,20)), by = "DSTday", length.out = 10)
seq(c(ISOdate(2000,3,20)), by = "7 DSTdays", length.out = 4)
```

sequence

Create A Vector of Sequences

Description

For each element of `nvec` the sequence `seq_len(nvec[i])` is created. These are concatenated and the result returned.

Usage

```
sequence(nvec)
```

Arguments

`nvec` a non-negative integer vector each element of which specifies the end point of a sequence.

Details

Earlier versions of `sequence` used to work for 0 or negative inputs as `seq(x) == 1:x`.

Note that `sequence <- function(nvec) unlist(lapply(nvec, seq_len))` and it mainly exists in reverence to the very early history of R.

See Also

[gl](#), [seq](#), [rep](#).

Examples

```
sequence(c(3,2))# the concatenated sequences 1:3 and 1:2.
#> [1] 1 2 3 1 2
```

sets

Set Operations

Description

Performs **set** union, intersection, (asymmetric!) difference, equality and membership on two vectors.

Usage

```
union(x, y)
intersect(x, y)
setdiff(x, y)
setequal(x, y)

is.element(el, set)
```

Arguments

`x`, `y`, `el`, `set`
vectors (of the same mode) containing a sequence of items (conceptually) with no duplicated values.

Details

Each of `union`, `intersect`, `setdiff` and `setequal` will discard any duplicated values in the arguments, and they apply [as.vector](#) to their arguments (and so in particular coerce factors to character vectors).

`is.element(x, y)` is identical to `x %in% y`.

Value

A vector of the same `mode` as `x` or `y` for `setdiff` and `intersect`, respectively, and of a common mode for `union`.

A logical scalar for `setequal` and a logical of the same length as `x` for `is.element`.

See Also

`%in%`

`'plotmath'` for the use of `union` and `intersect` in plot annotation.

Examples

```
(x <- c(sort(sample(1:20, 9)),NA))
(y <- c(sort(sample(3:23, 7)),NA))
union(x, y)
intersect(x, y)
setdiff(x, y)
setdiff(y, x)
setequal(x, y)

## True for all possible x & y :
setequal( union(x,y),
          c(setdiff(x,y), intersect(x,y), setdiff(y,x)))

is.element(x, y)# length 10
is.element(y, x)# length 8
```

setTimeLimit

Set CPU and/or Elapsed Time Limits

Description

Functions to set CPU and/or elapsed time limits for top-level computations or the current session.

Usage

```
setTimeLimit(cpu = Inf, elapsed = Inf, transient = FALSE)
```

```
setSessionTimeLimit(cpu = Inf, elapsed = Inf)
```

Arguments

`cpu` **double.** Limit on total cpu time.

`elapsed` **double.** Limit on elapsed time.

`transient` **logical.** If TRUE, the limits apply only to the rest of the current computation.

Details

`setTimeLimit` sets limits which apply to each top-level computation, that is a command line (including any continuation lines) entered at the console or from a file. If it is called from within a computation the limits apply to the rest of the computation and (unless `transient = TRUE` to subsequent top-level computations.

`setSessionTimeLimit` sets limits for the rest of the session. Once a session limit is reached it is reset to `Inf`.

Setting any limit has a small overhead – well under 1% on the systems measured.

Time limits are checked whenever a user interrupt could occur. This will happen frequently in R code and during `Sys.sleep`, but only at points in compiled C and Foreign code identified by the code author.

‘Total cpu time’ includes that used by child processes where the latter is reported.

It is possible (but very unusual) to build R without support for `proc.time`, in which case these functions have no effect.

showConnections *Display Connections*

Description

Display aspects of connections.

Usage

```
showConnections(all = FALSE)
getConnection(what)
closeAllConnections()
```

```
stdin()
stdout()
stderr()
```

Arguments

<code>all</code>	logical: if true all connections, including closed ones and the standard ones are displayed. If false only open user-created connections are included.
<code>what</code>	integer: a row number of the table given by <code>showConnections</code> .

Details

`stdin()`, `stdout()` and `stderr()` are standard connections corresponding to input, output and error on the console respectively (and not necessarily to file streams). They are text-mode connections of class "terminal" which cannot be opened or closed, and are read-only, write-only and write-only respectively. The `stdout()` and `stderr()` connections can be re-directed by `sink` (and in some circumstances the output from `stdout()` can be split: see the help page).

The encoding for `stdin()` when redirected can be set by the command-line flag `--encoding`.

`showConnections` returns a matrix of information. If a connection object has been lost or forgotten, `getConnection` will take a row number from the table and return a connection object

for that connection, which can be used to close the connection, for example. However, if there is no R level object referring to the connection it will be closed automatically at the next garbage collection.

`closeAllConnections` closes (and destroys) all user connections, restoring all `sink` diversions as it does so.

Value

`stdin()`, `stdout()` and `stderr()` return connection objects.

`showConnections` returns a character matrix of information with a row for each connection, by default only for open non-standard connections.

`getConnection` returns a connection object, or `NULL`.

Note

`stdin()` refers to the ‘console’ and not to the C-level ‘`stdin`’ of the process. The distinction matters in GUI consoles (which may not have an active ‘`stdin`’, and if they do it may not be connected to console input), and also in embedded applications. If you want access to the C-level file stream ‘`stdin`’, use `file("stdin")`.

When R is reading a script from a file, the *file* is the ‘console’: this is traditional usage to allow in-line data (see ‘An Introduction to R’ for an example).

Examples

```
showConnections(all = TRUE)

textConnection(letters)
# oops, I forgot to record that one
showConnections()
# class      description      mode text  isopen  can read can write
#3 "letters" "textConnection" "r"  "text" "opened" "yes"    "no"
## Not run: close(getConnection(3))

showConnections()
```

shQuote

Quote Strings for Use in OS Shells

Description

Quote a string to be passed to an operating system shell.

Usage

```
shQuote(string, type = c("sh", "csh", "cmd"))
```

Arguments

string	a character vector, usually of length one.
type	character: the type of shell. Partial matching is supported. "cmd" refers to the Windows NT shell, and is the default under Windows.

Details

The default type of quoting supported under Unix-alikes is that for the Bourne shell `sh`. If the string does not contain single quotes, we can just surround it with single quotes. Otherwise, the string is surrounded in double quotes, which suppresses all special meanings of metacharacters except dollar, backquote and backslash, so these (and of course double quote) are preceded by backslash. This type of quoting is also appropriate for `bash`, `ksh` and `zsh`.

The other type of quoting is for the C-shell (`csh` and `tcsh`). Once again, if the string does not contain single quotes, we can just surround it with single quotes. If it does contain single quotes, we can use double quotes provided it does not contain dollar or backquote (and we need to escape backslash, exclamation mark and double quote). As a last resort, we need to split the string into pieces not containing single quotes and surround each with single quotes, and the single quotes with double quotes.

`sQuote` for quoting English text.

Examples

```
test <- "abc$def`gh`i\\j"
cat(shQuote(test), "\n")
## Not run: system(paste("echo", shQuote(test)))
test <- "don't do it!"
cat(shQuote(test), "\n")

tryit <- paste("use the", sQuote("-c"), "switch\nlike this")
cat(shQuote(tryit), "\n")
## Not run: system(paste("echo", shQuote(tryit)))
cat(shQuote(tryit, type="csh"), "\n")

## Windows-only example.
perlcmd <- 'print "Hello World\n";'
## Not run: shell(paste("perl -e", shQuote(perlcmd), type="cmd"))
```

sign	<i>Sign Function</i>
------	----------------------

Description

`sign` returns a vector with the signs of the corresponding elements of `x` (the sign of a real number is 1, 0, or -1 if the number is positive, zero, or negative, respectively).

Note that `sign` does not operate on complex vectors.

Usage

```
sign(x)
```

Arguments

`x` a numeric vector

Details

This is a generic function: methods can be defined for it directly or via the [Math](#) group generic.

See Also

[abs](#)

Examples

```
sign(pi) # == 1
sign(-2:3) # -1 -1 0 1 1 1
```

Signals	<i>Interrupting Execution of R</i>
---------	------------------------------------

Description

On receiving `SIGUSR1` R will save the workspace and quit. `SIGUSR2` has the same result except that the `.Last` function and `on.exit` expressions will not be called.

Usage

```
kill -USR1 pid
kill -USR2 pid
```

Arguments

`pid` The process ID of the R process

Warning

It is possible that one or more R objects will be undergoing modification at the time the signal is sent. These objects could be saved in a corrupted form.

sink

Send R Output to a File

Description

`sink` diverts R output to a connection.

`sink.number()` reports how many diversions are in use.

`sink.number(type = "message")` reports the number of the connection currently being used for error messages.

Usage

```
sink(file = NULL, append = FALSE, type = c("output", "message"),
      split = FALSE)
```

```
sink.number(type = c("output", "message"))
```

Arguments

<code>file</code>	a writable connection or a character string naming the file to write to, or <code>NULL</code> to stop sink-ing.
<code>append</code>	logical. If <code>TRUE</code> , output will be appended to <code>file</code> ; otherwise, it will overwrite the contents of <code>file</code> .
<code>type</code>	character. Either the output stream or the messages stream.
<code>split</code>	logical: if <code>TRUE</code> , output will be sent to the new sink and to the current output stream, like the Unix program <code>tee</code> .

Details

`sink` diverts R output to a connection. If `file` is a character string, a file connection with that name will be established for the duration of the diversion.

Normal R output (to connection `stdout`) is diverted by the default `type = "output"`. Only prompts and (most) messages continue to appear on the console. Messages sent to `stderr()` (including those from `message`, `warning` and `stop`) can be diverted by `sink(type = "message")` (see below).

`sink()` or `sink(file=NULL)` ends the last diversion (of the specified type). There is a stack of diversions for normal output, so output reverts to the previous diversion (if there was one). The stack is of up to 21 connections (20 diversions).

If `file` is a connection it will be opened if necessary (in "wt" mode) and closed once it is removed from the stack of diversions.

`split = TRUE` only splits R output (via `Rvprintf`) and the default output from `writeln`: it does not split all output that might be sent to `stdout()`.

Sink-ing the messages stream should be done only with great care. For that stream `file` must be an already open connection, and there is no stack of connections.

Value

`sink` returns `NULL`.

For `sink.number()` the number (0, 1, 2, ...) of diversions of output in place.

For `sink.number("message")` the connection number used for messages, 2 if no diversion has been used.

Warning

Do not use a connection that is open for `sink` for any other purpose. The software will stop you closing one such inadvertently.

Do not sink the messages stream unless you understand the source code implementing it and hence the pitfalls.

Note

`sink(split = TRUE)` is only available on systems which support the C99 function `va_copy` (or under the name `__va_copy`), but we know of no current systems which do not.

See Also

[capture.output](#)

Examples

```
sink("sink-examp.txt")
i <- 1:10
outer(i, i, "*")
sink()
unlink("sink-examp.txt")
## Not run:
## capture all the output to a file.
zz <- file("all.Rout", open="wt")
sink(zz)
sink(zz, type="message")
try(log("a"))
## back to the console
sink(type="message")
sink()
try(log("a"))
## End(Not run)
```

Details

This operator supports the formal classes of package **methods**, and is enabled only when **methods** is loaded (as per default). See [slot](#) for further details.

As from R 2.7.0 it is checked that `object` is an S4 object (see [isS4](#)), and as from R 2.8.0 it is an error to attempt to use `@` on any other object. (There is an exception for name `.Data` for internal use only.)

If `name` is not a slot name, an error is thrown.

Value

The current contents of the slot.

See Also

[Extract](#), [slot](#)

socketSelect	<i>Wait on Socket Connections</i>
--------------	-----------------------------------

Description

Waits for the first of several socket connections to become available.

Usage

```
socketSelect(socklist, write = FALSE, timeout = NULL)
```

Arguments

<code>socklist</code>	list of open socket connections
<code>write</code>	logical. If TRUE wait for corresponding socket to become available for writing; otherwise wait for it to become available for reading.
<code>timeout</code>	numeric or NULL. Time in seconds to wait for a socket to become available; NULL means wait indefinitely.

Details

The values in `write` are recycled if necessary to make up a logical vector the same length as `socklist`. Socket connections can appear more than once in `socklist`; this can be useful if you want to determine whether a socket is available for reading or writing.

Value

Logical the same length as `socklist` indicating whether the corresponding socket connection is available for output or input, depending on the corresponding value of `write`.

Examples

```
## Not run:
## test whether socket connection s is available for writing or reading
socketSelect(list(s,s),c(TRUE,FALSE),timeout=0)
## End(Not run)
```

 solve

Solve a System of Equations

Description

This generic function solves the equation $a \%*\% x = b$ for x , where b can be either a vector or a matrix.

Usage

```
solve(a, b, ...)

## Default S3 method:
solve(a, b, tol, LINPACK = FALSE, ...)
```

Arguments

<code>a</code>	a square numeric or complex matrix containing the coefficients of the linear system.
<code>b</code>	a numeric or complex vector or matrix giving the right-hand side(s) of the linear system. If missing, <code>b</code> is taken to be an identity matrix and <code>solve</code> will return the inverse of <code>a</code> .
<code>tol</code>	the tolerance for detecting linear dependencies in the columns of <code>a</code> . If <code>LINPACK</code> is <code>TRUE</code> the default is <code>1e-7</code> , otherwise it is <code>.Machine\$double.eps</code> . Future versions of R may use a tighter tolerance. Not presently used with complex matrices <code>a</code> .
<code>LINPACK</code>	logical. Should <code>LINPACK</code> be used (for compatibility with R < 1.7.0)? Otherwise <code>LAPACK</code> is used.
<code>...</code>	further arguments passed to or from other methods

Details

`a` or `b` can be complex, but this uses double complex arithmetic which might not be available on all platforms and `LAPACK` will always be used.

The row and column names of the result are taken from the column names of `a` and of `b` respectively. If `b` is missing the column names of the result are the row names of `a`. No check is made that the column names of `a` and the row names of `b` are equal.

For back-compatibility `a` can be a (real) QR decomposition, although `qr.solve` should be called in that case. `qr.solve` can handle non-square systems.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`solve.qr` for the `qr` method, `chol2inv` for inverting from the Choleski factor `backsolve`, `qr.solve`.

Examples

```

hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
h8 <- hilbert(8); h8
sh8 <- solve(h8)
round(sh8 %*% h8, 3)

A <- hilbert(4)
A[] <- as.complex(A)
## might not be supported on all platforms
try(solve(A))

```

 sort

Sorting or Ordering Vectors

Description

Sort (or *order*) a vector or factor (partially) into ascending (or descending) order. For ordering along more than one variable, e.g., for sorting data frames, see [order](#).

Usage

```

sort(x, decreasing = FALSE, ...)

## Default S3 method:
sort(x, decreasing = FALSE, na.last = NA, ...)

sort.int(x, partial = NULL, na.last = NA, decreasing = FALSE,
         method = c("shell", "quick"), index.return = FALSE)

```

Arguments

<code>x</code>	for <code>sort</code> an R object with a class or a numeric, complex, character or logical vector. For <code>sort.int</code> , a numeric, complex, character or logical vector, or a factor.
<code>decreasing</code>	logical. Should the sort be increasing or decreasing? Not available for partial sorting.
<code>...</code>	arguments to be passed to or from methods or (for the default methods and objects without a class) to <code>sort.int</code> .
<code>na.last</code>	for controlling the treatment of NAs. If <code>TRUE</code> , missing values in the data are put last; if <code>FALSE</code> , they are put first; if <code>NA</code> , they are removed.
<code>partial</code>	<code>NULL</code> or an integer vector of indices for partial sorting.
<code>method</code>	character string specifying the algorithm used.
<code>index.return</code>	logical indicating if the ordering index vector should be returned as well; this is only available for a few cases, the default <code>na.last = NA</code> and full sorting of non-factors.

Details

`sort` is a generic function for which methods can be written, and `sort.int` is the internal method which is compatible with S if only the first three arguments are used.

The default `sort` method makes use of `order` for objects with classes, which in turn makes use of the generic function `xtfrm`.

If `partial` is not `NULL`, it is taken to contain indices of elements of `x` which are to be placed in their correct positions by partial sorting. After the sort, the values specified in `partial` are in their correct position in the sorted array. Any values smaller than these values are guaranteed to have a smaller index in the sorted array and any values which are greater are guaranteed to have a bigger index in the sorted array. (This is included for efficiency, and many of the options are not available for partial sorting. It is only substantially more efficient if `partial` has a handful of elements, and a full sort is done if there are more than 10.) Names are discarded for partial sorting.

Complex values are sorted first by the real part, then the imaginary part.

The sort order for character vectors will depend on the collating sequence of the locale in use: see [Comparison](#). The sort order for factors is the order of their levels (which is particularly appropriate for ordered factors).

Method `"shell"` uses Shellsort (an $O(n^{4/3})$ variant from Sedgewick (1996)). If `x` has names a stable sort is used, so ties are not reordered. (This only matters if names are present.)

Method `"quick"` uses Singleton's Quicksort implementation and is only available when `x` is numeric (double or integer) and `partial` is `NULL`. (For other types of `x` Shellsort is used, silently.) It is normally somewhat faster than Shellsort (perhaps twice as fast on vectors of length a million) but has poor performance in the rare worst case. (Peto's modification using a pseudo-random midpoint is used to make the worst case rarer.) This is not a stable sort, and ties may be reordered.

Value

For `sort`, the result depends on the S3 method which is dispatched. If `x` does not have a class the rest of this section applies. For classed objects which do not have a specific method the default method will be used and is equivalent to `x[order(x, ...)]`: this depends on the class having a suitable method for `[]` (and also that `order` will work, which is not the case for a class based on a list).

For `sort.int` the sorted vector unless `index.return` is true, when the result is a list with components named `x` and `ix` containing the sorted numbers and the ordering index vector. In the latter case, if `method == "quick"` ties may be reversed in the ordering, unlike `sort.list`, as quicksort is not stable.

All attributes are removed from the return value (see Becker *et al*, 1988, p.146) except names, which are sorted. (If `partial` is specified even the names are removed.) Note that this means that the returned value has no class, except for factors and ordered factors (which are treated specially and whose result is transformed back to the original class).

## End(Not run)
```

source

Read R Code from a File or a Connection

Description

`source` causes R to accept its input from the named file or URL (the name must be quoted) or connection. Input is read and [parsed](#) by from that file until the end of the file is reached, then the parsed expressions are evaluated sequentially in the chosen environment.

Usage

```
source(file, local = FALSE, echo = verbose, print.eval = echo,
       verbose = getOption("verbose"),
       prompt.echo = getOption("prompt"),
       max.deparse.length = 150, chdir = FALSE,
       encoding = getOption("encoding"),
       continue.echo = getOption("continue"),
       skip.echo = 0, keep.source = getOption("keep.source"))
```

Arguments

<code>file</code>	a connection or a character string giving the pathname of the file or URL to read from. "" indicates the connection <code>stdin()</code> .
<code>local</code>	if <code>local</code> is <code>FALSE</code> , the statements scanned are evaluated in the user's workspace (the global environment), otherwise in the environment calling <code>source</code> .
<code>echo</code>	logical; if <code>TRUE</code> , each expression is printed after parsing, before evaluation.
<code>print.eval</code>	logical; if <code>TRUE</code> , the result of <code>eval(i)</code> is printed for each expression <code>i</code> ; defaults to the value of <code>echo</code> .
<code>verbose</code>	if <code>TRUE</code> , more diagnostics (than just <code>echo = TRUE</code>) are printed during parsing and evaluation of input, including extra info for each expression.
<code>prompt.echo</code>	character; gives the prompt to be used if <code>echo = TRUE</code> .
<code>max.deparse.length</code>	integer; is used only if <code>echo</code> is <code>TRUE</code> and gives the maximal number of characters output for the deparse of a single expression.
<code>chdir</code>	logical; if <code>TRUE</code> and <code>file</code> is a pathname, the R working directory is temporarily changed to the directory containing <code>file</code> for evaluating.
<code>encoding</code>	character vector. The encoding(s) to be assumed when <code>file</code> is a character string: see <code>file</code> . A possible value is "unknown" when the encoding is guesses: see the 'Details'.
<code>continue.echo</code>	character; gives the prompt to use on continuation lines if <code>echo = TRUE</code> .
<code>skip.echo</code>	integer; how many comment lines at the start of the file to skip if <code>echo = TRUE</code> .
<code>keep.source</code>	logical: should the source formatting be retained when echo expressions, if possible?

Details

Note that running code via `source` differs in a few respects from entering it at the R command line. Since expressions are not executed at the top level, auto-printing is not done. So you will need to include explicit `print` calls for things you want to be printed (and remember that this includes plotting by **lattice**, FAQ Q7.22). Since the complete file is parsed before any of it is run, syntax errors result in none of the code being run. If an error occurs in running a syntactically correct script, anything assigned into the workspace by code that has been run will be kept (just as from the command line), but diagnostic information such as `traceback()` will contain additional calls to `eval.with.vis`, an undocumented internal function.

All versions of R accept input from a connection with end of line marked by LF (as used on Unix), CRLF (as used on DOS/Windows) or CR (as used on classic MacOS). The final line can be incomplete, that is missing the final end-of-line marker.

If `options("keep.source")` is true (the default in interactive use), the source of functions is kept so they can be listed exactly as input. This imposes a limit of 128K bytes on the function size and a nesting limit of 265. Use `keep.source = FALSE` when these limits might take effect: if exceeded they generate an error.

This paragraph applies if `file` is a filename (rather than a connection). If `encoding = "unknown"`, an attempt is made to guess the encoding. The result of `localeToCharset()` is used as a guide. If `encoding` has two or more elements, they are tried in turn until the file/URL can be read without error in the trial encoding.

If `file` is a connection (including one specified by "`"`", it is not possible to re-encode the input inside `source`, and so the `encoding` argument is just used to mark character strings in the parsed input: see `parse`.

Unlike input from a console, lines in the file or on a connection can contain an unlimited number of characters.

When `skip.echo > 0`, that many comment lines at the start of the file will not be echoed. This does not affect the execution of the code at all. If there are executable lines within the first `skip.echo` lines, echoing will start with the first of them.

If `echo` is true and a deparsed expression exceeds `max.deparse.length`, that many characters are output followed by `.... [TRUNCATED]`.

Examples

```
## If you want to source() a bunch of files, something like
## the following may be useful:
sourceDir <- function(path, trace = TRUE, ...) {
  for (nm in list.files(path, pattern = "\\.[RrSsQq]$")) {
    if(trace) cat(nm,":")
    source(file.path(path, nm), ...)
    if(trace) cat("\n")
  }
}
```

Description

Special mathematical functions related to the beta and gamma functions.

Usage

```

beta(a, b)
lbeta(a, b)

gamma(x)
lgamma(x)
psigamma(x, deriv = 0)
digamma(x)
trigamma(x)

choose(n, k)
lchoose(n, k)
factorial(x)
lfactorial(x)

```

Arguments

`a, b` non-negative numeric vectors.
`x, n` numeric vectors.
`k, deriv` integer vectors.

Details

The functions `beta` and `lbeta` return the beta function and the natural logarithm of the beta function,

$$B(a, b) = \frac{\Gamma(a)\Gamma(b)}{\Gamma(a+b)}.$$

The formal definition is

$$B(a, b) = \int_0^1 t^{a-1}(1-t)^{b-1} dt$$

(Abramowitz and Stegun section 6.2.1, page 258). Note that it is only defined in \mathbb{R} for non-negative a and b , and is infinite if either is zero.

The functions `gamma` and `lgamma` return the gamma function $\Gamma(x)$ and the natural logarithm of the absolute value of the gamma function. The gamma function is defined by (Abramowitz and Stegun section 6.1.1, page 255)

$$\Gamma(x) = \int_0^\infty t^{x-1} e^{-t} dt$$

for all real x except zero and negative integers (when NaN is returned). `factorial(x)` ($x!$ for non-negative integer x) is defined to be `gamma(x+1)` and `lfactorial` to be `lgamma(x+1)`.

The functions `digamma` and `trigamma` return the first and second derivatives of the logarithm of the gamma function. `psigamma(x, deriv)` (`deriv` ≥ 0) computes the `deriv`-th derivative of $\psi(x)$.

$$\text{digamma}(x) = \psi(x) = \frac{d}{dx} \ln \Gamma(x) = \frac{\Gamma'(x)}{\Gamma(x)}$$

This is often called the ‘polygamma’ function, e.g. in Abramowitz and Stegun (section 6.4.1, page 260); and its higher derivatives (`deriv` = 2:4) have occasionally been called ‘tetragamma’, ‘pentagamma’, and ‘hexagamma’.

The functions `choose` and `lchoose` return binomial coefficients and their logarithms. Note that `choose(n, k)` is defined for all real numbers n and integer k . For $k \geq 1$ as $n(n-1) \cdots (n-k+1)$.

$1/k!$, as 1 for $k = 0$ and as 0 for negative k . Non-integer values of k are rounded to an integer, with a warning.

`choose(*, k)` uses direct arithmetic (instead of `[1]gamma` calls) for small k , for speed and accuracy reasons. Note the function `combn` (package `utils`) for enumeration of all possible combinations.

The `gamma`, `lgamma`, `digamma` and `trigamma` functions are generic: methods can be defined for them individually or via the `Math` group generic.

Source

`gamma`, `lgamma`, `beta` and `lbeta` are based on C translations of Fortran subroutines by W. Fullerton of Los Alamos Scientific Laboratory (now available as part of SLATEC).

`digamma`, `trigamma` and `psigamma` are based on

Amos, D. E. (1983). A portable Fortran subroutine for derivatives of the psi function, Algorithm 610, *ACM Transactions on Mathematical Software* **9**(4), 494–502.

k <- -1:6
cbind(k=k, choose(1/2, k), mychoose(1/2, k))

## Binomial theorem for n=1/2 ;
## sqrt(1+x) = (1+x)^(1/2) = sum_{k=0}^Inf choose(1/2, k) * x^k :
k <- 0:10 # 10 is sufficient for ~ 9 digit precision:
sqrt(1.25)
sum(choose(1/2, k)* .25^k)

```

split

Divide into Groups and Reassemble

Description

`split` divides the data in the vector `x` into the groups defined by `f`. The replacement forms replace values corresponding to such a division. `unsplit` reverses the effect of `split`.

Usage

```

split(x, f, drop = FALSE, ...)
split(x, f, drop = FALSE, ...) <- value
unsplit(value, f, drop = FALSE)

```

Arguments

`x` vector or data frame containing values to be divided into groups.

`f` a ‘factor’ in the sense that `as.factor(f)` defines the grouping, or a list of such factors in which case their interaction is used for the grouping.

drop	logical indicating if levels that do not occur should be dropped (if <code>f</code> is a factor or a list).
value	a list of vectors or data frames compatible with a splitting of <code>x</code> . Recycling applies if the lengths do not match.
...	further potential arguments passed to methods.

Details

`split` and `split<-` are generic functions with default and `data.frame` methods. The data frame method can also be used to split a matrix into a list of matrices, and the replacement form likewise, provided they are invoked explicitly.

`unsplit` works with lists of vectors or data frames (assumed to have compatible structure, as if created by `split`). It puts elements or rows back in the positions given by `f`. In the data frame case, row names are obtained by unsplitting the row name vectors from the elements of `value`.

`f` is recycled as necessary and if the length of `x` is not a multiple of the length of `f` a warning is printed.

Any missing values in `f` are dropped together with the corresponding values of `x`.

Value

The value returned from `split` is a list of vectors containing the values for the groups. The components of the list are named by the levels of `f` (after converting to a factor, or if already a factor and `drop=TRUE`, dropping unused levels).

The replacement forms return their right hand side. `unsplit` returns a vector or data frame for which `split(x, f)` equals `value`

split(ma, col(ma))

split(1:10, 1:2)

```

sprintf

Use C-style String Formatting Commands

Description

A wrapper for the C function `sprintf`, that returns a character vector containing a formatted combination of text and variable values.

Usage

```

sprintf(fmt, ...)
gettextf(fmt, ..., domain = NULL)

```

Arguments

<code>fmt</code>	a character vector of format strings, each of up to 8192 bytes.
<code>...</code>	values to be passed into <code>fmt</code> . Only logical, integer, real and character vectors are supported, but some coercion will be done: see the ‘Details’ section.
<code>domain</code>	see gettext .

Details

`sprintf` is a wrapper for the system `sprintf` C-library function. Attempts are made to check that the mode of the values passed match the format supplied, and R’s special values (`NA`, `Inf`, `-Inf` and `NaN`) are handled correctly.

`gettextf` is a convenience function which provides C-style string formatting with possible translation of the format string.

The arguments (including `fmt`) are recycled if possible a whole number of times to the length of the longest, and then the formatting is done in parallel.

The following is abstracted from Kernighan and Ritchie (see References). The string `fmt` contains normal characters, which are passed through to the output string, and also conversion specifications which operate on the arguments provided through `...`. The allowed conversion specifications start with a `%` and end with one of the letters in the set `diFeEGsX%`. These letters denote the following types:

- d, i, x, X** Integer value, `x` and `X` being hexadecimal (using the same case for `a-f` as the code). Numeric variables with exactly integer values will be coerced to integer. Formats `d` and `i` can also be used for logical variables, which will be converted to `0`, `1` or `NA`.
- f** Double precision value, in decimal notation of the form `"[-]mmm.ddd"`. The number of decimal places is specified by the precision: the default is 6; a precision of 0 suppresses the decimal point. Non-finite values are converted to `NA`, `NaN` or (perhaps a sign followed by) `Inf`.
- e, E** Double precision value, in decimal notation of the form `[-]m.ddde[+-]xx` or `[-]m.dddE[+-]xx`.
- g, G** Double precision value, in `%e` or `%E` format if the exponent is less than -4 or greater than or equal to the precision, and `%f` format otherwise.
- a, A** Double precision value, in binary notation of the form `[-]0xh.hhhp[+-]d`. This is a binary fraction expressed in hex multiplied by a (decimal) power of 2. The number of hex digits after the decimal point is specified by the precision: the default is enough digits to represent exactly the internal binary representation. Non-finite values are converted to `NA`, `NaN` or (perhaps a sign followed by) `Inf`. Format `%a` uses lower-case for `x`, `p` and the hex values: format `%A` uses upper-case.

This might not be supported on all platforms as it is a feature of C99. The format is not uniquely defined: although it would be possible to make the leading `h` always zero or one, this is not always done. Most systems will suppress trailing zeros, but a few do not. On a well-written platform, for normal numbers there will be a leading one before the decimal point plus (by default) 13 hexadecimal digits, hence 53 bits. (The treatment of denormalized numbers is very platform-dependent.)

- s** Character string. Character `NA`s are converted to `"NA"`.
- %** Literal `%` (none of the extra formatting characters given below are permitted in this case).

Conversion by `as.character` is used for non-character arguments with `s` and by `as.double` for non-double arguments with `f`, `e`, `E`, `g`, `G`. NB: the length is determined before conversion, so do not rely on the internal coercion if this would change the length. The coercion is done only once, so if `length(fmt) > 1` then all elements must expect the same types of arguments.

In addition, between the initial `%` and the terminating conversion character there may be, in any order:

- m.n** Two numbers separated by a period, denoting the field width (`m`) and the precision (`n`).
 - Left adjustment of converted argument in its field.
 - + Always print number with sign: by default only negative numbers are printed with a sign.
- a space** Prefix a space if the first character is not a sign.
- 0** For numbers, pad to the field width with leading zeros.

Further, immediately after `%` may come `1$` to `99$` to refer to numbered argument: this allows arguments to be referenced out of order and is mainly intended for translators of error messages. If this is done it is best if all formats are numbered: if not the unnumbered ones process the arguments in order. See the examples. This notation allows arguments to be used more than once, in which case they must be used as the same type (integer, double or character).

A field width or precision (but not both) may be indicated by an asterisk *: in this case an argument specifies the desired number. A negative field width is taken as a '-' flag followed by a positive field width. A negative precision is treated as if the precision were omitted. The argument should be integer, but a double argument will be coerced to integer.

There is a limit of 8192 bytes on elements of `fmt` and also on strings included by a `%s` conversion specification.

Field widths and precisions of `%s` conversions are interpreted as bytes, not characters, as described in the C standard.

Value

A character vector of length that of the longest input. If any element of `fmt` or any character argument is declared as UTF-8, the element of the result will be in UTF-8 and have the encoding declared as UTF-8. Otherwise it will be in the current locale's encoding.

Warning

The format string is passed down the OS's `printf` function, and incorrect formats can cause the latter to crash the R process. R does perform basic sanity checks on the format, but not all possible user errors will be caught and some might be terminal.

Author(s)

Original code by Jonathan Rougier.

References

Examples

```
## be careful with the format: most things in R are floats
## only integer-valued reals get coerced to integer.

sprintf("%s is %f feet tall\n", "Sven", 7.1)      # OK
try(sprintf("%s is %i feet tall\n", "Sven", 7.1)) # not OK
try(sprintf("%s is %i feet tall\n", "Sven", 7))  # OK

## use a literal % :

sprintf("%.0f%% said yes (out of a sample of size %.0f)", 66.666, 3)

## various formats of pi :

sprintf("%f", pi)
sprintf("%.3f", pi)
sprintf("%1.0f", pi)
```

```

sprintf("%5.1f", pi)
sprintf("%05.1f", pi)
sprintf("%+f", pi)
sprintf("% f", pi)
sprintf("%-10f", pi) # left justified
sprintf("%e", pi)
sprintf("%E", pi)
sprintf("%g", pi)
sprintf("%g", 1e6 * pi) # -> exponential
sprintf("%.9g", 1e6 * pi) # -> "fixed"
sprintf("%G", 1e-6 * pi)

## no truncation:
sprintf("%1.f", 101)

## re-use one argument three times, show difference between %x and %X
xx <- sprintf("%1$d %1$x %1$X", 0:15)
xx <- matrix(xx, dimnames=list(rep("", 16), "%d%x%X"))
noquote(format(xx, justify="right"))

## More sophisticated:

sprintf("min 10-char string '%10s'",
       c("a", "ABC", "and an even longer one"))

n <- 1:18
sprintf(paste("e with %2d digits = %.", n, "g", sep=""), n, exp(1))

## Using arguments out of order
sprintf("second %2$1.0f, first %1$5.2f, third %3$1.0f", pi, 2, 3)

## Using asterisk for width or precision
sprintf("precision %.*f, width '%*.3f'", 3, pi, 8, pi)

## Asterisk and argument re-use, 'e' example reiterated:
sprintf("e with %1$2d digits = %2$.*1$g", n, exp(1))

## re-cycle arguments
sprintf("%s %d", "test", 1:3)

## binary output showing rounding/representation errors
x <- seq(0, 1.0, 0.1); y <- c(0, .1, .2, .3, .4, .5, .6, .7, .8, .9, 1)
cbind(x, sprintf("%a", x), sprintf("%a", y))

```

sQuote

Quote Text

Description

Single or double quote text by combining with appropriate single or double left and right quotation marks.

Usage

```

sQuote(x)
dQuote(x)

```

Arguments

x an R object, to be coerced to a character vector.

Details

The purpose of the functions is to provide a simple means of markup for quoting text to be used in the R output, e.g., in warnings or error messages.

The choice of the appropriate quotation marks depends on both the locale and the available character sets. Older Unix/X11 fonts displayed the grave accent (ASCII code 0x60) and the apostrophe (0x27) in a way that they could also be used as matching open and close single quotation marks. Using modern fonts, or non-Unix systems, these characters no longer produce matching glyphs. Unicode provides left and right single quotation mark characters (U+2018 and U+2019); if Unicode markup cannot be assumed to be available, it seems good practice to use the apostrophe as a non-directional single quotation mark.

Similarly, Unicode has left and right double quotation mark characters (U+201C and U+201D); if only ASCII's typewriter characteristics can be employed, then the ASCII quotation mark (0x22) should be used as both the left and right double quotation mark.

Some other locales also have the directional quotation marks, notably on Windows. TeX uses grave and apostrophe for the directional single quotation marks, and doubled grave and doubled apostrophe for the directional double quotation marks.

What rendering is used depend on the `options` setting for `useFancyQuotes`. If this is `FALSE` then the unidirectional ASCII quotation style is used. If this is `TRUE` (the default), Unicode directional quotes are used where available (currently, UTF-8 locales on Unix-alikes and all Windows locales except C): if set to "UTF-8" UTF-8 markup is used (whatever the current locale). If set to "TeX", TeX-style markup is used. Finally, if this is set to a character vector of length four, the first two entries are used for beginning and ending single quotes and the second two for beginning and ending double quotes: this can be used to implement non-English quoting conventions such as the use of guillemets.

Where fancy quotes are used, you should be aware that they may not be rendered correctly as not all fonts include the requisite glyphs: for example some have directional single quotes but not directional double quotes.

Value

A character vector in the current locale's encoding.

      dQuote("Spanish question"), "styles\n")
}
options(op)

```

srcfile

References to source files

Description

These functions are for working with source files.

Usage

```

srcfile(filename, encoding = getOption("encoding"))
srcfilecopy(filename, lines)
getSrcLines(srcfile, first, last)
srcref(srcfile, lloc)
## S3 method for class 'srcfile':
print(x, ...)
## S3 method for class 'srcfile':
open(con, line, ...)
## S3 method for class 'srcfile':
close(con, ...)
## S3 method for class 'srcref':
print(x, useSource = TRUE, ...)
## S3 method for class 'srcref':
as.character(x, useSource = TRUE, ...)
.isOpen(srcfile)

```

Arguments

filename	The name of a file
encoding	The character encoding to assume for the file
lines	A character vector of source lines. Other R objects will be coerced to character.
srcfile	A <code>srcfile</code> object.
first, last, line	Line numbers.

<code>lloc</code>	A vector of four values giving a source location; see ‘Details’.
<code>x, con</code>	An object of the appropriate type.
<code>useSource</code>	Whether to read the <code>srcfile</code> to obtain the text of a <code>srcref</code> .
<code>...</code>	Additional arguments to the methods; these will be ignored.

Details

These functions and classes handle source code references.

The `srcfile` function produces an object of class `srcfile`, which contains the name and directory of a source code file, along with its timestamp, for use in source level debugging (not yet implemented) and source echoing. The encoding of the file is saved; see [file](#) for a discussion of encodings, and [iconvlist](#) for a list of allowable encodings on your platform.

The `srcfilecopy` function produces an object of the descendant class `srcfilecopy`, which saves the source lines in a character vector.

The `getSrcLines` function reads the specified lines from `srcfile`.

The `srcref` function produces an object of class `srcref`, which describes a range of characters in a `srcfile`. The `lloc` value gives the following values: `c(first_line, first_column, last_line, last_column)`.

Methods are defined for `print`, `open`, and `close` for classes `srcfile` and `srcfilecopy`. The `open` method opens its internal file connection at a particular line; if it was already open, it will be repositioned to that line.

Methods are defined for `print` and `as.character` for class `srcref`. The `as.character` method will read the associated source file to obtain the text corresponding to the reference. If an error occurs (e.g. the file no longer exists), text like `<srcref: "file" chars 1:1 to 2:10>` will be returned instead, indicating the `line:column` ranges of the first and last character.

Lists of `srcref` objects may be attached to expressions as the `"srcref"` attribute. (The list of `srcref` objects should be the same length as the expression.) By default, expressions are printed by `print.default` using the associated `srcref`. To see deparsed code instead, call `print` with argument `useSource = FALSE`. If a `srcref` object is printed with `useSource = FALSE`, the `<srcref: ...>` record will be printed.

`.isOpen` is intended for internal use: it checks whether the connection associated with a `srcfile` object is open.

Value

`srcfile` returns a `srcfile` object.

`srcfilecopy` returns a `srcfilecopy` object.

`getSrcLines` returns a character vector of source code lines.

`srcref` returns a `srcref` object.

Author(s)

Duncan Murdoch

Examples

```
src <- srcfile(system.file("DESCRIPTION", package = "base"))
getSrcLines(src, 1, 4)
ref <- srcref(src, c(1, 1, 2, 1000))
ref
print(ref, useSource = FALSE)
```

Startup

Initialization at Start of an R Session

Description

In R, the startup mechanism is as follows.

Unless `--no-environ` was given on the command line, R searches for site and user files to process for setting environment variables. The name of the site file is the one pointed to by the environment variable `R_ENVIRON`; if this is unset or empty, `'R_HOME/etc/Renviron.site'` is used (if it exists, which it does not in a 'factory-fresh' installation). The name of the user file can be specified by the `R_ENVIRON_USER` environment variable; if this is unset, the user files searched for are `'Renviron'` in the current or in the user's home directory (in that order). See 'Details' for how the files are read.

Then R searches for the site-wide startup profile unless the command line option `--no-site-file` was given. The name of this file is taken from the value of the `R_PROFILE` environment variable. If this variable is unset, the default is `'R_HOME/etc/Rprofile.site'`, which is used if it exists (which it does not in a 'factory-fresh' installation). This code is sourced into the **base** package. Users need to be careful not to unintentionally overwrite objects in **base**, and it is normally advisable to use `local` if code needs to be executed: see the examples.

Then, unless `--no-init-file` was given, R searches for a user profile file. The name of this file can be specified by the `R_PROFILE_USER` environment variable. If this is unset, a file called `'Rprofile'` in the current directory or in the user's home directory (in that order) is searched for. The user profile is sourced into the user workspace.

Note that when the site and user profile files are sourced only the **base** package is loaded, so objects in other packages need to be referred to by e.g. `utils:::dump.frames` or after explicitly loading the package concerned.

It then loads a saved image of the user workspace from `'RData'` if there is one (unless `--no-restore-data` or `--no-restore` was specified on the command line).

Next, if a function `.First` is found on the search path, it is executed as `.First()`. Finally, function `.First.sys()` in the **base** package is run. This calls `require` to attach the default packages specified by `options("defaultPackages")`. If the **methods** package is included, this will have been attached earlier (by function `.OptRequireMethods()`) so that name space initializations such as those from the user workspace will proceed correctly.

A function `.First` (and `.Last`) can be defined in appropriate `'Rprofile'` or `'Rprofile.site'` files or have been saved in `'RData'`. If you want a different set of packages than the default ones when you start, insert a call to `options` in the `'Rprofile'` or `'Rprofile.site'` file. For example, `options(defaultPackages = character())` will attach no extra packages on startup (only the base package) (or set `R_DEFAULT_PACKAGES=NULL` as an environment variable before running R). Using `options(defaultPackages = "")` or `R_DEFAULT_PACKAGES=""` enforces the R *system* default.

On front-ends which support it, the commands history is read from the file specified by the environment variable `R_HISTFILE` (default `‘.Rhistory’`) unless `‘--no-restore-history’` was specified (or `‘--no-restore’`).

The command-line flag `‘--vanilla’` implies `‘--no-site-file’`, `‘--no-init-file’`, `‘--no-restore’` and `‘--no-environ’`.

Usage

```
.First <- function() { ..... }

.Rprofile <startup file>
```

Details

Note that there are two sorts of files used in startup: *environment files* which contain lists of environment variables to be set, and *profile files* which contain R code.

Lines in a site or user environment file should be either comment lines starting with #, or lines of the form `name=value`. The latter sets the environmental variable `name` to `value`, overriding an existing value. If `value` contains an expression of the form ``${foo}-bar`}, the value is that of the environmental variable `foo` if that exists and is set to a non-empty value, otherwise `bar`. (If it is of the form ``${foo}`}, the default is `“”`.) This construction can be nested, so `bar` can be of the same form (as in ``${foo}-${bar}-blah`}). Note that the braces are essential: ``${HOME}` will not be interpreted.

Leading and trailing white space in `value` are stripped. `value` is then processed in a similar way to a Unix shell: in particular the outermost level of (single or double) quotes is stripped, and backslashes are removed except inside quotes.

Note

The file `‘R_HOME/etc/Renviron’` is always read very early in the start-up processing. It contains environment variables set by R in the configure process. Values in that file can be overridden in site or user environment files: do not change `‘R_HOME/etc/Renviron’` itself. Note that this is distinct from `‘R_HOME/etc/Renviron.site’`.

Examples

```
## Not run:
## Example ~/.Renviron on Unix
R_LIBS=~ /R/library
PAGER=/usr/local/bin/less

## Example .Renviron on Windows
```

```

R_LIBS=C:/R/library
MY_TCLTK="c:/Program Files/Tcl/bin"

## Example of setting R_DEFAULT_PACKAGES (from R CMD check)
R_DEFAULT_PACKAGES='utils,grDevices,graphics,stats'
# this loads the packages in the order given, so they appear on
# the search path in reverse order.

## Example of .Rprofile
options(width=65, digits=5)
options(show.signif.stars=FALSE)
setHook(packageEvent("grDevices", "onLoad"),
        function(...) grDevices::ps.options(horizontal=FALSE))
set.seed(1234)
.First <- function() cat("\n Welcome to R!\n\n")
.Last <- function() cat("\n Goodbye!\n\n")

## Example of Rprofile.site
local({
  # add MASS to the default packages, set a CRAN mirror
  old <- getOption("defaultPackages"); r <- getOption("repos")
  r["CRAN"] <- "http://my.local.cran"
  options(defaultPackages = c(old, "MASS"), repos = r)
})

## if .Renviron contains
FOOBAR="coo\bar"doh\ex"abc\"def'"

## then we get
> cat(Sys.getenv("FOOBAR"), "\n")
coo\bardoh\exabc"def'
## End(Not run)

```

stop

Stop Function Execution

Description

`stop` stops execution of the current expression and executes an error action.
`geterrmessage` gives the last error message.

Usage

```
stop(..., call. = TRUE, domain = NULL)
geterrmessage()
```

Arguments

<code>...</code>	zero or more objects which can be coerced to character (and which are pasted together with no separator) or a single condition object.
<code>call.</code>	logical, indicating if the call should become part of the error message.
<code>domain</code>	see gettext . If NA, messages will not be translated.

Details

The error action is controlled by error handlers established within the executing code and by the current default error handler set by `options(error=)`. The error is first signaled as if using `signalCondition()`. If there are no handlers or if all handlers return, then the error message is printed (if `options("show.error.messages")` is true) and the default error handler is used. The default behaviour (the NULL error-handler) in interactive use is to return to the top level prompt or the top level browser, and in non-interactive use to (effectively) call `q("no", status=1, runLast=FALSE)`. The default handler stores the error message in a buffer; it can be retrieved by `geterrmessage()`. It also stores a trace of the call stack that can be retrieved by `traceback()`.

Errors will be truncated to `getOption("warning.length")` characters, default 1000.

If a condition object is supplied it should be the only argument, and further arguments will be ignored, with a warning.

Value

`geterrmessage` gives the last error message, as a character string ending in `"\n"`.

See Also

`warning`, `try` to catch errors and retry, and `options` for setting error handlers. `stopifnot` for validity testing. `tryCatch` and `withCallingHandlers` can be used to establish custom handlers while executing an expression.

`gettext` for the mechanisms for the automated translation of messages.

Examples

```
options(error = expression(NULL))
# don't stop on stop(.) << Use with CARE! >>

iter <- 12
if(iter > 10) stop("too many iterations")

tst1 <- function(...) stop("dummy error")
tst1(1:10, long, calling, expression)

tst2 <- function(...) stop("dummy error", call. = FALSE)
tst2(1:10, longcalling, expression, but.not.seen.in.Error)

options(error = NULL) # revert to default
```

`stopifnot`*Ensure the 'Truth' of R Expressions*

Description

If any of the expressions in `...` are not `all TRUE`, `stop` is called, producing an error message indicating the *first* of the elements of `...` which were not true.

Usage

```
stopifnot(...)
```

Arguments

`...` any number of (`logical`) R expressions, which should evaluate to `TRUE`.

Details

This function is intended for use in regression tests or also argument checking of functions, in particular to make them easier to read.

```
stopifnot(A, B) is conceptually equivalent to { if(any(is.na(A)) || !all(A))  
stop(...) ; if(any(is.na(B)) || !all(B)) stop(...) }.
```

Value

(`NULL` if all statements in `...` are `TRUE`.)

See Also

`stop`, `warning`.

Examples

```
stopifnot(1 == 1, all.equal(pi, 3.14159265), 1 < 2) # all TRUE  
  
m <- matrix(c(1,3,3,1), 2,2)  
stopifnot(m == t(m), diag(m) == rep(1,2)) # all(.) | => TRUE  
  
op <- options(error = expression(NULL))  
# "disable stop(.)" << Use with CARE! >>  
  
stopifnot(all.equal(pi, 3.141593), 2 < 2, all(1:10 < 12), "a" < "b")  
stopifnot(all.equal(pi, 3.1415927), 2 < 2, all(1:10 < 12), "a" < "b")  
  
options(op) # revert to previous error handler
```

strptime

*Date-time Conversion Functions to and from Character***Description**

Functions to convert between character representations and objects of classes "POSIXlt" and "POSIXct" representing calendar dates and times.

Usage

```
## S3 method for class 'POSIXct':
format(x, format = "", tz = "", usetz = FALSE, ...)
## S3 method for class 'POSIXlt':
format(x, format = "", usetz = FALSE, ...)

## S3 method for class 'POSIXt':
as.character(x, ...)

strftime(x, format="", usetz = FALSE, ...)
strptime(x, format, tz = "")

ISOdatetime(year, month, day, hour, min, sec, tz = "")
ISOdate(year, month, day, hour = 12, min = 0, sec = 0, tz = "GMT")
```

Arguments

<code>x</code>	An object to be converted.
<code>tz</code>	A timezone specification to be used for the conversion. System-specific (see as.POSIXlt), but "" is the current time zone, and "GMT" is UTC.
<code>format</code>	A character string. The default is "%Y-%m-%d %H:%M:%S" if any component has a time component which is not midnight, and "%Y-%m-%d" otherwise. If options ("digits.secs") is set, up to the specified number of digits will be printed for seconds.
<code>...</code>	Further arguments to be passed from or to other methods.
<code>usetz</code>	logical. Should the timezone be appended to the output? This is used in printing times, and as a workaround for problems with using "%Z" on most Linux systems.
<code>year, month, day</code>	numerical values to specify a day.
<code>hour, min, sec</code>	numerical values for a time within a day. Fractional seconds are allowed.

Details

The `format` and `as.character` methods and `strftime` convert objects from the classes "POSIXlt" and "POSIXct" (not `strftime`) to character vectors.

`strptime` converts character strings to class "POSIXlt": its input `x` is first coerced to character if necessary. Each string is processed as far as necessary for the format specified: any trailing characters are ignored.

`strptime` is an alias for `format.POSIXlt`, and `format.POSIXct` first converts to class `"POSIXlt"` by calling `as.POSIXlt`. Note that only that conversion depends on the time zone.

The usual vector re-cycling rules are applied to `x` and `format` so the answer will be of length that of the longer of the vectors.

Locale-specific conversions to and from character strings are used where appropriate and available. This affects the names of the days and months, the AM/PM indicator (if used) and the separators in formats such as `%x` and `%X` (via the setting of the `LC_TIME` locale category).

The details of the formats are system-specific, but the following are defined by the ISO C / POSIX standard for `strptime` and are likely to be widely available. A *conversion specification* is introduced by `%`, usually followed by a single letter or `O` or `E` and then a single letter. Any character in the format string not part of a conversion specification is interpreted literally (and `%%` gives `%`). Widely implemented conversion specifications include

- %a** Abbreviated weekday name in the current locale. (Also matches full name on input.)
- %A** Full weekday name in the current locale. (Also matches abbreviated name on input.)
- %b** Abbreviated month name in the current locale. (Also matches full name on input.)
- %B** Full month name in the current locale. (Also matches abbreviated name on input.)
- %c** Date and time, locale-specific.
- %d** Day of the month as decimal number (01–31).
- %H** Hours as decimal number (00–23).
- %I** Hours as decimal number (01–12).
- %j** Day of year as decimal number (001–366).
- %m** Month as decimal number (01–12).
- %M** Minute as decimal number (00–59).
- %p** AM/PM indicator in the locale. Used in conjunction with `%I` and **not** with `%H`. An empty string in some locales.
- %S** Second as decimal number (00–61), allowing for up to two leap-seconds (but POSIX-compliant OSes will ignore leap seconds).
- %U** Week of the year as decimal number (00–53) using Sunday as the first day 1 of the week (and typically with the first Sunday of the year as day 1 of week 1). The US convention.
- %w** Weekday as decimal number (0–6, Sunday is 0).
- %W** Week of the year as decimal number (00–53) using Monday as the first day of week (and typically with the first Monday of the year as day 1 of week 1). The UK convention.
- %x** Date, locale-specific.
- %X** Time, locale-specific.
- %y** Year without century (00–99). If you use this on input, which century you get is system-specific. So don't! Often values up to 68 (or 69) are prefixed by 20 and 69 (or 70) to 99 by 19.
- %Y** Year with century.
- %z** (output only.) Offset from Greenwich, so `-0800` is 8 hours west of Greenwich.
- %Z** (output only.) Time zone as a character string (empty if not available).

Where leading zeros are shown they will be used on output but are optional on input.

Also defined in the current standards but less widely implemented (e.g. not for output on Windows) are

- %C** Century (00–99): the integer part of the year divided by 100.

- %D** Locale-specific date format such as `%m/%d/%y`: ISO C99 says it should be that exact format.
- %e** Day of the month as decimal number (1–31), with a leading space for a single-digit number.
- %F** Equivalent to `%Y-%m-%d` (the ISO 8601 date format).
- %g** The last two digits of the week-based year (see `%V`). (Typically accepted but ignored on input.)
- %G** The week-based year (see `%V`) as a decimal number. (Typically accepted but ignored on input.)
- %h** Equivalent to `%b`.
- %k** The 24-hour clock time with single digits preceded by a blank.
- %l** The 12-hour clock time with single digits preceded by a blank.
- %n** Newline on output, arbitrary whitespace on input.
- %r** The 12-hour clock time (using the locale's AM or PM).
- %R** Equivalent to `%H:%M`.
- %t** Tab on output, arbitrary whitespace on input.
- %T** Equivalent to `%H:%M:%S`.
- %u** Weekday as a decimal number (1–7, Monday is 1).
- %V** Week of the year as decimal number (00–53) as defined in ISO 8601. If the week (starting on Monday) containing 1 January has four or more days in the new year, then it is considered week 1. Otherwise, it is the last week of the previous year, and the next week is week 1. (Typically accepted but ignored on input.)

For output (and possibly input) there are also `%O[dHImMUVwWy]` which may emit numbers in an alternative locale-dependent format (e.g. roman numerals), and `%E[cCYyXx]` which can use an alternative 'era' (e.g. a different religious calendar). Which of these are supported is OS-dependent.

Specific to `R` is `%OSn`, which for output gives the seconds to $0 \leq n \leq 6$ decimal places (and if `%OS` is not followed by a digit, it uses the setting of `getOption("digits.secs")`, or if that is unset, $n = 3$). Further, for `strptime` `%OS` will input seconds including fractional seconds. Note that `%S` ignores (and not rounds) fractional parts on output.

The behaviour of other conversion specifications (and even if other character sequences commencing with `%` are conversion specifications) is system-specific.

`ISOdatetime` and `ISOdate` are convenience wrappers for `strptime`, that differ only in their defaults and that `ISOdate` sets a timezone. (For dates without times it would be better to use the `"Date"` class.)

Value

The format methods and `strptime` return character vectors representing the time. NA times are returned as `NA_character_`.

`strptime` turns character representations into an object of class `"POSIXlt"`. The timezone is used to set the `isdst` component and to set the `"tzzone"` attribute if `tz != ""`.

`ISOdatetime` and `ISOdate` return an object of class `"POSIXct"`.

Note

The default formats follow the rules of the ISO 8601 international standard which expresses a day as `"2001-02-28"` and a time as `"14:01:02"` using leading zeroes as here. The ISO form uses no space to separate dates and times.

If the date string does not specify the date completely, the returned answer may be system-specific. The most common behaviour is to assume that unspecified seconds, minutes or hours are zero,

and a missing year, month or day is the current one. If it specifies a date incorrectly, reliable implementations will give an error and the date is reported as NA. Unfortunately some common implementations (such as 'glibc') are unreliable and guess at the intended meaning.

If the timezone specified is invalid on your system, what happens is system-specific but it will probably be ignored.

OS facilities will probably not print years before 1CE (aka 1AD) correctly.

Remember that in most timezones some times do not occur and some occur twice because of transitions to/from summer time. What happens in those cases is OS-specific.

[DateTimeClasses](#) for details of the date-time classes; [locales](#) to query or set a locale.

Your system's help pages on `strptime` and `strptime` to see how to specify their formats. (On some systems `strptime` is replaced by corrected code from 'glibc', when all the conversion specifications described here are supported, but with no alternative number representation nor era available in any locale.)

Examples

```
## locale-specific version of date()
format(Sys.time(), "%a %b %d %X %Y %Z")

## time to sub-second accuracy (if supported by the OS)
format(Sys.time(), "%H:%M:%OS3")

## read in date info in format 'ddmmmyyyy'
## This will give NA(s) in some locales; setting the C locale
## as in the commented lines will overcome this on most systems.
## lct <- Sys.getlocale("LC_TIME"); Sys.setlocale("LC_TIME", "C")
x <- c("1jan1960", "2jan1960", "31mar1960", "30jul1960")
z <- strptime(x, "%d%b%Y")
## Sys.setlocale("LC_TIME", lct)
z

## read in date/time info in format 'm/d/y h:m:s'
dates <- c("02/27/92", "02/27/92", "01/14/92", "02/28/92", "02/01/92")
times <- c("23:03:20", "22:29:56", "01:03:30", "18:21:03", "16:56:26")
x <- paste(dates, times)
strptime(x, "%m/%d/%y %H:%M:%S")

## time with fractional seconds
z <- strptime("20/2/06 11:16:16.683", "%d/%m/%y %H:%M:%OS")
z # prints without fractional seconds
op <- options(digits.secs=3)
z
options(op)
```

```
## timezones are not portable, but 'EST5EDT' comes pretty close.
(x <- strptime(c("2006-01-08 10:07:52", "2006-08-07 19:33:02"),
              "%Y-%m-%d %H:%M:%S", tz="EST5EDT"))
attr(,"tzone")
```

strsplit

Split the Elements of a Character Vector

Description

Split the elements of a character vector `x` into substrings according to the presence of substring `split` within them.

Usage

```
strsplit(x, split, extended = TRUE, fixed = FALSE, perl = FALSE)
```

Arguments

<code>x</code>	character vector, each element of which is to be split. Other inputs, including a factor, will give an error.
<code>split</code>	character vector (or object which can be coerced to such) containing regular expression(s) (unless <code>fixed = TRUE</code>) to use for splitting. If empty matches occur, in particular if <code>split</code> has length 0, <code>x</code> is split into single characters. If <code>split</code> has length greater than 1, it is re-cycled along <code>x</code> .
<code>extended</code>	logical. If <code>TRUE</code> (the default), extended regular expression matching is used, and if <code>FALSE</code> basic regular expressions are used.
<code>fixed</code>	logical. If <code>TRUE</code> match <code>split</code> exactly, otherwise use regular expressions. Has priority over <code>perl</code> and <code>extended</code> .
<code>perl</code>	logical. Should perl-compatible regexps be used? Has priority over <code>extended</code> .

Details

Argument `split` will be coerced to character, so you will see uses with `split = NULL` to mean `split = character(0)`, including in the examples below.

Note that splitting into single characters can be done *via* `split=character(0)` or `split=""`; the two are equivalent. The definition of ‘character’ here depends on the locale (and perhaps OS): in a single-byte locale it is a byte, and in a multi-byte locale it is the unit represented by a ‘wide character’ (almost always a Unicode point).

A missing value of `split` does not split the corresponding element(s) of `x` at all.

The algorithm applied to each input string is

```
repeat {
  if the string is empty
    break.
  if there is a match
    add the string to the left of the match to the output.
    remove the match and all to the left of it.
  else
```

```

        add the string to the output.
        break.
    }

```

Note that this means that if there is a match at the beginning of a (non-empty) string, the first element of the output is "", but if there is a match at the end of the string, the output is the same as with the match removed.

Value

A list of length `length(x)` the *i*-th element of which contains the vector of splits of `x[i]`.

If `fixed = TRUE` or `perl = TRUE` and if any element of `x` or `split` is declared to be in UTF-8 (see [Encoding](#), non-ASCII character strings in the result will be in UTF-8 and have the encoding declared as UTF-8. Otherwise they will be in the current locale's encoding, and be declared to have the encoding of the current locale if either Latin-1 or UTF-8 and the corresponding input had a declared encoding.

Warning

The standard regular expression code has been reported to be very slow when applied to extremely long character strings (tens of thousands of characters or more): the code used when `perl = TRUE` seems much faster and more reliable for such usages.

The `perl = TRUE` option is only implemented for single-byte and UTF-8 encodings, and will warn if used in a non-UTF-8 multibyte locale.

Examples

```

noquote(strsplit("A text I want to display with spaces", NULL)[[1]])

x <- c(as = "asfef", qu = "qwerty", "yuiop[", "b", "stuff.blah.yech")
# split x on the letter e
strsplit(x, "e")

unlist(strsplit("a.b.c", "."))
## [1] "" "" "" "" ""
## Note that 'split' is a regexp!
## If you really want to split on '.', use
unlist(strsplit("a.b.c", "\\."))
## [1] "a" "b" "c"
## or
unlist(strsplit("a.b.c", ".", fixed = TRUE))

## a useful function: rev() for strings
strReverse <- function(x)
  sapply(lapply(strsplit(x, NULL), rev), paste, collapse="")
strReverse(c("abc", "Statistics"))

## get the first names of the members of R-core

```

```

a <- readLines(file.path(R.home("doc"), "AUTHORS"))[-(1:8)]
a <- a[(0:2)-length(a)]
(a <- sub(" .*", "", a))
# and reverse them
strReverse(a)

## Note that final empty strings are not produced:
strsplit(paste(c("", "a", ""), collapse="#"), split="#")[[1]]
# [1] "" "a"
## and also an empty string is only produced before a definite match:
strsplit("", " ")[[1]] # character(0)
strsplit(" ", " ")[[1]] # [1] ""

```

strtrim

*Trim Character Strings to Specified Widths***Description**

Trim character strings to specified display widths.

Usage

```
strtrim(x, width)
```

Arguments

x a character vector, or an object which can be coerced to a character vector by [as.character](#).

width Positive integer values: recycled to the length of **x**.

Details

‘Width’ is interpreted as the display width in a monospaced font. What happens with non-printable characters (such as backspace, tab) is implementation-dependent and may depend on the locale (e.g. they may be included in the count or they may be omitted).

Using this function rather than [substr](#) is important when there might be double-width characters in character vectors

Value

A character vector of the same length and with the same attributes as **x** (after possible coercion).

Elements of the result will have the encoding declared as that of the current locale (see [Encoding](#) if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8).

Examples

```
strtrim(c("abcdef", "abcdef", "abcdef"), c(1,5,10))
```

structure	<i>Attribute Specification</i>
-----------	--------------------------------

Description

`structure` returns the given object with further [attributes](#) set.

Usage

```
structure(.Data, ...)
```

Arguments

<code>.Data</code>	an object which will have various attributes attached to it.
<code>...</code>	attributes, specified in <code>tag=value</code> form, which will be attached to data.

Details

Adding a class `"factor"` will ensure that numeric codes are given integer storage mode.

For historical reasons (these names are used when deparsing), attributes `".Dim"`, `".Dimnames"`, `".Names"`, `".Tsp"` and `".Label"` are renamed to `"dim"`, `"dimnames"`, `"names"`, `"tsp"` and `"levels"`.

It is possible to give the same tag more than once, in which case the last value assigned wins. As with other ways of assigning attributes, using `tag=NULL` removes attribute `tag` from `.Data` if it is present.

[attributes](#), [attr](#).

Examples

```
structure(1:6, dim = 2:3)
```

strwrap

*Wrap Character Strings to Format Paragraphs***Description**

Each character string in the input is first split into paragraphs (or lines containing whitespace only). The paragraphs are then formatted by breaking lines at word boundaries. The target columns for wrapping lines and the indentation of the first and all subsequent lines of a paragraph can be controlled independently.

Usage

```
strwrap(x, width = 0.9 * getOption("width"), indent = 0,
        exdent = 0, prefix = "", simplify = TRUE)
```

Arguments

<code>x</code>	a character vector, or an object which can be converted to a character vector by as.character .
<code>width</code>	a positive integer giving the target column for wrapping lines in the output.
<code>indent</code>	a non-negative integer giving the indentation of the first line in a paragraph.
<code>exdent</code>	a non-negative integer specifying the indentation of subsequent lines in paragraphs.
<code>prefix</code>	a character string to be used as prefix for each line.
<code>simplify</code>	a logical. If <code>TRUE</code> , the result is a single character vector of line text; otherwise, it is a list of the same length as <code>x</code> the elements of which are character vectors of line text obtained from the corresponding element of <code>x</code> . (Hence, the result in the former case is obtained by unlisting that of the latter.)

Details

Whitespace (space, tab or newline characters) in the input is destroyed. Double spaces after periods (thought as representing sentence ends) are preserved. Currently, possible sentence ends at line breaks are not considered specially.

Indentation is relative to the number of characters in the prefix string.

Value

A character vector in the current locale's encoding.

Examples

```
## Read in file 'THANKS'.
x <- paste(readLines(file.path(R.home("doc"), "THANKS")), collapse = "\n")
## Split into paragraphs and remove the first three ones
x <- unlist(strsplit(x, "\n[ \t\n]*\n"))[-(1:3)]
## Join the rest
x <- paste(x, collapse = "\n\n")
## Now for some fun:
writeLines(strwrap(x, width = 60))
```

```

writeLines(strwrap(x, width = 60, indent = 5))
writeLines(strwrap(x, width = 60, exdent = 5))
writeLines(strwrap(x, prefix = "THANKS> "))

## Note that messages are wrapped AT the target column indicated by
## 'width' (and not beyond it).
## From an R-devel posting by J. Hosking <jh910@juno.com>.
x <- paste(sapply(sample(10, 100, replace=TRUE),
  function(x) substring("aaaaaaaaaa", 1, x)), collapse = " ")
sapply(10:40,
  function(m)
    c(target = m, actual = max(nchar(strwrap(x, m)))))

```

subset

Subsetting Vectors, Matrices and Data Frames

Description

Return subsets of vectors, matrices or data frames which meet conditions.

Usage

```

subset(x, ...)

## Default S3 method:
subset(x, subset, ...)

## S3 method for class 'matrix':
subset(x, subset, select, drop = FALSE, ...)

## S3 method for class 'data.frame':
subset(x, subset, select, drop = FALSE, ...)

```

Arguments

x	object to be subsetted.
subset	logical expression indicating elements or rows to keep: missing values are taken as false.
select	expression, indicating columns to select from a data frame.
drop	passed on to [indexing operator.
...	further arguments to be passed to or from other methods.

Details

This is a generic function, with methods supplied for matrices, data frames and vectors (including lists). Packages and users can add further methods.

For ordinary vectors, the result is simply `x[subset & !is.na(subset)]`.

For data frames, the `subset` argument works on the rows. Note that `subset` will be evaluated in the data frame, so columns can be referred to (by name) as variables in the expression (see the examples).

The `select` argument exists only for the methods for data frames and matrices. It works by first replacing column names in the selection expression with the corresponding column numbers in the data frame and then using the resulting integer vector to index the columns. This allows the use of the standard indexing conventions so that for example ranges of columns can be specified easily, or single columns can be dropped (see the examples).

The `drop` argument is passed on to the indexing method for matrices and data frames: note that the default for matrices is different from that for indexing.

Value

An object similar to `x` contain just the selected elements (for a vector), rows and columns (for a matrix or data frame), and so on.

subset(airquality, Day == 1, select = -Temp)
subset(airquality, select = Ozone:Wind)

with(airquality, subset(Ozone, Temp > 80))

## sometimes requiring a logical 'subset' argument is a nuisance
nm <- rownames(state.x77)
start_with_M <- nm %in% grep("^M", nm, value=TRUE)
subset(state.x77, start_with_M, Illiteracy:Murder)
```

substitute

Substituting and Quoting Expressions

Description

`substitute` returns the parse tree for the (unevaluated) expression `expr`, substituting any variables bound in `env`.

`quote` simply returns its argument. The argument is not evaluated and can be any R expression.

Usage

```
substitute(expr, env)
quote(expr)
```

Arguments

`expr` Any syntactically valid R expression

`env` An environment or a list object. Defaults to the current evaluation environment.

Details

The typical use of `substitute` is to create informative labels for data sets and plots. The `myplot` example below shows a simple use of this facility. It uses the functions `deparse` and `substitute` to create labels for a plot which are character string versions of the actual arguments to the function `myplot`.

Substitution takes place by examining each component of the parse tree as follows: If it is not a bound symbol in `env`, it is unchanged. If it is a promise object, i.e., a formal argument to a function or explicitly created using `delayedAssign()`, the expression slot of the promise replaces the symbol. If it is an ordinary variable, its value is substituted, unless `env` is `.GlobalEnv` in which case the symbol is left unchanged.

`substitute` is a primitive function so positional matching is used and names of supplied arguments are ignored.

Value

The `mode` of the result is generally `"call"` but may in principle be any type. In particular, single-variable expressions have `mode "name"` and constants have the appropriate base mode.

Note

Substitute works on a purely lexical basis. There is no guarantee that the resulting expression makes any sense.

Substituting and quoting often causes confusion when the argument is `expression(...)`. The result is a call to the `expression` constructor function and needs to be evaluated with `eval` to give the actual expression object.

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`missing` for argument ‘missingness’, `bquote` for partial substitution, `sQuote` and `dQuote` for adding quotation marks to strings.

Examples

```
require(graphics)
(s.e <- substitute(expression(a + b), list(a = 1))) #> expression(1 + b)
(s.s <- substitute( a + b,                list(a = 1))) #> 1 + b
c(mode(s.e), typeof(s.e)) # "call", "language"
c(mode(s.s), typeof(s.s)) # (the same)
# but:
(e.s.e <- eval(s.e))      #> expression(1 + b)
c(mode(e.s.e), typeof(e.s.e)) # "expression", "expression"

substitute(x <- x + 1, list(x=1)) # nonsense

myplot <- function(x, y)
  plot(x, y, xlab=deparse(substitute(x)),
       ylab=deparse(substitute(y)))
```

```
## Simple examples about lazy evaluation, etc:

f1 <- function(x, y = x)           { x <- x + 1; y }
s1 <- function(x, y = substitute(x)) { x <- x + 1; y }
s2 <- function(x, y) { if(missing(y)) y <- substitute(x); x <- x + 1; y }
a <- 10
f1(a) # 11
s1(a) # 11
s2(a) # a
typeof(s2(a)) # "symbol"
```

substr

Substrings of a Character Vector

Description

Extract or replace substrings in a character vector.

Usage

```
substr(x, start, stop)
substring(text, first, last = 1000000)
substr(x, start, stop) <- value
substring(text, first, last = 1000000) <- value
```

Arguments

`x`, `text` a character vector.
`start`, `first` integer. The first element to be replaced.
`stop`, `last` integer. The last element to be replaced.
`value` a character vector, recycled if necessary.

Details

`substring` is compatible with `S`, with `first` and `last` instead of `start` and `stop`. For vector arguments, it expands the arguments cyclically to the length of the longest *provided* none are of zero length.

When extracting, if `start` is larger than the string length then "" is returned.

For the extraction functions, `x` or `text` will be converted to a character vector by `as.character` if it is not already one.

For the replacement functions, if `start` is larger than the string length then no replacement is done. If the portion to be replaced is longer than the replacement string, then only the portion the length of the string is replaced.

If any argument is an NA element, the corresponding element of the answer is NA.

Elements of the result will be have the encoding declared as that of the current locale (see [Encoding](#) if the corresponding input had a declared encoding and the current locale is either Latin-1 or UTF-8.

Value

For `substr`, a character vector of the same length and with the same attributes as `x` (after possible coercion).

For `substring`, a character vector of length the longest of the arguments. This will have names taken from `x` (if it has any after coercion, repeated as needed), and other attributes copied from `x` if it is the longest of the arguments).

Elements of `x` with a declared encoding (see [Encoding](#)) will be returned with the same encoding.

Note

The S4 version of `substring<-` ignores `last`; this version does not.

These functions are often used with `nchar` to truncate a display. That does not really work (you want to limit the width, not the number of characters, so it would be better to use `strtrim`), but at least make sure you use `nchar(type="c")` (the default since R 2.6.0).

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole. (`substring`.)

[strsplit](#), [paste](#), [nchar](#).

Examples

```
substr("abcdef", 2, 4)
substring("abcdef", 1:6, 1:6)
## strsplit is more efficient ...

substr(rep("abcdef", 4), 1:4, 4:5)
x <- c("asfef", "qwerty", "yuiop[", "b", "stuff.blah.yech")
substr(x, 2, 5)
substring(x, 2, 4:6)

substring(x, 2) <- c("..", "+++")
x
```

sum

Sum of Vector Elements

Description

`sum` returns the sum of all the values present in its arguments.

Usage

```
sum(..., na.rm = FALSE)
```

Arguments

`...` numeric or complex or logical vectors.
`na.rm` logical. Should missing values be removed?

Details

This is a generic function: methods can be defined for it directly or via the [Summary](#) group generic. For this to work properly, the arguments `...` should be unnamed, and `dispatch` is on the first argument.

If `na.rm` is `FALSE` an NA value in any of the arguments will cause a value of NA to be returned, otherwise NA values are ignored.

Logical true values are regarded as one, false values as zero. For historical reasons, `NULL` is accepted and treated as if it were `integer(0)`.

Value

The sum. If all of `...` are of type integer or logical, then the sum is integer, and in that case the result will be NA (with a warning) if integer overflow occurs. Otherwise it is a length-one numeric or complex vector.

NB: the sum of an empty set is zero, by definition.

S4 methods

This is part of the S4 [Summary](#) group generic. Methods for it must use the signature `x, ..., na.rm`.

`'plotmath'` for the use of `sum` in plot annotation.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[colSums](#) for row and column sums.

Description

`summary` is a generic function used to produce result summaries of the results of various model fitting functions. The function invokes particular [methods](#) which depend on the [class](#) of the first argument.

Usage

```
summary(object, ...)

## Default S3 method:
summary(object, ..., digits = max(3, getOption("digits")-3))
## S3 method for class 'data.frame':
summary(object, maxsum = 7,
         digits = max(3, getOption("digits")-3), ...)

## S3 method for class 'factor':
summary(object, maxsum = 100, ...)

## S3 method for class 'matrix':
summary(object, ...)
```

Arguments

object	an object for which a summary is desired.
maxsum	integer, indicating how many levels should be shown for factors .
digits	integer, used for number formatting with signif() (for <code>summary.default</code>) or format() (for <code>summary.data.frame</code>).
...	additional arguments affecting the summary produced.

Details

For [factors](#), the frequency of the first `maxsum - 1` most frequent levels is shown, where the less frequent levels are summarized in "(Others)" (resulting in `maxsum` frequencies).

The functions `summary.lm` and `summary.glm` are examples of particular methods which summarize the results produced by [lm](#) and [glm](#).

Value

The form of the value returned by `summary` depends on the class of its argument. See the documentation of the particular methods for details of what is produced by that method.

References

Chambers, J. M. and Hastie, T. J. (1992) *Statistical Models in S*. Wadsworth & Brooks/Cole.

Examples

```
summary(attenu, digits = 4) #-> summary.data.frame(...), default precision
summary(attenu $ station, maxsum = 20) #-> summary.factor(...)

lst <- unclass(attenu$station) > 20 # logical with NAs
## summary.default() for logicals -- different from *.factor:
summary(lst)
summary(as.factor(lst))
```

 svd *Singular Value Decomposition of a Matrix*

Description

Compute the singular-value decomposition of a rectangular matrix.

Usage

```
svd(x, nu = min(n, p), nv = min(n, p), LINPACK = FALSE)
```

```
La.svd(x, nu = min(n, p), nv = min(n, p))
```

Arguments

<code>x</code>	a real or complex matrix whose SVD decomposition is to be computed.
<code>nu</code>	the number of left singular vectors to be computed. This must be between 0 and <code>n = nrow(x)</code> .
<code>nv</code>	the number of right singular vectors to be computed. This must be between 0 and <code>p = ncol(x)</code> .
<code>LINPACK</code>	logical. Should LINPACK be used (for compatibility with R < 1.7.0)? In this case <code>nu</code> must be 0, <code>nrow(x)</code> or <code>ncol(x)</code> .

Details

The singular value decomposition plays an important role in many statistical techniques. `svd` and `La.svd` provide two slightly different interfaces. The main functions used are the LAPACK routines DGESDD and ZGESVD; `svd(LINPACK = TRUE)` provides an interface to the LINPACK routine DSVDC, purely for backwards compatibility.

Computing the singular vectors is the slow part for large matrices. The computation will be more efficient if `nu <= min(n, p)` and `nv <= min(n, p)`, and even more efficient if one or both are zero.

Unsuccessful results from the underlying LAPACK code will result in an error giving a positive error code: these can only be interpreted by detailed study of the FORTRAN code.

Value

The SVD decomposition of the matrix as computed by LAPACK/LINPACK,

$$X = UDV'$$

where U and V are orthogonal, V' means V transposed, and D is a diagonal matrix with the singular values D_{ii} . Equivalently, $D = U'XV$, which is verified in the examples, below.

The returned value is a list with components

<code>d</code>	a vector containing the singular values of <code>x</code> , of length <code>min(n, p)</code> .
<code>u</code>	a matrix whose columns contain the left singular vectors of <code>x</code> , present if <code>nu > 0</code> . Dimension <code>c(n, nu)</code> .
<code>v</code>	a matrix whose columns contain the right singular vectors of <code>x</code> , present if <code>nv > 0</code> . Dimension <code>c(p, nv)</code> .

For `La.svd` the return value replaces `v` by `vt`, the (conjugated if complex) transpose of `v`.

[eigen](#), [qr](#).

Examples

```
hilbert <- function(n) { i <- 1:n; 1 / outer(i - 1, i, "+") }
X <- hilbert(9)[,1:6]
(s <- svd(X))
D <- diag(s$d)
s$u %*% D %*% t(s$v) # X = U D V'
t(s$u) %*% X %*% s$v # D = U' X V
```

sweep

Sweep out Array Summaries

Description

Return an array obtained from an input array by sweeping out a summary statistic.

Usage

```
sweep(x, MARGIN, STATS, FUN="-", check.margin=TRUE, ...)
```

Arguments

<code>x</code>	an array.
<code>MARGIN</code>	a vector of indices giving the extents of <code>x</code> which correspond to <code>STATS</code> .
<code>STATS</code>	the summary statistic which is to be swept out.
<code>FUN</code>	the function to be used to carry out the sweep. In the case of binary operators such as <code>" / "</code> etc., the function name must backquoted or quoted. (FUN is found by a call to match.fun .)
<code>check.margin</code>	logical. If TRUE (the default), warn if the length or dimensions of <code>STATS</code> do not match the specified dimensions of <code>x</code> . Set to FALSE for a small speed gain when you <i>know</i> that dimensions match.
<code>...</code>	optional arguments to <code>FUN</code> .

Details

The consistency check among `STATS`, `MARGIN` and `x` is stricter if `STATS` is an array than if it is a vector. In the vector case, some kinds of recycling are allowed without a warning. Use `sweep(x, MARGIN, as.array(STATS))` if `STATS` is a vector and you want to be warned if any recycling occurs.

Value

An array with the same shape as `x`, but with the summary statistics swept out.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[apply](#) on which `sweep` used to be based; [scale](#) for centering and scaling.

Examples

```
require(stats) # for median
med.att <- apply(attitude, 2, median)
sweep(data.matrix(attitude), 2, med.att)# subtract the column medians

## More sweeping:
A <- array(1:24, dim = 4:2)

## no warnings in normal use
sweep(A, 1, 5)
(A.min <- apply(A, 1, min)) # == 1:4
sweep(A, 1, A.min)
sweep(A, 1:2, apply(A, 1:2, median))

## warnings when mismatch
sweep(A, 1, 1:3)## STATS does not recycle
sweep(A, 1, 6:1)## STATS is longer

## exact recycling:
sweep(A, 1, 1:2)## no warning
sweep(A, 1, as.array(1:2))## warning
```

 switch

Select One of a List of Alternatives

Description

`switch` evaluates `EXPR` and accordingly chooses one of the further arguments (in `...`).

Usage

```
switch(EXPR, ...)
```

Arguments

`EXPR` an expression evaluating to a number or a character string.
`...` the list of alternatives, given explicitly.

Details

If the value of `EXPR` is an integer between 1 and `nargs() - 1` then the corresponding element of `...` is evaluated and the result returned.

If `EXPR` returns a character string then that string is used to match the names of the elements in `...`. If there is an exact match then that element is evaluated and returned if there is one, otherwise the next element is chosen, e.g., `switch("cc", a=1, cc=, d=2)` evaluates to 2.

In the case of no match, if there's a further argument in `switch` that one is returned, otherwise `NULL`.

Warning

Beware of partial matching: an alternative `E = foo` will match the first argument `EXPR` unless that is named. See the examples for good practice in naming the first argument.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

Examples

```
require(stats)
centre <- function(x, type) {
  switch(type,
    mean = mean(x),
    median = median(x),
    trimmed = mean(x, trim = .1))
}
x <- rcauchy(10)
centre(x, "mean")
centre(x, "median")
centre(x, "trimmed")

ccc <- c("b", "QQ", "a", "A", "bb")
for(ch in ccc)
  cat(ch, ":", switch(EXPR = ch, a=1, b=2:3), "\n")
for(ch in ccc)
  cat(ch, ":", switch(EXPR = ch, a=, A=1, b=2:3, "Otherwise: last"), "\n")

## Numeric EXPR don't allow an 'otherwise':
for(i in c(-1:3, 9)) print(switch(i, 1, 2, 3, 4))
```

Description

Outlines R syntax and gives the precedence of operators

Details

The following unary and binary operators are defined. They are listed in precedence groups, from highest to lowest.

[[[indexing
:: :::	access variables in a name space
\$ @	component / slot extraction
^	exponentiation (right to left)
- +	unary minus and plus
:	sequence operator
%any%	special operators
* /	multiply, divide
+ -	(binary) add, subtract
< > <= >= == !=	ordering and comparison
!	negation
& &&	and
	or
~	as in formulae
-> ->>	rightwards assignment
=	assignment (right to left)
<- <<-	assignment (right to left)
?	help (unary and binary)

Within an expression operators of equal precedence are evaluated from left to right except where indicated.

The links in the **See Also** section cover most other aspects of the basic syntax.

Note

There are substantial precedence differences between R and S. In particular, in S ? has the same precedence as (binary) + - and & && | || have equal precedence.

Sys.getenv

Get Environment Variables

Description

Sys.getenv obtains the values of the environment variables.

Usage

```
Sys.getenv(x = NULL, unset = "")
```

Arguments

`x` a character vector, or NULL.
`unset` a character string.

Details

Both arguments will be coerced to character if necessary.

Setting `unset = NA` will enable unset variables and those set to the value "" to be distinguished, if the OS does.

Value

A vector of the same length as `x`, with the variable names as its `names` attribute. Each element holds the value of the environment variable named by the corresponding component of `x` (or the value of `unset` if no environment variable with that name was found).

On most platforms `Sys.getenv()` will return a named vector giving the values of all the environment variables, sorted in the current locale. It may be confused by names containing = which some platforms allow but POSIX does not.

See Also

[Sys.setenv](#), [Sys.getlocale](#) for the locale in use, [getwd](#) for the working directory.

The help for [‘environment variables’](#) lists many of the environment variables used by R.

Examples

```
## whether HOST is set will be shell-dependent e.g. Solaris' csh does not.
Sys.getenv(c("R_HOME", "R_PAPERSIZE", "R_PRINTCMD", "HOST"))

names(s <- Sys.getenv()) # all settings (the values could be very long)

## Language and Locale settings -- but rather use Sys.getlocale()
s[grep("^L(C|ANG)", names(s))]
```

 Sys.glob

Wildcard Expansion on File Paths

Description

Function to do wildcard expansion (also known as ‘globbing’) on file paths.

Not all platforms support this.

Usage

```
Sys.glob(paths, dirmark = FALSE)
```

Arguments

`paths` character vector of patterns for relative or absolute filepaths. Missing values will be ignored.
`dirmark` logical: should matches to directories from patterns that do not already end in / have a slash appended? May not be supported on all platforms.

Details

This expands wildcards in file paths. For precise details, see your system's documentation on the `glob` system call. There is a POSIX 1003.2 standard (see <http://www.opengroup.org/onlinepubs/009695399/functions/glob.html>) but some OSes will go beyond this (in particular some BSD-based OSes also do tilde expansion, see [path.expand](#)).

All systems should interpret `*` (match zero or more characters), `?` (match a single character) and `[` (begin a character class or range). If a filename starts with `.` this must be matched explicitly. By default paths ending in `/` will be accepted and matched only to directories.

The rest of these details are indicative (and based on the POSIX standard).

`[` begins a character class. If the first character in `[...]` is not `!`, this is a character class which matches a single character against any of the characters specified. The class cannot be empty, so `]` can be included provided it is first. If the first character is `!`, the character class matches a single character which is *none* of the specified characters.

Character classes can include ranges such as `[A-Z]`: include `-` as a character by having it first or last in a class. (The interpretation of ranges should be locale-specific, so the example is not a good idea in an Estonian locale.)

One can remove the special meaning of `?`, `*` and `[` by preceding them by a backslash (except within a character class).

Value

A character vector of matched file paths. The order is system-specific (but in the order of the elements of `paths`): it is normally collated in either the current locale or in byte (ASCII) order.

Directory errors are normally ignored, so the matches are to accessible file paths (but not necessarily accessible files).

On platforms which do not have the `glob` system call (nor, as for `R` under Windows, an emulation), `paths` is returned unchanged.

See Also

[path.expand](#).

[Quotes](#) for handling backslashes in character strings.

Examples

```
## Not run:
Sys.glob(file.path(R.home(), "library", "*", "R", "*.rdx"))
## End(Not run)
```

Description

Reports system and user information.

Usage

```
Sys.info()
```

Details

This function is not implemented on all R platforms, and returns `NULL` when not available. Where possible it is based on POSIX system calls.

`Sys.info()` returns details of the platform R is running on, whereas `R.version` gives details of the platform R was built on: they may well be different.

Value

A character vector with fields

<code>sysname</code>	The operating system.
<code>release</code>	The OS release.
<code>version</code>	The OS version.
<code>nodename</code>	A name by which the machine is known on the network (if any).
<code>machine</code>	A concise description of the hardware.
<code>login</code>	The user's login name, or "unknown" if it cannot be ascertained.
<code>user</code>	The name of the real user ID, or "unknown" if it cannot be ascertained.

The first five fields come from the `uname(2)` system call. The login name comes from `getlogin(2)`, and the user name from `getpwuid(getuid())`

Note

The meaning of OS 'release' and 'version' is system-dependent and there is no guarantee that the node or login or user names will be what you might reasonably expect. (In particular on some Linux distributions the login name is unknown from sessions with re-directed inputs.)

See Also

`.Platform`, and `R.version.sessionInfo()` gives a synopsis of both your system and the R session.

Examples

```
Sys.info()
## An alternative (and probably better) way to get the login name on Unix
Sys.getenv("LOGNAME")
```

Description

These functions provide access to `environments` ('frames' in S terminology) associated with functions further up the calling stack.

Usage

```

sys.call(which = 0)
sys.frame(which = 0)
sys.nframe()
sys.function(which = 0)
sys.parent(n = 1)

sys.calls()
sys.frames()
sys.parents()
sys.on.exit()
sys.status()
parent.frame(n = 1)

```

Arguments

<code>which</code>	the frame number if non-negative, the number of frames to go back if negative.
<code>n</code>	the number of generations to go back. (See the ‘Details’ section.)

Details

`.GlobalEnv` is given number 0 in the list of frames. Each subsequent function evaluation increases the frame stack by 1 and the call, function definition and the environment for evaluation of that function are returned by `sys.call`, `sys.function` and `sys.frame` with the appropriate index.

`sys.call`, `sys.frame` and `sys.function` accept integer values for the argument `which`. Non-negative values of `which` are frame numbers whereas negative values are counted back from the frame number of the current evaluation.

The parent frame of a function evaluation is the environment in which the function was called. It is not necessarily numbered one less than the frame number of the current evaluation, nor is it the environment within which the function was defined. `sys.parent` returns the number of the parent frame if `n` is 1 (the default), the grandparent if `n` is 2, and so on. See also the Note.

`sys.nframe` returns an integer, the number of the current frame as described in the first paragraph.

`sys.calls` and `sys.frames` give a pairlist of all the active calls and frames, respectively, and `sys.parents` returns an integer vector of indices of the parent frames of each of those frames.

Notice that even though the `sys.xxx` functions (except `sys.status`) are interpreted, their contexts are not counted nor are they reported. There is no access to them.

`sys.status()` returns a list with components `sys.calls`, `sys.parents` and `sys.frames`, the results of calls to those three functions (which this will include the call to `sys.status`: see the first example).

`sys.on.exit()` returns the expression stored for use by `on.exit` in the function currently being evaluated. (Note that this differs from S, which returns a list of expressions for the current frame and its parents.)

`parent.frame(n)` is a convenient shorthand for `sys.frame(sys.parent(n))` (implemented slightly more efficiently).

Value

`sys.call` returns a call, `sys.function` a function definition, and `sys.frame` and `parent.frame` return an environment.

For the other functions, see the ‘Details’ section.

Note

Strictly, `sys.parent` and `parent.frame` refer to the *context* of the parent interpreted function. So internal functions (which may or may not set contexts and so may or may not appear on the call stack) are not counted, and S3 methods can also do surprising things.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole. (not `parent.frame`.)

See Also

[eval](#) for a usage of `sys.frame` and `parent.frame`.

Examples

```
require(utils)

## Note: the first two examples will give different results
## if run by example().
ff <- function(x) gg(x)
gg <- function(y) sys.status()
str(ff(1))

gg <- function(y) {
  ggg <- function() {
    cat("current frame is", sys.nframe(), "\n")
    cat("parents are", sys.parents(), "\n")
    print(sys.function(0)) # ggg
    print(sys.function(2)) # gg
  }
  if(y > 0) gg(y-1) else ggg()
}
gg(3)

t1 <- function() {
  aa <- "here"
  t2 <- function() {
    ## in frame 2 here
    cat("current frame is", sys.nframe(), "\n")
    str(sys.calls()) ## list with two components t1() and t2()
    cat("parents are frame numbers", sys.parents(), "\n") ## 0 1
    print(ls(envir=sys.frame(-1))) ## [1] "aa" "t2"
    invisible()
  }
  t2()
}
t1()

test.sys.on.exit <- function() {
  on.exit(print(1))
  ex <- sys.on.exit()
  str(ex)
```

```

    cat("exiting...\n")
  }
test.sys.on.exit()
## gives 'language print(1)', prints 1 on exit

## An example where the parent is not the next frame up the stack
## since method dispatch uses a frame.
as.double.foo <- function(x)
{
  str(sys.calls())
  print(sys.frames())
  print(sys.parents())
  print(sys.frame(-1)); print(parent.frame())
  x
}
t2 <- function(x) as.double(x)
a <- structure(pi, class = "foo")
t2(a)

```

Sys.setenv

Set or Unset Environment Variables

Description

`Sys.setenv` sets environment variables (for other processes called from within R or future calls to `Sys.getenv` from this R process).

`Sys.unsetenv` removes environment variables.

Usage

```
Sys.setenv(...)
```

```
Sys.unsetenv(x)
```

Arguments

`...` named arguments with values coercible to a character string.

`x` a character vector, or an object coercible to character.

Details

The names `setenv` and `putenv` come from different Unix traditions: R also has `Sys.putenv`, but this is now deprecated. The internal code uses `setenv` if available, otherwise `putenv`.

Non-standard R names must be quoted in `Sys.setenv`: see the examples. Most platforms (and POSIX) do not allow names containing "=".

There may be system-specific limits on the maximum length of the values of individual environment variables or of all environment variables.

Value

A logical vector, with elements being true if (un)setting the corresponding variable succeeded. (For `Sys.unsetenv` this includes attempting to remove a non-existent variable.)

Note

Not all systems need support `Sys.setenv` (although all known current platforms do) nor `Sys.unsetenv`. If `Sys.unsetenv` is not supported, it will at least try to set the value of the environment variable to "", with a warning.

See Also

[Sys.getenv](#), [Startup](#) for ways to set environment variables for the R session.

[setwd](#) for the working directory.

The help for [‘environment variables’](#) lists many of the environment variables used by R.

Examples

```
print(Sys.setenv(R_TEST="testit", "A+C"=123)) # `A+C` could also be used
Sys.getenv("R_TEST")
Sys.unsetenv("R_TEST") # may warn and not succeed
Sys.getenv("R_TEST", unset=NA)
```

Sys.sleep

Suspend Execution for a Time Interval

Description

Suspend execution of R expressions for a given number of seconds

Usage

```
Sys.sleep(time)
```

Arguments

`time` The time interval to suspend execution for, in seconds.

Details

Using this function allows R to be given very low priority and hence not to interfere with more important foreground tasks. A typical use is to allow a process launched from R to set itself up and read its input files before R execution is resumed.

The intention is that this function suspends execution of R expressions but wakes the process up often enough to respond to GUI events, typically every 0.5 seconds.

There is no guarantee that the process will sleep for the whole of the specified interval, and it may well take slightly longer in real time to resume execution. The resolution of the time interval is system-dependent, but will normally be down to 0.02 secs or better. (On modern Unix-alikes it will be better than 1ms.)

Value

Invisible NULL.

Note

This function may not be implemented on all systems.

Examples

```
testit <- function(x)
{
  p1 <- proc.time()
  Sys.sleep(x)
  proc.time() - p1 # The cpu usage should be negligible
}
testit(3.7)
```

sys.source

Parse and Evaluate Expressions from a File

Description

Parses expressions in the given file, and then successively evaluates them in the specified environment.

Usage

```
sys.source(file, envir = baseenv(), chdir = FALSE,
           keep.source = getOption("keep.source.pkgs"))
```

Arguments

file	a character string naming the file to be read from
envir	an R object specifying the environment in which the expressions are to be evaluated. May also be a list or an integer. The default value <code>NULL</code> corresponds to evaluation in the base environment. This is probably not what you want; you should typically supply an explicit <code>envir</code> argument.
chdir	logical; if <code>TRUE</code> , the R working directory is changed to the directory containing <code>file</code> for evaluating.
keep.source	logical. If <code>TRUE</code> , functions keep their source including comments, see options (<code>keep.source = *</code>) for more details.

Details

For large files, `keep.source = FALSE` may save quite a bit of memory. In order for the code being evaluated to use the correct environment (for example, in global assignments), source code in packages should call `topenv()`, which will return the name space, if any, the environment set up by `sys.source`, or the global environment if a saved image is being used.

See Also

[source](#), and [library](#) which uses `sys.source`.

Examples

```
## a simple way to put some objects in an environment
## high on the search path
tmp <- tempfile()
writeLines("aaa <- pi", tmp)
env <- attach(NULL, name = "myenv")
sys.source(tmp, env)
unlink(tmp)
search()
aaa
detach("myenv")
```

Sys.time

Get Current Date and Time

Description

`Sys.time` and `Sys.Date` returns the system's idea of the current date with and without time.

Usage

```
Sys.time()
Sys.Date()
```

Details

`Sys.time` returns an absolute date-time value which can be converted in various time zones and may return different days.

`Sys.Date` returns the day in the current timezone.

Value

`Sys.time` returns an object of class "POSIXct" (see [DateTimeClasses](#)). On some systems it will have sub-second accuracy, but on others it will increment in seconds. On systems conforming to POSIX 1003.1-2001 the time will be reported in microsecond increments.

`Sys.Date` returns an object of class "Date" (see [Date](#)).

See Also

[date](#) for the system time in a fixed-format character string; the elapsed time component of [proc.time](#) for possibly finer resolution in changes in time.

[Sys.timezone](#).

Examples

```
Sys.time()
## print with possibly greater accuracy:
op <- options(digits.secs=6)
Sys.time()
options(op)

## locale-specific version of date()
```

```
format(Sys.time(), "%a %b %d %X %Y")
```

```
Sys.Date()
```

Sys.which	<i>Find Full Paths of Executables</i>
-----------	---------------------------------------

Description

This is an interface to the system command `which`.

Usage

```
Sys.which(names)
```

Arguments

`names` Character vector of names of possible executables.

Details

The system command `which` reports on the full names of an executable (including an executable script) found on the current path.

Value

A character vector of the same length as `names`, named by `names`. The elements are either the full path to the executable/script or "" if no executable of that name was found.

Examples

```
## the first two are likely to exist everywhere
## texi2dvi exists on most Unix-alikes and under MiKTeX
Sys.which(c("ftp", "ping", "texi2dvi", "this-does-not-exist"))
```

system	<i>Invoke a System Command</i>
--------	--------------------------------

Description

`system` invokes the OS command specified by `command`.

Usage

```
system(command, intern = FALSE, ignore.stderr = FALSE,
        wait = TRUE, input = NULL, show.output.on.console = TRUE,
        minimized = FALSE, invisible = TRUE)
```

Arguments

<code>command</code>	the system command to be invoked, as a string.
<code>intern</code>	a logical (not NA) which indicates whether to make the output of the command an R object. Not available unless <code>popen</code> is supported on the platform.
<code>ignore.stderr</code>	a logical indicating whether error messages written to ‘ <code>stderr</code> ’ should be ignored.
<code>wait</code>	a logical indicating whether the R interpreter should wait for the command to finish, or run it asynchronously. This will be ignored (and the interpreter will always wait) if <code>intern = TRUE</code> .
<code>input</code>	if a character vector is supplied, this is copied one string per line to a temporary file, and the standard input of <code>command</code> is redirected to the file.
<code>show.output.on.console</code> , <code>minimized</code> , <code>invisible</code>	arguments that are accepted on other platforms but ignored on this one, with a warning.

Details

`command` is parsed as a command plus arguments separated by spaces. So if the path to the command (or a filepath argument) contains spaces, it must be quoted e.g. by `shQuote`.

How the command is run differs by platform: Unix-alikes use a shell (‘`/bin/sh`’ by default), and Windows executes the command directly (extensions ‘`.exe`’, ‘`.com`’) or as a batch file (extensions ‘`.cmd`’ and ‘`.bat`’).

If `intern` is `TRUE` then `popen` is used to invoke the command and the output collected, line by line, into an R `character` vector. If `intern` is `FALSE` then the C function `system` is used to invoke the command.

The ordering of arguments after the first two has changed from time to time: it is recommended to name all arguments after the first.

Value

If `intern = TRUE`, a character vector giving the output of the command, one line per character string. (Output lines of more than 8095 characters will be split.) If the command could not be run or gives an error this will be reported on the shell’s ‘`stderr`’ (unless `popen` is not supported, when there is an R error).

If `intern = FALSE`, the return value is an error code (0 for success), given the invisible attribute (so needs to be printed explicitly). If the command could not be run for any reason, the value is $256 \times 127 = 52512$. Otherwise if `wait = TRUE` the value is 256 times the error code returned by the command, and if `wait = FALSE` it is 0 (the conventional success value).

Stdout and stderr

Error messages written to ‘`stderr`’ will be sent by the shell to the terminal unless `ignore.stderr = TRUE`. They can be captured (in the most likely shells) by

```
system("some command 2>&1", intern=TRUE)
```

What happens to output sent to ‘`stdout`’ and ‘`stderr`’ if `intern = FALSE` is interface-specific, and it is unsafe to assume that such messages will appear on the console (they do on the MacOS X console but not on the **gnomeGUI** console, for example).

Note

wait is implemented by appending & to the command: this is shell-dependent, but required by POSIX and so widely supported.

See Also

[.Platform](#) for platform-specific variables.

Examples

```
# list all files in the current directory using the -F flag
## Not run: system("ls -F")

# t1 is a character vector, each one
# representing a separate line of output from who
# (if the platform has popen and who)
t1 <- try(system("who", intern = TRUE))

try(system("ls fizzlepuzzli", intern = TRUE, ignore.stderr = TRUE))
# empty since file doesn't exist
```

system.file

Find Names of R System Files

Description

Finds the full file names of files in packages etc.

Usage

```
system.file(..., package = "base", lib.loc = NULL)
```

Arguments

...	character strings, specifying subdirectory and file(s) within some package. The default, none, returns the root of the package. Wildcards are not supported.
package	a character string with the name of a single package. An error occurs if more than one package name is given.
lib.loc	a character vector with path names of R libraries, or NULL. The default value of NULL corresponds to all libraries currently known. If the default is used, the loaded packages are searched before the libraries.

Value

A character vector of positive length, containing the file names that matched ..., or the empty string, "", if none matched. If matching the root of a package, there is no trailing separator.

As a special case, `system.file()` gives the root of the **base** package only.

See Also

[R.home](#) for the root directory of the R installation, [list.files](#)

Examples

```

system.file()                # The root of the 'base' package
system.file(package = "stats") # The root of package 'stats'
system.file("INDEX")
system.file("help", "AnIndex", package = "splines")

```

system.time	<i>CPU Time Used</i>
-------------	----------------------

Description

Return CPU (and other) times that `expr` used.

Usage

```

system.time(expr, gcFirst = TRUE)
unix.time(expr, gcFirst = TRUE)

```

Arguments

<code>expr</code>	Valid R expression to be timed.
<code>gcFirst</code>	Logical - should a garbage collection be performed immediately before the timing? Default is TRUE.

Details

`system.time` calls the function `proc.time`, evaluates `expr`, and then calls `proc.time` once more, returning the difference between the two `proc.time` calls.

`unix.time` is an alias of `system.time`, for compatibility with S.

Timings of evaluations of the same expression can vary considerably depending on whether the evaluation triggers a garbage collection. When `gcFirst` is TRUE a garbage collection (`gc`) will be performed immediately before the evaluation of `expr`. This will usually produce more consistent timings.

Value

A object of class "proc_time": see `proc.time` for details.

Note

It is possible to compile R without support for `system.time`, when the function will throw an error.

See Also

`proc.time`, `time` which is for time series.

Examples

```

require(stats)
system.time(for(i in 1:100) mad(runif(1000)))
## Not run:
exT <- function(n = 1000) {
  # Purpose: Test if system.time works ok;  n: loop size
  system.time(for(i in 1:n) x <- mean(rt(1000, df=4)))
}
#-- Try to interrupt one of the following (using Ctrl-C / Escape):
exT()          #- about 3 secs on a 1GHz PIII
system.time(exT())  #~ +/- same
## End(Not run)

```

t

*Matrix Transpose***Description**

Given a matrix or `data.frame` `x`, `t` returns the transpose of `x`.

Usage

```
t(x)
```

Arguments

`x` a matrix or data frame, typically.

Details

This is a generic function for which methods can be written. The description here applies to the default and "data.frame" methods.

A data frame is first coerced to a matrix: see `as.matrix`. When `x` is a vector, it is treated as a column, i.e., the result is a 1-row matrix.

Value

A matrix, with `dim` and `dimnames` constructed appropriately from those of `x`, and other attributes except names copied across.

Note

The *conjugate* transpose of a complex matrix A , denoted A^H or A^* , is computed as `Conj(t(A))`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`aperm` for permuting the dimensions of arrays.

Examples

```
a <- matrix(1:30, 5, 6)
ta <- t(a) ##-- i.e., a[i, j] == ta[j, i] for all i, j :
for(j in seq(ncol(a)))
  if(! all(a[, j] == ta[j, ])) stop("wrong transpose")
```

table

*Cross Tabulation and Table Creation***Description**

`table` uses the cross-classifying factors to build a contingency table of the counts at each combination of factor levels.

Usage

```
table(..., exclude = if (useNA == "no") c(NA, NaN), useNA = c("no",
  "ifany", "always"), dnn = list.names(...), deparse.level = 1)

as.table(x, ...)
is.table(x)

## S3 method for class 'table':
as.data.frame(x, row.names = NULL, ...,
  responseName = "Freq")
```

Arguments

<code>...</code>	one or more objects which can be interpreted as factors (including character strings), or a list (or data frame) whose components can be so interpreted. (For <code>as.table</code> and <code>as.data.frame</code> , arguments passed to specific methods.)
<code>exclude</code>	levels to remove from all factors in <code>...</code> . If set to <code>NULL</code> , it implies <code>useNA="always"</code> .
<code>useNA</code>	whether to include extra NA levels in the table.
<code>dnn</code>	the names to be given to the dimensions in the result (the <i>dimnames names</i>).
<code>deparse.level</code>	controls how the default <code>dnn</code> is constructed. See details.
<code>x</code>	an arbitrary R object, or an object inheriting from class "table" for the <code>as.data.frame</code> method.
<code>row.names</code>	a character vector giving the row names for the data frame.
<code>responseName</code>	The name to be used for the column of table entries, usually counts.

Details

If the argument `dnn` is not supplied, the internal function `list.names` is called to compute the 'dimname names'. If the arguments in `...` are named, those names are used. For the remaining arguments, `deparse.level = 0` gives an empty name, `deparse.level = 1` uses the supplied argument if it is a symbol, and `deparse.level = 2` will deparse the argument.

Only when `exclude` is specified and non-NULL (i.e., not by default), will `table` potentially drop levels of factor arguments.

Both `exclude` and `useNA` operate on an "all or none" basis. If you want to control the dimensions of a multiway table separately, modify each argument using `factor` or `addNA`.

The summary method for class "table" (used for objects created by `table` or `xtabs`) which gives basic information and performs a chi-squared test for independence of factors (note that the function `chisq.test` currently only handles 2-d tables).

Value

`table()` returns a *contingency table*, an object of class "table", an array of integer values. Note that unlike S the result is always an array, a 1D array if one factor is given.

`as.table` and `is.table` coerce to and test for contingency table, respectively.

The `as.data.frame` method for objects inheriting from class "table" can be used to convert the array-based representation of a contingency table to a data frame containing the classifying factors and the corresponding entries (the latter as component named by `responseName`). This is the inverse of `xtabs`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`tabulate` is the underlying function and allows finer control.

Use `ftable` for printing (and more) of multidimensional tables. `margin.table`, `prop.table`, `addmargins`.

Examples

```
require(stats) # for rpois and xtabs
## Simple frequency distribution
table(rpois(100,5))
## Check the design:
with(warpbreaks, table(wool, tension))
table(state.division, state.region)

# simple two-way contingency table
with(airquality, table(cut(Temp, quantile(Temp)), Month))

a <- letters[1:3]
table(a, sample(a)) # dnn is c("a", "")
table(a, sample(a), deparse.level = 0) # dnn is c("", "")
table(a, sample(a), deparse.level = 2) # dnn is c("a", "sample(a)")

## xtabs() <-> as.data.frame.table() :
UCBAdmissions ## already a contingency table
DF <- as.data.frame(UCBAdmissions)
class(tab <- xtabs(Freq ~ ., DF)) # xtabs & table
## tab *is* "the same" as the original table:
all(tab == UCBAdmissions)
all.equal(dimnames(tab), dimnames(UCBAdmissions))
```

```

a <- rep(c(NA, 1/0:3), 10)
table(a)
table(a, exclude=NULL)
b <- factor(rep(c("A","B","C"), 10))
table(b)
table(b, exclude="B")
d <- factor(rep(c("A","B","C"), 10), levels=c("A","B","C","D","E"))
table(d, exclude="B")
print(table(b,d), zero.print = ".")

## NA counting:
is.na(d) <- 3:4
d. <- addNA(d)
d.[1:7]
table(d.) # ", exclude = NULL" is not needed
## i.e., if you want to count the NA's of 'd', use
table(d, useNA="ifany")

## Two-way tables with NA counts. The 3rd variant is absurd, but shows
## something that cannot be done using exclude or useNA.
with(airquality,
     table(OzHi=Ozone > 80, Month, useNA="ifany"))
with(airquality,
     table(OzHi=Ozone > 80, Month, useNA="always"))
with(airquality,
     table(OzHi=Ozone > 80, addNA(Month)))

```

tabulate

Tabulation for Vectors

Description

`tabulate` takes the integer-valued vector `bin` and counts the number of times each integer occurs in it.

Usage

```
tabulate(bin, nbins = max(1, bin))
```

Arguments

`bin` a numeric vector (of positive integers), or a factor.
`nbins` the number of bins to be used.

Details

`tabulate` is used as the basis of the `table` function.

If `bin` is a factor, its internal integer representation is tabulated.

If the elements of `bin` are numeric but not integers, they are truncated to the nearest integer.

Value

An integer vector (without names). There is a bin for each of the values 1, ..., `nbins`; values outside that range are (silently) ignored.

See Also

[table](#), [factor](#).

Examples

```

tabulate(c(2,3,5))
tabulate(c(2,3,3,5), nbins = 10)
tabulate(c(-2,0,2,3,3,5)) # -2 and 0 are ignored
tabulate(c(-2,0,2,3,3,5), nbins = 3)
tabulate(factor(letters[1:10]))

```

tapply

Apply a Function Over a “Ragged” Array

Description

Apply a function to each cell of a ragged array, that is to each (non-empty) group of values given by a unique combination of the levels of certain factors.

Usage

```
tapply(X, INDEX, FUN = NULL, ..., simplify = TRUE)
```

Arguments

X	an atomic object, typically a vector.
INDEX	list of factors, each of same length as X. The elements are coerced to factors by as.factor .
FUN	the function to be applied. In the case of functions like <code>+</code> , <code>%*%</code> , etc., the function name must be quoted. If FUN is NULL, tapply returns a vector which can be used to subscript the multi-way array tapply normally produces.
...	optional arguments to FUN: the Note section.
simplify	If FALSE, tapply always returns an array of mode "list". If TRUE (the default), then if FUN always returns a scalar, tapply returns an array with the mode of the scalar.

Value

When FUN is present, tapply calls FUN for each cell that has any data in it. If FUN returns a single atomic value for each such cell (e.g., functions `mean` or `var`) and when `simplify` is TRUE, tapply returns a multi-way [array](#) containing the values, and NA for the empty cells. The array has the same number of dimensions as INDEX has components; the number of levels in a dimension is the number of levels (`nlevels()`) in the corresponding component of INDEX. Note that if the return value has a class (e.g. an object of class "Date") the class is discarded.

Note that contrary to S, `simplify = TRUE` always returns an array, possibly 1-dimensional.

If FUN does not return a single atomic value, tapply returns an array of mode `list` whose components are the values of the individual calls to FUN, i.e., the result is a list with a `dim` attribute.

When there is an array answer, its `dimnames` are named by the names of INDEX and are based on the levels of the grouping factors (possibly after coercion).

For a list result, the elements corresponding to empty cells are NULL.

Note

Optional arguments to FUN supplied by the ... argument are not divided into cells. It is therefore inappropriate for FUN to expect additional arguments with the same length as X.

tapply(1:3, ind) #-> the split vector
tapply(1:3, ind, sum)
```

taskCallback

Add or remove a top-level task callback

Description

`addTaskCallback` registers an R function that is to be called each time a top-level task is completed.

`removeTaskCallback` un-registers a function that was registered earlier via `addTaskCallback`.

These provide low-level access to the internal/native mechanism for managing task-completion actions. One can use [taskCallbackManager](#) at the S-language level to manage S functions that are called at the completion of each task. This is easier and more direct.

Usage

```
addTaskCallback(f, data = NULL, name = character(0))
removeTaskCallback(id)
```

Arguments

<code>f</code>	the function that is to be invoked each time a top-level task is successfully completed. This is called with 5 or 4 arguments depending on whether <code>data</code> is specified or not, respectively. The return value should be a logical value indicating whether to keep the callback in the list of active callbacks or discard it.
<code>data</code>	if specified, this is the 5-th argument in the call to the callback function <code>f</code> .
<code>id</code>	a string or an integer identifying the element in the internal callback list to be removed. Integer indices are 1-based, i.e the first element is 1. The names of currently registered handlers is available using <code>getTaskCallbackNames</code> and is also returned in a call to <code>addTaskCallback</code> .
<code>name</code>	character: names to be used.

Details

Top-level tasks are individual expressions rather than entire lines of input. Thus an input line of the form `expression1 ; expression2` will give rise to 2 top-level tasks.

A top-level task callback is called with the expression for the top-level task, the result of the top-level task, a logical value indicating whether it was successfully completed or not (always TRUE at present), and a logical value indicating whether the result was printed or not. If the `data` argument was specified in the call to `addTaskCallback`, that value is given as the fifth argument.

The callback function should return a logical value. If the value is FALSE, the callback is removed from the task list and will not be called again by this mechanism. If the function returns TRUE, it is kept in the list and will be called on the completion of the next top-level task.

Value

`addTaskCallback` returns an integer value giving the position in the list of task callbacks that this new callback occupies. This is only the current position of the callback. It can be used to remove the entry as long as no other values are removed from earlier positions in the list first.

`removeTaskCallback` returns a logical value indicating whether the specified element was removed. This can fail (i.e., return FALSE) if an incorrect name or index is given that does not correspond to the name or position of an element in the list.

Note

This is an experimental feature and the interface may be changed in the future.

There is also C-level access to top-level task callbacks to allow C routines rather than R functions be used.

sum(1:10)
sum(1:10)
sum(1:10)
## End(Not run)

```

taskCallbackManager

Create an R-level task callback manager

Description

This provides an entirely S-language mechanism for managing callbacks or actions that are invoked at the conclusion of each top-level task. Essentially, we register a single R function from this manager with the underlying, native task-callback mechanism and this function handles invoking the other R callbacks under the control of the manager. The manager consists of a collection of functions that access shared variables to manage the list of user-level callbacks.

Usage

```

taskCallbackManager(handlers = list(), registered = FALSE,
                    verbose = FALSE)

```

Arguments

handlers	this can be a list of callbacks in which each element is a list with an element named "f" which is a callback function, and an optional element named "data" which is the 5-th argument to be supplied to the callback when it is invoked. Typically this argument is not specified, and one uses <code>add</code> to register callbacks after the manager is created.
registered	a logical value indicating whether the <code>evaluate</code> function has already been registered with the internal task callback mechanism. This is usually <code>FALSE</code> and the first time a callback is added via the <code>add</code> function, the <code>evaluate</code> function is automatically registered. One can control when the function is registered by specifying <code>TRUE</code> for this argument and calling <code>addTaskCallback</code> manually.
verbose	a logical value, which if <code>TRUE</code> , causes information to be printed to the console about certain activities this dispatch manager performs. This is useful for debugging callbacks and the handler itself.

Value

A list containing 6 functions:

<code>add</code>	register a callback with this manager, giving the function, an optional 5-th argument, an optional name by which the callback is stored in the list, and a <code>register</code> argument which controls whether the <code>evaluate</code> function is registered with the internal C-level dispatch mechanism if necessary.
<code>remove</code>	remove an element from the manager's collection of callbacks, either by name or position/index.
<code>evaluate</code>	the 'real' callback function that is registered with the C-level dispatch mechanism and which invokes each of the R-level callbacks within this manager's control.
<code>suspend</code>	a function to set the suspend state of the manager. If it is suspended, none of the callbacks will be invoked when a task is completed. One sets the state by specifying a logical value for the <code>status</code> argument.
<code>register</code>	a function to register the <code>evaluate</code> function with the internal C-level dispatch mechanism. This is done automatically by the <code>add</code> function, but can be called manually.
<code>callbacks</code>	returns the list of callbacks being maintained by this manager.

Note

This is an experimental feature and the interface may be changed in the future.

Examples

```
# create the manager
h <- taskCallbackManager()

# add a callback
```

```

h$add(function(expr, value, ok, visible) {
  cat("In handler\n")
  return(TRUE)
}, name = "simpleHandler")

# look at the internal callbacks.
getTaskCallbackNames()

# look at the R-level callbacks
names(h$callbacks())

getTaskCallbackNames()
removeTaskCallback("R-taskCallbackManager")

```

taskCallbackNames *Query the names of the current internal top-level task callbacks*

Description

This provides a way to get the names (or identifiers) for the currently registered task callbacks that are invoked at the conclusion of each top-level task. These identifiers can be used to remove a callback.

Usage

```
getTaskCallbackNames()
```

Value

A character vector giving the name for each of the registered callbacks which are invoked when a top-level task is completed successfully. Each name is the one used when registering the callbacks and returned as the in the call to [addTaskCallback](#).

Note

One can use [taskCallbackManager](#) to manage user-level task callbacks, i.e., S-language functions, entirely within the S language and access the names more directly.

  return(TRUE)
}, name = "simpleHandler")

getTaskCallbackNames()

# now remove it by name
removeTaskCallback("simpleHandler")

```

```
h <- taskCallbackManager()
h$add(function(expr, value, ok, visible) {
  cat("In handler\n")
  return(TRUE)
}, name = "simpleHandler")
getTaskCallbackNames()
removeTaskCallback("R-taskCallbackManager")
```

`tempfile`*Create Names for Temporary Files*

Description

`tempfile` returns a vector of character strings which can be used as names for temporary files.

Usage

```
tempfile(pattern = "file", tmpdir = tmpdir())
tmpdir()
```

Arguments

<code>pattern</code>	a non-empty character vector giving the initial part of the name.
<code>tmpdir</code>	a non-empty character vector giving the directory name

Details

If `pattern` has length greater than one then the result is of the same length giving a temporary file name for each component of `pattern`.

The names are very likely to be unique among calls to `tempfile` in an R session and across simultaneous R sessions. The filenames are guaranteed not to be currently in use.

The file name is made of the `pattern` and a random suffix in hex. By default, the filenames will be in the directory given by `tmpdir()`. This will be a subdirectory of the temporary directory found by the following rule. The environment variables `TMPDIR`, `TMP` and `TEMP` are checked in turn and the first found which points to a writable directory is used: if none succeeds `‘/tmp’` is used.

Value

For `tempfile` a character vector giving the names of possible (temporary) files. Note that no files are generated by `tempfile`.

For `tmpdir`, the path of the per-session temporary directory.

textConnection *Text Connections*

Description

Input and output text connections.

Usage

```
textConnection(object, open = "r", local = FALSE)

textConnectionValue(con)
```

Arguments

<code>object</code>	character. A description of the connection. For an input this is an R character vector object, and for an output connection the name for the R character vector to receive the output, or <code>NULL</code> (for none).
<code>open</code>	character. Either "r" (or equivalently "") for an input connection or "w" or "a" for an output connection.
<code>local</code>	logical. Used only for output connections. If <code>TRUE</code> , output is assigned to a variable in the calling environment. Otherwise the global environment is used.
<code>con</code>	An output text connection.

Details

An input text connection is opened and the character vector is copied at time the connection object is created, and `close` destroys the copy.

An output text connection is opened and creates an R character vector of the given name in the user's workspace or in the calling environment, depending on the value of the `local` argument. This object will at all times hold the completed lines of output to the connection, and `isIncomplete` will indicate if there is an incomplete final line. Closing the connection will output the final line, complete or not. (A line is complete once it has been terminated by end-of-line, represented by "\n" in R.) The output character vector has locked bindings (see `lockBinding`) until `close` is called on the connection. The character vector can also be retrieved *via* `textConnectionValue`, which is the only way to do so if `object = NULL`. If the current locale is detected as Latin-1 or UTF-8, non-ASCII elements of the character vector will be marked accordingly (see `Encoding`).

Opening a text connection with `mode = "a"` will attempt to append to an existing character vector with the given name in the user's workspace or the calling environment. If none is found (even if an object exists of the right name but the wrong type) a new character vector will be created, with a warning.

You cannot `seek` on a text connection, and `seek` will always return zero as the position.

Value

For `textConnection`, a connection object of class `"textConnection"` which inherits from class `"connection"`.

For `textConnectionValue`, a character vector.

Note

As output text connections keep the character vector up to date line-by-line, they are relatively expensive to use, and it is often better to use an anonymous `file()` connection to collect output.

On (rare) platforms where `vsprintf` does not return the needed length of output there is a 100,000 character limit on the length of line for output connections: longer lines will be truncated with a warning.

`tilde`*Tilde Operator*

Description

Tilde is used to separate the left- and right-hand sides in model formula.

Usage

```
y ~ model
```

Arguments

`y`, `model` symbolic expressions.

Details

The left-hand side is optional, and one-sided formulae are used in some contexts.

[formula](#)

`timezones`*Time Zones*

Description

Information about time zones in R. `Sys.timezone` returns the current time zone.

Usage

```
Sys.timezone()
```

Details

Time zones are a system-specific topic, but as from R 2.7.0 almost all R platforms use the same underlying code, used by Linux, Mac OS X, Solaris, AIX, FreeBSD, Sun Java >= 1.4 and Tcl >= 8.5, and supplied with R on Windows.

It is not in general possible to retrieve the system's own name(s) for the current timezone, but `Sys.timezone` will retrieve the name it uses for the current time (and the name may differ depending on whether daylight saving time is in effect).

On most platforms it is possible to set the time zone via the environment variable `TZ`: see the section on 'Time zone names' for suitable values.

Note that the principal difficulty with time zones is their individual history: over the last 100 years places have changed their affiliation between major time zones, have opted out of (or in to) DST in various years or adopted rule changes late or not at all. This often involves tiny administrative units in the US/Canada: Iowa had 23 different implementations of DST in the 1960's!

Time zones did not come into use until the second half of the nineteenth century, and DST was first introduced in the early twentieth century, most widely during the First World War (in 1916). The most common implementation of `POSIXct` is a signed 32-bit integers and so only goes back to the end of 1901: on such systems `R` assumes that dates prior to that are in the same time zone as they were in 1902.

Value

`Sys.timezone` returns an OS-specific character string, possibly an empty string. Typically this is an abbreviation such as "EST".

Time zone names

Where OSes describe their valid time zones can be obscure. The help for the C function `tzset` can be helpful, but it can also be inaccurate. There is a cumbersome POSIX specification (listed under environment variable `TZ` at http://www.opengroup.org/onlinepubs/009695399/basedefs/xbd_chap08.html), which is often at least partially supported, but there usually are other more user-friendly ways to specify timezones.

Many systems make use of a timezone database compiled by Arthur Olson, in which the preferred way to refer to a time zone by a location (typically of a city) e.g. `Europe/London`, `America/Los_Angeles`, `Pacific/Easter`. Some traditional designations are also allowed such as `EST5EDT` or `GB`. (Beware that some of these designations may not be what you think: in particular `EST` is a time zone used in Canada *without* daylight savings time, and not `EST5EDT` nor (Australian) Eastern Standard Time.) The designation can also be an optional colon prepended to the path to a file giving compiled zone information (and the examples above are all files in a system-specific location). See <http://www.twinsun.com/tz/tz-link.htm> for more details and references.

For most Unix-alikes use the Olson databases. The system-specific default location in the file system varies, e.g. `‘/usr/share/zoneinfo’`, `‘/usr/etc/zoneinfo’`, `‘/usr/lib/zoneinfo’` or `‘/usr/share/lib/zoneinfo’`.

Note

There is currently (2007/8) considerable disruption over changes to the timings of the DST transitions, aimed at energy conservation. These often have short notice and time zone databases may not be up to date (even if the OS has been updated recently).

Note that except on Windows, the operation of time zones is an OS service, and even on Windows a third-party database is used and can be updated (see the section on ‘Time zone names’). Incorrect results will never be an `R` issue, so please ensure that you have the courtesy not to blame `R` for them.

```

`toString`*Convert an R Object to a Character String*

Description

This is a helper function for `format` to produce a single character string describing an R object.

Usage

```
toString(x, ...)  
  
## Default S3 method:  
toString(x, width = NULL, ...)
```

Arguments

<code>x</code>	The object to be converted.
<code>width</code>	Suggestion for the maximum field width. Values of <code>NULL</code> or <code>0</code> indicate no maximum. The minimum value accepted is 6 and smaller values are taken as 6.
<code>...</code>	Optional arguments passed to or from methods.

Details

This is a generic function for which methods can be written: only the default method is described here. Most methods should honor the `width` argument to specify the maximum display width (as measured by `nchar(type = "width")` of the result.

The default method first converts `x` to character and then concatenates the elements separated by `", "`. If `width` is supplied and is not `NULL`, the default method returns the first `width - 4` characters of the result with `....` appended, if the full result would use more than `width` characters.

Value

A character vector of length 1 is returned.

toString(x)  
toString(x, width=8)
```

trace

*Interactive Tracing and Debugging of Calls to a Function or Method***Description**

A call to `trace` allows you to insert debugging code (e.g., a call to `browser` or `recover`) at chosen places in any function. A call to `untrace` cancels the tracing. Specified methods can be traced the same way, without tracing all calls to the function. Trace code can be any R expression. Tracing can be temporarily turned on or off globally by calling `tracingState`.

Usage

```
trace(what, tracer, exit, at, print, signature,
      where = topenv(parent.frame()), edit = FALSE)
untrace(what, signature = NULL, where = topenv(parent.frame()))

tracingState(on = NULL)
.doTrace(expr, msg)
```

Arguments

<code>what</code>	The name (quoted or not) of a function to be traced or untraced. For <code>untrace</code> or for <code>trace</code> with more than one argument, more than one name can be given in the quoted form, and the same action will be applied to each one.
<code>tracer</code>	Either a function or an unevaluated expression. The function will be called or the expression will be evaluated either at the beginning of the call, or before those steps in the call specified by the argument <code>at</code> . See the details section.
<code>exit</code>	Either a function or an unevaluated expression. The function will be called or the expression will be evaluated on exiting the function. See the details section.
<code>at</code>	optional numeric vector. If supplied, <code>tracer</code> will be called just before the corresponding step in the body of the function. See the details section.
<code>print</code>	If <code>TRUE</code> (as per default), a descriptive line is printed before any trace expression is evaluated.
<code>signature</code>	If this argument is supplied, it should be a signature for a method for function <code>what</code> . In this case, the method, and <i>not</i> the function itself, is traced.
<code>edit</code>	For complicated tracing, such as tracing within a loop inside the function, you will need to insert the desired calls by editing the body of the function. If so, supply the <code>edit</code> argument either as <code>TRUE</code> , or as the name of the editor you want to use. Then <code>trace()</code> will call <code>edit</code> and use the version of the function after you edit it. See the details section for additional information.
<code>where</code>	where to look for the function to be traced; by default, the top-level environment of the call to <code>trace</code> . An important use of this argument is to trace a function when it is called from a package with a name space. The current name space mechanism imports the functions to be called (with the exception of functions in the base package). The functions being called are <i>not</i> the same objects seen from the top-level (in general, the imported packages may not even be attached). Therefore, you must ensure that the correct versions are being traced. The way to do this is to set argument <code>where</code> to a function in the name space. The tracing computations

	will then start looking in the environment of that function (which will be the name space of the corresponding package). (Yes, it's subtle, but the semantics here are central to how name spaces work in R.)
<code>on</code>	logical; a call to the support function <code>tracingState</code> returns <code>TRUE</code> if tracing is globally turned on, <code>FALSE</code> otherwise. An argument of one or the other of those values sets the state. If the tracing state is <code>FALSE</code> , none of the trace actions will actually occur (used, for example, by debugging functions to shut off tracing during debugging).
<code>expr, msg</code>	arguments to the support function <code>.doTrace</code> , calls to which are inserted into the modified function or method: <code>expr</code> is the tracing action (such as a call to <code>browser()</code>), and <code>msg</code> is a string identifying the place where the trace action occurs.

Details

The `trace` function operates by constructing a revised version of the function (or of the method, if signature is supplied), and assigning the new object back where the original was found. If only the `what` argument is given, a line of trace printing is produced for each call to the function (back compatible with the earlier version of `trace`).

The object constructed by `trace` is from a class that extends "function" and which contains the original, untraced version. A call to `untrace` re-assigns this version.

If the argument `tracer` or `exit` is the name of a function, the tracing expression will be a call to that function, with no arguments. This is the easiest and most common case, with the functions `browser` and `recover` the likeliest candidates; the former browses in the frame of the function being traced, and the latter allows browsing in any of the currently active calls.

The `tracer` or `exit` argument can also be an unevaluated expression (such as returned by a call to `quote` or `substitute`). This expression itself is inserted in the traced function, so it will typically involve arguments or local objects in the traced function. An expression of this form is useful if you only want to interact when certain conditions apply (and in this case you probably want to supply `print=FALSE` in the call to `trace` also).

When the `at` argument is supplied, it should be a vector of integers referring to the substeps of the body of the function (this only works if the body of the function is enclosed in `{ ... }`). In this case `tracer` is *not* called on entry, but instead just before evaluating each of the steps listed in `at`. (Hint: you don't want to try to count the steps in the printed version of a function; instead, look at `as.list(body(f))` to get the numbers associated with the steps in function `f`.)

An intrinsic limitation in the `exit` argument is that it won't work if the function itself uses `on.exit`, since the existing calls will override the one supplied by `trace`.

Tracing does not nest. Any call to `trace` replaces previously traced versions of that function or method (except for edited versions as discussed below), and `untrace` always restores an untraced version. (Allowing nested tracing has too many potentials for confusion and for accidentally leaving traced versions behind.)

When the `edit` argument is used repeatedly with no call to `untrace` on the same function or method in between, the previously edited version is retained. If you want to throw away all the previous tracing and then edit, call `untrace` before the next call to `trace`. Editing may be combined with automatic tracing; just supply the other arguments such as `tracer`, and the `edit` argument as well. The `edit=TRUE` argument uses the default editor (see `edit`).

Tracing primitive functions (builtins and specials) from the base package works, but only by a special mechanism and not very informatively. Tracing a primitive causes the primitive to be replaced by a function with argument `...(only)`. You can get a bit of information out, but not much. A warning message is issued when `trace` is used on a primitive.

The practice of saving the traced version of the function back where the function came from means that tracing carries over from one session to another, *if* the traced function is saved in the session image. (In the next session, `untrace` will remove the tracing.) On the other hand, functions that were in a package, not in the global environment, are not saved in the image, so tracing expires with the session for such functions.

Tracing a method is basically just like tracing a function, with the exception that the traced version is stored by a call to `setMethod` rather than by direct assignment, and so is the untraced version after a call to `untrace`.

The version of `trace` described here is largely compatible with the version in S-Plus, although the two work by entirely different mechanisms. The S-Plus `trace` uses the session frame, with the result that tracing never carries over from one session to another (R does not have a session frame). Another relevant distinction has nothing directly to do with `trace`: The browser in S-Plus allows changes to be made to the frame being browsed, and the changes will persist after exiting the browser. The R browser allows changes, but they disappear when the browser exits. This may be relevant in that the S-Plus version allows you to experiment with code changes interactively, but the R version does not. (A future revision may include a 'destructive' browser for R.)

Value

In the simple version (just the first argument), invisible `NULL`. Otherwise, the traced function(s) name(s). The relevant consequence is the assignment that takes place.

Note

The version of function tracing that includes any of the arguments except for the function name requires the **methods** package (because it uses special classes of objects to store and restore versions of the traced functions).

If `methods` dispatch is not currently on, `trace` will load the `methods` name space, but will not put the `methods` package on the search list.

See Also

`browser` and `recover`, the likeliest tracing functions; also, `quote` and `substitute` for constructing general expressions.

Examples

```
require(graphics)

## Very simple use
trace(sum)
hist(stats::rnorm(100)) # shows about 3-4 calls to sum()
untrace(sum)

if(.isMethodsDispatchOn()) { # non-simple use needs 'methods' package

f <- function(x, y) {
  y <- pmax(y, .001)
  x ^ y
}
```

```

}

## arrange to call the browser on entering and exiting
## function f
trace("f", browser, exit = browser)

## instead, conditionally assign some data, and then browse
## on exit, but only then. Don't bother me otherwise

trace("f", quote(if(any(y < 0)) yOrig <- y),
      exit = quote(if(exists("yOrig")) browser()),
      print = FALSE)

## trace a utility function, with recover so we
## can browse in the calling functions as well.

trace("as.matrix", recover)

## turn off the tracing

untrace(c("f", "as.matrix"))

## Not run:
## trace calls to the function lm() that come from
## the nlme package.
## (The function nlme is in that package, and the package
## has a name space, so the where= argument must be used
## to get the right version of lm)

trace(lm, exit = recover, where = nlme)
## End(Not run)
}

```

traceback

Print Call Stacks

Description

By default `traceback()` prints the call stack of the last uncaught error, i.e., the sequence of calls that lead to the error. This is useful when an error occurs with an unidentifiable error message. It can also be used to print arbitrary lists of deparsed calls.

Usage

```
traceback(x = NULL, max.lines = getOption("deparse.max.lines"))
```

Arguments

`x` NULL (default, meaning `.Traceback`), or a list or pairlist of deparsed calls.

`max.lines` The maximum number of lines to be printed *per call*. The default is unlimited.

Details

The stack of the last uncaught error is stored as a list of deparsed calls in `.Traceback`, which `traceback` prints in a user-friendly format. The stack of deparsed calls always contains all function calls and all foreign function calls (such as `.Call`): if profiling is in progress it will include calls to some primitive functions. (Calls to builtins are included, but not to specials.)

Errors which are caught *via* `try` or `tryCatch` do not generate a traceback, so what is printed is the call sequence for the last uncaught error, and not necessarily for the last error.

Value

`traceback()` returns nothing, but prints the deparsed call stack deepest call first. The calls may print on more than one line, and the first line for each call is labelled by the frame number. The number of lines printed per call can be limited via `max.lines`.

Warning

It is undocumented where `.Traceback` is stored nor that it is visible, and this is subject to change. Prior to R 2.4.0 it was stored in the workspace, but no longer.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

Examples

```
foo <- function(x) { print(1); bar(2) }
bar <- function(x) { x + a.variable.which.does.not.exist }
## Not run:
foo(2) # gives a strange error
traceback()
## End(Not run)
## 2: bar(2)
## 1: foo(2)
bar
## Ah, this is the culprit ...
```

Description

This function marks an object so that a message is printed whenever the internal function `duplicate` is called. This happens when two objects share the same memory and one of them is modified. It is a major cause of hard-to-predict memory use in R.

Usage

```
tracemem(x)
untracemem(x)
retracemem(x, previous = NULL)
```

Arguments

<code>x</code>	An R object, not a function or environment or NULL.
<code>previous</code>	A value as returned by <code>tracemem</code> or <code>retracemem</code> .

Details

This functionality is optional, determined at compilation, because it makes R run a little more slowly even when no objects are being traced. `tracemem` and `untracemem` give errors when R is not compiled with memory profiling; `retracemem` does not (so it can be left in code during development).

When an object is traced any copying of the object by the C function `duplicate` or by arithmetic or mathematical operations produces a message to standard output. The message consists of the string `tracemem`, the identifying strings for the object being copied and the new object being created, and a stack trace showing where the duplication occurred. `retracemem()` is used to indicate that a variable should be considered a copy of a previous variable (e.g. after subscripting).

The messages can be turned off with `tracingState`.

It is not possible to trace functions, as this would conflict with `trace` and it is not useful to trace NULL, environments, promises, weak references, or external pointer objects, as these are not duplicated.

Value

A character string for identifying the object in the trace output (an address in hex enclosed in angle brackets), or NULL (invisibly for `untracemem`).

See Also

`trace`, `Rprofmem`

<http://developer.r-project.org/memory-profiling.html>

Examples

```
## Not run:
a <- 1:10
tracemem(a)
## b and a share memory
b <- a
b[1] <- 1
untracemem(a)

## copying in lm
d <- stats::rnorm(10)
tracemem(d)
lm(d ~ a+log(b))

## f is not a copy and is not traced
f <- d[-1]
f+1
## indicate that f should be traced as a copy of d
retracemem(f, retracemem(d))
f+1
## End(Not run)
```

`transform`*Transform an Object, for Example a Data Frame*

Description

`transform` is a generic function, which—at least currently—only does anything useful with data frames. `transform.default` converts its first argument to a data frame if possible and calls `transform.data.frame`.

Usage

```
transform(`_data`, ...)
```

Arguments

<code>_data</code>	The object to be transformed
<code>...</code>	Further arguments of the form <code>tag=value</code>

Details

The `...` arguments to `transform.data.frame` are tagged vector expressions, which are evaluated in the data frame `_data`. The tags are matched against names (`_data`), and for those that match, the value replace the corresponding variable in `_data`, and the others are appended to `_data`.

Value

The modified value of `_data`.

Note

Prior to R 2.3.0, the first argument was named `x`, but this caused trouble if people wanted to create a variable of that name. Names starting with an underscore are syntactically invalid, so the current choice should be less problematic.

If some of the values are not vectors of the appropriate length, you deserve whatever you get!

Peter Dalgaard

See Also

[subset](#), [list](#), [data.frame](#)

Examples

```
transform(airquality, Ozone = -Ozone)
transform(airquality, new = -Ozone, Temp = (Temp-32)/1.8)

attach(airquality)
transform(Ozone, logOzone = log(Ozone)) # marginally interesting ...
detach(airquality)
```

Description

These functions give the obvious trigonometric functions. They respectively compute the cosine, sine, tangent, arc-cosine, arc-sine, arc-tangent, and the two-argument arc-tangent.

Usage

```
cos(x)
sin(x)
tan(x)
acos(x)
asin(x)
atan(x)
atan2(y, x)
```

Arguments

`x`, `y` numeric or complex vectors.

Details

The arc-tangent of two arguments `atan2(y, x)` returns the angle between the x-axis and the vector from the origin to (x, y) , i.e., for positive arguments `atan2(y, x) == atan(y/x)`.

Angles are in radians, not degrees (i.e., a right angle is $\pi/2$).

All except `atan2` are generic functions: methods can be defined for them individually or via the [Math](#) group generic.

Complex values

For the inverse trigonometric functions, branch cuts are defined as in Abramowitz and Stegun, figure 4.4, page 79. Continuity on the branch cuts is standard.

For `asin()` and `acos()`, there are two cuts, both along the real axis: $(-\infty, -1]$ and $[1, \infty)$. Functions `asin()` and `acos()` are continuous from above on the interval $(-\infty, -1]$ and continuous from below on $[1, \infty)$.

For `atan()` there are two cuts, both along the pure imaginary axis: $(-\infty i, -1i]$ and $[1i, \infty i)$. It is continuous from the left on the interval $(-\infty i, -1i]$ and from the right on the interval $[1i, \infty i)$.

S4 methods

All except `atan2` are S4 generic functions: methods can be defined for them individually or via the [Math](#) group generic.

try

Try an Expression Allowing Error Recovery

Description

`try` is a wrapper to run an expression that might fail and allow the user's code to handle error-recovery.

Usage

```
try(expr, silent = FALSE)
```

Arguments

<code>expr</code>	an R expression to try.
<code>silent</code>	logical: should the report of error messages be suppressed?

Details

`try` evaluates an expression and traps any errors that occur during the evaluation. If an error occurs then the error message is printed to the `stderr` connection unless `options("show.error.messages")` is false or the call includes `silent = TRUE`. The error message is also stored in a buffer where it can be retrieved by `geterrmessage`. (This should not be needed as the value returned in case of an error contains the error message.) `try` is implemented using `tryCatch`.

Value

The value of the expression if `expr` is evaluated without error, but an invisible object of class "try-error" containing the error message if it fails.

See Also

[options](#) for setting error handlers and suppressing the printing of error messages; [geterrmessage](#) for retrieving the last error message. `tryCatch` provides another means of catching and handling errors.

Examples

```

## this example will not work correctly in example(try), but
## it does work correctly if pasted in
options(show.error.messages = FALSE)
try(log("a"))
print(.Last.value)
options(show.error.messages = TRUE)

## alternatively,
print(try(log("a"), TRUE))

## run a simulation, keep only the results that worked.
set.seed(123)
x <- stats::rnorm(50)
doit <- function(x)
{
  x <- sample(x, replace=TRUE)
  if(length(unique(x)) > 30) mean(x)
  else stop("too few unique points")
}
## alternative 1
res <- lapply(1:100, function(i) try(doit(x), TRUE))
## alternative 2
## Not run:
res <- vector("list", 100)
for(i in 1:100) res[[i]] <- try(doit(x), TRUE)
## End(Not run)
unlist(res[sapply(res, function(x) !inherits(x, "try-error"))])

```

typeof

*The Type of an Object***Description**

typeof determines the (R internal) type or storage mode of any object

Usage

```
typeof(x)
```

Arguments

x any R object.

Value

A character string. The possible values are listed in the structure `TypeTable` in `'src/main/util.c'`. Current values are the vector types "logical", "integer", "double", "complex", "character", "raw" and "list", "NULL", "closure" (function), "special" and "builtin" (basic functions and operators), "environment", "S4" (some S4 objects) and others that are unlikely to be seen at user level ("symbol", "pairlist", "promise", "language", "char", "...", "any", "expression", "externalptr", "bytecode" and "weakref").

See Also

[mode](#), [storage.mode](#).

[isS4](#) to determine if an object has an S4 class.

Examples

```
typeof(2)
mode(2)
```

unique

Extract Unique Elements

Description

`unique` returns a vector, data frame or array like `x` but with duplicate elements/rows removed.

Usage

```
unique(x, incomparables = FALSE, ...)

## Default S3 method:
unique(x, incomparables = FALSE, fromLast = FALSE, ...)

## S3 method for class 'matrix':
unique(x, incomparables = FALSE, MARGIN = 1,
      fromLast = FALSE, ...)

## S3 method for class 'array':
unique(x, incomparables = FALSE, MARGIN = 1,
      fromLast = FALSE, ...)
```

Arguments

<code>x</code>	a vector or a data frame or an array or NULL.
<code>incomparables</code>	a vector of values that cannot be compared. <code>FALSE</code> is a special value, meaning that all values can be compared, and may be the only value accepted for methods other than the default. It will be coerced internally to the same type as <code>x</code> .
<code>fromLast</code>	logical indicating if duplication should be considered from the last, i.e., the last (or rightmost) of identical elements will be kept. This only matters for names or dimnames .
<code>...</code>	arguments for particular methods.
<code>MARGIN</code>	the array margin to be held fixed: a single integer.

Details

This is a generic function with methods for vectors, data frames and arrays (including matrices).

The array method calculates for each element of the dimension specified by `MARGIN` if the remaining dimensions are identical to those for an earlier element (in row-major order). This would most commonly be used for matrices to find unique rows (the default) or columns (with `MARGIN = 2`).

Note that unlike the Unix command `uniq` this omits *duplicated* and not just *repeated* elements/rows. That is, an element is omitted if it is identical to any previous element and not just if it is the same as the immediately previous one. (For the latter, see [rle](#)).

Missing values are regarded as equal, but `NaN` is not equal to `NA_real_`.

Values in `incomparables` will never be marked as duplicated. This is intended to be used for a fairly small set of values and will not be efficient for a very large set.

Value

For a vector, an object of the same type of `x`, but with only one copy of each duplicated element. No attributes are copied (so the result has no names).

For a data frame, a data frame is returned with the same columns but possibly fewer rows (and with row names from the first occurrences of the unique rows).

A matrix or array is subsetted by `[, drop = FALSE]`, so dimensions and dimnames are copied appropriately, and the result always has the same number of dimensions as `x`.

Warning

Using this for lists is potentially slow, especially if the elements are not atomic vectors (see [vector](#)) or differ only in their attributes. In the worst case it is $O(n^2)$.

See Also

[duplicated](#) which gives the indices of duplicated elements.

[rle](#) which is the equivalent of the Unix `uniq -c` command.

Examples

```
x <- c(3:5, 11:8, 8 + 0:5)
(ux <- unique(x))
(u2 <- unique(x, fromLast = TRUE)) # different order
stopifnot(identical(sort(ux), sort(u2)))

length(unique(sample(100, 100, replace=TRUE)))
## approximately 100(1 - 1/e) = 63.21

unique(iris)
```

`unlink`*Delete Files and Directories*

Description

`unlink` deletes the file(s) or directories specified by `x`.

Usage

```
unlink(x, recursive = FALSE)
```

Arguments

<code>x</code>	a character vector with the names of the file(s) or directories to be deleted. Wildcards (normally <code>*</code> and <code>?</code>) are allowed.
<code>recursive</code>	logical. Should directories be deleted recursively?

Details

If `recursive = FALSE` directories are not deleted, not even empty ones.

On most platforms `'file'` includes symbolic links, fifos and sockets.

Wildcard expansion is done by the internal code of `Sys.glob`. Wildcards never match a leading `'.'` in the filename, and files `'.'` and `'..'` will never be considered for deletion. Wildcards will only be expanded if the system supports it. Most systems will support not only `*` and `?` but character classes such as `'[a-z]'` (see the man pages for `glob`). The metacharacters `*` `?` `[` can occur in Unix filenames, and this makes it difficult to use `unlink` to delete such files (see [file.remove](#)), although escaping the metacharacters by backslashes usually works. As from R 2.8.0, if a metacharacter matches nothing it is considered as a literal character.

`recursive = TRUE` is not supported on all platforms, and may be ignored, with a warning.

Value

0 for success, 1 for failure. Not deleting a non-existent file is not a failure, nor is being unable to delete a directory if `recursive = FALSE`. However, missing values in `x` result are regarded as failures.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

[file.remove](#).

unlist

*Flatten Lists***Description**

Given a list structure `x`, `unlist` simplifies it to produce a vector which contains all the atomic components which occur in `x`.

Usage

```
unlist(x, recursive = TRUE, use.names = TRUE)
```

Arguments

<code>x</code>	an R object, typically a list or vector.
<code>recursive</code>	logical. Should unlisting be applied to list components of <code>x</code> ?
<code>use.names</code>	logical. Should names be preserved?

Details

`unlist` is generic: you can write methods to handle specific classes of objects, see [InternalMethods](#), and note, e.g., `relist` with the `unlist` method for `relistable` objects.

If `recursive = FALSE`, the function will not recurse beyond the first level items in `x`.

Factors are treated specially. If all non-list elements of `x` are factors (or ordered factors) then the result will be a factor with levels the union of the level sets of the elements, in the order the levels occur in the level sets of the elements (which means that if all the elements have the same level set, that is the level set of the result).

`x` can be an atomic vector, but then `unlist` does nothing useful, not even drop names.

By default, `unlist` tries to retain the naming information present in `x`. If `use.names = FALSE` all naming information is dropped.

Where possible the list elements are coerced to a common mode during the unlisting, and so the result often ends up as a character vector. Vectors will be coerced to the highest type of the components in the hierarchy `NULL < raw < logical < integer < real < complex < character < list < expression`: pairlists are treated as lists.

A list is a (generic) vector, and the simplified vector might still be a list (and might be unchanged). Non-vector elements of the list (for example language elements such as names, formulas and calls) are not coerced, and so a list containing one or more of these remains a list. (The effect of unlisting an `lm` fit is a list which has individual residuals as components.)

Value

NULL or an expression or a vector of an appropriate mode to hold the list components.

The output type is determined from the highest type of the components in the hierarchy `NULL < raw < logical < integer < real < complex < character < list < expression`, after coercion of pairlists to lists.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`c`, `as.list`, `relist`.

Examples

```
unlist(options())
unlist(options(), use.names=FALSE)

l.ex <- list(a = list(1:5, LETTERS[1:5]), b = "z", c = NA)
unlist(l.ex, recursive = FALSE)
unlist(l.ex, recursive = TRUE)

l1 <- list(a="a", b=2, c=pi+2i)
unlist(l1) # a character vector
l2 <- list(a="a", b=as.name("b"), c=pi+2i)
unlist(l2) # remains a list
```

unname	<i>Remove 'names' or 'dimnames'</i>
--------	-------------------------------------

Description

Remove the `names` or `dimnames` attribute of an R object.

Usage

```
unname(obj, force = FALSE)
```

Arguments

<code>obj</code>	an R object.
<code>force</code>	logical; if true, the <code>dimnames</code> are even removed from <code>data.frames</code> . <i>This argument is currently experimental and hence might change!</i>

Value

Object as `obj` but without `names` or `dimnames`.

Examples

```
require(graphics); require(stats)

## Answering a question on R-help (14 Oct 1999):
col3 <- 750+ 100*rt(1500, df = 3)
breaks <- factor(cut(col3,breaks=360+5*(0:155)))
z <- table(breaks)
z[1:5] # The names are larger than the data ...
barplot(unname(z), axes= FALSE)
```

UseMethod

Class Methods

Description

R possesses a simple generic function mechanism which can be used for an object-oriented style of programming. Method dispatch takes place based on the class(es) of the first argument to the generic function or of the object supplied as an argument to `UseMethod` or `NextMethod`.

Usage

```
UseMethod(generic, object)
```

```
NextMethod(generic = NULL, object = NULL, ...)
```

Arguments

<code>generic</code>	a character string naming a function (and not a built-in operator). Required for <code>UseMethod</code> .
<code>object</code>	for <code>UseMethod</code> : an object whose class will determine the method to be dispatched. Defaults to the first argument of the enclosing function.
<code>...</code>	further arguments to be passed to the next method.

Details

An R object is a data object which has a `class` attribute (and this can be tested by `is.object`). A class attribute is a character vector giving the names of the classes from which the object *inherits*. If the object does not have a class attribute, it has an implicit class. Matrices and arrays have class `"matrix"` or `"array"` followed by the class of the underlying vector. Most vectors have class the result of `mode(x)`, except that integer vectors have class `c("integer", "numeric")` and real vectors have class `c("double", "numeric")`.

When a function calling `UseMethod("fun")` is applied to an object with class attribute `c("first", "second")`, the system searches for a function called `fun.first` and, if it finds it, applies it to the object. If no such function is found a function called `fun.second` is tried. If no class name produces a suitable function, the function `fun.default` is used, if it exists, or an error results.

Function `methods` can be used to find out about the methods for a particular generic function or class.

`UseMethod` is a primitive function so positional matching is used and names of supplied arguments are ignored. It is not the only means of dispatch of methods, for there are [internal generic](#) and [group generic](#) functions. `UseMethod` currently dispatches on the implicit class even for arguments that are not objects, but the other means of dispatch do not.

`NextMethod` invokes the next method (determined by the class vector, either of the object supplied to the generic, or of the first argument to the function containing `NextMethod` if a method was invoked directly). Normally `NextMethod` is used with only one argument, `generic`, but if further arguments are supplied these modify the call to the next method.

`NextMethod` should not be called except in methods called by `UseMethod` or from internal generics (see [InternalGenerics](#)). In particular it will not work inside anonymous calling functions (e.g. `get("print.ts")` (`AirPassengers`)).

Name spaces can register methods for generic functions. To support this, `UseMethod` and `NextMethod` search for methods in two places: first in the environment in which the generic function is called, and then in the registration data base for the environment in which the generic is defined (typically a name space). So methods for a generic function need to be available in the environment of the call to the generic, or they must be registered. (It does not matter whether they are visible in the environment in which the generic is defined.)

Technical Details

Now for some obscure details that need to appear somewhere. These comments will be slightly different than those in Chambers(1992). (See also the draft 'R Language Definition'.) `UseMethod` creates a new function call with arguments matched as they came in to the generic. Any local variables defined before the call to `UseMethod` are retained (unlike S). Any statements after the call to `UseMethod` will not be evaluated as `UseMethod` does not return. `UseMethod` can be called with more than two arguments: a warning will be given and additional arguments ignored. (They are not completely ignored in S.) If it is called with just one argument, the class of the first argument of the enclosing function is used as `object`: unlike S this is the first actual argument passed and not the current value of the object of that name.

`NextMethod` works by creating a special call frame for the next method. If no new arguments are supplied, the arguments will be the same in number, order and name as those to the current method but their values will be promises to evaluate their name in the current method and environment. Any named arguments matched to `...` are handled specially: they either replace existing arguments of the same name or are appended to the argument list. They are passed on as the promise that was supplied as an argument to the current environment. (S does this differently!) If they have been evaluated in the current (or a previous environment) they remain evaluated. (This is a complex area, and subject to change: see the draft 'R Language Definition'.)

The search for methods for `NextMethod` is slightly different from that for `UseMethod`. Finding no `fun.default` is not necessarily an error, as the search continues to the generic itself. This is to pick up an [internal generic](#) like `[]` which has no separate default method, and succeeds only if the generic is a [primitive](#) function or a wrapper for a `.Internal` function of the same name. (When a primitive is called as the default method, argument matching may not work as described above due to the different semantics of primitives.)

You will see objects such as `.Generic`, `.Method`, and `.Class` used in methods. These are set in the environment within which the method is evaluated by the dispatch mechanism, which is as follows:

1. Find the context for the calling function (the generic): this gives us the unevaluated arguments for the original call.
2. Evaluate the object (usually an argument) to be used for dispatch, and find a method (possibly the default method) or throw an error.
3. Create an environment for evaluating the method and insert special variables (see below) into that environment. Also copy any variables in the environment of the generic that are not formal (or actual) arguments.
4. Fix up the argument list to be the arguments of the call matched to the formals of the method.

`.Generic` is a length-one character vector naming the generic function.

`.Method` is a character vector (normally of length one) naming the method function. (For functions in the group generic `Ops` it is of length two.)

`.Class` is a character vector of classes used to find the next method. `NextMethod` adds an attribute "previous" to `.Class` giving the `.Class` last used for dispatch, and shifts `.Class` along to that used for dispatch.

`.GenericCallEnv` and `.GenericDefEnv` are the environments of the call to be generic and defining the generic respectively. (The latter is used to find methods registered for the generic.)

Note that `.Class` is set when the generic is called, and is unchanged if the class of the dispatching argument is changed in a method. It is possible to change the method that `NextMethod` would dispatch by manipulating `.Class`, but ‘this is not recommended unless you understand the inheritance mechanism thoroughly’ (Chambers & Hastie, 1992, p. 469).

Note

This scheme is called *S3* (S version 3). For new projects, it is recommended to use the more flexible and robust *S4* scheme provided in the `methods` package.

UserHooks

Functions to Get and Set Hooks for Load, Attach, Detach and Unload

Description

These functions allow users to set actions to be taken before packages are attached/detached and name spaces are (un)loaded.

Usage

```
getHook(hookName)
setHook(hookName, value,
        action = c("append", "prepend", "replace"))

packageEvent(pkgname,
             event = c("onLoad", "attach", "detach", "onUnload"))
```

Arguments

<code>hookName</code>	character string: the hook name
<code>pkgname</code>	character string: the package/name space name. If versioned install has been used, <code>pkgname</code> should be the unversioned name of the package (but any version information will be stripped).
<code>event</code>	character string: an event for the package
<code>value</code>	A function, or for <code>action="replace"</code> , NULL.
<code>action</code>	The action to be taken. The names can be abbreviated.

Details

`setHook` provides a general mechanism for users to register hooks, a list of functions to be called from system (or user) functions. The initial set of hooks is associated with events on packages/name spaces: these hooks are named via calls to `packageEvent`.

To remove a hook completely, call `setHook(hookName, NULL, "replace")`.

When an R package is attached by `library`, it can call initialization code via a function `.First.lib`, and when it is `detach`-ed it can tidy up via a function `.Last.lib`. Users can add their own initialization code via the hooks provided by these functions, functions which will be called as `funname(pkgname, pkgpath)` inside a `try` call. (The attach hook is called after `.First.lib` and the detach hook before `.Last.lib`.)

If a package has a name space, there are two further actions, when the name space is loaded (before being attached and after `.onLoad` is called) and when it is unloaded (after being detached and before `.onUnload`). Note that code in these hooks is run without the package being on the search path, so objects in the package need to be referred to using the double colon operator as in the example. (Unlike `.onLoad`, the user hook is run after the name space has been sealed.)

Hooks are normally run in the order shown by `getHook`, but the "detach" and "onUnload" hooks are run in reverse order so the default for package events is to add hooks 'inside' existing ones.

Note that when an R session is finished, packages are not detached and name spaces are not unloaded, so the corresponding hooks will not be run.

The hooks are stored in the environment `.userHooksEnv` in the base package, with 'mangled' names.

Value

For `getHook` function, a list of functions (possible empty). For `setHook` function, no return value. For `packageEvent`, the derived hook name (a character string).

See Also

`library`, `detach`, `loadNamespace`.

Other hooks may be added later: `plot.new` and `persp` already have them.

Examples

```
setHook(packageEvent("grDevices", "onLoad"),
        function(...) grDevices::ps.options(horizontal=FALSE))
```

utf8Conversion

Convert to or from UTF-8-encoded Character Vectors

Description

Conversion of UTF-8 encoded character vectors to and from integer vectors.

Usage

```
utf8ToInt(x)
intToUtf8(x, multiple = FALSE)
```

Arguments

<code>x</code>	object to be converted.
<code>multiple</code>	logical: should the conversion be to a single character string or multiple individual characters?

Details

These will work in any locale, including on machines that do not otherwise support multi-byte character sets.

Value

`utf8ToInt` converts a length-one character string encoded in UTF-8 to an integer vector of (numeric) UTF-8 code points.

`intToUtf8` converts a vector of (numeric) UTF-8 code points either to a single character string or a character vector of single characters. (For a single character string 0 is silently omitted: otherwise 0 is mapped to ". Non-integral numeric values are truncated to integers.) The `Encoding` is declared as "UTF-8".

Examples

```
## Not run:
## will only display in some locales and fonts
intToUtf8(0x03B2L) # Greek beta
## End(Not run)
```

vector

Vectors

Description

`vector` produces a vector of the given length and mode.

`as.vector`, a generic, attempts to coerce its argument into a vector of mode `mode` (the default is to coerce to whichever mode is most convenient).

`is.vector` returns TRUE if `x` is a vector (of mode logical, integer, real, complex, character, raw or list if not specified) or expression and FALSE otherwise.

Usage

```
vector(mode = "logical", length = 0)
as.vector(x, mode = "any")
is.vector(x, mode = "any")
```

Arguments

<code>mode</code>	A character string giving an atomic mode or "list", or (not for <code>vector</code>) "any".
<code>length</code>	A non-negative integer specifying the desired length.
<code>x</code>	An object.

Details

The atomic modes are "logical", "integer", "numeric", "complex", "character" and "raw".

`is.vector` returns FALSE if `x` has any attributes except names. (This is incompatible with S.) On the other hand, `as.vector` removes *all* attributes including names for results of atomic mode.

Note that factors are *not* vectors; `is.vector` returns FALSE and `as.vector` converts to a character vector for mode = "any".

Value

For `vector`, a vector of the given length and mode. Logical vector elements are initialized to FALSE, numeric vector elements to 0, character vector elements to "", raw vector elements to nul bytes and list elements to NULL.

All attributes are removed from the answer if it is of an atomic mode.

Note

`as.vector` and `is.vector` are quite distinct from the meaning of the formal class "vector" in the **methods** package, and hence `as(x, "vector")` and `is(x, "vector")`.

modes of "symbol", "pairlist" and "expression" are allowed but have long been undocumented.

See Also

`c`, `is.numeric`, `is.list`, etc.

Examples

```
df <- data.frame(x=1:3, y=5:7)
## Not run:
## Error:
  as.vector(data.frame(x=1:3, y=5:7), mode="numeric")
## End(Not run)

x <- c(a = 1, b = 2)
is.vector(x)
as.vector(x)
all.equal(x, as.vector(x)) ## FALSE

###-- All the following are TRUE:
is.list(df)
! is.vector(df)
! is.vector(df, mode="list")

is.vector(list(), mode="list")
is.vector(NULL, mode="NULL")
```

warning

*Warning Messages***Description**

Generates a warning message that corresponds to its argument(s) and (optionally) the expression or function from which it was called.

Usage

```
warning(..., call. = TRUE, immediate. = FALSE, domain = NULL)
suppressWarnings(expr)
```

Arguments

...	zero or more objects which can be coerced to character (and which are pasted together with no separator) or a single condition object.
call.	logical, indicating if the call should become part of the warning message.
immediate.	logical, indicating if the call should be output immediately, even if <code>getOption("warn") <= 0</code> .
expr	expression to evaluate.
domain	see <code>gettext</code> . If NA, messages will not be translated.

Details

The result *depends* on the value of `getOption("warn")` and on handlers established in the executing code.

If a condition object is supplied it should be the only argument, and further arguments will be ignored, with a message.

`warning` signals a warning condition by (effectively) calling `signalCondition`. If there are no handlers or if all handlers return, then the value of `warn = getOption("warn")` is used to determine the appropriate action. If `warn` is negative warnings are ignored; if it is zero they are stored and printed after the top-level function has completed; if it is one they are printed as they occur and if it is 2 (or larger) warnings are turned into errors. Calling `warning(immediate. = TRUE)` turns `warn <= 0` into `warn = 1` for this call only.

If `warn` is zero (the default), a read-only variable `last.warning` is created. It contains the warnings which can be printed via a call to `warnings`.

Warnings will be truncated to `getOption("warning.length")` characters, default 1000, indicated by `[... truncated]`.

While the warning is being processed, a `muffleWarning` restart is available. If this restart is invoked with `invokeRestart`, then `warning` returns immediately.

An attempt is made to coerce other types of inputs to `warning` to character vectors.

`suppressWarnings` evaluates its expression in a context that ignores all warnings.

Examples

```
testit <- function() warning("testit")
testit() ## shows call
testit <- function() warning("problem in testit", call. = FALSE)
testit() ## no call
suppressWarnings(warning("testit"))
```

warnings

Print Warning Messages

Description

`warnings` and its `print` method print the variable `last.warning` in a pleasing form.

Usage

```
warnings(...)
```

Arguments

... arguments to be passed to [cat](#).

Details

See the description of [options\("warn"\)](#) for the circumstances under which there is a `last.warning` object and `warnings()` is used. In essence this is if `options(warn = 0)` and `warning` has been called at least once.

It is possible that `last.warning` refers to the last recorded warning and not to the last warning, for example if `options(warn)` has been changed or if a catastrophic error occurred.

Warning

It is undocumented where `last.warning` is stored nor that it is visible, and this is subject to change. Prior to R 2.4.0 it was stored in the workspace, but no longer.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

[warning](#).

Examples

```
## NB this example is intended to be pasted in,
##   rather than run by example()
ow <- options("warn")
for(w in -1:1) {
  options(warn = w); cat("\n warn =",w,"\n")
  for(i in 1:3) { cat(i,"..\n"); m <- matrix(1:7, 3,4) }
}
warnings()
options(ow) # reset
```

weekdays

*Extract Parts of a POSIXt or Date Object***Description**

Extract the weekday, month or quarter, or the Julian time (days since some origin). These are generic functions: the methods for the internal date-time classes are documented here.

Usage

```
weekdays(x, abbreviate)
## S3 method for class 'POSIXt':
weekdays(x, abbreviate = FALSE)
## S3 method for class 'Date':
weekdays(x, abbreviate = FALSE)

months(x, abbreviate)
## S3 method for class 'POSIXt':
months(x, abbreviate = FALSE)
## S3 method for class 'Date':
months(x, abbreviate = FALSE)

quarters(x, abbreviate)
## S3 method for class 'POSIXt':
quarters(x, ...)
## S3 method for class 'Date':
quarters(x, ...)

julian(x, ...)
## S3 method for class 'POSIXt':
julian(x, origin = as.POSIXct("1970-01-01", tz="GMT"), ...)
## S3 method for class 'Date':
julian(x, origin = as.Date("1970-01-01"), ...)
```

Arguments

<code>x</code>	an object inheriting from class "POSIXt" or "Date".
<code>abbreviate</code>	logical. Should the names be abbreviated?
<code>origin</code>	an length-one object inheriting from class "POSIXt" or "Date".
<code>...</code>	arguments for other methods.

Value

`weekdays` and `months` return a character vector of names in the locale in use.

`quarters` returns a character vector of "Q1" to "Q4".

`julian` returns the number of days (possibly fractional) since the origin, with the origin as a "origin" attribute.

Note

Other components such as the day of the month or the year are very easy to compute: just use `as.POSIXlt` and extract the relevant component.

See Also

[DateTimeClasses](#), [Date](#)

Examples

```
weekdays(.leap.seconds)
months(.leap.seconds)
quarters(.leap.seconds)

## Julian Day Number (JDN, http://en.wikipedia.org/wiki/Julian_day)
## is the number of days since noon UTC on the first day of 4317 BC.
julian(Sys.Date(), -2440588) # for a day
floor(as.numeric(julian(Sys.time())) + 2440587.5) # for a date-time
```

which

Which indices are TRUE?

Description

Give the TRUE indices of a logical object, allowing for array indices.

Usage

```
which(x, arr.ind = FALSE)
```

Arguments

`x` a [logical](#) vector or array. `NA`s are allowed and omitted (treated as if `FALSE`).

`arr.ind` logical; should **array indices** be returned when `x` is an array?

Value

If `arr.ind == FALSE` (the default), an integer vector with `length` equal to `sum(x)`, i.e., to the number of `TRUE`s in `x`; Basically, the result is `(1:length(x))[x]`.

If `arr.ind == TRUE` and `x` is an [array](#) (has a `dim` attribute), the result is a matrix whose rows each are the indices of one element of `x`; see Examples below.

Author(s)

Werner Stahel and Peter Holzer (holzer@stat.math.ethz.ch), for the array case.

See Also

[Logic](#), [which.min](#) for the index of the minimum or maximum, and [match](#) for the first index of an element in a vector, i.e., for a scalar a , `match(a, x)` is equivalent to `min(which(x == a))` but much more efficient.

Examples

```
which(LETTERS == "R")
which(ll <- c(TRUE,FALSE,TRUE,NA,FALSE,FALSE,TRUE))#> 1 3 7
names(ll) <- letters[seq(ll)]
which(ll)
which((1:12)%%2 == 0) # which are even?
which(1:10 > 3, arr.ind=TRUE)

( m <- matrix(1:12,3,4) )
which(m %% 3 == 0)
which(m %% 3 == 0, arr.ind=TRUE)
rownames(m) <- paste("Case",1:3, sep="_")
which(m %% 5 == 0, arr.ind=TRUE)

dim(m) <- c(2,2,3); m
which(m %% 3 == 0, arr.ind=FALSE)
which(m %% 3 == 0, arr.ind=TRUE)

vm <- c(m)
dim(vm) <- length(vm) #-- funny thing with length(dim(...)) == 1
which(vm %% 3 == 0, arr.ind=TRUE)
```

which.min

Where is the Min() or Max() ?

Description

Determines the location, i.e., index of the (first) minimum or maximum of a numeric vector.

Usage

```
which.min(x)
which.max(x)
```

Arguments

x numeric (integer or double) vector, whose [min](#) or [max](#) is searched for.

Value

Missing and NaN values are discarded.

an [integer](#) of length 1 or 0 (iff x has no non-NAs), giving the index of the *first* minimum or maximum respectively of x .

If this extremum is unique (or empty), the results are the same as (but more efficient than) `which(x == min(x))` or `which(x == max(x))` respectively.

Author(s)

Martin Maechler

See Also[which](#), [max.col](#), [max](#), etc.[which.is.max](#) in package **nnet** differs in breaking ties at random (and having a ‘fuzz’ in the definition of ties).**Examples**

```
x <- c(1:4, 0:5, 11)
which.min(x)
which.max(x)

## it *does* work with NA's present, by discarding them:
presidents[1:30]
range(presidents, na.rm = TRUE)
which.min(presidents) # 28
which.max(presidents) # 2
```

with

Evaluate an Expression in a Data Environment

Description

Evaluate an R expression in an environment constructed from data, possibly modifying the original data.

Usage

```
with(data, expr, ...)
within(data, expr, ...)
```

Arguments

<code>data</code>	data to use for constructing an environment. For the default <code>with</code> method this may be an environment, a list, a data frame, or an integer as in <code>sys.call</code> . For <code>within</code> , it can be a list or a data frame.
<code>expr</code>	expression to evaluate.
<code>...</code>	arguments to be passed to future methods.

Details

`with` is a generic function that evaluates `expr` in a local environment constructed from `data`. The environment has the caller’s environment as its parent. This is useful for simplifying calls to modeling functions. (Note: if `data` is already an environment then this is used with its existing parent.)

Note that assignments within `expr` take place in the constructed environment and not in the user’s workspace.

`within` is similar, except that it examines the environment after the evaluation of `expr` and makes the corresponding modifications to `data` (this may fail in the data frame case if objects are created which cannot be stored in a data frame), and returns it. `within` can be used as an alternative to `transform`.

Value

For `with`, the value of the evaluated `expr`. For `within`, the modified object.

See Also

[evalq](#), [attach](#), [assign](#), [transform](#).

Examples

```
require(stats); require(graphics)
#examples from glm:
## Not run:
library(MASS)
with(anorexia, {
  anorex.1 <- glm(Postwt ~ Prewt + Treat + offset(Prewt),
                 family = gaussian)
  summary(anorex.1)
})
## End(Not run)

aq <- within(airquality, {      # Notice that multiple vars can be changed
  lOzone<-log(Ozone)
  Month<-factor(month.abb[Month])
  cTemp <- round((Temp - 32) * 5/9, 1) # From Fahrenheit to Celsius
  rm(Day, Temp)
})
head(aq)

with(data.frame(u = c(5,10,15,20,30,40,60,80,100),
               lot1 = c(118,58,42,35,27,25,21,19,18),
               lot2 = c(69,35,26,21,18,16,13,12,12)),
     list(summary(glm(lot1 ~ log(u), family = Gamma)),
          summary(glm(lot2 ~ log(u), family = Gamma))))

# example from boxplot:
with(ToothGrowth, {
  boxplot(len ~ dose, boxwex = 0.25, at = 1:3 - 0.2,
          subset = (supp == "VC"), col = "yellow",
          main = "Guinea Pigs' Tooth Growth",
          xlab = "Vitamin C dose mg",
          ylab = "tooth length", ylim = c(0,35))
  boxplot(len ~ dose, add = TRUE, boxwex = 0.25, at = 1:3 + 0.2,
          subset = supp == "OJ", col = "orange")
  legend(2, 9, c("Ascorbic acid", "Orange juice"),
        fill = c("yellow", "orange"))
})

# alternate form that avoids subset argument:
with(subset(ToothGrowth, supp == "VC"),
     boxplot(len ~ dose, boxwex = 0.25, at = 1:3 - 0.2,
```

```

col = "yellow", main = "Guinea Pigs' Tooth Growth",
xlab = "Vitamin C dose mg",
ylab = "tooth length", ylim = c(0,35))
with(subset(ToothGrowth, supp == "OJ"),
  boxplot(len ~ dose, add = TRUE, boxwex = 0.25, at = 1:3 + 0.2,
    col = "orange"))
legend(2, 9, c("Ascorbic acid", "Orange juice"),
  fill = c("yellow", "orange"))

```

write

Write Data to a File

Description

The data (usually a matrix) `x` are written to file `file`. If `x` is a two-dimensional matrix you need to transpose it to get the columns in `file` the same as those in the internal representation.

Usage

```

write(x, file = "data",
      ncolumns = if(is.character(x)) 1 else 5,
      append = FALSE, sep = " ")

```

Arguments

<code>x</code>	the data to be written out.
<code>file</code>	A connection, or a character string naming the file to write to. If "", print to the standard output connection. If it is " <code> cmd</code> ", the output is piped to the command given by ' <code>cmd</code> '.
<code>ncolumns</code>	the number of columns to write the data in.
<code>append</code>	if TRUE the data <code>x</code> are appended to the connection.
<code>sep</code>	a string used to separate columns. Using <code>sep = "\t"</code> gives tab delimited output; default is " ".

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`write` is a wrapper for `cat`, which gives further details on the format used.

`save` for writing any R objects, `write.table` for data frames, and `scan` for reading data.

Examples

```
# create a 2 by 5 matrix
x <- matrix(1:10,ncol=5)

# the file data contains x, two rows, five cols
# 1 3 5 7 9 will form the first row
write(t(x))

# Writing to the "console" 'tab-delimited'
# two rows, five cols but the first row is 1 2 3 4 5
write(x, "", sep = "\t")
unlink("data") # tidy up
```

writeLines

Write Lines to a Connection

Description

Write text lines to a connection.

Usage

```
writeLines(text, con = stdout(), sep = "\n")
```

Arguments

text	A character vector
con	A connection object or a character string.
sep	character. A string to be written to the connection after each line of text.

Details

If the `con` is a character string, the function calls `file` to obtain a file connection which is opened for the duration of the function call.

If the connection is open it is written from its current position. If it is not open, it is opened for the duration of the call in "wt" mode and then closed again.

Normally `writeLines` is used with a text-mode connection, and the default separator is converted to the normal separator for that platform (LF on Unix/Linux, CRLF on Windows). For more control, open a binary connection and specify the precise value you want written to the file in `sep`. For even more control, use `writeChar` on a binary connection.

[connections](#), [writeChar](#), [writeBin](#), [readLines](#), [cat](#)

`xtfrm`*Auxiliary Function for Sorting and Ranking*

Description

A generic auxiliary function that produces a numeric vector which will sort in the same order as `x`.

Usage

```
xtfrm(x)
```

Arguments

`x` an R object.

Details

This is a special case of ranking, but as a less general function than `rank` is more suitable to be made generic. The default method is equivalent to `rank(x, ties.method="min", na.last="keep")`, so NA values are given rank NA and all tied values are given equal integer rank.

The `factor` method extracts the codes. The `Surv` method sorts first on times and then on status code(s).

The default method will make use of `==`, `>` and `is.na` methods for the class of `x`, but might be rather slow when doing so.

Value

A numeric (usually integer) vector of the same length as `x`.

See Also

[rank](#), [sort](#), [order](#).

`zpackages`*Listing of Packages*

Description

`.packages` returns information about package availability.

Usage

```
.packages(all.available = FALSE, lib.loc = NULL)
```

Arguments

`all.available`

logical; if TRUE return a character vector of all available packages in `lib.loc`.

`lib.loc`

a character vector describing the location of R library trees to search through, or NULL. The default value of NULL corresponds to all libraries currently known.

Details

`.packages()` returns the names of the currently attached packages *invisibly* whereas `.packages(all.available = TRUE)` gives (visibly) *all* packages available in the library location path `lib.loc`. If versioned installs have been used, the names returned will be of the form `pkgname_version`.

For a package to be regarded as being available it must have a ‘DESCRIPTION’ file containing a valid `version` field.

Value

A character vector of package base names, invisible unless `all.available = TRUE`.

Author(s)

R core; Guido Masarotto for the `all.available=TRUE` part of `.packages`.

See Also

`library`, `.libPaths`.

Examples

```
.packages()                # maybe just "base"
.packages(all.available = TRUE) # return all available as character vector
require(splines)
.packages()                # "splines", too
detach("package:splines")
```

zutils

Miscellaneous Internal/Programming Utilities

Description

Miscellaneous internal/programming utilities.

Usage

```
.standard_regexps()
```

Details

`.standard_regexps` returns a list of ‘standard’ regexps, including elements named `valid_package_name` and `valid_package_version` with the obvious meanings. The regexps are not anchored.

Chapter 2

The datasets package

`datasets-package` *The R Datasets Package*

Description

Base R datasets

Details

This package contains a variety of datasets. For a complete list, use `library(help="datasets")`.

Author(s)

tl <- pred$pred - 1.96 * pred$se
tu <- pred$pred + 1.96 * pred$se
ts.plot(AirPassengers, 10^tl, 10^tu, log = "y", lty = c(1,2,2))

## full ML fit is the same if the series is reversed, CSS fit is not
ap0 <- rev(log10(AirPassengers))
attributes(ap0) <- attributes(AirPassengers)
arima(ap0, c(0, 1, 1), seasonal = list(order=c(0, 1, 1), period=12))
arima(ap0, c(0, 1, 1), seasonal = list(order=c(0, 1, 1), period=12),
     method = "CSS")

## Structural Time Series
```

```

ap <- log10(AirPassengers) - 2
(fit <- StructTS(ap, type= "BSM"))
par(mfrow=c(1,2))
plot(cbind(ap, fitted(fit)), plot.type = "single")
plot(cbind(ap, tsSmooth(fit)), plot.type = "single")
## End(Not run)

```

airquality

New York Air Quality Measurements

Description

Daily air quality measurements in New York, May to September 1973.

Usage

```
airquality
```

Format

A data frame with 154 observations on 6 variables.

[, 1]	Ozone	numeric	Ozone (ppb)
[, 2]	Solar.R	numeric	Solar R (lang)
[, 3]	Wind	numeric	Wind (mph)
[, 4]	Temp	numeric	Temperature (degrees F)
[, 5]	Month	numeric	Month (1–12)
[, 6]	Day	numeric	Day of month (1–31)

Details

Daily readings of the following air quality values for May 1, 1973 (a Tuesday) to September 30, 1973.

- **Ozone:** Mean ozone in parts per billion from 1300 to 1500 hours at Roosevelt Island
- **Solar.R:** Solar radiation in Langleys in the frequency band 4000–7700 Angstroms from 0800 to 1200 hours at Central Park
- **Wind:** Average wind speed in miles per hour at 0700 and 1000 hours at LaGuardia Airport
- **Temp:** Maximum daily temperature in degrees Fahrenheit at La Guardia Airport.

Source

The data were obtained from the New York State Department of Conservation (ozone data) and the National Weather Service (meteorological data).

attitude

The Chatterjee-Price Attitude Data

Description

From a survey of the clerical employees of a large financial organization, the data are aggregated from the questionnaires of the approximately 35 employees for each of 30 (randomly selected) departments. The numbers give the percent proportion of favourable responses to seven questions in each department.

Usage

```
attitude
```

Format

A dataframe with 30 observations on 7 variables. The first column are the short names from the reference, the second one the variable names in the data frame:

Y	rating	numeric	Overall rating
X[1]	complaints	numeric	Handling of employee complaints
X[2]	privileges	numeric	Does not allow special privileges
X[3]	learning	numeric	Opportunity to learn
X[4]	raises	numeric	Raises based on performance
X[5]	critical	numeric	Too critical
X[6]	advancel	numeric	Advancement

beavers

Body Temperature Series of Two Beavers

Description

Reynolds (1994) describes a small part of a study of the long-term temperature dynamics of beaver *Castor canadensis* in north-central Wisconsin. Body temperature was measured by telemetry every 10 minutes for four females, but data from a one period of less than a day for each of two animals is used there.

Usage

```

beaver1
beaver2

```

Format

The `beaver1` data frame has 114 rows and 4 columns on body temperature measurements at 10 minute intervals.

The `beaver2` data frame has 100 rows and 4 columns on body temperature measurements at 10 minute intervals.

The variables are as follows:

day Day of observation (in days since the beginning of 1990), December 12–13 (`beaver1`) and November 3–4 (`beaver2`).

time Time of observation, in the form 0330 for 3:30am

temp Measured body temperature in degrees Celsius.

activ Indicator of activity outside the retreat.

Note

The observation at 22:20 is missing in `beaver1`.

Source

BOD

Biochemical Oxygen Demand

Description

The BOD data frame has 6 rows and 2 columns giving the biochemical oxygen demand versus time in an evaluation of water quality.

Usage

BOD

Format

This data frame contains the following columns:

Time A numeric vector giving the time of the measurement (days).

demand A numeric vector giving the biochemical oxygen demand (mg/l).

ChickWeight

*Weight versus age of chicks on different diets***Description**

The `ChickWeight` data frame has 578 rows and 4 columns from an experiment on the effect of diet on early growth of chicks.

Usage

```
ChickWeight
```

Format

This data frame contains the following columns:

weight a numeric vector giving the body weight of the chick (gm).

Time a numeric vector giving the number of days since birth when the measurement was made.

Chick an ordered factor with levels 18 < ... < 48 giving a unique identifier for the chick. The ordering of the levels groups chicks on the same diet together and orders them according to their final weight (lightest to heaviest) within diet.

Diet a factor with levels 1, ..., 4 indicating which experimental diet the chick received.

Details

The body weights of the chicks were measured at birth and every second day thereafter until day 20. They were also measured on day 21. There were four groups on chicks on different protein diets.

summary( fm1 )
```

`chickwts`*Chicken Weights by Feed Type*

Description

An experiment was conducted to measure and compare the effectiveness of various feed supplements on the growth rate of chickens.

Usage

```
chickwts
```

Format

A data frame with 71 observations on 2 variables.

weight a numeric variable giving the chick weight.

feed a factor giving the feed type.

Details

Newly hatched chicks were randomly allocated into six groups, and each group was given a different feed supplement. Their weights in grams after six weeks are given along with feed types.

CO2

*Carbon Dioxide uptake in grass plants***Description**

The CO2 data frame has 84 rows and 5 columns of data from an experiment on the cold tolerance of the grass species *Echinochloa crus-galli*.

Usage

CO2

Format

This data frame contains the following columns:

Plant an ordered factor with levels Qn1 < Qn2 < Qn3 < ... < Mc1 giving a unique identifier for each plant.

Type a factor with levels Quebec Mississippi giving the origin of the plant

Treatment a factor with levels nonchilled chilled

conc a numeric vector of ambient carbon dioxide concentrations (mL/L).

uptake a numeric vector of carbon dioxide uptake rates ($\mu\text{mol}/\text{m}^2 \text{ sec}$).

Details

The CO_2 uptake of six plants from Quebec and six plants from Mississippi was measured at several levels of ambient CO_2 concentration. Half the plants of each type were chilled overnight before the experiment was conducted.

```

`co2`*Mauna Loa Atmospheric CO2 Concentration*

Description

Atmospheric concentrations of CO₂ are expressed in parts per million (ppm) and reported in the preliminary 1997 SIO manometric mole fraction scale.

Usage`co2`**Format**

A time series of 468 observations; monthly from 1959 to 1997.

Details

The values for February, March and April of 1964 were missing and have been obtained by interpolating linearly between the values for January and May of 1964.

     las = 1)
title(main = "co2 data set")
```

`crimtab`*Student's 3000 Criminals Data*

Description

Data of 3000 male criminals over 20 years old undergoing their sentences in the chief prisons of England and Wales.

Usage`data(crimtab)`

Format

A `table` object of `integer` counts, of dimension 42×22 with a total count, `sum(crimtab)` of 3000.

The 42 `rownames` ("9.4", "9.5", ...) correspond to midpoints of intervals of finger lengths whereas the 22 column names (`colnames`) ("142.24", "144.78", ...) correspond to (body) heights of 3000 criminals, see also below.

Details

Student is the pseudonym of William Sealy Gosset. In his 1908 paper he wrote (on page 13) at the beginning of section VI entitled *Practical Test of the forgoing Equations*:

“Before I had succeeded in solving my problem analytically, I had endeavoured to do so empirically. The material used was a correlation table containing the height and left middle finger measurements of 3000 criminals, from a paper by W. R. MacDonell (*Biometrika*, Vol. I., p. 219). The measurements were written out on 3000 pieces of cardboard, which were then very thoroughly shuffled and drawn at random. As each card was drawn its numbers were written down in a book, which thus contains the measurements of 3000 criminals in a random order. Finally, each consecutive set of 4 was taken as a sample—750 in all—and the mean, standard deviation, and correlation of each sample determined. The difference between the mean of each sample and the mean of the population was then divided by the standard deviation of the sample, giving us the z of Section III.”

The table is in fact page 216 and not page 219 in MacDonell(1902). In the MacDonell table, the middle finger lengths were given in mm and the heights in feet/inches intervals, they are both converted into cm here. The midpoints of intervals were used, e.g., where MacDonell has $4'7''9/16 - 8''9/16$, we have 142.24 which is $2.54 * 56 = 2.54 * (4'8'')$.

MacDonell credited the source of data (page 178) as follows: *The data on which the memoir is based were obtained, through the kindness of Dr Garson, from the Central Metric Office, New Scotland Yard...* He pointed out on page 179 that : *The forms were drawn at random from the mass on the office shelves; we are therefore dealing with a random sampling.*

Source

<http://pbil.univ-lyon1.fr/R/donnees/criminals1902.txt> thanks to Jean R. Lobry and Anne-Béatrice Dufour.

References

Garson, J.G. (1900) The metric system of identification of criminals, as used in in Great Britain and Ireland. *The Journal of the Anthropological Institute of Great Britain and Ireland* **30**, 161–198.

MacDonell, W.R. (1902) On criminal anthropometry and the identification of criminals. *Biometrika* **1**, 2, 177–227.

Student (1908) The probable error of a mean. *Biometrika* **6**, 1–25.

Examples

```
require(stats)
dim(crimtab)
utils::str(crimtab)
## for nicer printing:
local({cT <- crimtab
      colnames(cT) <- substring(colnames(cT), 2, 3)
      print(cT, zero.print = " ")
})
```

```

## Repeat Student's experiment:

# 1) Reconstitute 3000 raw data for heights in inches and rounded to
#     nearest integer as in Student's paper:

(heIn <- round(as.numeric(colnames(crimtab)) / 2.54))
d.hei <- data.frame(height = rep(heIn, colSums(crimtab)))

# 2) shuffle the data:

set.seed(1)
d.hei <- d.hei[sample(1:3000), , drop = FALSE]

# 3) Make 750 samples each of size 4:

d.hei$sample <- as.factor(rep(1:750, each = 4))

# 4) Compute the means and standard deviations (n) for the 750 samples:

h.mean <- with(d.hei, tapply(height, sample, FUN = mean))
h.sd    <- with(d.hei, tapply(height, sample, FUN = sd)) * sqrt(3/4)

# 5) Compute the difference between the mean of each sample and
#     the mean of the population and then divide by the
#     standard deviation of the sample:

zobs <- (h.mean - mean(d.hei[, "height"])) / h.sd

# 6) Replace infinite values by +/- 6 as in Student's paper:

zobs[infZ <- is.infinite(zobs)] # 3 of them
zobs[infZ] <- 6 * sign(zobs[infZ])

# 7) Plot the distribution:

require(grDevices); require(graphics)
hist(x = zobs, probability = TRUE, xlab = "Student's z",
     col = grey(0.8), border = grey(0.5),
     main = "Distribution of Student's z score for 'crimtab' data")

```

```

euro

*Conversion Rates of Euro Currencies***Description**

Conversion rates between the various Euro currencies.

Usage

```
euro
euro.cross
```

Format

`euro` is a named vector of length 11, `euro.cross` a matrix of size 11 by 11, with `dimnames`.

Details

The data set `euro` contains the value of 1 Euro in all currencies participating in the European monetary union (Austrian Schilling ATS, Belgian Franc BEF, German Mark DEM, Spanish Peseta ESP, Finnish Markka FIM, French Franc FRF, Irish Punt IEP, Italian Lira ITL, Luxembourg Franc LUF, Dutch Guilder NLG and Portuguese Escudo PTE). These conversion rates were fixed by the European Union on December 31, 1998. To convert old prices to Euro prices, divide by the respective rate and round to 2 digits.

The data set `euro.cross` contains conversion rates between the various Euro currencies, i.e., the result of `outer(1 / euro, euro)`.

Examples

```

cbind(euro)

## These relations hold:
euro == signif(euro,6) # [6 digit precision in Euro's definition]
all(euro.cross == outer(1/euro, euro))

## Convert 20 Euro to Belgian Franc

```

```

20 * euro["BEF"]
## Convert 20 Austrian Schilling to Euro
20 / euro["ATS"]
## Convert 20 Spanish Pesetas to Italian Lira
20 * euro.cross["ESP", "ITL"]

require(graphics)
dotchart(euro,
         main = "euro data: 1 Euro in currency unit")
dotchart(1/euro,
         main = "euro data: 1 currency unit in Euros")
dotchart(log(euro, 10),
         main = "euro data: log10(1 Euro in currency unit)")

```

eurodist

Distances Between European Cities

Description

The data give the road distances (in km) between 21 cities in Europe. The data are taken from a table in *The Cambridge Encyclopaedia*.

Usage

```
eurodist
```

Format

A `dist` object based on 21 objects. (You must have the **stats** package loaded to have the methods for this kind of object available).

Source

Crystal, D. Ed. (1990) *The Cambridge Encyclopaedia*. Cambridge: Cambridge University Press,

EuStockMarkets

Daily Closing Prices of Major European Stock Indices, 1991–1998

Description

Contains the daily closing prices of major European stock indices: Germany DAX (Ibis), Switzerland SMI, France CAC, and UK FTSE. The data are sampled in business time, i.e., weekends and holidays are omitted.

Usage

```
EuStockMarkets
```

Format

A multivariate time series with 1860 observations on 4 variables. The object is of class `"mts"`.

Source

The data were kindly provided by Erste Bank AG, Vienna, Austria.

faithful

Old Faithful Geyser Data

Description

Waiting time between eruptions and the duration of the eruption for the Old Faithful geyser in Yellowstone National Park, Wyoming, USA.

Usage

```
faithful
```

Format

A data frame with 272 observations on 2 variables.

[,1]	eruptions	numeric	Eruption time in mins
[,2]	waiting	numeric	Waiting time to next eruption (in mins)

Details

A closer look at `faithful$eruptions` reveals that these are heavily rounded times originally in seconds, where multiples of 5 are more frequent than expected under non-human measurement. For a better version of the eruption times, see the example below.

There are many versions of this dataset around: Azzalini and Bowman (1990) use a more complete version.

Source

W. Härdle.

References

Härdle, W. (1991) *Smoothing Techniques with Implementation in S*. New York: Springer.

`geyser` in package **MASS** for the Azzalini–Bowman version.

Examples

```
require(stats); require(graphics)
f.tit <- "faithful data: Eruptions of Old Faithful"

ne60 <- round(e60 <- 60 * faithful$eruptions)
all.equal(e60, ne60)           # relative diff. ~ 1/10000
```

```

table(zapsmall(abs(e60 - ne60))) # 0, 0.02 or 0.04
faithful$better.eruptions <- ne60 / 60
te <- table(ne60)
te[te >= 4] # (too) many multiples of 5 !
plot(names(te), te, type="h", main = f.tit, xlab = "Eruption time (sec)")

plot(faithful[, -3], main = f.tit,
     xlab = "Eruption time (min)",
     ylab = "Waiting time to next eruption (min)")
lines(lowess(faithful$eruptions, faithful$waiting, f = 2/3, iter = 3),
      col = "red")

```

Formaldehyde

Determination of Formaldehyde

Description

These data are from a chemical experiment to prepare a standard curve for the determination of formaldehyde by the addition of chromotropic acid and concentrated sulphuric acid and the reading of the resulting purple color on a spectrophotometer.

Usage

Formaldehyde

Format

A data frame with 6 observations on 2 variables.

[,1]	carb	numeric	Carbohydrate (ml)
[,2]	optden	numeric	Optical Density

Source

```

freeny

Freeny's Revenue Data

Description

Freeny's data on quarterly revenue and explanatory variables.

Usage

```
freeny
freeny.x
freeny.y
```

Format

There are three 'freeny' data sets.

`freeny.y` is a time series with 39 observations on quarterly revenue from (1962,2Q) to (1971,4Q).

`freeny.x` is a matrix of explanatory variables. The columns are `freeny.y` lagged 1 quarter, price index, income level, and market potential.

Finally, `freeny` is a data frame with variables `y`, `lag.quarterly.revenue`, `price.index`, `income.level`, and `market.potential` obtained from the above two data objects.

Source

Examples

```
require(stats); require(graphics)
summary(freeny)
pairs(freeny, main = "freeny data")
# gives warning: freeny$y has class "ts"

summary(fm1 <- lm(y ~ ., data = freeny))
opar <- par(mfrow = c(2, 2), oma = c(0, 0, 1.1, 0),
            mar = c(4.1, 4.1, 2.1, 1.1))

plot(fm1)
par(opar)
```

HairEyeColor

*Hair and Eye Color of Statistics Students***Description**

Distribution of hair and eye color and sex in 592 statistics students.

Usage

```
HairEyeColor
```

Format

A 3-dimensional array resulting from cross-tabulating 592 observations on 3 variables. The variables and their levels are as follows:

No	Name	Levels
1	Hair	Black, Brown, Red, Blond
2	Eye	Brown, Blue, Hazel, Green
3	Sex	Male, Female

Details

The Hair \times Eye table comes from a survey of students at the University of Delaware reported by Snee (1974). The split by Sex was added by Friendly (1992a) for didactic purposes.

This data set is useful for illustrating various techniques for the analysis of contingency tables, such as the standard chi-squared test or, more generally, log-linear modelling, and graphical methods such as mosaic plots, sieve diagrams or association plots.

Source

<http://euclid.psych.yorku.ca/ftp/sas/vcd/catdata/haireye.sas>

Snee (1974) gives the two-way table aggregated over Sex. The Sex split of the ‘Brown hair, Brown eye’ cell was changed in R 2.6.0 to agree with that used by Friendly (2000).

```

Indometh

*Pharmacokinetics of Indomethicin***Description**

The `Indometh` data frame has 66 rows and 3 columns of data on the pharmacokinetics of indomethicin.

Usage

```
Indometh
```

Format

This data frame contains the following columns:

Subject an ordered factor with containing the subject codes. The ordering is according to increasing maximum response.

time a numeric vector of times at which blood samples were drawn (hr).

conc a numeric vector of plasma concentrations of indomethicin (mcg/ml).

Details

Each of the six subjects were given an intravenous injection of indomethicin.

          data = Indometh, subset = Subject == 1)
summary(fm1)
```

infert

*Infertility after Spontaneous and Induced Abortion***Description**

This is a matched case-control study dating from before the availability of conditional logistic regression.

Usage

infert

Format

1.	Education	0 = 0-5 years 1 = 6-11 years 2 = 12+ years
2.	age	age in years of case
3.	parity	count
4.	number of prior induced abortions	0 = 0 1 = 1 2 = 2 or more
5.	case status	1 = case 0 = control
6.	number of prior spontaneous abortions	0 = 0 1 = 1 2 = 2 or more
7.	matched set number	1-83
8.	stratum number	1-63

Note

One case with two prior spontaneous abortions and two prior induced abortions is omitted.

Source

Trichopoulos et al. (1976) *Br. J. of Obst. and Gynaec.* **83**, 645–650.

Examples

```
require(stats)
modell1 <- glm(case ~ spontaneous+induced, data=infert, family=binomial())
summary(modell1)
## adjusted for other potential confounders:
summary(model2 <- glm(case ~ age+parity+education+spontaneous+induced,
                      data=infert, family=binomial()))
## Really should be analysed by conditional logistic regression
## which is in the survival package
if(require(survival)){
```

```

model3 <- clogit(case~spontaneous+induced+strata(stratum), data=infert)
print(summary(model3))
detach()# survival (conflicts)
}

```

InsectSprays *Effectiveness of Insect Sprays*

Description

The counts of insects in agricultural experimental units treated with different insecticides.

Usage

```
InsectSprays
```

Format

A data frame with 72 observations on 2 variables.

[,1]	count	numeric	Insect count
[,2]	spray	factor	The type of spray

Source

Beall, G., (1942) The Transformation of data from entomological field experiments, *Biometrika*, **29**, 243–262.

References

McNeil, D. (1977) *Interactive Data Analysis*. New York: Wiley.

Examples

```

require(stats); require(graphics)
boxplot(count ~ spray, data = InsectSprays,
        xlab = "Type of spray", ylab = "Insect count",
        main = "InsectSprays data", varwidth = TRUE, col = "lightgray")

```

iris *Edgar Anderson's Iris Data*

Description

This famous (Fisher's or Anderson's) iris data set gives the measurements in centimeters of the variables sepal length and width and petal length and width, respectively, for 50 flowers from each of 3 species of iris. The species are *Iris setosa*, *versicolor*, and *virginica*.

Usage

```
iris
iris3
```

Format

`iris` is a data frame with 150 cases (rows) and 5 variables (columns) named `Sepal.Length`, `Sepal.Width`, `Petal.Length`, `Petal.Width`, and `Species`.

`iris3` gives the same data arranged as a 3-dimensional array of size 50 by 4 by 3, as represented by S-PLUS. The first dimension gives the case number within the species subsample, the second the measurements with names `Sepal L.`, `Sepal W.`, `Petal L.`, and `Petal W.`, and the third the species.

Source

Fisher, R. A. (1936) The use of multiple measurements in taxonomic problems. *Annals of Eugenics*, 7, Part II, 179–188.

The data were collected by Anderson, Edgar (1935). The irises of the Gaspé Peninsula, *Bulletin of the American Iris Society*, 59, 2–5.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole. (has `iris3` as `iris`.)

See Also

[matplot](#) some examples of which use `iris`.

Examples

```
dni3 <- dimnames(iris3)
ii <- data.frame(matrix(aperm(iris3, c(1,3,2)), ncol=4,
                        dimnames = list(NULL, sub(" L.", ".Length",
                                                  sub(" W.", ".Width", dni3[[2]]))),
                  Species = gl(3, 50, labels=sub("S", "s", sub("V", "v", dni3[[3]]))))
all.equal(ii, iris) # TRUE
```

`islands`*Areas of the World's Major Landmasses*

Description

The areas in thousands of square miles of the landmasses which exceed 10,000 square miles.

Usage

```
islands
```

lh

Luteinizing Hormone in Blood Samples

Description

A regular time series giving the luteinizing hormone in blood samples at 10 mins intervals from a human female, 48 samples.

Usage

lh

Source

P.J. Diggle (1990) *Time Series: A Biostatistical Introduction*. Oxford, table A.1, series 3

LifeCycleSavings *Intercountry Life-Cycle Savings Data*

Description

Data on the savings ratio 1960–1970.

Usage

LifeCycleSavings

Format

A data frame with 50 observations on 5 variables.

[,1]	sr	numeric	aggregate personal savings
[,2]	pop15	numeric	% of population under 15
[,3]	pop75	numeric	% of population over 75
[,4]	dpi	numeric	real per-capita disposable income
[,5]	ddpi	numeric	% growth rate of dpi

Details

Under the life-cycle savings hypothesis as developed by Franco Modigliani, the savings ratio (aggregate personal saving divided by disposable income) is explained by per-capita disposable income, the percentage rate of change in per-capita disposable income, and two demographic variables: the percentage of population less than 15 years old and the percentage of the population over 75 years old. The data are averaged over the decade 1960–1970 to remove the business cycle or other short-term fluctuations.

Source

The data were obtained from Belsley, Kuh and Welsch (1980). They in turn obtained the data from Sterling (1977).

References

 longley

Longley's Economic Regression Data

Description

A macroeconomic data set which provides a well-known example for a highly collinear regression.

Usage

```
longley
```

Format

A data frame with 7 economical variables, observed yearly from 1947 to 1962 ($n = 16$).

GNP.deflator: GNP implicit price deflator (1954 = 100)

GNP: Gross National Product.

Unemployed: number of unemployed.

Armed.Forces: number of people in the armed forces.

Population: 'noninstitutionalized' population ≥ 14 years of age.

Year: the year (time).

Employed: number of people employed.

The regression `lm(Employed ~ .)` is known to be highly collinear.

morley

Michaelson-Morley Speed of Light Data

Description

The classical data of Michaelson and Morley on the speed of light. The data consists of five experiments, each consisting of 20 consecutive ‘runs’. The response is the speed of light measurement, suitably coded.

Usage

```
morley
```

Format

A data frame contains the following components:

Expt The experiment number, from 1 to 5.

Run The run number within each experiment.

Speed Speed-of-light measurement.

Details

The data is here viewed as a randomized block experiment with ‘experiment’ and ‘run’ as the factors. ‘run’ may also be considered a quantitative variate to account for linear (or polynomial) changes in the measurement over the course of a single experiment.

Source

A. J. Weekes (1986) *A Genstat Primer*. London: Edward Arnold.

Examples

```
require(stats); require(graphics)
morley$Expt <- factor(morley$Expt)
morley$Run <- factor(morley$Run)

xtabs(~ Expt + Run, data = morley)# 5 x 20 balanced (two-way)
plot(Speed ~ Expt, data = morley,
     main = "Speed of Light Data", xlab = "Experiment No.")
fm <- aov(Speed ~ Run + Expt, data = morley)
summary(fm)
fm0 <- update(fm, . ~ . - Run)
anova(fm0, fm)
```

mtcars

*Motor Trend Car Road Tests***Description**

The data was extracted from the 1974 *Motor Trend* US magazine, and comprises fuel consumption and 10 aspects of automobile design and performance for 32 automobiles (1973–74 models).

Usage

```
mtcars
```

Format

A data frame with 32 observations on 11 variables.

[, 1]	mpg	Miles/(US) gallon
[, 2]	cyl	Number of cylinders
[, 3]	disp	Displacement (cu.in.)
[, 4]	hp	Gross horsepower
[, 5]	drat	Rear axle ratio
[, 6]	wt	Weight (lb/1000)

## End(Not run)
```

occupationalStatus *Occupational Status of Fathers and their Sons*

Description

Cross-classification of a sample of British males according to each subject's occupational status and his father's occupational status.

Usage

```
occupationalStatus
```

Format

A `table` of counts, with classifying factors `origin` (father's occupational status; levels 1:8) and `destination` (son's occupational status; levels 1:8).

Source

Goodman, L. A. (1979) Simple Models for the Analysis of Association in Cross-Classifications having Ordered Categories. *J. Am. Stat. Assoc.*, **74** (367), 537–552.

The data set has been in package `gnm` and been provided by the package authors.

Examples

```
require(stats); require(graphics)

plot(occupationalStatus)

## Fit a uniform association model separating diagonal effects
Diag <- as.factor(diag(1:8))
Rscore <- scale(as.numeric(row(occupationalStatus)), scale = FALSE)
Cscore <- scale(as.numeric(col(occupationalStatus)), scale = FALSE)
modUnif <- glm(Freq ~ origin + destination + Diag + Rscore:Cscore,
              family = poisson, data = occupationalStatus)

summary(modUnif)
plot(modUnif) # 4 plots, with warning about h_ii ~= 1
```

Orange

*Growth of Orange Trees***Description**

The Orange data frame has 35 rows and 3 columns of records of the growth of orange trees.

Usage

```
Orange
```

Format

This data frame contains the following columns:

Tree an ordered factor indicating the tree on which the measurement is made. The ordering is according to increasing maximum diameter.

age a numeric vector giving the age of the tree (days since 1968/12/31)

circumference a numeric vector of trunk circumferences (mm). This is probably “circumference at breast height”, a standard measurement in forestry.

Source

Draper, N. R. and Smith, H. (1998), *Applied Regression Analysis (3rd ed)*, Wiley (exercise 24.N).

Pinheiro, J. C. and Bates, D. M. (2000) *Mixed-effects Models in S and S-PLUS*, Springer.

Examples

```
require(stats); require(graphics)
coplot(circumference ~ age | Tree, data = Orange, show.given = FALSE)
fml <- nls(circumference ~ SSlogis(age, Asym, xmid, scal),
          data = Orange, subset = Tree == 3)
plot(circumference ~ age, data = Orange, subset = Tree == 3,
     xlab = "Tree age (days since 1968/12/31)",
     ylab = "Tree circumference (mm)", las = 1,
     main = "Orange tree data and fitted model (Tree 3 only)")
age <- seq(0, 1600, length.out = 101)
lines(age, predict(fml, list(age = age)))
```

OrchardSprays

*Potency of Orchard Sprays***Description**

An experiment was conducted to assess the potency of various constituents of orchard sprays in repelling honeybees, using a Latin square design.

Usage

OrchardSprays

Format

A data frame with 64 observations on 4 variables.

[,1]	rowpos	numeric	Row of the design
[,2]	colpos	numeric	Column of the design
[,3]	treatment	factor	Treatment level
[,4]	decrease	numeric	Response

Details

Individual cells of dry comb were filled with measured amounts of lime sulphur emulsion in sucrose solution. Seven different concentrations of lime sulphur ranging from a concentration of 1/100 to 1/1,562,500 in successive factors of 1/5 were used as well as a solution containing no lime sulphur.

The responses for the different solutions were obtained by releasing 100 bees into the chamber for two hours, and then measuring the decrease in volume of the solutions in the various cells.

An 8×8 Latin square design was used and the treatments were coded as follows:

A	highest level of lime sulphur
B	next highest level of lime sulphur
.	.
.	.
.	.
G	lowest level of lime sulphur
H	no lime sulphur

     main = "pressure data: Vapor Pressure of Mercury")
```

 Puromycin

Reaction velocity of an enzymatic reaction

Description

The `Puromycin` data frame has 23 rows and 3 columns of the reaction velocity versus substrate concentration in an enzymatic reaction involving untreated cells or cells treated with Puromycin.

Usage

```
Puromycin
```

Format

This data frame contains the following columns:

conc a numeric vector of substrate concentrations (ppm)

rate a numeric vector of instantaneous reaction rates (counts/min/min)

state a factor with levels `treated` `untreated`

Details

Data on the velocity of an enzymatic reaction were obtained by Treloar (1974). The number of counts per minute of radioactive product from the reaction was measured as a function of substrate concentration in parts per million (ppm) and from these counts the initial rate (or velocity) of the reaction was calculated (counts/min/min). The experiment was conducted once with the enzyme treated with Puromycin, and once with the enzyme untreated.

Examples

```
require(stats); require(graphics)
plot(rate ~ conc, data = Puromycin, las = 1,
      xlab = "Substrate concentration (ppm)",
      ylab = "Reaction velocity (counts/min/min)",
      pch = as.integer(Puromycin$state),
      col = as.integer(Puromycin$state),
      main = "Puromycin data and fitted Michaelis-Menten curves")
## simplest form of fitting the Michaelis-Menten model to these data
fm1 <- nls(rate ~ Vm * conc / (K + conc), data = Puromycin,
           subset = state == "treated",
           start = c(Vm = 200, K = 0.05), trace = TRUE)
fm2 <- nls(rate ~ Vm * conc / (K + conc), data = Puromycin,
           subset = state == "untreated",
           start = c(Vm = 160, K = 0.05), trace = TRUE)
summary(fm1)
summary(fm2)
## using partial linearity
fm3 <- nls(rate ~ conc / (K + conc), data = Puromycin,
           subset = state == "treated", start = c(K = 0.05),
           algorithm = "plinear", trace = TRUE)
## using a self-starting model
fm4 <- nls(rate ~ SSmicmen(conc, Vm, K), data = Puromycin,
           subset = state == "treated")
summary(fm4)
## add fitted lines to the plot
conc <- seq(0, 1.2, length.out = 101)
lines(conc, predict(fm1, list(conc = conc)), lty = 1, col = 1)
lines(conc, predict(fm2, list(conc = conc)), lty = 2, col = 2)
legend(0.8, 120, levels(Puromycin$state),
      col = 1:2, lty = 1:2, pch = 1:2)
```

 quakes

Locations of Earthquakes off Fiji

Description

The data set give the locations of 1000 seismic events of MB > 4.0. The events occurred in a cube near Fiji since 1964.

Usage

quakes

Format

A data frame with 1000 observations on 5 variables.

[,1]	lat	numeric	Latitude of event
[,2]	long	numeric	Longitude
[,3]	depth	numeric	Depth (km)
[,4]	mag	numeric	Richter Magnitude
[,5]	stations	numeric	Number of stations reporting

Details

There are two clear planes of seismic activity. One is a major plate junction; the other is the Tonga trench off New Zealand. These data constitute a subsample from a larger dataset of containing 5000 observations.

Source

This is one of the Harvard PRIM-H project data sets. They in turn obtained it from Dr. John Woodhouse, Dept. of Geophysics, Harvard University.

Examples

```
require(graphics)
pairs(quakes, main = "Fiji Earthquakes, N = 1000", cex.main=1.2, pch=".")
```

 randu

Random Numbers from Congruential Generator RANDU

Description

400 triples of successive random numbers were taken from the VAX FORTRAN function RANDU running under VMS 1.5.

Usage

randu

Format

A data frame with 400 observations on 3 variables named x , y and z which give the first, second and third random number in the triple.

Details

In three dimensional displays it is evident that the triples fall on 15 parallel planes in 3-space. This can be shown theoretically to be true for all triples from the RANDU generator.

These particular 400 triples start 5 apart in the sequence, that is they are $((U[5i+1], U[5i+2], U[5i+3]), i=0, \dots, 399)$, and they are rounded to 6 decimal places.

Under VMS versions 2.0 and higher, this problem has been fixed.

Source

David Donoho

Examples

```
## Not run:
## We could re-generate the dataset by the following R code
seed <- as.double(1)
RANDU <- function() {
  seed <-<- ((2^16 + 3) * seed) %% (2^31)
  seed/(2^31)
}
for(i in 1:400) {
  U <- c(RANDU(), RANDU(), RANDU(), RANDU(), RANDU())
  print(round(U[1:3], 6))
}
## End(Not run)
```

rivers

Lengths of Major North American Rivers

Description

This data set gives the lengths (in miles) of 141 “major” rivers in North America, as compiled by the US Geological Survey.

Usage

```
rivers
```

Format

A vector containing 141 observations.

Source

World Almanac and Book of Facts, 1975, page 406.

References

rock

Measurements on Petroleum Rock Samples

Description

Measurements on 48 rock samples from a petroleum reservoir.

Usage

rock

Format

A data frame with 48 rows and 4 numeric columns.

[,1]	area	area of pores space, in pixels out of 256 by 256
[,2]	peri	perimeter in pixels
[,3]	shape	perimeter/sqrt(area)
[,4]	perm	permeability in milli-Darcies

Details

Twelve core samples from petroleum reservoirs were sampled by 4 cross-sections. Each core sample was measured for permeability, and each cross-section has total area of pores, total perimeter of pores, and shape.

Source

Data from BP Research, image analysis by Ronit Katz, U. Oxford.

sleep

Student's Sleep Data

Description

Data which show the effect of two soporific drugs (increase in hours of sleep compared to control) on 10 patients.

Usage

sleep

Format

A data frame with 20 observations on 2 variables.

[, 1]	extra	numeric	increase in hours of sleep
[, 2]	group	factor	drug given

t.test(extra ~ group, data = sleep, paired = TRUE)
```

stackloss

Brownlee's Stack Loss Plant Data

Description

Operational data of a plant for the oxidation of ammonia to nitric acid.

Usage

```
stackloss

stack.x
stack.loss
```

Format

stackloss is a data frame with 21 observations on 4 variables.

[,1]	Air Flow	Flow of cooling air
[,2]	Water Temp	Cooling Water Inlet Temperature
[,3]	Acid Conc.	Concentration of acid [per 1000, minus 500]
[,4]	stack.loss	Stack loss

For compatibility with S-PLUS, the data sets `stack.x`, a matrix with the first three (independent) variables of the data frame, and `stack.loss`, the numeric vector giving the fourth (dependent) variable, are provided as well.

Details

“Obtained from 21 days of operation of a plant for the oxidation of ammonia (NH₃) to nitric acid (HNO₃). The nitric oxides produced are absorbed in a countercurrent absorption tower”. (Brownlee, cited by Dodge, slightly reformatted by MM.)

Air Flow represents the rate of operation of the plant. Water Temp is the temperature of cooling water circulated through coils in the absorption tower. Acid Conc. is the concentration of the acid circulating, minus 50, times 10: that is, 89 corresponds to 58.9 per cent acid. stack.loss (the dependent variable) is 10 times the percentage of the ingoing ammonia to the plant that escapes

from the absorption column unabsorbed; that is, an (inverse) measure of the over-all efficiency of the plant.

state

US State Facts and Figures

Description

Data sets related to the 50 states of the United States of America.

Usage

```
state.abb
state.area
state.center
state.division
state.name
state.region
state.x77
```

Details

R currently contains the following “state” data sets. Note that all data are arranged according to alphabetical order of the state names.

state.abb: character vector of 2-letter abbreviations for the state names.

state.area: numeric vector of state areas (in square miles).

state.center: list with components named *x* and *y* giving the approximate geographic center of each state in negative longitude and latitude. Alaska and Hawaii are placed just off the West Coast.

state.division: factor giving state divisions (New England, Middle Atlantic, South Atlantic, East South Central, West South Central, East North Central, West North Central, Mountain, and Pacific).

state.name: character vector giving the full state names.

state.region: factor giving the region (Northeast, South, North Central, West) that each state belongs to.

state.x77: matrix with 50 rows and 8 columns giving the following statistics in the respective columns.

Population: population estimate as of July 1, 1975

Income: per capita income (1974)

Illiteracy: illiteracy (1970, percent of population)

Life Exp: life expectancy in years (1969–71)

Murder: murder and non-negligent manslaughter rate per 100,000 population (1976)

HS Grad: percent high-school graduates (1970)

Frost: mean number of days with minimum temperature below freezing (1931–1960) in capital or large city

Area: land area in square miles

sunspot.month

Monthly Sunspot Data, 1749–1997

Description

Monthly numbers of sunspots.

Usage

sunspot.month

Format

The univariate time series `sunspot.year` and `sunspot.month` contain 289 and 2988 observations, respectively. The objects are of class "ts".

Source

World Data Center-C1 For Sunspot Index Royal Observatory of Belgium, Av. Circulaire, 3, B-1180 BRUSSELS http://www.oma.be/KSB-ORB/SIDC/sidc_txt.html

See Also

`sunspot.month` is a longer version of `sunspots` that runs until 1988 rather than 1983.

Examples

```

require(stats); require(graphics)
## Compare the monthly series
plot (sunspot.month, main = "sunspot.month [stats]", col = 2)
lines(sunspots) # "very barely" see something

## Now look at the difference :
all(tsp(sunspots)      [c(1,3)] ==
     tsp(sunspot.month)[c(1,3)]) ## Start & Periodicity are the same
n1 <- length(sunspots)
table(eq <- sunspots == sunspot.month[1:n1]) #> 132 are different !
i <- which(!eq)
rug(time(eq)[i])
s1 <- sunspots[i] ; s2 <- sunspot.month[i]
cbind(i = i, sunspots = s1, ss.month = s2,
      perc.diff = round(100*2*abs(s1-s2)/(s1+s2), 1))

```

sunspot.year	<i>Yearly Sunspot Data, 1700–1988</i>
--------------	---------------------------------------

Description

Yearly numbers of sunspots.

Usage

```
sunspot.year
```

Format

The univariate time series `sunspot.year` contains 289 observations, and is of class "ts".

Source

H. Tong (1996) *Non-Linear Time Series*. Clarendon Press, Oxford, p. 471.

sunspots	<i>Monthly Sunspot Numbers, 1749–1983</i>
----------	---

Description

Monthly mean relative sunspot numbers from 1749 to 1983. Collected at Swiss Federal Observatory, Zurich until 1960, then Tokyo Astronomical Observatory.

Usage

```
sunspots
```

Format

A time series of monthly data from 1749 to 1983.

Source

Andrews, D. F. and Herzberg, A. M. (1985) *Data: A Collection of Problems from Many Fields for the Student and Research Worker*. New York: Springer-Verlag.

See Also

`sunspot.month` has a longer (and a bit different) series.

Examples

```
require(graphics)
plot(sunspots, main = "sunspots data", xlab = "Year",
     ylab = "Monthly sunspot numbers")
```

swiss

Swiss Fertility and Socioeconomic Indicators (1888) Data

Description

Standardized fertility measure and socio-economic indicators for each of 47 French-speaking provinces of Switzerland at about 1888.

Usage

```
swiss
```

Format

A data frame with 47 observations on 6 variables, *each* of which is in percent, i.e., in [0, 100].

[,1]	Fertility	I_g , ‘common standardized fertility measure’
[,2]	Agriculture	% of males involved in agriculture as occupation
[,3]	Examination	% draftees receiving highest mark on army examination
[,4]	Education	% education beyond primary school for draftees.
[,5]	Catholic	% ‘catholic’ (as opposed to ‘protestant’).
[,6]	Infant.Mortality	live births who live less than 1 year.

All variables but ‘Fertility’ give proportions of the population.

Details

(paraphrasing Mosteller and Tukey):

Switzerland, in 1888, was entering a period known as the *demographic transition*; i.e., its fertility was beginning to fall from the high level typical of underdeveloped countries.

The data collected are for 47 French-speaking “provinces” at about 1888.

Here, all variables are scaled to [0, 100], where in the original, all but "Catholic" were scaled to [0, 1].

Note

Files for all 182 districts in 1888 and other years have been available at <http://opr.princeton.edu/archive/eufert/switz.html> or <http://opr.princeton.edu/archive/pefp/switz.asp>.

They state that variables Examination and Education are averages for 1887, 1888 and 1889.

Theoph

Pharmacokinetics of theophylline

Description

The Theoph data frame has 132 rows and 5 columns of data from an experiment on the pharmacokinetics of theophylline.

Usage

Theoph

Format

This data frame contains the following columns:

Subject an ordered factor with levels 1, ..., 12 identifying the subject on whom the observation was made. The ordering is by increasing maximum concentration of theophylline observed.

Wt weight of the subject (kg).

Dose dose of theophylline administered orally to the subject (mg/kg).

Time time since drug administration when the sample was drawn (hr).

conc theophylline concentration in the sample (mg/L).

Details

Boeckmann, Sheiner and Beal (1994) report data from a study by Dr. Robert Upton of the kinetics of the anti-asthmatic drug theophylline. Twelve subjects were given oral doses of theophylline then serum concentrations were measured at 11 time points over the next 25 hours.

These data are analyzed in Davidian and Giltinan (1995) and Pinheiro and Bates (2000) using a two-compartment open pharmacokinetic model, for which a self-starting model function, `SSfol`, is available.

```

Titanic

Survival of passengers on the Titanic

Description

This data set provides information on the fate of passengers on the fatal maiden voyage of the ocean liner 'Titanic', summarized according to economic status (class), sex, age and survival.

Usage

Titanic

Format

A 4-dimensional array resulting from cross-tabulating 2201 observations on 4 variables. The variables and their levels are as follows:

No	Name	Levels
1	Class	1st, 2nd, 3rd, Crew
2	Sex	Male, Female
3	Age	Child, Adult
4	Survived	No, Yes

Details

The sinking of the Titanic is a famous event, and new books are still being published about it. Many well-known facts—from the proportions of first-class passengers to the ‘women and children first’ policy, and the fact that that policy was not entirely successful in saving the women and children in the third class—are reflected in the survival rates for various classes of passenger.

These data were originally collected by the British Board of Trade in their investigation of the sinking. Note that there is not complete agreement among primary sources as to the exact numbers on board, rescued, or lost.

Due in particular to the very successful film ‘Titanic’, the last years saw a rise in public interest in the Titanic. Very detailed data about the passengers is now available on the Internet, at sites such as *Encyclopedia Titanica* (<http://www.rmplc.co.uk/eduweb/sites/phind>).

Source

Dawson, Robert J. MacG. (1995), The ‘Unusual Episode’ Data Revisited. *Journal of Statistics Education*, 3. <http://www.amstat.org/publications/jse/v3n3/datasets.dawson.html>

The source provides a data set recording class, sex, age, and survival status for each person on board of the Titanic, and is based on data originally collected by the British Board of Trade and reprinted in:

British Board of Trade (1990), *Report on the Loss of the ‘Titanic’ (S.S.)*. British Board of Trade Inquiry Report (reprint). Gloucester, UK: Allan Sutton Publishing.

Examples

```
require(graphics)
mosaicplot(Titanic, main = "Survival on the Titanic")
## Higher survival rates in children?
apply(Titanic, c(3, 4), sum)
## Higher survival rates in females?
apply(Titanic, c(2, 4), sum)
## Use loglm() in package 'MASS' for further analysis ...
```

Description

The response is the length of odontoblasts (teeth) in each of 10 guinea pigs at each of three dose levels of Vitamin C (0.5, 1, and 2 mg) with each of two delivery methods (orange juice or ascorbic acid).

Usage

```
ToothGrowth
```

Format

A data frame with 60 observations on 3 variables.

[,1]	len	numeric	Tooth length
[,2]	supp	factor	Supplement type (VC or OJ).
[,3]	dose	numeric	Dose in milligrams.

Examples

```
require(graphics)
coplot(len ~ dose | supp, data = ToothGrowth, panel = panel.smooth,
       xlab = "ToothGrowth data: length vs dose, given type of supplement")
```

treering

Yearly Treering Data, -6000–1979

Description

Contains normalized tree-ring widths in dimensionless units.

Usage

```
treering
```

Format

A univariate time series with 7981 observations. The object is of class "ts".

Each tree ring corresponds to one year.

Details

The data were recorded by Donald A. Graybill, 1980, from Gt Basin Bristlecone Pine 2805M, 3726-11810 in Methuselah Walk, California.

Source

Time Series Data Library: <http://www-personal.buseco.monash.edu.au/~hyndman/TSDL/>, series 'CA535.DAT'

summary(fm1 <- lm(log(Volume) ~ log(Girth), data = trees))
summary(fm2 <- update(fm1, ~ . + log(Height), data = trees))
step(fm2)
## i.e., Volume ~ c * Height * Girth^2 seems reasonable
```

UCBAdmissions

*Student Admissions at UC Berkeley***Description**

Aggregate data on applicants to graduate school at Berkeley for the six largest departments in 1973 classified by admission and sex.

Usage

```
UCBAdmissions
```

Format

A 3-dimensional array resulting from cross-tabulating 4526 observations on 3 variables. The variables and their levels are as follows:

No	Name	Levels
1	Admit	Admitted, Rejected
2	Gender	Male, Female
3	Dept	A, B, C, D, E, F

Details

This data set is frequently used for illustrating Simpson's paradox, see Bickel et al. (1975). At issue is whether the data show evidence of sex bias in admission practices. There were 2691 male applicants, of whom 1198 (44.5%) were admitted, compared with 1835 female applicants of whom 557 (30.4%) were admitted. This gives a sample odds ratio of 1.83, indicating that males were almost twice as likely to be admitted. In fact, graphical methods (as in the example below) or log-linear modelling show that the apparent association between admission and sex stems from differences in the tendency of males and females to apply to the individual departments (females used to apply *more* to departments with higher rejection rates).

This data set can also be used for illustrating methods for graphical display of categorical data, such as the general-purpose mosaic plot or the ourfold display for 2-by-2-by-*k* tables. See the home page of Michael Friendly (<http://www.math.yorku.ca/SCS/friendly.html>) for further information.

```

UKDriverDeaths

Road Casualties in Great Britain 1969–84

Description

UKDriverDeaths is a time series giving the monthly totals of car drivers in Great Britain killed or seriously injured Jan 1969 to Dec 1984. Compulsory wearing of seat belts was introduced on 31 Jan 1983.

Seatbelts is more information on the same problem.

Usage

```

UKDriverDeaths
Seatbelts

```

Format

Seatbelts is a multiple time series, with columns

DriversKilled car drivers killed.

drivers same as UKDriverDeaths.

front front-seat passengers killed or seriously injured.

rear rear-seat passengers killed or seriously injured.

kms distance driven.

PetrolPrice petrol price.

VanKilled number of van ('light goods vehicle') drivers.

law 0/1: was the law in effect that month?

      seasonal = list(order= c(1,0,0)), xreg = X)

```

 UKgas

UK Quarterly Gas Consumption

Description

Quarterly UK gas consumption from 1960Q1 to 1986Q4, in millions of therms.

Usage

UKgas

Format

A quarterly time series of length 108.

Source

Durbin, J. and Koopman, S. J. (2001) *Time Series Analysis by State Space Methods*. Oxford University Press. <http://www.ssfpack.com/dkbook/>

Examples

```
## maybe str(UKgas) ; plot(UKgas) ...
```

UKLungDeaths

Monthly Deaths from Lung Diseases in the UK

Description

Three time series giving the monthly deaths from bronchitis, emphysema and asthma in the UK, 1974–1979, both sexes (`ldeaths`), males (`mdeaths`) and females (`fdeaths`).

Usage

```
ldeaths
fdeaths
mdeaths
```

Source

P. J. Diggle (1990) *Time Series: A Biostatistical Introduction*. Oxford, table A.3

Examples

```
require(stats); require(graphics) # for time
plot(ldeaths)
plot(mdeaths, fdeaths)
## Better labels:
yr <- floor(tt <- time(mdeaths))
plot(mdeaths, fdeaths,
      xy.labels = paste(month.abb[12*(tt - yr)], yr-1900, sep=""))
```

USAccDeaths

Accidental Deaths in the US 1973–1978

Description

A time series giving the monthly totals of accidental deaths in the USA. The values for the first six months of 1979 are 7798 7406 8363 8460 9217 9316.

Usage

```
USAccDeaths
```

Source

 USArrests

Violent Crime Rates by US State

Description

This data set contains statistics, in arrests per 100,000 residents for assault, murder, and rape in each of the 50 US states in 1973. Also given is the percent of the population living in urban areas.

Usage

USArrests

Format

A data frame with 50 observations on 4 variables.

[,1]	Murder	numeric	Murder arrests (per 100,000)
[,2]	Assault	numeric	Assault arrests (per 100,000)
[,3]	UrbanPop	numeric	Percent urban population
[,4]	Rape	numeric	Rape arrests (per 100,000)

Source

World Almanac and Book of facts 1975. (Crime rates).

Statistical Abstracts of the United States 1975. (Urban rates).

pairs(USJudgeRatings, main = "USJudgeRatings data")
```

USPersonalExpenditure
Personal Expenditure Data

Description

This data set consists of United States personal expenditures (in billions of dollars) in the categories; food and tobacco, household operation, medical and health, personal care, and private education for the years 1940, 1945, 1950, 1955 and 1960.

Usage

```
USPersonalExpenditure
```

Format

A matrix with 5 rows and 5 columns.

Source

The World Almanac and Book of Facts, 1962, page 756.

References

Tukey, J. W. (1977) *Exploratory Data Analysis*. Addison-Wesley.
McNeil, D. R. (1977) *Interactive Data Analysis*. Wiley.

Examples

```
require(stats) # for medpolish
USPersonalExpenditure
medpolish(log10(USPersonalExpenditure))
```

 uspop

Populations Recorded by the US Census

Description

This data set gives the population of the United States (in millions) as recorded by the decennial census for the period 1790–1970.

Usage

```
uspop
```

Format

A time series of 19 values.

Source

McNeil, D. R. (1977) *Interactive Data Analysis*. New York: Wiley.

Examples

```
require(graphics)
plot(uspop, log = "y", main = "uspop data", xlab = "Year",
     ylab = "U.S. Population (millions)")
```

 VADeaths

Death Rates in Virginia (1940)

Description

Death rates per 1000 in Virginia in 1940.

Usage

```
VADeaths
```

Format

A matrix with 5 rows and 4 columns.

Details

The death rates are measured per 1000 population per year. They are cross-classified by age group (rows) and population group (columns). The age groups are: 50–54, 55–59, 60–64, 65–69, 70–74 and the population groups are Rural/Male, Rural/Female, Urban/Male and Urban/Female.

This provides a rather nice 3-way analysis of variance example.

Source

Molyneaux, L., Gilliam, S. K., and Florant, L. C. (1947) Differences in Virginia death rates by color, sex, age, and rural or urban residence. *American Sociological Review*, **12**, 525–535.

References

McNeil, D. R. (1977) *Interactive Data Analysis*. Wiley.

Examples

```
require(stats); require(graphics)
n <- length(dr <- c(VADeaths))
nam <- names(VADeaths)
d.VAD <- data.frame(
  Drate = dr,
  age = rep(ordered(rownames(VADeaths)), length.out=n),
  gender= gl(2,5,n, labels= c("M", "F")),
  site = gl(2,10, labels= c("rural", "urban")))
coplot(Drate ~ as.numeric(age) | gender * site, data = d.VAD,
       panel = panel.smooth, xlab = "VADeaths data - Given: gender")
summary(aov.VAD <- aov(Drate ~ .^2, data = d.VAD))

filled.contour(volcano, color.palette = terrain.colors, asp = 1)
title(main = "volcano data: filled contour map")
```

warpbreaks

*The Number of Breaks in Yarn during Weaving***Description**

This data set gives the number of warp breaks per loom, where a loom corresponds to a fixed length of yarn.

Usage

```
warpbreaks
```

Format

A data frame with 54 observations on 3 variables.

[, 1]	breaks	numeric	The number of breaks
[, 2]	wool	factor	The type of wool (A or B)
[, 3]	tension	factor	The level of tension (L, M, H)

There are measurements on 9 looms for each of the six types of warp (AL, AM, AH, BL, BM, BH).

women

Average Heights and Weights for American Women

Description

This data set gives the average heights and weights for American women aged 30–39.

Usage

```
women
```

Format

A data frame with 15 observations on 2 variables.

```
[,1] height numeric Height (in)
[,2] weight numeric Weight (lbs)
```

Details

The data set appears to have been taken from the American Society of Actuaries *Build and Blood Pressure Study* for some (unknown to us) earlier year.

The World Almanac notes: “The figures represent weights in ordinary indoor clothing and shoes, and heights with shoes”.

Source

The World Almanac and Book of Facts, 1975.

Chapter 3

The grDevices package

grDevices-package *The R Graphics Devices and Support for Colours and Fonts*

Description

Graphics devices and support for base and grid graphics

Details

This package contains functions which support both [base](#) and [grid](#) graphics.

For a complete list of functions, use `library(help="grDevices")`.

Author(s)

R Development Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

as.graphicsAnnot *Coerce an Object for Graphics Annotation*

Description

Coerce an R object into a form suitable for graphics annotation.

Usage

```
as.graphicsAnnot(x)
```

Arguments

x an R object

Details

Expressions, calls and names (as used by `plotmath`) are passed through unchanged. All other objects with an S3 class (as determined by `is.object`) are coerced by `as.character` to character vectors.

All the **graphics** and **grid** functions which use this coerce calls and names to expressions internally.

Value

A language object or a character vector.

<code>boxplot.stats</code>	<i>Box Plot Statistics</i>
----------------------------	----------------------------

Description

This function is typically called by another function to gather the statistics necessary for producing box plots, but may be invoked separately.

Usage

```
boxplot.stats(x, coef = 1.5, do.conf = TRUE, do.out = TRUE)
```

Arguments

<code>x</code>	a numeric vector for which the boxplot will be constructed (NAs and NaNs are allowed and omitted).
<code>coef</code>	this determines how far the plot ‘whiskers’ extend out from the box. If <code>coef</code> is positive, the whiskers extend to the most extreme data point which is no more than <code>coef</code> times the length of the box away from the box. A value of zero causes the whiskers to extend to the data extremes (and no outliers be returned).
<code>do.conf, do.out</code>	logicals; if FALSE, the <code>conf</code> or <code>out</code> component respectively will be empty in the result.

Details

The two ‘hinges’ are versions of the first and third quartile, i.e., close to `quantile(x, c(1, 3)/4)`. The hinges equal the quartiles for odd n (where $n <- \text{length}(x)$) and differ for even n . Whereas the quartiles only equal observations for $n \%\% 4 == 1$ ($n \equiv 1 \pmod{4}$), the hinges do so *additionally* for $n \%\% 4 == 2$ ($n \equiv 2 \pmod{4}$), and are in the middle of two observations otherwise.

The notches (if requested) extend to $\pm 1.58 \text{ IQR}/\sqrt{n}$. This seems to be based on the same calculations as the formula with 1.57 in Chambers *et al.* (1983, p. 62), given in McGill *et al.* (1978, p. 16). They are based on asymptotic normality of the median and roughly equal sample sizes for the two medians being compared, and are said to be rather insensitive to the underlying distributions of the samples. The idea appears to be to give roughly a 95% confidence interval for the difference in two medians.

Value

List with named components as follows:

stats	a vector of length 5, containing the extreme of the lower whisker, the lower ‘hinge’, the median, the upper ‘hinge’ and the extreme of the upper whisker.
n	the number of non-NA observations in the sample.
conf	the lower and upper extremes of the ‘notch’ (<code>if(do.conf)</code>). See the details.
out	the values of any data points which lie beyond the extremes of the whiskers (<code>if(do.out)</code>).

Note that `$stats` and `$conf` are sorted in *increasing* order, unlike `S`, and that `$n` and `$out` include any `+/- Inf` values.

```
require(stats)
x <- c(1:100, 1000)
(b1 <- boxplot.stats(x))
(b2 <- boxplot.stats(x, do.conf=FALSE, do.out=FALSE))
stopifnot(b1 $ stats == b2 $ stats) # do.out=F is still robust
boxplot.stats(x, coef = 3, do.conf=FALSE)
## no outlier treatment:
boxplot.stats(x, coef = 0)

boxplot.stats(c(x, NA)) # slight change : n is 101
(r <- boxplot.stats(c(x, -1:1/0)))
stopifnot(r$out == c(1000, -Inf, Inf))
```

 cairo

Cairo-based SVG, PDF and PostScript Graphics Devices

Description

Graphics devices for SVG, PDF and PostScript graphics files.

Usage

```
svg(filename = if(onefile) "Rplots.svg" else "Rplot%03d.svg",
     width = 7, height = 7, pointsize = 12,
     onefile = FALSE, bg = "white", antialias)

cairo_pdf(filename = if(onefile) "Rplots.pdf" else "Rplot%03d.pdf",
           width = 7, height = 7, pointsize = 12,
           onefile = FALSE, bg = "white", antialias)

cairo_ps(filename = if(onefile) "Rplots.ps" else "Rplot%03d.ps",
          width = 7, height = 7, pointsize = 12,
          onefile = FALSE, bg = "white", antialias)
```

Arguments

filename	the name of the output file. The page number is substituted if a C integer format is included in the character string, as in the default. (The result must be less than <code>PATH_MAX</code> characters long, and may be truncated if not. See postscript for further details.) Tilde expansion is performed where supported by the platform.
width	the width of the device in inches.
height	the height of the device in inches.
pointsize	the default pointsize of plotted text (in big points).
onefile	should all plots appear in one file or in separate files?
bg	the initial background colour: can be overridden by setting <code>par("bg")</code> .
antialias	the type of anti-aliasing (if any) to be used. See X11 .

Details

SVG (Scalar Vector Graphics) is a W3C standard for vector graphics. See <http://www.w3.org/Graphics/SVG/>. The output is SVG version 1.1 for `onefile = FALSE` (the default), otherwise SVG 1.2. (Very few SVG viewers are capable of displaying multi-page SVG files.)

Note that unlike [postscript](#) and [pdf](#), `cairo_pdf` and `cairo_ps` sometimes record *bitmaps* and not vector graphics: a resolution of 72dpi is used. On the other hand, they can (on suitable platforms) include a much wider range of UTF-8 glyphs, and embed the fonts used. They are somewhat experimental.

R can be compiled without support for any of these devices: this will be reported if you attempt to use them on a system where they are not supported. They all require cairo version 1.2 or later.

If you plot more than one page on one of these devices and do not include something like `%d` for the sequence number in `file` (or set `onefile=TRUE`) the file will contain the last page plotted.

The `cairo_ps` output is not yet encapsulated (that is coming in cairo 1.6).

There is full support of transparency, but using this is one of the things liable to trigger bitmap output (and will always do so for `cairo_ps`).

Value

A plot device is opened: nothing is returned to the R interpreter.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is in pixels (`svg`) or inches.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are multiples of 1/96 inch.
- Circle radii have a minimum of 1/72 inch.
- Colours are interpreted by the viewing application.

See Also

check.options

Set Options with Consistency Checks

Description

Utility function for setting options with some consistency checks. The `attributes` of the new settings in `new` are checked for consistency with the *model* (often default) list in `name.opt`.

Usage

```
check.options(new, name.opt, reset = FALSE, assign.opt = FALSE,
             envir = .GlobalEnv,
             check.attributes = c("mode", "length"),
             override.check = FALSE)
```

Arguments

<code>new</code>	a <i>named</i> list
<code>name.opt</code>	character with the name of R object containing the default list.
<code>reset</code>	logical; if TRUE, reset the options from <code>name.opt</code> . If there is more than one R object with name <code>name.opt</code> , remove the first one in the <code>search()</code> path.
<code>assign.opt</code>	logical; if TRUE, assign the ...
<code>envir</code>	the <i>environment</i> used for <code>get</code> and <code>assign</code> .
<code>check.attributes</code>	character containing the attributes which <code>check.options</code> should check.

`override.check`

logical vector of length `length(new)` (or 1 which entails recycling). For those `new[i]` where `override.check[i] == TRUE`, the checks are overridden and the changes made anyway.

Value

A list of components with the same names as the one called `name.opt`. The values of the components are changed from the `new` list, as long as these pass the checks (when these are not overridden according to `override.check`).

Note

Option "names" is exempt from all the checks or warnings, as in the application it can be `NULL` or a variable-length character vector.

Author(s)

Martin Maechler

See Also

[ps.options](#) and [pdf.options](#), which use `check.options`.

Examples

```
(L1 <- list(a=1:3, b=pi, ch="CH"))
check.options(list(a=0:2), name.opt = "L1")
check.options(NULL, reset = TRUE, name.opt = "L1")
```

chull

Compute Convex Hull of a Set of Points

Description

Computes the subset of points which lie on the convex hull of the set of points specified.

Usage

```
chull(x, y = NULL)
```

Arguments

`x`, `y` coordinate vectors of points. This can be specified as two vectors `x` and `y`, a 2-column matrix `x`, a list `x` with two components, etc, see [xy.coords](#).

Details

[xy.coords](#) is used to interpret the specification of the points. The algorithm is that given by Eddy (1977).

'Peeling' as used in the S function `chull` can be implemented by calling `chull` recursively.

Value

An integer vector giving the indices of the points lying on the convex hull, in clockwise order.

Examples

```
require(stats)
X <- matrix(rnorm(2000), ncol = 2)
chull(X)
## Not run:
# Example usage from graphics package
plot(X, cex = 0.5)
hpts <- chull(X)
hpts <- c(hpts, hpts[1])
lines(X[hpts, ])
## End(Not run)
```

cm

Unit Transformation

Description

Translates from inches to cm (centimeters).

Usage

```
cm(x)
```

Arguments

x numeric vector

Examples

```
cm(1) # = 2.54

## Translate *from* cm *to* inches:

10 / cm(1) # -> 10cm are 3.937 inches
```

col2rgb

*Color to RGB Conversion***Description**

R color to RGB (red/green/blue) conversion.

Usage

```
col2rgb(col, alpha = FALSE)
```

Arguments

col	vector of any of the three kind of R colors, i.e., either a color name (an element of <code>colors()</code>), a hexadecimal string of the form "#rrggbb", or an integer <code>i</code> meaning <code>palette()[i]</code> . Non-string values are coerced to integer.
alpha	logical value indicating whether alpha channel values should be returned.

Details

For integer colors, 0 is shorthand for the current `par("bg")` (and hence is only relevant to base graphics), and `NA` means transparent.

For character colors, "NA" is equivalent to `NA` above.

Value

an integer matrix with three or four rows and number of columns the length (and names if any) as `col`.

Author(s)

Martin Maechler

Examples

```
col2rgb("peachpuff")
col2rgb(c(blu = "royalblue", reddish = "tomato")) # names kept

col2rgb(1:8) # the ones from the palette() :

col2rgb(paste("gold", 1:4, sep=""))

col2rgb("#08a0ff")
## all three kind of colors mixed :
col2rgb(c(red="red", palette= 1:3, hex="#abcdef"))

##-- NON-INTRODUCTORY examples --

grC <- col2rgb(paste("gray", 0:100, sep=""))
```

```

table(print(diff(grC["red",])))# '2' or '3': almost equidistant
## The 'named' grays are in between {"slate gray" is not gray, strictly}
col2rgb(c(g66="gray66", darkg= "dark gray", g67="gray67",
          g74="gray74", gray =      "gray", g75="gray75",
          g82="gray82", light="light gray", g83="gray83"))

crgb <- col2rgb(cc <- colors())
colnames(crgb) <- cc
t(crgb)## The whole table

ccodes <- c(256^(2:0) %**% crgb)## = internal codes
## How many names are 'aliases' of each other:
table(tcc <- table(ccodes))
length(uc <- unique(sort(ccodes))) # 502
## All the multiply named colors:
mult <- uc[tcc >= 2]
cl <- lapply(mult, function(m) cc[ccodes == m])
names(cl) <- apply(col2rgb(sapply(cl, function(x)x[1])),
                  2, function(n)paste(n, collapse=", "))
utils::str(cl)
## Not run:
if(require(xgobi)) { ## Look at the color cube dynamically :
  tc <- t(crgb[, !duplicated(ccodes)])
  table(is.gray <- tc[,1] == tc[,2] & tc[,2] == tc[,3])# (397, 105)
  xgobi(tc, color = c("gold", "gray")[1 + is.gray])
}
## End(Not run)

```

colorRamp

Color interpolation

Description

These functions return functions that interpolate a set of given colors to create new color palettes (like [topo.colors](#)) and color ramps, functions that map the interval $[0, 1]$ to colors (like [grey](#)).

Usage

```

colorRamp(colors, bias = 1, space = c("rgb", "Lab"),
          interpolate = c("linear", "spline"))
colorRampPalette(colors, ...)

```

Arguments

colors	Colors to interpolate
bias	A positive number. Higher values give more widely spaced colors at the high end.
space	Interpolation in RGB or CIE Lab color spaces
interpolate	Use spline or linear interpolation.
...	arguments to pass to colorRamp.

Details

The CIE Lab color space is approximately perceptually uniform, and so gives smoother and more uniform color ramps. On the other hand, palettes that vary from one hue to another via white may have a more symmetrical appearance in RGB space.

The conversion formulas in this function do not appear to be completely accurate and the color ramp may not reach the extreme values in Lab space. Future changes in the R color model may change the colors produced with `space="Lab"`.

Value

`colorRamp` returns a function that maps values between 0 and 1 to colors. `colorRampPalette` returns a function that takes an integer argument and returns that number of colors interpolating the given sequence (similar to `heat.colors` or `terrain.colors`).

See Also

Good starting points for interpolation are the "sequential" and "diverging" ColorBrewer palettes in the RColorBrewer package

Examples

```
require(graphics)

## Here space="rgb" gives palettes that vary only in saturation,
## as intended.
## With space="Lab" the steps are more uniform, but the hues
## are slightly purple.
filled.contour(volcano,
               color.palette =
                 colorRampPalette(c("red", "white", "blue")),
               asp = 1)
filled.contour(volcano,
               color.palette =
                 colorRampPalette(c("red", "white", "blue"),
                                 space = "Lab"),
               asp = 1)

## Interpolating a 'sequential' ColorBrewer palette
YlOrBr <- c("#FFFFFFD4", "#FED98E", "#FE9929", "#D95F0E", "#993404")
filled.contour(volcano,
               color.palette = colorRampPalette(YlOrBr, space = "Lab"),
               asp = 1)
filled.contour(volcano,
               color.palette = colorRampPalette(YlOrBr, space = "Lab",
                                                bias = 0.5),
               asp = 1)

## 'jet.colors' is "as in Matlab"
## (and hurting the eyes by over-saturation)
jet.colors <-
  colorRampPalette(c("#00007F", "blue", "#007FFF", "cyan",
                    "#7FFF7F", "yellow", "#FF7F00", "red", "#7F0000"))
filled.contour(volcano, color = jet.colors, asp = 1)

## space="Lab" helps when colors don't form a natural sequence
```

```
m <- outer(1:20,1:20,function(x,y) sin(sqrt(x*y)/3))
rgb.palette <- colorRampPalette(c("red", "orange", "blue"),
                               space = "rgb")
Lab.palette <- colorRampPalette(c("red", "orange", "blue"),
                               space = "Lab")
filled.contour(m, col = rgb.palette(20))
filled.contour(m, col = Lab.palette(20))
```

colors

Color Names

Description

Returns the built-in color names which R knows about.

Usage

```
colors()
colours()
```

Details

These color names can be used with a `col=` specification in graphics functions.

An even wider variety of colors can be created with primitives `rgb` and `hsv` or the derived `rainbow`, `heat.colors`, etc.

Value

A character vector containing all the built-in color names.

See Also

[palette](#) for setting the ‘palette’ of colors for `par(col=<num>)`; [rgb](#), [hsv](#), [hcl](#), [gray](#); [rainbow](#) for a nice example; and [heat.colors](#), [topo.colors](#) for images.

[col2rgb](#) for translating to RGB numbers and extended examples.

Examples

```
c1 <- colors()
length(c1); c1[1:20]
```

contourLines *Calculate Contour Lines*

Description

Calculate contour lines for a given set of data.

Usage

```
contourLines(x = seq(0, 1, length.out = nrow(z)),
             y = seq(0, 1, length.out = ncol(z)),
             z, nlevels = 10,
             levels = pretty(range(z, na.rm=TRUE), nlevels))
```

Arguments

<code>x, y</code>	locations of grid lines at which the values in <code>z</code> are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If <code>x</code> is a list, its components <code>x\$x</code> and <code>x\$y</code> are used for <code>x</code> and <code>y</code> , respectively. If the list has component <code>z</code> this is used for <code>z</code> .
<code>z</code>	a matrix containing the values to be plotted (NAs are allowed). Note that <code>x</code> can be used instead of <code>z</code> for convenience.
<code>nlevels</code>	number of contour levels desired iff <code>levels</code> is not supplied.
<code>levels</code>	numeric vector of levels at which to draw contour lines.

Details

`contourLines` draws nothing, but returns a set of contour lines.

There is currently no documentation about the algorithm. The source code is in '[R_HOME/src/main/plot3d.c](#)'.

Value

A list of contours. Each contour is a list with elements:

<code>level</code>	The contour level.
<code>x</code>	The x-coordinates of the contour.
<code>y</code>	The y-coordinates of the contour.

See Also

`options("max.countour.segments")` for the maximal complexity of a single contour line.

`contour`.

Examples

```
x <- 10*1:nrow(volcano)
y <- 10*1:ncol(volcano)
contourLines(x, y, volcano)
```

convertColor *Convert between colour spaces*

Description

Convert colours between standard colour space representations. This function is experimental.

Usage

```
convertColor(color, from, to, from.ref.white, to.ref.white,
             scale.in=1, scale.out=1, clip=TRUE)
```

Arguments

<code>color</code>	A matrix whose rows specify colors.
<code>from, to</code>	Input and output color spaces. See ‘Details’ below.
<code>from.ref.white, to.ref.white</code>	Reference whites or NULL if these are built in to the definition, as for RGB spaces. D65 is the default, see ‘Details’ for others.
<code>scale.in, scale.out</code>	Input is divided by <code>scale.in</code> , output is multiplied by <code>scale.out</code> . Use NULL to suppress scaling when input or output is not numeric.
<code>clip</code>	If TRUE, truncate RGB output to [0,1], FALSE return out-of-range RGB, NA set out of range colors to NaN.

Details

Color spaces are specified by objects of class `colorConverter`, created by `colorConverter` or `make.rgb`. Built-in color spaces may be referenced by strings: "XYZ", "sRGB", "Apple RGB", "CIE RGB", "Lab", "Luv". The converters for these colour spaces are in the object `colorspaces`.

The "sRGB" color space is that used by standard PC monitors. "Apple RGB" is used by Apple monitors. "Lab" and "Luv" are approximately perceptually uniform spaces standardized by the Commission Internationale d’Eclairage. XYZ is a 1931 CIE standard capable of representing all visible colors (and then some), but not in a perceptually uniform way.

The Lab and Luv spaces describe colors of objects, and so require the specification of a reference ‘white light’ color. Illuminant D65 is a standard indirect daylight, Illuminant D50 is close to direct sunlight, and Illuminant A is the light from a standard incandescent bulb. Other standard CIE illuminants supported are B, C, E and D55. RGB colour spaces are defined relative to a particular reference white, and can be only approximately translated to other reference whites. The Bradford chromatic adaptation algorithm is used for this.

The RGB color spaces are specific to a particular class of display. An RGB space cannot represent all colors, and the `clip` option controls what is done to out-of-range colors.

Value

A 3-row matrix whose columns specify the colors.

References

For all the conversion equations <http://www.brucelindbloom.com/>

For the white points <http://www.efg2.com/Lab/Graphics/Colors/Chromaticity.htm>

See Also

[col2rgb](#) and [colors](#) for ways to specify colors in graphics.

[make.rgb](#) for specifying other colour spaces.

Examples

```
require(graphics); require(stats) # for na.omit
par(mfrow=c(2,2))
## The displayable colors from four planes of Lab space
ab <- expand.grid(a=(-10:15)*10,b=(-15:10)*10)

Lab <- cbind(L=20,ab)
srgb <- convertColor(Lab,from="Lab",to="sRGB",clip=NA)
clipped <- attr(na.omit(srgb),"na.action")
srgb[clipped,] <- 0
cols <- rgb(srgb[,1],srgb[,2],srgb[,3])
image((-10:15)*10,(-15:10)*10,matrix(1:(26*26),ncol=26),col=cols,
      xlab="a",ylab="b",main="Lab: L=20")

Lab <- cbind(L=40,ab)
srgb <- convertColor(Lab,from="Lab",to="sRGB",clip=NA)
clipped <- attr(na.omit(srgb),"na.action")
srgb[clipped,] <- 0
cols <- rgb(srgb[,1],srgb[,2],srgb[,3])
image((-10:15)*10,(-15:10)*10,matrix(1:(26*26),ncol=26),col=cols,
      xlab="a",ylab="b",main="Lab: L=40")

Lab <- cbind(L=60,ab)
srgb <- convertColor(Lab,from="Lab",to="sRGB",clip=NA)
clipped <- attr(na.omit(srgb),"na.action")
srgb[clipped,] <- 0
cols <- rgb(srgb[,1],srgb[,2],srgb[,3])
image((-10:15)*10,(-15:10)*10,matrix(1:(26*26),ncol=26),col=cols,
      xlab="a",ylab="b",main="Lab: L=60")

Lab <- cbind(L=80,ab)
srgb <- convertColor(Lab,from="Lab",to="sRGB",clip=NA)
clipped <- attr(na.omit(srgb),"na.action")
srgb[clipped,] <- 0
cols <- rgb(srgb[,1],srgb[,2],srgb[,3])
image((-10:15)*10,(-15:10)*10,matrix(1:(26*26),ncol=26),col=cols,
      xlab="a",ylab="b",main="Lab: L=80")

(cols <- t(col2rgb(palette())))
(lab <- convertColor(cols,from="sRGB",to="Lab",scale.in=255))
round(convertColor(lab,from="Lab",to="sRGB",scale.out=255))
```

dev.interactive *Is the Current Graphics Device Interactive ?*

Description

Test if the current graphics device (or that which would be opened) is interactive.

Usage

```
dev.interactive(orElse = FALSE)
deviceIsInteractive(name = NULL)
```

Arguments

orElse	logical; if TRUE, the function also returns TRUE when <code>.Device == "null device"</code> and <code>getOption("device")</code> is among the known interactive devices.
name	one or more device names as a character vector, or NULL to give the existing list.

Details

The X11 (Unix), windows (Windows) and quartz (MacOS X, on-screen types only) are regarded as interactive, together with JavaGD (from the package of the same name) and CairoWin and CairoX11 (from package **Cairo**). Packages can add their devices to the list by calling `deviceIsInteractive`.

Value

`dev.interactive()` returns a logical, TRUE if and only if an interactive (screen) device is in use.

`deviceIsInteractive` returns the updated list of known interactive devices, invisibly unless `name = NULL`.

See Also

[Devices](#) for the available devices on your platform.

Examples

```
dev.interactive()
print(deviceIsInteractive(NULL))
```

dev.size	<i>Find Size of Device Surface</i>
----------	------------------------------------

Description

Find the dimensions of the device surface of the current device.

Usage

```
dev.size(units = c("in", "cm", "px"))
```

Arguments

`units` the units in which to return the value – inches, cm, or pixels (device units).

Value

A two-element numeric vector giving width and height of the current device; a new device is opened if there is none, similarly to [dev.new\(\)](#).

See Also

The size information in inches can be obtained by [par\("din"\)](#), but this provides a way to access it independent of the graphics sub-system in use.

Examples

```
dev.size("cm")
```

dev.xxx	<i>Control Multiple Devices</i>
---------	---------------------------------

Description

These functions provide control over multiple graphics devices.

Usage

```
dev.cur()
dev.list()
dev.next(which = dev.cur())
dev.prev(which = dev.cur())
dev.off(which = dev.cur())
dev.set(which = dev.next())
dev.new(...)
graphics.off()
```

Arguments

`which` An integer specifying a device number.
`...` arguments to be passed to the device selected.

Details

Only one device is the ‘active’ device: this is the device in which all graphics operations occur. There is a "null device" which is always open but is really a placeholder: any attempt to use it will open a new device specified by `getOption("device")`.

Devices are associated with a name (e.g., "X11" or "postscript") and a number in the range 1 to 63; the "null device" is always device 1. Once a device has been opened the null device is not considered as a possible active device. There is a list of open devices, and this is considered as a circular list not including the null device. `dev.next` and `dev.prev` select the next open device in the appropriate direction, unless no device is open.

`dev.off` shuts down the specified (by default the current) device. If the current device is shut down and any other devices are open, the next open device is made current. It is an error to attempt to shut down device 1. `graphics.off()` shuts down all open graphics devices.

`dev.set` makes the specified device the active device. If there is no device with that number, it is equivalent to `dev.next`. If `which = 1` it opens a new device and selects that.

`dev.new` opens a new device. Normally R will open a new device automatically when needed, but this enables you to open further devices in a platform-independent way. (For which device is used see `getOption("device")`.) Note that care is needed with file-based devices such as `pdf` and `postscript` and in that case file names such as ‘Rplots.pdf’, ‘Rplots1.pdf’, ..., ‘Rplots999.pdf’ are tried in turn. Only named arguments are passed to the device, and then only if they match the argument list of the device. Even so, care is needed with the interpretation of e.g. `width`, and for the standard bitmap devices `units="in"`, `res=72` is forced if neither is supplied but both `width` and `height` are.

Value

`dev.cur` returns a length-one named integer vector giving the number and name of the active device, or 1, the null device, if none is active.

`dev.list` returns the numbers of all open devices, except device 1, the null device. This is a numeric vector with a `names` attribute giving the device names, or `NULL` if there is no open device.

`dev.next` and `dev.prev` return the number and name of the next / previous device in the list of devices. This will be the null device if and only if there are no open devices.

`dev.off` returns the number and name of the new active device (after the specified device has been shut down).

`dev.set` returns the number and name of the new active device.

`dev.new` returns the return value of the device opened, usually invisible `NULL`.

Examples

```
## Not run:
## Unix-specific example
x11()
plot(1:10)
x11()
plot(rnorm(10))
```

```

dev.set(dev.prev())
abline(0,1)# through the 1:10 points
dev.set(dev.next())
abline(h=0, col="gray")# for the residual plot
dev.set(dev.prev())
dev.off(); dev.off()#- close the two X devices
## End(Not run)

```

dev2

Copy Graphics Between Multiple Devices

Description

`dev.copy` copies the graphics contents of the current device to the device specified by `which` or to a new device which has been created by the function specified by `device` (it is an error to specify both `which` and `device`). (If recording is off on the current device, there are no contents to copy: this will result in no plot or an empty plot.) The device copied to becomes the current device.

`dev.print` copies the graphics contents of the current device to a new device which has been created by the function specified by `device` and then shuts the new device.

`dev.copy2eps` is similar to `dev.print` but produces an EPSF output file in portrait orientation (`horizontal = FALSE`). `dev.copy2pdf` is the analogue for PDF output.

`dev.control` allows the user to control the recording of graphics operations in a device. If `displaylist` is "inhibit" ("enable") then recording is turned off (on). It is only safe to change this at the beginning of a plot (just before or just after a new page). Initially recording is on for screen devices, and off for print devices.

Usage

```

dev.copy(device, ..., which = dev.next())
dev.print(device = postscript, ...)
dev.copy2eps(...)
dev.copy2pdf(..., out.type = "pdf")
dev.control(displaylist = c("inhibit", "enable"))

```

Arguments

<code>device</code>	A device function (e.g., <code>x11</code> , <code>postscript</code> , ...)
<code>...</code>	Arguments to the device function above: for <code>dev.copy2eps</code> arguments to <code>postscript</code> and for <code>dev.copy2pdf</code> , arguments to <code>pdf</code> . For <code>dev.print</code> , this includes <code>which</code> and by default any <code>postscript</code> arguments.
<code>which</code>	A device number specifying the device to copy to.
<code>out.type</code>	The name of the output device: can be "pdf", or "quartz" (some Mac OS X builds) or "cairo" (some Unix-alikes, see <code>cairo_pdf</code>).
<code>displaylist</code>	A character string: the only valid values are "inhibit" and "enable".

Details

Note that these functions copy the *device region* and not a plot: the background colour of the device surface is part of what is copied. Most screen devices default to a transparent background, which is probably not what is needed when copying to a device such as `png`.

For `dev.copy2eps` and `dev.copy2pdf`, `width` and `height` are taken from the current device unless otherwise specified. If just one of `width` and `height` is specified, the other is adjusted to preserve the aspect ratio of the device being copied. The default file name is `Rplot.eps` or `Rplot.pdf`, and can be overridden by specifying a `file` argument.

Copying to devices such as `postscript` and `pdf` which need font families pre-specified needs extra care – R is unaware of which families were used in a plot and so they will need to manually specified by the `fonts` argument passed as part of `...`. Similarly, if the device to be copied from was opened with a `family` argument, a suitable `family` argument will need to be included in `...`

The default for `dev.print` is to produce and print a postscript copy, if `options("printcmd")` is set suitably.

`dev.print` is most useful for producing a postscript print (its default) when the following applies. Unless `file` is specified, the plot will be printed. Unless `width`, `height` and `pointsize` are specified the plot dimensions will be taken from the current device, shrunk if necessary to fit on the paper. (`pointsize` is rescaled if the plot is shrunk.) If `horizontal` is not specified and the plot can be printed at full size by switching its value this is done instead of shrinking the plot region.

If `dev.print` is used with a specified device (even `postscript`) it sets the `width` and `height` in the same way as `dev.copy2eps`. This will not be appropriate unless the device specifies dimensions in inches, in particular not for `png` and `jpeg`.

Value

`dev.copy` returns the name and number of the device which has been copied to.

`dev.print`, `dev.copy2eps` and `dev.copy2pdf` return the name and number of the device which has been copied from.

Note

Most devices (including all screen devices) have a display list which records all of the graphics operations that occur in the device. `dev.copy` copies graphics contents by copying the display list from one device to another device. Also, automatic redrawing of graphics contents following the resizing of a device depends on the contents of the display list.

After the command `dev.control("inhibit")`, graphics operations are not recorded in the display list so that `dev.copy` and `dev.print` will not copy anything and the contents of a device will not be redrawn automatically if the device is resized.

The recording of graphics operations is relatively expensive in terms of memory so the command `dev.control("inhibit")` can be useful if memory usage is an issue.

`dev.cur` and other `dev.xxx` functions.

Examples

```
## Not run:
x11()
```

```

plot(rnorm(10), main="Plot 1")
dev.copy(device=x11)
mtext("Copy 1", 3)
dev.print(width=6, height=6, horizontal=FALSE) # prints it
dev.off(dev.prev())
dev.off()
## End(Not run)

```

dev2bitmap

*Graphics Device for Bitmap Files via GhostScript***Description**

bitmap generates a graphics file. dev2bitmap copies the current graphics device to a file in a graphics format.

Usage

```

bitmap(file, type = "png16m", height = 7, width = 7, res = 72,
       units = "in", pointsize, taa = NA, gaa = NA, ...)

dev2bitmap(file, type = "png16m", height = 7, width = 7, res = 72,
          units = "in", pointsize, ...,
          method = c("postscript", "pdf"), taa = NA, gaa = NA)

```

Arguments

file	The output file name, with an appropriate extension.
type	The type of bitmap. the default is "png256".
width, height	Dimensions of the display region.
res	Resolution, in dots per inch.
units	The units in which height and width are given. Can be in (inches), px (pixels), cm or mm.
pointsize	The pointsize to be used for text: defaults to something reasonable given the width and height
...	Other parameters passed to postscript or pdf .
method	Should the plot be done by postscript or pdf ?
taa, gaa	Number of bits of antialiasing for text and for graphics respectively. Usually 4 (for best effect) or 2. Not supported on all types.

Details

dev2bitmap works by copying the current device to a [postscript](#) or [pdf](#) device, and post-processing the output file using [ghostscript](#). bitmap works in the same way using a [postscript](#) device and post-processing the output as 'printing'.

You will need [ghostscript](#): the full path to the executable can be set by the environment variable `R_GSCMD`. (If this is unset the command "gs" is used, which will work if it is in your path.)

The types available will depend on the version of ghostscript, but are likely to include "pcxmono", "pcxgray", "pcx16", "pcx256", "pcx24b", "pcxcmyk", "pbm", "pbmraw", "pgm", "pgmraw", "pgnm", "pgnmraw", "pnm", "pnmraw", "ppm", "ppmraw", "pkm", "pkmraw", "tiffcrle", "tiffg3", "tiffg32d", "tiffg4", "tiffllzw", "tiffpack", "tiff12nc", "tiff24nc", "psmono", "psgray", "psrgb", "bit", "bitrgb", "bitcmyk", "pngmono", "pnggray", "pngalpha", "png16", "png256", "png16m", "png48", "jpeg", "jpeggray", "pdfwrite".

The default type, "png16m" supports 24-bit colour and anti-aliasing. Versions of R prior to 2.7.0 defaulted to "png256", which used a palette of 256 colours and could be a more compact representation. Monochrome graphs can use "pngmono", or "pnggray" if anti-aliasing is desired.

For formats which contain a single image, a file specification like `Rplots%03d.png` can be used: this is interpreted by GhostScript.

For `dev2bitmap` if just one of `width` and `height` is specified, the other is chosen to preserve aspect ratio of the device being copied. The main reason to prefer `method = "pdf"` over the default would be to allow semi-transparent colours to be used.

For graphics parameters such as `"cra"` that need to work in pixels, the default resolution of 72dpi is always used.

Value

None.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the "R Internals Manual". These devices follow the underlying device, so when viewed at the stated `res`:

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is (for the standard GhostScript setup) URW Nimbus Sans.
- Line widths are as a multiple of 1/96 inch, with no minimum.
- Circle of any radius are allowed.
- Colours are interpreted by the viewing/printing application.

See Also

`savePlot`, which for windows and X11 (`type = "Cairo"`) provides a simple way to record a PNG record of the current plot.

`postscript`, `pdf`, `png` and `jpeg` and on Windows `bmp`.

To display an array of data, see `image`.

<code>devAskNewPage</code>	<i>Prompt before New Page</i>
----------------------------	-------------------------------

Description

This function can be used to control (for the current device) whether the user is prompted before starting a new page of output.

Usage

```
devAskNewPage(ask = NULL)
```

Arguments

<code>ask</code>	NULL or a logical value. If TRUE, the user is prompted before a new page of output is started.
------------------	--

Details

If the current device is the null device, this will open a graphics device.

The default argument just returns the current setting and does not change it.

The default value when a device is opened is taken from the setting of `options("device.ask.default")`.

The precise circumstances when the user will be asked to confirm a new page depend on the graphics subsystem. Obviously this needs to be an interactive session. In addition ‘recording’ needs to be in operation, so only when the display list is enabled (see `dev.control`) which it usually is only on a screen device.

Value

The current prompt setting *before* any new setting is applied.

See Also

`plot.new`, `grid.newpage`

Devices	<i>List of Graphical Devices</i>
---------	----------------------------------

Description

The following graphics devices are currently available:

- `postscript` Writes PostScript graphics commands to a file
- `pdf` Write PDF graphics commands to a file
- `pictex` Writes LaTeX/PicTeX graphics commands to a file
- `xfig` Device for XFIG graphics file format
- `bitmap` bitmap pseudo-device via GhostScript (if available).

The following devices will be functional if `R` was compiled to use them (they exist but will return with a warning on other systems):

- `X11` The graphics device for the X11 Window system
- `bmp` Windows bitmap device
- `jpeg` JPEG bitmap device
- `png` PNG bitmap device
- `tiff` TIFF bitmap device
- `cairo_pdf`, `cairo_ps` PDF and PostScript devices based on cairo graphics.
- `quartz` The graphics device for the Mac OS X native Quartz 2d graphics system. (This is only functional on Mac OS X, but unlike `R < 2.7.0` can be used from the command line and not just from the GUI console.)

Details

If no device is open, using a high-level graphics function will cause a device to be opened. Which device is given by `options("device")` which is initially set as the most appropriate for each platform: a screen device for most interactive use and `pdf` (or the setting of `R_DEFAULT_DEVICE`) otherwise. The exception is interactive use under Unix if no screen device is known to be available, when `pdf()` is used.

See Also

The individual help files for further information on any of the devices listed here; `X11.options`, `quartz.options`, `ps.options` and `pdf.options` for how to customize devices. `dev.interactive`, `dev.cur`, `dev.print`, `graphics.off`, `image`, `dev2bitmap.capabilities` to see if `X11`, `jpeg` `png` and `quartz` are available.

Examples

```
## Not run:
## open the default screen device on this platform if no device is
## open
if(dev.cur() == 1) dev.new()
## End(Not run)
```

Description

Runs Ghostscript to process a PDF or PostScript file and embed all fonts in the file.

Usage

```
embedFonts(file, format, outfile = file, fontpaths = "",
           options = "")
```

Arguments

<code>file</code>	a character string giving the name of the original file.
<code>format</code>	either "pswrite" or "pdfwrite". If not specified, it is guessed from the suffix of <code>file</code> .
<code>outfile</code>	the name of the new file (with fonts embedded).
<code>fontpaths</code>	a character vector giving directories that Ghostscript will search for fonts.
<code>options</code>	a character string containing further options to Ghostscript.

Details

This function is not necessary if you just use the standard default fonts for PostScript and PDF output.

If you use a special font, this function is useful for embedding that font in your PostScript or PDF document so that it can be shared with others without them having to install your special font (provided the font licence allows this).

If the special font is not installed for Ghostscript, you will need to tell Ghostscript where the font is, using something like `options="-sFONTPATH=path/to/font"`.

This function relies on a suitable Ghostscript executable being in your path, or the environment variable `R_GSCMD` (the same as `bitmap`) being set as the full path to the Ghostscript executable. This defaults to "gs".

Note that Ghostscript may do font substitution, so the font embedded may differ from that specified in the original file.

Value

The shell command used to invoke Ghostscript is returned invisibly. This may be useful for debugging purposes as you can run the command by hand in a shell to look for problems.

[postscriptFonts, Devices](#).

Paul Murrell and Brian Ripley (2006) Non-standard fonts in PostScript and PDF graphics. *R News*, 6(2):41–47. http://cran.r-project.org/doc/Rnews/Rnews_2006-2.pdf.

extendrange

Extend a Numerical Range by a Small Percentage

Description

Extends a numerical range by a small percentage, i.e., fraction, *on both sides*.

Usage

```
extendrange(x, r = range(x, na.rm = TRUE), f = 0.05)
```

Arguments

x	numeric vector; not used if r is specified.
r	numeric vector of length 2; defaults to the range of x.
f	number specifying the fraction by which the range should be extended.

Value

A numeric vector of length 2, $r + c(-f, f) * \text{diff}(r)$.

See Also

[range](#); [pretty](#) which can be considered a sophisticated extension of [extendrange](#).

Examples

```
x <- 1:5
(r <- range(x))          # 1 5
extendrange(x)          # 0.8 5.2
extendrange(x, f= 0.01) # 0.96 5.04
## Use 'r' if you have it already:
stopifnot(identical(extendrange(r=r),
                    extendrange(x)))
```

getGraphicsEvent *Wait for a mouse or keyboard event from a graphics window*

Description

This function waits for input from a graphics window in the form of a mouse or keyboard event.

Usage

```
getGraphicsEvent(prompt = "Waiting for input",
                 onMouseDown = NULL, onMouseMove = NULL,
                 onMouseUp = NULL, onKeybd = NULL)
```

Arguments

prompt	prompt to be displayed to the user
onMouseDown	a function to respond to mouse clicks
onMouseMove	a function to respond to mouse movement
onMouseUp	a function to respond to mouse button releases
onKeybd	a function to respond to key presses

Details

This function allows user input from some graphics devices (currently only the Windows screen display). When called, event handlers may be installed to respond to events involving the mouse or keyboard.

The mouse event handlers should be functions with header `function(buttons, x, y)`. The coordinates `x` and `y` will be passed to mouse event handlers in device independent coordinates (i.e. the lower left corner of the window is $(0, 0)$, the upper right is $(1, 1)$). The `buttons` argument will be a vector listing the buttons that are pressed at the time of the event, with 0 for left, 1 for middle, and 2 for right.

The keyboard event handler should be a function with header `function(key)`. A single element character vector will be passed to this handler, corresponding to the key press. Shift and other modifier keys will have been processed, so `shift-a` will be passed as `"A"`. The following special keys may also be passed to the handler:

- Control keys, passed as `"Ctrl-A"`, etc.
- Navigation keys, passed as one of `"Left"`, `"Up"`, `"Right"`, `"Down"`, `"PgUp"`, `"PgDn"`, `"End"`, `"Home"`
- Edit keys, passed as one of `"Ins"`, `"Del"`
- Function keys, passed as one of `"F1"`, `"F2"`, ...

The event handlers are standard R functions, and will be executed in an environment as though they had been called directly from `getGraphicsEvent`.

Events will be processed until

- one of the event handlers returns a non-NULL value which will be returned as the value of `getGraphicsEvent`, or
- the user interrupts the function from the console.

Value

A non-NULL value returned from one of the event handlers.

Duncan Murdoch

Examples

```
## Not run:
mousedown <- function(buttons, x, y) {
  plx <- grconvertX(x, "ndc", "user")
  ply <- grconvertY(y, "ndc", "user")
  cat("Buttons ", paste(buttons, collapse=" "), " at ndc",
      x, y, "user", plx, ply, "\n")
  points(plx, ply, col="red", pch=19, cex=2)
  if (x > 0.85 && y > 0.85) "Done"
  else NULL
}

mousemove <- function(buttons, x, y) {
  plx <- grconvertX(x, "ndc", "user")
  ply <- grconvertY(y, "ndc", "user")
  points(plx, ply)
```

```
        NULL
    }

    keybd <- function(key) {
        cat("Key <", key, ">\n", sep = "")
    }

    plot(0:1, 0:1, type='n')
    getGraphicsEvent("Click on upper right to quit",
                    onMouseDown = mousedown,
                    onMouseMove = mousemove,
                    onKeybd = keybd)

## End(Not run)
```

gray

Gray Level Specification

Description

Create a vector of colors from a vector of gray levels.

Usage

```
gray(level)
grey(level)
```

Arguments

level a vector of desired gray levels between 0 and 1; zero indicates "black" and one indicates "white".

Details

The values returned by `gray` can be used with a `col=` specification in graphics functions or in [par](#).

`grey` is an alias for `gray`.

Value

A vector of colors of the same length as `level`.

See Also

[rainbow](#), [hsv](#), [hcl](#), [rgb](#).

Examples

```
gray(0:8 / 8)
```

gray.colors *Gray Color Palette*

Description

Create a vector of n gamma-corrected gray colors.

Usage

```
gray.colors(n, start = 0.3, end = 0.9, gamma = 2.2)
grey.colors(n, start = 0.3, end = 0.9, gamma = 2.2)
```

Arguments

n	the number of gray colors (≥ 1) to be in the palette.
start	starting gray level in the palette (should be between 0 and 1 where zero indicates "black" and one indicates "white").
end	ending gray level in the palette.
gamma	the gamma correction.

Details

The function `gray.colors` chooses a series of n gamma-corrected gray levels between `start` and `end`: $(start^\gamma, \dots, end^\gamma)^{1/\gamma}$. The returned palette contains the corresponding gray colors. This palette is used in `barplot.default`.

`gray.colors` is an alias for `gray.colors`.

Value

A vector of n gray colors.

See Also

[gray](#), [rainbow](#), [palette](#).

Examples

```
require(graphics)

pie(rep(1,12), col = gray.colors(12))
barplot(1:12, col = gray.colors(12))
```

hcl *HCL Color Specification*

Description

Create a vector of colors from vectors specifying hue, chroma and luminance.

Usage

```
hcl(h = 0, c = 35, l = 85, alpha, fixup = TRUE)
```

Arguments

<code>h</code>	The hue of the color specified as an angle in the range [0,360]. 0 yields red, 120 yields green 240 yields blue, etc.
<code>c</code>	The chroma of the color. The upper bound for chroma depends on hue and luminance.
<code>l</code>	A value in the range [0,100] giving the luminance of the colour. For a given combination of hue and chroma, only a subset of this range is possible.
<code>alpha</code>	numeric vector of values in the range [0, 1] for alpha transparency channel (0 means transparent and 1 means opaque).
<code>fixup</code>	a logical value which indicates whether the resulting RGB values should be corrected to ensure that a real color results. if <code>fixup</code> is <code>FALSE</code> RGB components lying outside the range [0,1] will result in an NA value.

Details

This function corresponds to polar coordinates in the CIE-LUV color space. Steps of equal size in this space correspond to approximately equal perceptual changes in color. Thus, `hcl` can be thought of as a perceptually based version of `hsv`.

The function is primarily intended as a way of computing colors for filling areas in plots where area corresponds to a numerical value (pie charts, bar charts, mosaic plots, histograms, etc). Choosing colors which have equal chroma and luminance provides a way of minimising the irradiation illusion which would otherwise produce a misleading impression of how large the areas are.

The default values of chroma and luminance make it possible to generate a full range of hues and have a relatively pleasant pastel appearance.

The RGB values produced by this function correspond to the sRGB color space used on most PC computer displays. There are other packages which provide more general color space facilities.

Semi-transparent colors ($0 < \text{alpha} < 1$) are supported only on some devices: see [rgb](#).

Value

A vector of character strings which can be used as color specifications by R graphics functions.

Note

At present there is no guarantee that the colours rendered by R graphics devices will correspond to their sRGB description. It is planned to adopt sRGB as the standard R color description in future.

Hershey

*Hershey Vector Fonts in R***Description**

If the `family` graphical parameter (see `par`) has been set to one of the Hershey fonts (see ‘Details’) Hershey vector fonts are used to render text.

When using the `text` and `contour` functions Hershey fonts may be selected via the `vfont` argument, which is a character vector of length 2 (see ‘Details’ for valid values). This allows Cyrillic to be selected, which is not available via the font families.

Usage

```
Hershey
```

Details

The Hershey fonts have two advantages:

1. vector fonts describe each character in terms of a set of points; R renders the character by joining up the points with straight lines. This intimate knowledge of the outline of each character means that R can arbitrarily transform the characters, which can mean that the vector fonts look better for rotated text.
2. this implementation was adapted from the GNU libplot library which provides support for non-ASCII and non-English fonts. This means that it is possible, for example, to produce weird plotting symbols and Japanese characters.

Drawback:

You cannot use mathematical expressions (`plotmath`) with Hershey fonts.

The Hershey characters are organised into a set of fonts. A particular font is selected by specifying one of the following font families via `par(family)` and specifying the desired font face (plain, bold, italic, bold-italic) via `par(font)`.

family	faces available
"HersheySerif"	plain, bold, italic, bold-italic
"HersheySans"	plain, bold, italic, bold-italic
"HersheyScript"	plain, bold
"HersheyGothicEnglish"	plain
"HersheyGothicGerman"	plain
"HersheyGothicItalian"	plain
"HersheySymbol"	plain, bold, italic, bold-italic
"HersheySansSymbol"	plain, italic

In the `vfont` specification for the `text` and `contour` functions, the Hershey font is specified by a `typeface` (e.g., `serif` or `sans serif`) and a `fontindex` or ‘style’ (e.g., `plain` or `italic`). The first element of `vfont` specifies the typeface and the second element specifies the fontindex. The first table produced by `demo(Hershey)` shows the character a produced by each of the different fonts.

The available `typeface` and `fontindex` values are available as list components of the variable `Hershey`. The allowed pairs for `(typeface, fontindex)` are:

<code>serif</code>	<code>plain</code>
<code>serif</code>	<code>italic</code>
<code>serif</code>	<code>bold</code>
<code>serif</code>	<code>bold italic</code>
<code>serif</code>	<code>cyrillic</code>
<code>serif</code>	<code>oblique cyrillic</code>
<code>serif</code>	<code>EUC</code>
<code>sans serif</code>	<code>plain</code>
<code>sans serif</code>	<code>italic</code>
<code>sans serif</code>	<code>bold</code>
<code>sans serif</code>	<code>bold italic</code>
<code>script</code>	<code>plain</code>
<code>script</code>	<code>italic</code>
<code>script</code>	<code>bold</code>
<code>gothic english</code>	<code>plain</code>
<code>gothic german</code>	<code>plain</code>
<code>gothic italian</code>	<code>plain</code>
<code>serif symbol</code>	<code>plain</code>
<code>serif symbol</code>	<code>italic</code>
<code>serif symbol</code>	<code>bold</code>
<code>serif symbol</code>	<code>bold italic</code>
<code>sans serif symbol</code>	<code>plain</code>
<code>sans serif symbol</code>	<code>italic</code>

and the indices of these are available as `Hershey$allowed`.

Escape sequences: The string to be drawn can include escape sequences, which all begin with a `\`. When `R` encounters a `\`, rather than drawing the `\`, it treats the subsequent character(s) as a coded description of what to draw.

One useful escape sequence (in the current context) is of the form: `\123`. The three digits following the `\` specify an octal code for a character. For example, the octal code for `p` is 160 so the strings `"p"` and `"\160"` are equivalent. This is useful for producing characters when there is not an appropriate key on your keyboard.

The other useful escape sequences all begin with `\\`. These are described below. Remember that backslashes have to be doubled in `R` character strings, so they need to be entered with *four* backslashes.

Symbols: an entire string of Greek symbols can be produced by selecting the `HersheySymbol` or `HersheySansSymbol` family or the `Serif Symbol` or `Sans Serif Symbol` typeface. To allow Greek symbols to be embedded in a string which uses a non-symbol typeface, there are a set of symbol escape sequences of the form `*ab`. For example, the escape sequence `*a` produces a Greek alpha. The second table in `demo(Hershey)` shows all of the symbol escape sequences and the symbols that they produce.

ISO Latin-1: further escape sequences of the form `*ab` are provided for producing ISO Latin-1 characters. Another option is to use the appropriate octal code. The (non-ASCII) ISO Latin-1 characters are in the range 241...377. For example, `\366` produces the character `o` with an umlaut. The third table in `demo(Hershey)` shows all of the ISO Latin-1 escape sequences. These characters can be used directly in a Latin-1 locale or on a system with MBCS support. (In the latter, characters not in Latin-1 are replaced by a dot.)

Several characters are missing, c-cedilla has no cedilla and ‘sharp s’ (U+00DF, also known as ‘esszett’) is rendered as `ss`.

Special Characters: a set of characters are provided which do not fall into any standard font. These can only be accessed by escape sequence. For example, `\\LI` produces the zodiac sign for Libra, and `\\JU` produces the astronomical sign for Jupiter. The fourth table in `demo(Hershey)` shows all of the special character escape sequences.

Cyrillic Characters: cyrillic characters are implemented according to the K018-R encoding, and can be used directly in such a locale using the Serif typeface and Cyrillic (or Oblique Cyrillic) fontindex. Alternatively they can be specified via an octal code in the range 300 to 337 for lower case characters or 340 to 377 for upper case characters. The fifth table in `demo(Hershey)` shows the octal codes for the available Cyrillic characters.

Cyrillic has to be selected via a `("serif", fontindex)` pair rather than via a font family.

Japanese Characters: 83 Hiragana, 86 Katakana, and 603 Kanji characters are implemented according to the EUC-JP (Extended Unix Code) encoding. Each character is identified by a unique hexadecimal code. The Hiragana characters are in the range 0x2421 to 0x2473, Katakana are in the range 0x2521 to 0x2576, and Kanji are (scattered about) in the range 0x3021 to 0x6d55.

When using the Serif typeface and EUC fontindex, these characters can be produced by a *pair* of octal codes. Given the hexadecimal code (e.g., 0x2421), take the first two digits and add 0x80 and do the same to the second two digits (e.g., 0x21 and 0x24 become 0xa4 and 0xa1), then convert both to octal (e.g., 0xa4 and 0xa1 become 244 and 241). For example, the first Hiragana character is produced by `\244\241`.

It is also possible to use the hexadecimal code directly. This works for all non-EUC fonts by specifying an escape sequence of the form `\\#J1234`. For example, the first Hiragana character is produced by `\\#J2421`.

The Kanji characters may be specified in a third way, using the so-called "Nelson Index", by specifying an escape sequence of the form `\\#N1234`. For example, the (obsolete) Kanji for ‘one’ is produced by `\\#N0001`.

`demo(Japanese)` shows the available Japanese characters.

Raw Hershey Glyphs: all of the characters in the Hershey fonts are stored in a large array. Some characters are not accessible in any of the Hershey fonts. These characters can only be accessed via an escape sequence of the form `\\#H1234`. For example, the fleur-de-lys is produced by `\\#H0746`. The sixth and seventh tables of `demo(Hershey)` shows all of the available raw glyphs.

hsv

*HSV Color Specification***Description**

Create a vector of colors from vectors specifying hue, saturation and value.

Usage

```
hsv(h = 1, s = 1, v = 1, gamma = 1, alpha)
```

Arguments

<code>h, s, v</code>	numeric vectors of values in the range $[0, 1]$ for ‘hue’, ‘saturation’ and ‘value’ to be combined to form a vector of colors. Values in shorter arguments are recycled.
<code>gamma</code>	a gamma-correction exponent, γ
<code>alpha</code>	numeric vector of values in the range $[0, 1]$ for alpha transparency channel (0 means transparent and 1 means opaque).

Details

Semi-transparent colors ($0 < \alpha < 1$) are supported only on some devices: see [rgb](#).

Value

This function creates a vector of colors corresponding to the given values in HSV space. The values returned by `hsv` can be used with a `col=` specification in graphics functions or in `par`.

Gamma correction

For each color, (r, g, b) in RGB space (with all values in $[0, 1]$), the final color corresponds to $(r^\gamma, g^\gamma, b^\gamma)$.

See Also

[hcl](#) for a perceptually based version of `hsv()`, [rgb](#) and [rgb2hsv](#) for RGB to HSV conversion; [rainbow](#), [gray](#).

Examples

```
require(graphics)

hsv(.5, .5, .5)

## Look at gamma effect:
n <- 20; y <- -sin(3*pi*((1:n)-1/2)/n)
op <- par(mfrow=c(3,2),mar=rep(1.5,4))
for(gamma in c(.4, .6, .8, 1, 1.2, 1.5))
  plot(y, axes = FALSE, frame.plot = TRUE,
       xlab = "", ylab = "", pch = 21, cex = 30,
       bg = rainbow(n, start=.85, end=.1, gamma = gamma),
```

```

      main = paste("Red tones; gamma=", format(gamma))
par(op)

```

Japanese

*Japanese characters in R***Description**

The implementation of Hershey vector fonts provides a large number of Japanese characters (Hiragana, Katakana, and Kanji).

Details

Without keyboard support for typing Japanese characters, the only way to produce these characters is to use special escape sequences: see [Hershey](#).

For example, the Hiragana character for the sound "ka" is produced by `\\#J242b` and the Katakana character for this sound is produced by `\\#J252b`. The Kanji ideograph for "one" is produced by `\\#J306c` or `\\#N0001`.

The output from `demo(Japanese)` shows tables of the escape sequences for the available Japanese characters.

```

 make.rgb

Create colour spaces

Description

These functions specify colour spaces for use in `convertColor`.

Usage

```
make.rgb(red, green, blue, name = NULL, white = "D65",
         gamma = 2.2)
```

```
colorConverter(toXYZ, fromXYZ, name, white=NULL)
```

Arguments

<code>red, green, blue</code>	Chromaticity (xy or xyY) of RGB primaries
<code>name</code>	Name for the colour space
<code>white</code>	Character string specifying the reference white (see 'Details').
<code>gamma</code>	Display gamma (nonlinearity). A positive number or the string "sRGB"
<code>fromXYZ</code>	Function to convert from XYZ tristimulus coordinates to this space
<code>toXYZ</code>	Function to convert from this space to XYZ tristimulus coordinates.

Details

An RGB colour space is defined by the chromaticities of the red, green and blue primaries. These are given as vectors of length 2 or 3 in xyY coordinates (the Y component is not used and may be omitted). The chromaticities are defined relative to a reference white, which must be one of the CIE standard illuminants: "A", "B", "C", "D50", "D55", "D60", "E" (usually "D65").

The display gamma is most commonly 2.2, though 1.8 is used for Apple RGB. The sRGB standard specifies a more complicated function that is close to a gamma of 2.2; `gamma="sRGB"` uses this function.

Colour spaces other than RGB can be specified directly by giving conversions to and from XYZ tristimulus coordinates. The functions should take two arguments. The first is a vector giving the coordinates for one colour. The second argument is the reference white. If a specific reference white is included in the definition of the colour space (as for the RGB spaces) this second argument should be ignored and may be . . .

Value

An object of class `colorConverter`

`convertColor`

Examples

```
(pal <- make.rgb(red= c(0.6400,0.3300),
                green=c(0.2900,0.6000),
                blue= c(0.1500,0.0600),
                name = "PAL/SECAM RGB"))

## converter for sRGB in #rrggbb format
hexcolor <- colorConverter(toXYZ = function(hex,...) {
  rgb <- t(col2rgb(hex))/255
  colorspace$sRGB$toXYZ(rgb,...) },
  fromXYZ = function(xyz,...) {
  rgb <- colorspace$sRGB$fromXYZ(xyz,..)
  rgb <- round(rgb,5)
  if (min(rgb) < 0 || max(rgb) > 1)
    as.character(NA)
  else
    rgb(rgb[1],rgb[2],rgb[3])},
  white = "D65", name = "#rrggbb")

(cols <- t(col2rgb(palette())))
(luv <- convertColor(cols,from="sRGB", to="Luv", scale.in=255))
(hex <- convertColor(luv, from="Luv", to=hexcolor, scale.out=NULL))

## must make hex a matrix before using it
(cc <- round(convertColor(as.matrix(hex), from= hexcolor, to= "sRGB",
                        scale.in=NULL, scale.out=255)))
stopifnot(cc == cols)
```

n2mfrow

*Compute Default mfrow From Number of Plots***Description**

Easy setup for plotting multiple figures (in a rectangular layout) on one page. This computes a sensible default for `par(mfrow)`.

Usage

```
n2mfrow(nr.plots)
```

Arguments

```
nr.plots      integer; the number of plot figures you'll want to draw.
```

Value

A length two integer vector `nr, nc` giving the number of rows and columns, fulfilling `nr >= nc >= 1` and `nr * nc >= nr.plots`.

Author(s)

Martin Maechler

See Also

[par](#), [layout](#).

Examples

```
require(graphics)

n2mfrow(8) # 3 x 3

n <- 5 ; x <- seq(-2,2, len=51)
## suppose now that 'n' is not known {inside function}
op <- par(mfrow = n2mfrow(n))
for (j in 1:n)
  plot(x, x^j, main = substitute(x^ exp, list(exp = j)), type = "l",
       col = "blue")

sapply(1:10, n2mfrow)
```

nclass

Compute the Number of Classes for a Histogram

Description

Compute the number of classes for a histogram.

Usage

```
nclass.Sturges(x)
nclass.scott(x)
nclass.FD(x)
```

Arguments

x A data vector.

Details

`nclass.Sturges` uses Sturges' formula, implicitly basing bin sizes on the range of the data.

`nclass.scott` uses Scott's choice for a normal distribution based on the estimate of the standard error, unless that is zero where it returns 1.

`nclass.FD` uses the Freedman-Diaconis choice based on the inter-quartile range ([IQR](#)) unless that's zero where it reverts to `mad(x, constant=2)` and when that is 0 as well, returns 1.

Value

The suggested number of classes.

nclass.Sturges(x)

## Compare them:
NC <- function(x) c(Sturges = nclass.Sturges(x),
                   Scott = nclass.scott(x), FD = nclass.FD(x))
NC(x)
onePt <- rep(1, 11)
NC(onePt) # no longer gives NaN
```

palette

Set or View the Graphics Palette

Description

View or manipulate the color palette which is used when a `col=` has a numeric index.

Usage

```
palette(value)
```

Arguments

`value` an optional character vector.

Details

If `value` has length 1, it is taken to be the name of a built in color palette. If `value` has length greater than 1 it is assumed to contain a description of the colors which are to make up the new palette (either by name or by RGB levels).

If `value` is omitted or has length 0, no change is made the current palette.

Currently, the only built-in palette is "default".

Value

The palette which *was* in effect. This is [invisible](#) unless the argument is omitted.

See Also

`colors` for the vector of built-in named colors; `hsv`, `gray`, `rainbow`, `terrain.colors`,... to construct colors.

`colorRamp` to interpolate colors, making custom palettes; `col2rgb` for translating colors to RGB 3-vectors.

Examples

```
require(graphics)

palette()          # obtain the current palette
palette(rainbow(6)) # six color rainbow

(palette(gray(seq(0,.9,len=25)))) # gray scales; print old palette
matplot(outer(1:100,1:30), type='l', lty=1,lwd=2, col=1:30,
        main = "Gray Scales Palette",
        sub = "palette(gray(seq(0,.9,len=25)))")
palette("default") # reset back to the default
```

 Palettes

Color Palettes

Description

Create a vector of n contiguous colors.

Usage

```
rainbow(n, s = 1, v = 1, start = 0, end = max(1, n - 1)/n,
        gamma = 1, alpha = 1)
heat.colors(n, alpha = 1)
terrain.colors(n, alpha = 1)
topo.colors(n, alpha = 1)
cm.colors(n, alpha = 1)
```

Arguments

<code>n</code>	the number of colors (≥ 1) to be in the palette.
<code>s, v</code>	the ‘saturation’ and ‘value’ to be used to complete the HSV color descriptions.
<code>start</code>	the (corrected) hue in $[0,1]$ at which the rainbow begins.
<code>end</code>	the (corrected) hue in $[0,1]$ at which the rainbow ends.
<code>gamma</code>	the gamma correction, see argument <code>gamma</code> in hsv .
<code>alpha</code>	the alpha transparency, a number in $[0,1]$, see argument <code>alpha</code> in hsv .

Details

Conceptually, all of these functions actually use (parts of) a line cut out of the 3-dimensional color space, parametrized by `hsv(h, s, v, gamma)`, where `gamma=1` for the `foo.colors` function, and hence, equispaced hues in RGB space tend to cluster at the red, green and blue primaries.

Some applications such as contouring require a palette of colors which do not wrap around to give a final color close to the starting one.

With `rainbow`, the parameters `start` and `end` can be used to specify particular subranges of hues. The following values can be used when generating such a subrange: `red=0`, `yellow= $\frac{1}{6}$` , `green= $\frac{2}{6}$` , `cyan= $\frac{3}{6}$` , `blue= $\frac{4}{6}$` and `magenta= $\frac{5}{6}$` .

Value

A character vector, `cv`, of color names. This can be used either to create a user-defined color palette for subsequent graphics by `palette(cv)`, a `col=` specification in graphics functions or in `par`.

See Also

`colors`, `palette`, `hsv`, `hcl`, `rgb`, `gray` and `col2rgb` for translating to RGB numbers.

Examples

```
require(graphics)
# A Color Wheel
pie(rep(1,12), col=rainbow(12))

##----- Some palettes -----
demo.pal <-
  function(n, border = if (n<32) "light gray" else NA,
           main = paste("color palettes; n=",n),
           ch.col = c("rainbow(n, start=.7, end=.1)", "heat.colors(n)",
                     "terrain.colors(n)", "topo.colors(n)",
                     "cm.colors(n)"))
  {
    nt <- length(ch.col)
    i <- 1:n; j <- n / nt; d <- j/6; dy <- 2*d
    plot(i,i+d, type="n", yaxt="n", ylab="", main=main)
    for (k in 1:nt) {
      rect(i-.5, (k-1)*j+ dy, i+.4, k*j,
           col = eval(parse(text=ch.col[k])), border = border)
      text(2*j, k * j +dy/4, ch.col[k])
    }
  }
n <- if(.Device == "postscript") 64 else 16
# Since for screen, larger n may give color allocation problem
demo.pal(n)
```

Description

`pdf` starts the graphics device driver for producing PDF graphics.

Usage

```
pdf(file = ifelse(onefile, "Rplots.pdf", "Rplot%03d.pdf"),
    width, height, onefile, family, title, fonts, version,
    paper, encoding, bg, fg, pointsize, pagecentre, colormodel,
    useDingbats)
```

Arguments

<code>file</code>	a character string giving the name of the file. For use with <code>onefile=FALSE</code> give a C integer format such as "Rplot%03d.pdf" (the default in that case). (See postscript for further details.)
<code>width, height</code>	the width and height of the graphics region in inches. The default values are 7.
<code>onefile</code>	logical: if true (the default) allow multiple figures in one file. If false, generate a file with name containing the page number for each page. Defaults to TRUE.
<code>family</code>	the font family to be used, see postscript . Defaults to "Helvetica".
<code>title</code>	title string to embed as the <code>/Title</code> field in the file. Defaults to "R Graphics Output".
<code>fonts</code>	a character vector specifying R graphics font family names for fonts which will be included in the PDF file. Defaults to NULL.
<code>version</code>	a string describing the PDF version that will be required to view the output. This is a minimum, and will be increased (with a warning) if necessary. Defaults to "1.4", but see 'Details'.
<code>paper</code>	the target paper size. The choices are "a4", "letter", "legal" (or "us") and "executive" (and these can be capitalized), or "a4r" and "USr" for rotated ('landscape'). The default is "special", which means that the width and height specify the paper size. A further choice is "default"; if this is selected, the papersize is taken from the option "papersize" if that is set and as "a4" if it is unset or empty. Defaults "special".
<code>encoding</code>	the name of an encoding file. See postscript for details. Defaults to "default".
<code>bg</code>	the initial background color to be used. Defaults to "transparent".
<code>fg</code>	the initial foreground color to be used. Defaults to "black".
<code>pointsize</code>	the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch, but approximately in points. Defaults to 12.
<code>pagecentre</code>	logical: should the device region be centred on the page? – is only relevant for <code>paper != "special"</code> . Defaults to true.
<code>colormodel</code>	a character string describing the color model: currently allowed values are "rgb", "gray" and "cmyk". Defaults to "rgb".
<code>useDingbats</code>	logical. Should small circles be rendered <i>via</i> the Dingbats font? Defaults to true, which produces smaller and better output – this is provided for those who insist on using broken PDF viewers.

Details

All arguments except `file` default to values given by `pdf.options()`. The ultimate defaults are quoted in the arguments section.

`pdf()` opens the file `file` and the PDF commands needed to plot any graphics requested are sent to that file.

The `file` argument is interpreted as a C integer format as used by `sprintf`, with integer argument the page number. The default gives files ‘Rplot001.pdf’, ..., ‘Rplot999.pdf’, ‘Rplot1000.pdf’, ...

The `family` argument can be used to specify a PDF-specific font family as the initial/default font for the device.

If a device-independent R graphics font family is specified (e.g., via `par(family=)` in the graphics package), the PDF device makes use of the PostScript font mappings to convert the R graphics font family to a PDF-specific font family description. (See the documentation for `pdfFonts`.)

R does *not* embed fonts in the PDF file, so it is only straightforward to use mappings to the font families that can be assumed to be available in any PDF viewer: "Times" (equivalently "serif"), "Helvetica" (equivalently "sans") and "Courier" (equivalently "mono"). Other families may be specified, but it is the user's responsibility to ensure that these fonts are available on the system and third-party software, e.g., Ghostscript, may be required to embed the fonts so that the PDF can be included in other documents (e.g., LaTeX): see `embedFonts`. The URW-based families described for `postscript` can be used with viewers set up to use URW fonts, which is usual with those based on `xpdf` or Ghostscript. Since `embedFonts` makes use of Ghostscript, it should be able to embed the URW-based families for use with other viewers.

See `postscript` for details of encodings, as the internal code is shared between the drivers. The native PDF encoding is given in file ‘PDFDoc.enc’.

`pdf` writes uncompressed PDF. It is primarily intended for producing PDF graphics for inclusion in other documents, and PDF-includers such as `pdftex` are usually able to handle compression.

The PDF produced is fairly simple, with each page being represented as a single stream. The R graphics model does not distinguish graphics objects at the level of the driver interface.

The `version` argument declares the version of PDF that gets produced. The version must be at least 1.4 for semi-transparent output to be understood, and at least 1.3 if CID fonts are to be used: if these features are used the version number will be increased (with a warning). Specifying a low version number is useful if you want to produce PDF output that can be viewed on older or non-Adobe PDF viewers. (PDF 1.4 requires Acrobat 5 or later.)

Line widths as controlled by `par(lwd=)` are in multiples of 1/96 inch. Multiples less than 1 are allowed. `pch="."` with `cex = 1` corresponds to a square of side 1/72 inch, which is also the ‘pixel’ size assumed for graphics parameters such as "cra".

The `paper` argument sets the `/MediaBox` entry in the file, which defaults to `width` by `height`. If it is set to something other than "special", a device region of the specified size is (by default) centred on the rectangle given by the paper size: if either `width` or `height` is less than 0.1 or too large to give a total margin of 0.5 inch, it is reset to the corresponding paper dimension minus 0.5. Thus if you want the default behaviour of `postscript` use `pdf(paper="a4r", width=0, height=0)` to centre the device region on a landscape A4 page with 0.25 inch margins.

When the background colour is fully transparent (as is the initial default value), the PDF produced does not paint the background. Almost all PDF viewers will use a white canvas so the visual effect is if the background were white. This will not be the case when printing onto coloured paper, though.

Color models

The default color model is RGB, and model "gray" maps RGB colors to greyscale using perceived luminosity (biased towards green). "cmyk" outputs in CMYK colorspace. Nothing in R specifies the interpretation of the RGB or CMYK color spaces, and the simplest possible conversion to CMYK is used (http://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK).

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are as a multiple of 1/96 inch, with no minimum.
- Circles of any radius are allowed. Unless `useDingbats = FALSE`, opaque circles of less than 10 big points radius are rendered using char 108 in the Dingbats font: all semi-transparent and larger circles using a Bézier curve for each quadrant.
- Colours are interpreted by the viewing/printing application.

Note

Acrobat Reader does not use the fonts specified but rather emulates them from multiple-master fonts. This can be seen in imprecise centering of characters, for example the multiply and divide signs in Helvetica. This can be circumvented by embedding fonts where possible. Most other viewers substitute fonts, e.g. URW fonts for the standard Helvetica and Times fonts, and these too often have different font metrics from the true fonts.

Acrobat Reader 5.x and later can be extended by support for Asian and (so-called) Central European fonts (the latter only for 7.x and later, part of the ‘Extended’ pack for 8.x and later), and these will be needed for the full use of encodings other than Latin-1. See <http://www.adobe.com/products/acrobat/acrrasianfontpack.html> for Reader 5.x to 8.x, and Updates on <http://www.adobe.com> for 9.x.

More details of font families and encodings and especially handling text in a non-Latin-1 encoding and embedding fonts can be found in

Paul Murrell and Brian Ripley (2006) Non-standard fonts in PostScript and PDF graphics. *R News*, 6(2):41–47. http://cran.r-project.org/doc/Rnews/Rnews_2006-2.pdf.

Examples

```
## Not run:
## Test function for encodings
TestChars <- function(encoding="ISOLatin1", ...)
{
  pdf(encoding=encoding, ...)
  par(pty="s")
  plot(c(-1,16), c(-1,16), type="n", xlab="", ylab="",
        xaxs="i", yaxs="i")
  title(paste("Centred chars in encoding", encoding))
  grid(17, 17, lty=1)
  for(i in c(32:255)) {
    x <- i %% 16
    y <- i %% 16
    points(x, y, pch=i)
  }
}
```

```

    }
    dev.off()
}
## there will be many warnings.
TestChars("ISOLatin2")
## this does not view properly in older viewers.
TestChars("ISOLatin2", family="URWHelvetica")
## works well for viewing in gs-based viewers, and often in xpdf.
## End(Not run)

```

pdf.options

Auxiliary Function to Set/View Defaults for Arguments of pdf

Description

The auxiliary function `pdf.options` can be used to set or view (if called without arguments) the default values for some of the arguments to `pdf`.

`pdf.options` needs to be called before calling `pdf`, and the default values it sets can be overridden by supplying arguments to `pdf`.

Usage

```
pdf.options(..., reset = FALSE)
```

Arguments

<code>...</code>	arguments <code>width</code> , <code>height</code> , <code>onefile</code> , <code>family</code> , <code>title</code> , <code>fonts</code> , <code>paper</code> , <code>encoding</code> , <code>pointsize</code> , <code>bg</code> , <code>fg</code> , <code>pagecentre</code> , <code>useDingbats</code> and <code>colormodel</code> can be supplied.
<code>reset</code>	logical: should the defaults be reset to their ‘factory-fresh’ values?

Details

If both `reset = TRUE` and `...` are supplied the defaults are first reset to the ‘factory-fresh’ values and then the new values are applied.

Value

A named list of all the defaults. If any arguments are supplied the return values are the old values and the result has the visibility flag turned off.

See Also

[pdf](#), [ps.options](#).

Examples

```
pdf.options(bg = "pink")
utils::str(pdf.options())
pdf.options(reset = TRUE) # back to factory-fresh

```

Description

This function produces graphics suitable for inclusion in TeX and LaTeX documents.

Usage

```
pictex(file = "Rplots.tex", width = 5, height = 4, debug = FALSE,  
       bg = "white", fg = "black")
```

Arguments

file	the file where output will appear.
width	The width of the plot in inches.
height	the height of the plot in inches.
debug	should debugging information be printed.
bg	the background color for the plot. Ignored.
fg	the foreground color for the plot. Ignored.

Details

This driver does not have any font metric information, so the use of `plotmath` is not supported.

Multiple plots will be placed as separate environments in the output file.

Line widths are ignored except when setting the spacing of line textures. `pch="."` corresponds to a square of side 1pt.

This device does not support colour (nor does the PicTeX package), and all colour settings are ignored.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 5 inches by 5 inches.
- There is no `pointsize` argument: the default size is interpreted as 10 point.
- The only font family is `cms10`.
- Line widths are only used when setting the spacing on line textures.
- Circle of any radius are allowed.
- Colour is not supported.

Author(s)

This driver was provided by Valerio Aimale (valerio@svpop.com.dist.unige.it) of the Department of Internal Medicine, University of Genoa, Italy.

## \end{document}

##-- plain TeX Example --
\input pictex
$$ \input Rplots.tex $$
## End(Not run)
##-----
unlink("Rplots.tex")
```

Description

If the `text` argument to one of the text-drawing functions (`text`, `mtext`, `axis`, `legend`) in R is an expression, the argument is interpreted as a mathematical expression and the output will be formatted according to TeX-like rules. Expressions can also be used for titles, subtitles and x- and y-axis labels (but not for axis labels on `persp` plots).

In most cases other language objects (names and calls, including formulas) are coerced to expressions and so can also be used.

Details

A mathematical expression must obey the normal rules of syntax for any R expression, but it is interpreted according to very different rules than for normal R expressions.

It is possible to produce many different mathematical symbols, generate sub- or superscripts, produce fractions, etc.

The output from `demo(plotmath)` includes several tables which show the available features. In these tables, the columns of grey text show sample R expressions, and the columns of black text show the resulting output.

The available features are also described in the tables below:

Syntax	Meaning
<code>x + y</code>	x plus y
<code>x - y</code>	x minus y
<code>x*y</code>	juxtapose x and y
<code>x/y</code>	x forwardslash y
<code>x %+-% y</code>	x plus or minus y
<code>x %/% y</code>	x divided by y
<code>x %*% y</code>	x times y
<code>x %.% y</code>	x cdot y
<code>x[i]</code>	x subscript i
<code>x^2</code>	x superscript 2
<code>paste(x, y, z)</code>	juxtapose x, y, and z
<code>sqrt(x)</code>	square root of x
<code>sqrt(x, y)</code>	yth root of x
<code>x == y</code>	x equals y
<code>x != y</code>	x is not equal to y
<code>x < y</code>	x is less than y
<code>x <= y</code>	x is less than or equal to y
<code>x > y</code>	x is greater than y
<code>x >= y</code>	x is greater than or equal to y
<code>x %~~% y</code>	x is approximately equal to y
<code>x %==% y</code>	x and y are congruent
<code>x %==% y</code>	x is defined as y
<code>x %prop% y</code>	x is proportional to y
<code>plain(x)</code>	draw x in normal font
<code>bold(x)</code>	draw x in bold font
<code>italic(x)</code>	draw x in italic font
<code>bolditalic(x)</code>	draw x in bolditalic font
<code>symbol(x)</code>	draw x in symbol font
<code>list(x, y, z)</code>	comma-separated list
<code>...</code>	ellipsis (height varies)
<code>cdots</code>	ellipsis (vertically centred)
<code>ldots</code>	ellipsis (at baseline)
<code>x %subset% y</code>	x is a proper subset of y
<code>x %subseteq% y</code>	x is a subset of y
<code>x %notsubset% y</code>	x is not a subset of y
<code>x %supset% y</code>	x is a proper superset of y
<code>x %supseteq% y</code>	x is a superset of y
<code>x %in% y</code>	x is an element of y
<code>x %notin% y</code>	x is not an element of y
<code>hat(x)</code>	x with a circumflex

<code>tilde(x)</code>	x with a tilde
<code>dot(x)</code>	x with a dot
<code>ring(x)</code>	x with a ring
<code>bar(xy)</code>	xy with bar
<code>widehat(xy)</code>	xy with a wide circumflex
<code>widetilde(xy)</code>	xy with a wide tilde
<code>x %<->% y</code>	x double-arrow y
<code>x %->% y</code>	x right-arrow y
<code>x %<-% y</code>	x left-arrow y
<code>x %up% y</code>	x up-arrow y
<code>x %down% y</code>	x down-arrow y
<code>x %<=>% y</code>	x is equivalent to y
<code>x %=>% y</code>	x implies y
<code>x %<=% y</code>	y implies x
<code>x %dblup% y</code>	x double-up-arrow y
<code>x %dbldown% y</code>	x double-down-arrow y
<code>alpha - omega</code>	Greek symbols
<code>Alpha - Omega</code>	uppercase Greek symbols
<code>thetal, phil, sigmal, omegal</code>	cursive Greek symbols
<code>Upsilon1</code>	capital upsilon with hook
<code>aleph</code>	first letter of Hebrew alphabet
<code>infinity</code>	infinity symbol
<code>partialdiff</code>	partial differential symbol
<code>nabla</code>	nabla, gradient symbol
<code>32*degree</code>	32 degrees
<code>60*minute</code>	60 minutes of angle
<code>30*second</code>	30 seconds of angle
<code>displaystyle(x)</code>	draw x in normal size (extra spacing)
<code>textstyle(x)</code>	draw x in normal size
<code>scriptstyle(x)</code>	draw x in small size
<code>scriptscriptstyle(x)</code>	draw x in very small size
<code>underline(x)</code>	draw x underlined
<code>x ~ y</code>	put extra space between x and y
<code>x + phantom(0) + y</code>	leave gap for "0", but don't draw it
<code>x + over(1, phantom(0))</code>	leave vertical gap for "0" (don't draw)
<code>frac(x, y)</code>	x over y
<code>over(x, y)</code>	x over y
<code>atop(x, y)</code>	x over y (no horizontal bar)
<code>sum(x[i], i==1, n)</code>	sum x[i] for i equals 1 to n
<code>prod(plain(P) (X==x), x)</code>	product of P(X=x) for all values of x
<code>integral(f(x)*dx, a, b)</code>	definite integral of f(x) wrt x
<code>union(A[i], i==1, n)</code>	union of A[i] for i equals 1 to n
<code>intersect(A[i], i==1, n)</code>	intersection of A[i]
<code>lim(f(x), x %->% 0)</code>	limit of f(x) as x tends to 0
<code>min(g(x), x > 0)</code>	minimum of g(x) for x greater than 0
<code>inf(S)</code>	infimum of S
<code>sup(S)</code>	supremum of S
<code>x^y + z</code>	normal operator precedence
<code>x^(y + z)</code>	visible grouping of operands
<code>x^{y + z}</code>	invisible grouping of operands
<code>group("(", list(a, b), ")")</code>	specify left and right delimiters
<code>bgroup("(", atop(x, y), ")")</code>	use scalable delimiters

group(lceil, x, rceil) special delimiters

The symbol font uses Adobe Symbol encoding so, for example, a lower case mu can be obtained either by the special symbol `mu` or by `symbol("m")`. This provides access to symbols that have no special symbol name, for example, the universal, or forall, symbol is `symbol("\042")`.

Note to TeX users: TeX's `\Upsilon` is `Upsilon1`, TeX's `\varepsilon` is close to `epsilon`, and there is no equivalent of TeX's `\epsilon`. TeX's `\varpi` is close to `omega1`. `vartheta`, `varphi` and `varsigma` are allowed as synonyms for `theta1`, `phi1` and `sigma1`.

`sigma1` is also known as `stigma`, its Unicode name.

Control characters (e.g. `\n`) are not interpreted in character strings in plotmath, unlike normal plotting.

The fonts used are taken from the current font family, and so can be set by `par(family=)` in base graphics, and `gpar(fontfamily=)` in package **grid**.

Other symbols

On many OSES and some graphics devices many other symbols are available as part of the standard text font, and all of the symbols in the Adobe Symbol encoding are in principle available *via* changing the font face or (see 'Details') plotmath: see the examples section of `points` for a function to display them. ('In principle' because some of the glyphs are missing from some implementations of the symbol font.) Unfortunately, `postscript` and `pdf` have support for little more than European and CJK characters and the Adobe Symbol encoding (and in a few fonts, also Cyrillic characters).

In a UTF-8 locale any Unicode character can be entered, perhaps as a `\uxxxx` or `\Uxxxxxxxx` escape sequence, but the issue is whether the graphics device is apply to display the character. The widest range of characters is likely to be available in the `X11` device using `cairo`: see its help page for how installing additional fonts can help.

In non-UTF-8 locales there is normally no support for symbols not in the languages for which the current encoding was intended.

```

Description

Graphics devices for JPEG, PNG or TIFF format bitmap files.

Usage

```

bmp(filename = "Rplot%03d.bmp",
     width = 480, height = 480, units = "px",
     pointsize = 12, bg = "white", res = NA, ...,
     type = c("cairo", "Xlib", "quartz"), antialias)

jpeg(filename = "Rplot%03d.jpeg",
     width = 480, height = 480, units = "px",
     pointsize = 12, quality = 75, bg = "white", res = NA, ...,
     type = c("cairo", "Xlib", "quartz"), antialias)

png(filename = "Rplot%03d.png",
     width = 480, height = 480, units = "px",
     pointsize = 12, bg = "white", res = NA, ...,
     type = c("cairo", "Xlib", "cairo1", "quartz"), antialias)

tiff(filename = "Rplot%03d.tiff",
     width = 480, height = 480, units = "px", pointsize = 12,
     compression = c("none", "rle", "lzw", "jpeg", "zip"),
     bg = "white", res = NA, ...,
     type = c("cairo", "Xlib", "quartz"), antialias)

```

Arguments

filename	the name of the output file. The page number is substituted if a C integer format is included in the character string, as in the default. (The result must be less than <code>PATH_MAX</code> characters long, and may be truncated if not. See postscript for further details.) Tilde expansion is performed where supported by the platform.
width	the width of the device.
height	the height of the device.
units	The units in which height and width are given. Can be <code>px</code> (pixels, the default), <code>in</code> (inches), <code>cm</code> or <code>mm</code> .
pointsize	the default pointsize of plotted text, interpreted as big points (1/72 inch) at <code>res</code> dpi.
bg	the initial background colour: can be overridden by setting <code>par("bg")</code> .
quality	the ‘quality’ of the JPEG image, as a percentage. Smaller values will give more compression but also more degradation of the image.
compression	the type of compression to be used.
res	The nominal resolution in dpi which will be recorded in the bitmap file, if a positive integer. Also used for <code>units</code> other than the default, and to convert points to pixels.
...	for <code>type = "Xlib"</code> only, additional arguments to the underlying X11 device, such as <code>gamma</code> and <code>fonts</code> .
type	character string, one of <code>"Xlib"</code> (the only type prior to R 2.7.0) or <code>"quartz"</code> (some Mac OS X builds) or <code>"cairo"</code> or <code>"cairo1"</code> . The latter two will

only be available if the system was compiled with support for cairo – otherwise "Xlib" will be used. The default is set by `getOption("bitmapType")` – the ‘out of the box’ default is "quartz" or "cairo" where available, otherwise "Xlib".

`antialias` for `type = "cairo"`, giving the type of anti-aliasing (if any) to be used. See [X11](#). The default is set by `X11.options`.

Details

Plots in PNG and JPEG format can easily be converted to many other bitmap formats, and both can be displayed in modern web browsers. The PNG format is lossless and is best for line diagrams and blocks of colour. The JPEG format is lossy, but may be useful for image plots, for example. BMP is a standard format on Windows. TIFF is a meta-format: the default format written by `tiff` is lossless and stores RGB (and alpha where appropriate) values uncompressed—such files are widely accepted, which is their main virtue over PNG.

`png` supports transparent backgrounds: use `bg = "transparent"`. Not all PNG viewers render files with transparency correctly. When transparency is in use in the `type = "Xlib"` variant a very light grey is used as the background and so appear as transparent if used in the plot. This allows opaque white to be used, as in the example. The `type = "cairo"` and `type = "cairo1"` variants allows semi-transparent colours, including on a transparent or semi-transparent background.

`tiff(type = "cairo")` supports semi-transparent colours, including on a transparent or semi-transparent background.

R can be compiled without support for each of these devices: this will be reported if you attempt to use them on a system where they are not supported. For `type = "Xlib"` they may not be usable unless the X11 display is available to the owner of the R process. `type = "cairo"` requires cairo 1.2 or later. `type = "quartz"` uses the `quartz` device and so is only available where that is (on some Mac OS X) builds. It is at present experimental.

By default no resolution is recorded in the file. Viewers will often assume a nominal resolution of 72dpi when none is recorded. As resolutions in PNG files are recorded in pixels/metre, the reported dpi value will be changed slightly.

For graphics parameters that make use of dimensions in inches (including font sizes in points) the resolution used is `res` (or 72dpi if unset).

`png` will use a palette if there are less than 256 colours on the page, and record a 24-bit RGB file otherwise (or a 32-bit RGBA file if `type = "cairo"` and non-opaque colours are used).

`png(type = "cairo1")` uses cairo directly to output the file – the resolution is not recorded and the PNG format used is chosen by cairo (and undocumented – it is currently 32-bit RGBA, that is with an alpha channel whether used or not). It is included for use on platforms with cairo 1.0 (where `type = "cairo"` is not available).

Value

A plot device is opened: nothing is returned to the R interpreter.

Warnings

Note that by default the `width` and `height` are in pixels not inches. A warning will be issued if both are less than 20.

If you plot more than one page on one of these devices and do not include something like `%d` for the sequence number in `file`, the file will contain the last page plotted.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is in pixels.
- Font sizes are in big points interpreted at `res dpi`.
- The default font family is Helvetica.
- Line widths in 1/96 inch, minimum one pixel for `type = "Xlib"`, 0.01 for `type = "cairo"`.
- For `type = "Xlib"` circle radii are in pixels with minimum one.
- Colours are interpreted by the viewing application.

For `type = "quartz"` see the help for [quartz](#).

Note

For `type = "Xlib"` these devices are based on the [X11](#) device. The colour model used will be that set up by `X11.options` at the time the first Xlib-based devices was opened (or the first after all such devices have been closed).

[Devices](#), [dev.print](#)

[capabilities](#) to see if these devices are supported by this build of R, and if `type = "cairo"` is supported.

[bitmap](#) provides an alternative way to generate PNG and JPEG plots that does not depend on accessing the X11 display but does depend on having GhostScript installed. (Devices `GDD` in CRAN package **GDD** and `CairoJPEG / CairoPNG` in CRAN package **Cairo** are further alternatives using several other additional pieces of software.)

Examples

```
## these examples will work only if the devices are available
## and either cairo or an X11 display is available.

## copy current plot to a (large) PNG file
## Not run: dev.print(png, file="myplot.png", width=1024, height=768)

png(file="myplot.png", bg="transparent")
plot(1:10)
rect(1, 5, 3, 7, col="white")
dev.off()

## will make myplot1.jpeg and myplot2.jpeg
jpeg(file="myplot%d.jpeg")
example(rect)
dev.off()
```

postscript *PostScript Graphics*

Description

postscript starts the graphics device driver for producing PostScript graphics.

Usage

```
postscript(file = ifelse(onefile, "Rplots.ps", "Rplot%03d.ps"),
           onefile, family, title, fonts, encoding, bg, fg,
           width, height, horizontal, pointsize,
           paper, pagecentre, print.it, command, colormodel)
```

Arguments

file	a character string giving the name of the file. If it is "", the output is piped to the command given by the argument <code>command</code> . If it is of the form " <code> cmd</code> ", the output is piped to the command given by ' <code>cmd</code> '. For use with <code>onefile = FALSE</code> give a <code>printf</code> format such as " <code>Rplot%03d.ps</code> " (the default in that case). The string should not otherwise contain a <code>%</code> : if it is really necessary, use <code>%%</code> in the string for <code>%</code> in the file name. A single integer format matching the regular expression " <code>%[#0 +--]*[0-9.]*[diouxX]</code> " is allowed.
onefile	logical: if true (the default) allow multiple figures in one file. If false, generate a file name containing the page number for each page and use an EPSF header and no DocumentMedia comment. Defaults to the TRUE.
family	the initial font family to be used, normally as a character string. See the section 'Families'. Defaults to "Helvetica".
title	title string to embed as the Title comment in the file. Defaults to "R Graphics Output".
fonts	a character vector specifying additional R graphics font family names for font families whose declarations will be included in the PostScript file and are available for use with the device. See 'Families' below. Defaults to NULL.
encoding	the name of an encoding file. Defaults to "default". The latter is interpreted as "ISOLatin1.enc" unless the locale is recognized as corresponding to a language using ISO 8859-5,7,13,15 or KOI8-R,U. The file is looked for in the 'enc' directory of package grDevices if the path does not contain a path separator. An extension ".enc" can be omitted.
bg	the initial background color to be used. If "transparent" (or any other non-opaque colour), no background is painted. Defaults to "transparent".
fg	the initial foreground color to be used. Defaults to "black".
width, height	the width and height of the graphics region in inches. Default to <code>t0</code> . If <code>paper != "special"</code> and <code>width</code> or <code>height</code> is less than 0.1 or too large to give a total margin of 0.5 inch, it is reset to the corresponding paper dimension minus 0.5.

<code>horizontal</code>	the orientation of the printed image, a logical. Defaults to true, that is landscape orientation on paper sizes with width less than height.
<code>pointsize</code>	the default point size to be used. Strictly speaking, in bp, that is 1/72 of an inch, but approximately in points. Defaults to 12.
<code>paper</code>	the size of paper in the printer. The choices are "a4", "letter" (or "us"), "legal" and "executive" (and these can be capitalized). Also, "special" can be used, when arguments <code>width</code> and <code>height</code> specify the paper size. A further choice is "default" (the default): If this is selected, the <code>papersize</code> is taken from the option " <code>papersize</code> " if that is set and to "a4" if it is unset or empty.
<code>pagecentre</code>	logical: should the device region be centred on the page? Defaults to true.
<code>print.it</code>	logical: should the file be printed when the device is closed? (This only applies if <code>file</code> is a real file name.) Defaults to false.
<code>command</code>	the command to be used for 'printing'. Defaults to "default", the value of option " <code>printcmd</code> ". The length limit is <code>2*PATH_MAX</code> , typically 8096 bytes.
<code>colormodel</code>	a character string describing the color model: currently allowed values as "rgb", "rgb-nogray", "gray" and "cmyk". Defaults to "rgb".

Details

All arguments except `file` default to values given by `ps.options()`. The ultimate defaults are quoted in the arguments section.

`postscript` opens the file `file` and the PostScript commands needed to plot any graphics requested are written to that file. This file can then be printed on a suitable device to obtain hard copy.

The `file` argument is interpreted as a C integer format as used by `sprintf`, with integer argument the page number. The default gives files 'Rplot001.ps', ..., 'Rplot999.ps', 'Rplot1000.ps', ...

The postscript produced for a single R plot is EPS (*Encapsulated PostScript*) compatible, and can be included into other documents, e.g., into LaTeX, using `\includegraphics{<filename>}`. For use in this way you will probably want to use `setEPS()` to set the defaults as `horizontal = FALSE`, `onefile = FALSE`, `paper = "special"`. Note that the bounding box is for the *device* region: if you find the white space around the plot region excessive, reduce the margins of the figure region via `par(mar=)`.

Most of the PostScript prologue used is taken from the R character vector `.ps.prolog`. This is marked in the output, and can be changed by changing that vector. (This is only advisable for PostScript experts: the standard version is in `namespace:grDevices`.)

A PostScript device has a default family, which can be set by the user via `family`. If other font families are to be used when drawing to the PostScript device, these must be declared when the device is created via `fonts`; the font family names for this argument are R graphics font family names (see the documentation for `postscriptFonts`).

Line widths as controlled by `par(lwd=)` are in multiples of 1/96 inch: multiples less than 1 are allowed. `pch="."` with `cex = 1` corresponds to a square of side 1/72 inch, which is also the 'pixel' size assumed for graphics parameters such as "`cra`".

When the background colour is fully transparent (as is the initial default value), the PostScript produced does not paint the background. Almost all PostScript viewers will use a white canvas so the visual effect is if the background were white. This will not be the case when printing onto coloured paper, though.

Families

Font families are collections of fonts covering the five font faces, (conventionally plain, bold, italic, bold-italic and symbol) selected by the graphics parameter `par(font=)` or the grid parameter `gpar(fontface=)`. Font families can be specified either as an initial/default font family for the device via the `family` argument or after the device is opened by the graphics parameter `par(family=)` or the grid parameter `gpar(fontfamily=)`. Families which will be used in addition to the initial family must be specified in the `fonts` argument when the device is opened.

Font families are declared via a call to `postscriptFonts`.

The argument `family` specifies the initial/default font family to be used. In normal use it is one of "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" or "Times", and refers to the standard Adobe PostScript fonts families of those names which are included (or cloned) in all common PostScript devices.

Many PostScript emulators (including those based on `ghostscript`) use the URW equivalents of these fonts, which are "URWGothic", "URWBookman", "NimbusMon", "NimbusSan", "NimbusSanCond", "CenturySch", "URWPalladio" and "NimbusRom" respectively. If your PostScript device is using URW fonts, you will obtain access to more characters and more appropriate metrics by using these names. To make these easier to remember, "URWHelvetica" == "NimbusSan" and "URWTimes" == "NimbusRom" are also supported.

Another type of family makes use of CID-keyed fonts for East Asian languages – see `postscriptFonts`.

The `family` argument is normally a character string naming a font family, but family objects generated by `Type1Font` and `CIDFont` are also accepted. For compatibility with earlier versions of R, the initial family can also be specified as a vector of four or five afm files.

Note that R does not embed the font(s) used in the PostScript output: see `embedFonts` for a utility to help do so.

Encodings

Encodings describe which glyphs are used to display the character codes (in the range 0–255). Most commonly R uses ISOLatin1 encoding, and the examples for `text` are in that encoding. However, the encoding used on machines running R may well be different, and by using the `encoding` argument the glyphs can be matched to encoding in use. This suffices for European and Cyrillic languages, but not for CJK languages. For the latter, composite CID fonts are used. These fonts are useful for other languages: for example they may contain Greek glyphs. (The rest of this section applies only when CID fonts are not used.)

None of this will matter if only ASCII characters (codes 32–126) are used as all the encodings (except "TeXtext") agree over that range. Some encodings are supersets of ISOLatin1, too. However, if accented and special characters do not come out as you expect, you may need to change the encoding. Some other encodings are supplied with R: "WinAnsi.enc" and "MacRoman.enc" correspond to the encodings normally used on Windows and Classic MacOS (at least by Adobe), and "PDFDoc.enc" is the first 256 characters of the Unicode encoding, the standard for PDF. There are also encodings "ISOLatin2.enc", "CP1250.enc", "ISOLatin7.enc" (ISO 8859-13), "CP1257.enc", and "ISOLatin9.enc" (ISO 8859-15), "Cyrillic.enc" (ISO 8859-5), "KOI8-R.enc", "KOI8-U.enc", "CP1251.enc", "Greek.enc" (ISO 8859-7) and "CP1253.enc". Note that many glyphs in these encodings are not in the fonts corresponding to the standard families. (The Adobe ones for all but Courier, Helvetica and Times cover little more than Latin-1, whereas the URW ones also cover Latin-2, Latin-7, Latin-9 and Cyrillic but no Greek. The Adobe exceptions cover the Latin character sets, but not the Euro.)

If you specify the encoding, it is your responsibility to ensure that the PostScript font contains the glyphs used. One issue here is the Euro symbol which is in the WinAnsi and MacRoman encodings but may well not be in the PostScript fonts. (It is in the URW variants; it is not in the supplied Adobe Font Metric files.)

There is an exception. Character 45 ("-") is always set as minus (its value in Adobe ISOLatin1) even though it is hyphen in the other encodings. Hyphen is available as character 173 (octal 0255) in all the Latin encodings, Cyrillic and Greek. (This can be entered as "\uad" in a UTF-8 locale.) There are some discrepancies in accounts of glyphs 39 and 96: the supplied encodings (except CP1250 and CP1251) treat these as ‘quoteright’ and ‘quoteleft’ (rather than ‘quotesingle’/‘acute’ and ‘grave’ respectively), as they are in the Adobe documentation.

TeX fonts

TeX has traditionally made use of fonts such as Computer Modern which are encoded rather differently, in a 7-bit encoding. This encoding can be specified by `encoding = "TeXtext.enc"`, taking care that the ASCII characters `< > \ _ { }` are not available in those fonts.

There are supplied families `"ComputerModern"` and `"ComputerModernItalic"` which use this encoding, and which are only supported for `postscript` (and not `pdf`). They are intended to use with the Type 1 versions of the TeX CM fonts. It will normally be possible to include such output in TeX or LaTeX provided it is processed with `dvips -Ppfb -j0` or the equivalent on your system. (`-j0` turns off font subsetting.) When `family = "ComputerModern"` is used, the italic/bold-italic fonts used are slanted fonts (`cmsl10` and `cmbxsl10`). To use text italic fonts instead, set `family = "ComputerModernItalic"`.

These families use the TeX math italic and symbol fonts for a comprehensive but incomplete coverage of the glyphs covered by the Adobe symbol font in other families. This is achieved by special-casing the postscript code generated from the supplied ‘`CM_symbol_10.afm`’.

Color models

The default color model is RGB, with pure gray colors expressed as greyscales. Color model `"rgb-nogray"` uses only RGB, model `"cmyk"` only CMYK, and model `"gray"` only greyscales (and selecting any other colour is an error). Nothing in R specifies the interpretation of the RGB or CMYK color spaces, and the simplest possible conversion to CMYK is used (http://en.wikipedia.org/wiki/CMYK_color_model#Mapping_RGB_to_CMYK).

Printing

A postscript plot can be printed via `postscript` in two ways.

1. Setting `print.it = TRUE` causes the command given in argument `command` to be called with argument `"file"` when the device is closed. Note that the plot file is not deleted unless `command` arranges to delete it.
2. `file=""` or `file="|cmd"` can be used to print using a pipe on systems that support ‘`popen`’. Failure to open the command will probably be reported to the terminal but not to ‘`popen`’, in which case close the device by `dev.off` immediately.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 7 inches square.

- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are as a multiple of 1/96 inch, with no minimum.
- Circle of any radius are allowed.
- Colours are interpreted by the viewing/printing application.

Author(s)

Support for Computer Modern fonts is based on a contribution by Brian D'Urso (durso@hussle.harvard.edu).

More details of font families and encodings and especially handling text in a non-Latin-1 encoding and embedding fonts can be found in

Paul Murrell and Brian Ripley (2006) Non-standard fonts in PostScript and PDF graphics. *R News*, 6(2):41–47. http://cran.r-project.org/doc/Rnews/Rnews_2006-2.pdf.

Examples

```
require(graphics)
## Not run:
# open the file "foo.ps" for graphics output
postscript("foo.ps")
# produce the desired graph(s)
dev.off() # turn off the postscript device
postscript("|lp -dlw")
# produce the desired graph(s)
dev.off() # plot will appear on printer

# for URW PostScript devices
postscript("foo.ps", family = "NimbusSan")

## for inclusion in Computer Modern TeX documents, perhaps
postscript("cm_test.eps", width = 4.0, height = 3.0,
          horizontal = FALSE, onefile = FALSE, paper = "special",
          family = "ComputerModern", encoding = "TeXtext.enc")
## The resultant postscript file can be used by dvips -Ppfb -j0.

## To test out encodings, you can use
TestChars <- function(encoding="ISOLatin1", family="URWHelvetica")
{
  postscript(encoding=encoding, family=family)
  par(pty="s")
  plot(c(-1,16), c(-1,16), type="n", xlab="", ylab="",
        xaxs="i", yaxs="i")
  title(paste("Centred chars in encoding", encoding))
}
```

```

grid(17, 17, lty=1)
for(i in c(32:255)) {
  x <- i %% 16
  y <- i %/% 16
  points(x, y, pch=i)
}
dev.off()
}
## there will be many warnings. We use URW to get a complete enough
## set of font metrics.
TestChars()
TestChars("ISOLatin2")
TestChars("WinAnsi")
## End(Not run)

```

postscriptFonts *PostScript and PDF Font Families*

Description

These functions handle the translation of a R graphics font family name to a PostScript or PDF font description, used by the `postscript` or `pdf` graphics devices.

Usage

```

postscriptFonts(...)
pdfFonts(...)

```

Arguments

... either character strings naming mappings to display, or named arguments specifying mappings to add or change.

Details

If these functions are called with no argument they list all the existing mappings, whereas if they are called with named arguments they add (or change) mappings.

A PostScript or PDF device is created with a default font family (see the documentation for `postscript`), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for "family" in `par` and for "fontfamily" in `gpar` in the `grid` package).

The font family sent to the device is a simple string name, which must be mapped to a set of PostScript fonts. Separate lists of mappings for `postscript` and `pdf` devices are maintained for the current R session and can be added to by the user.

The `postscriptFonts` and `pdfFonts` functions can be used to list existing mappings and to define new mappings. The `Type1Font` and `CIDFont` functions can be used to create new mappings, when the `xxxFonts` function is used to add them to the database. See the examples.

Default mappings are provided for three device-independent family names: "sans" for a sans-serif font (to "Helvetica"), "serif" for a serif font (to "Times") and "mono" for a monospaced font (to "Courier").

Mappings for a number of standard Adobe fonts (and URW equivalents) are also provided: "AvantGarde", "Bookman", "Courier", "Helvetica", "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" and "Times"; "URWGothic", "URWBookman", "NimbusMon", "NimbusSan" (synonym "URWHelvetica"), "NimbusSanCond", "CenturySch", "URWPalladio" and "NimbusRom" (synonym "URWTimes").

There are also mappings for "ComputerModern" and "ComputerModernItalic".

Finally, there are some default mappings for East Asian locales described in a separate section.

The specification of font metrics and encodings is described in the help for the `postscript` function.

The fonts are not embedded in the resulting PostScript or PDF file, so software including the PostScript or PDF plot file should either embed the font outlines (usually from '.pfb' or '.pfa' files) or use DSC comments to instruct the print spooler or including application to do so (see also `embedFonts`).

A font family has both an R-level name, the argument name used when `postscriptFonts` was called, and an internal name, the `family` component. These two names are the same for all the pre-defined font families.

Once a font family is in use it cannot be changed. 'In use' means that it has been specified *via* a `family` or `fonts` argument to an invocation of the same graphics device already in the R session. (For these purposes `xfig` counts the same as `postscript` but only uses some of the predefined mappings.)

Value

A list of one or more font mappings.

East Asian fonts

There are some default mappings for East Asian locales: "Japan1", "Japan1HeiMin", "Japan1GothicBBB", and "Japan1Ryumin" for Japanese; "Korea1" and "Korea1deb" for Korean; "GB1" (Simplified Chinese) for mainland China and Singapore; "CNS1" (Traditional Chinese) for Hong Kong and Taiwan.

These refer to the following fonts

Japan1 (PS)	HeiseiKakuGo-W5 Linotype Japanese printer font
Japan1 (PDF)	KozMinPro-Regular-Acro from Adobe Reader 7.0 Japanese Font Pack
Japan1HeiMin (PS)	HeiseiMin-W3 Linotype Japanese printer font
Japan1HeiMin (PDF)	HeiseiMin-W3-Acro from Adobe Reader 7.0 Japanese Font Pack
Japan1GothicBBB	GothicBBB-Medium Japanese-market PostScript printer font
Japan1Ryumin	Ryumin-Light Japanese-market PostScript printer font
Korea1 (PS)	Baekmuk-Batang TrueType font found on some Linux systems
Korea1 (PDF)	HYSMyeongJoStd-Medium-Acro from Adobe Reader 7.0 Korean Font Pack
Korea1deb (PS)	Batang-Regular

	another name for Baekmuk-Batang
Korea1deb (PDF)	HYGothic-Medium-Acro from Adobe Reader 4.0 Korean Font Pack
GB1 (PS)	BousungEG-Light-GB TrueType font found on some Linux systems
GB1 (PDF)	STSong-Light-Acro from Adobe Reader 7.0 Simplified Chinese Font Pack
CNS1 (PS)	MOESung-Regular Ken Lunde's CJKV resources
CNS1 (PDF)	MSungStd-Light-Acro from Adobe Reader 7.0 Traditional Chinese Font Pack

Baekmuk-Batang can be found at <ftp://ftp.mizi.com/pub/baekmuk/>. BousungEG-Light-GB can be found at <ftp://ftp.gnu.org/pub/non-gnu/chinese-fonts-truetype/>. Ken Lunde's CJKV resources are at <ftp://ftp.oreilly.com/pub/examples/nutshell/cjkv/adobe/samples/>. These will need to be installed or otherwise made available to the postscript/PDF interpreter such as ghostscript (and not all interpreters can handle TrueType fonts).

You may well find that your postscript/PDF interpreters has been set up to provide aliases for many of these fonts. For example, ghostscript on Windows can optionally be installed to map common CJK fonts names to Windows TrueType fonts. (You may want to add the -Acro versions as well.)

Adding a mapping for a CID-keyed font is for gurus only.

Author(s)

Support for Computer Modern fonts is based on a contribution by Brian D'Urso (durso@hussle.harvard.edu).

Examples

```
postscriptFonts()
## This duplicates "ComputerModernItalic".
CMitalic <- Type1Font("ComputerModern2",
                    c("CM_regular_10.afm", "CM_boldx_10.afm",
                      "cmti10.afm", "cmbxti10.afm",
                      "CM_symbol_10.afm"),
                    encoding = "TeXtext.enc")
postscriptFonts(CMitalic = CMitalic)

## A CID font for Japanese using a different CMap and
## corresponding cmapEncoding.
`Jp_UCS-2` <- CIDFont("TestUCS2",
                    c("Adobe-Japan1-UniJIS-UCS2-H.afm",
                      "Adobe-Japan1-UniJIS-UCS2-H.afm",
                      "Adobe-Japan1-UniJIS-UCS2-H.afm",
                      "Adobe-Japan1-UniJIS-UCS2-H.afm"),
                    "UniJIS-UCS2-H", "UCS-2")
pdfFonts(`Jp_UCS-2` = `Jp_UCS-2`)
names(pdfFonts())
```

ps.options

Auxiliary Function to Set/View Defaults for Arguments of `postscript`

Description

The auxiliary function `ps.options` can be used to set or view (if called without arguments) the default values for some of the arguments to `postscript`.

`ps.options` needs to be called before calling `postscript`, and the default values it sets can be overridden by supplying arguments to `postscript`.

Usage

```
ps.options(..., reset = FALSE, override.check = FALSE)
```

```
setEPS(...)
```

```
setPS(...)
```

Arguments

`...` arguments `onfile`, `family`, `title`, `fonts`, `encoding`, `bg`, `fg`, `width`, `height`, `horizontal`, `pointsize`, `paper`, `pagecentre`, `print.it`, `command` and `colormodel` can be supplied. `onfile`, `horizontal` and `paper` are *ignored* for `setEPS` and `setPS`.

`reset` logical: should the defaults be reset to their ‘factory-fresh’ values?

`override.check`

logical argument passed to `check.options`. See the Examples.

Details

If both `reset = TRUE` and `...` are supplied the defaults are first reset to the ‘factory-fresh’ values and then the new values are applied.

For backwards compatibility argument `append` is accepted but ignored with a warning.

`setEPS` and `setPS` are wrappers to set defaults appropriate for figures for inclusion in documents (the default size is 7 inches square unless `width` or `height` is supplied) and for spooling to a PostScript printer respectively. For historical reasons the latter is the ultimate default.

Value

A named list of all the previous defaults. If `...` or `reset = TRUE` is supplied the result has the visibility flag turned off.

[postscript](#), [pdf.options](#)

Examples

```

ps.options(bg = "pink")
utils::str(ps.options())

### ---- error checking of arguments: ----
ps.options(width=0:12, onefile=0, bg=pi)
# override the check for 'width', but not 'bg':
ps.options(width=0:12, bg=pi, override.check = c(TRUE,FALSE))
utils::str(ps.options())
ps.options(reset = TRUE) # back to factory-fresh

```

quartz*MacOS X Quartz Device*

Description

quartz starts a graphics device driver for the Mac OS X System. It supports plotting both to the screen (the default) and to various graphics file formats.

Usage

```

quartz(title, width, height, pointsize, family, fontsmooth, antialias,
        type, file = NULL, bg, canvas, dpi)

quartz.options(..., reset = FALSE)

```

Arguments

title	title for the Quartz window (applies to on-screen output only), default "Quartz %d". A C-style format for an integer will be substituted by the device number (see the <code>file</code> argument to postscript for further details).
width	the width of the plotting area in inches. Default 7.
height	the height of the plotting area in inches. Default 7.
pointsize	the default pointsize to be used. Default 12.
family	this is the family name of the font that will be used by the device. Default "Helvetica".
fontsmooth	logical specifying if fonts should be smoothed. Default TRUE. Currently unused.
antialias	whether to use antialiasing. Default TRUE.
type	the type of output to use. See 'Details' for more information. Default "native".
file	an optional target for the graphics device. The default, NULL, selects a default name where one is needed. See 'Details' for more information.
bg	the initial background colour to use for the device. Default "transparent". An opaque colour such as "white" will normally be required on off-screen types that support transparency such as "png" and "tiff".
canvas	canvas colour to use for an on-screen device. Default "white", and will be forced to be an opaque colour.

<code>dpi</code>	resolution of the output. The default (<code>NA_real_</code>) for an on-screen display defaults to the resolution of the main screen, and to 72 dpi otherwise. See ‘Details’.
<code>...</code>	Any of the arguments to <code>quartz</code> except <code>file</code> .
<code>reset</code>	logical: should the defaults be reset to their defaults?

Details

The defaults for all but one of the arguments of `quartz` are set by `quartz.options`: the ‘Arguments’ section gives the ‘factory-fresh’ defaults.

The Quartz graphics device supports a variety of output types. On-screen output types are `"` or `"native"` (picks the best possible on-screen output), `"Cocoa"` (Mac OS X 10.4 and later) and `"Carbon"` (not currently implemented – potentially Mac OS X 10.3 and earlier). Off-screen output types produce output files and utilize the `file` argument. `type = "pdf"` gives PDF output. The following bitmap formats may be supported (on OS X 10.4 and later): `"png"`, `"jpeg"`, `"jpg"`, `"jpeg2000"`, `"tif"`, `"tiff"`, `"gif"`, `"psd"` (Adobe Photoshop), `"bmp"` (Windows bitmap), `"sgi"` and `"pict"`. (The availability of some formats is OS-version-dependent.)

To reproduce the default of older Quartz devices on-screen, set `dpi = 72` (for a permanent solution set `quartz.options(dpi = 72)`).

The `file` argument is used for off-screen drawing. The actual file is only created when the device is closed (e.g. using `dev.off()`). For the bitmap devices, the page number is substituted if a C integer format is included in the character string, e.g. `Rplot%03d.png`. (The result must be less than `PATH_MAX` characters long, and may be truncated if not. See [postscript](#) for further details.) If a `file` argument is not supplied, the default is `Rplots.pdf` or `Rplot%03d.type`.

If a device-independent R graphics font family is specified (e.g., via `par(family=)` in the graphics package), the Quartz device makes use of the Quartz font database (see `quartzFonts`) to convert the R graphics font family to a Quartz-specific font family description.

On-screen devices are launched with a semi-transparent canvas. Once a new plot is created, the canvas is first painted with the `canvas` colour and then the current background colour (which can be transparent or semi-transparent). Off-screen devices have no canvas colour, and so start with a transparent background where possible (e.g. `type="png"` and `type="tiff"`) – otherwise it appears that a solid white canvas is assumed in the Quartz code.

`title` can be used for on-screen output. It must be a single character string with an optional integer printf-style format that will be substituted by the device number. It is also optionally used (without a format) to give a title to a PDF file.

Calling `quartz()` sets `.Device` to `"quartz"` for on-scren devices and to `"quartz_off_screen"` otherwise.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Arial.
- Line widths are a multiple of 1/96 inch with no minimum set by R.
- Circle radii are real-valued with no minimum set by R.
- Colour interpretation is by the viewer, including the screen display.

See Also

[quartzFonts](#), [Devices](#).

[png](#) for way to access the bitmap types of this device via R's standard bitmap devices.

Examples

```
## Not run:
## put something this is your .Rprofile to customize the defaults
setHook(packageEvent("grDevices", "onLoad"),
        function(...) grDevices::quartz.options(width=8, height=6,
                                                pointsize=10))

## End(Not run)
```

quartzFonts

quartz Fonts

Description

These functions handle the translation of a device-independent R graphics font family name to a quartz font description.

Usage

```
quartzFont (family)
```

```
quartzFonts (...)
```

Arguments

<code>family</code>	a character vector containing the four PostScript font names for plain, bold, italic, and bolditalic versions of a font family.
<code>...</code>	either character strings naming mappings to display, or new (named) mappings to define.

Details

A quartz device is created with a default font (see the documentation for `quartz`), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for `gpar` in the `grid` package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to quartz fonts. A list of mappings is maintained and can be modified by the user.

The `quartzFonts` function can be used to list existing mappings and to define new mappings. The `quartzFont` function can be used to create a new mapping.

Default mappings are provided for three device-independent font family names: "sans" for a sans-serif font, "serif" for a serif font and "mono" for a monospaced font.

[quartz](#)

Examples

```
quartzFonts()  
quartzFonts("mono")
```

recordGraphics	<i>Record graphics operations</i>
----------------	-----------------------------------

Description

Records arbitrary code on the graphics engine display list. Useful for encapsulating calculations with graphical output that depends on the calculations. Intended *only* for expert use.

Usage

```
recordGraphics(expr, list, env)
```

Arguments

<code>expr</code>	object of mode expression or <code>call</code> or an unevaluated expression.
<code>list</code>	a list defining the environment in which <code>expr</code> is to be evaluated.
<code>env</code>	An environment specifying where R looks for objects not found in <code>envir</code> .

Details

The code in `expr` is evaluated in an environment constructed from `list`, with `env` as the parent of that environment.

All three arguments are saved on the graphics engine display list so that on a device resize or copying between devices, the original evaluation environment can be recreated and the code can be re-evaluated to reproduce the graphical output.

Value

The value from evaluating `expr`.

Warning

This function is not intended for general use. Incorrect or improper use of this function could lead to unintended and/or undesirable results.

An example of acceptable use is querying the current state of a graphics device or graphics system setting and then calling a graphics function.

An example of improper use would be calling the `assign` function to performing assignments in the global environment.

See Also

[eval](#)

Examples

```
require(graphics)

plot(1:10)
# This rectangle remains 1inch wide when the device is resized
recordGraphics(
  {
    rect(4, 2,
        4 + diff(par("usr")[1:2])/par("pin")[1], 3)
  },
  list(),
  getNamespace("graphics"))
```

recordPlot

Record and Replay Plots

Description

Functions to save the current plot in an R variable, and to replay it.

Usage

```
recordPlot()
replayPlot(x)
```

Arguments

x A saved plot.

Details

These functions record and replay the displaylist of the current graphics device. The returned object is of class "recordedplot", and `replayPlot` acts as a `print` method for that class.

Value

`recordPlot` returns an object of class "recordedplot".
`replayPlot` has no return value.

Warning

The format of recorded plots may change between R versions. Recorded plots should **not** be used as a permanent storage format for R plots.

R will always attempt to replay a recorded plot, but if the plot was recorded with a different R version then bad things may happen.

`rgb`*RGB Color Specification*

Description

This function creates colors corresponding to the given intensities (between 0 and `max`) of the red, green and blue primaries.

An alpha transparency value can also be specified (0 means fully transparent and `max` means opaque). If `alpha` is not specified, an opaque colour is generated.

The `names` argument may be used to provide names for the colors.

The values returned by these functions can be used with a `col=` specification in graphics functions or in `par`.

Usage

```
rgb(red, green, blue, alpha, names = NULL, maxColorValue = 1)
```

Arguments

`red`, `blue`, `green`, `alpha`

numeric vectors with values in $[0, M]$ where M is `maxColorValue`. When this is 255, the `red`, `blue`, `green`, and `alpha` values are coerced to integers in $0:255$ and the result is computed most efficiently.

`names`

character. The names for the resulting vector.

`maxColorValue`

number giving the maximum of the color values range, see above.

Details

The colors may be specified by passing a matrix or dataframe as argument `red`, and leaving `blue` and `green` missing. In this case the first three columns of `red` are taken to be the red, green and blue values.

Semi-transparent colors ($0 < \text{alpha} < 1$) are supported only on some devices: at the time of writing on the `pdf`, `windows`, `quartz` and `X11 (type="cairo")` devices and associated bitmap devices (`jpeg`, `png`, `bmp`, `tiff` and `bitmap`). They are supported by several third-party devices such as those in packages **Cairo**, **cairoDevice** and **JavaGD**. Only some of these devices support semi-transparent backgrounds.

Most other graphics devices plot semi-transparent colors as fully transparent, usually with a warning when first encountered.

Value

A character vector with elements of 7 or 9 characters, "#" followed by the red, blue, green and optionally alpha values in hexadecimal (after rescaling to $0 \dots 255$).

See Also

`col2rgb` for translating R colors to RGB vectors; `rainbow`, `hsv`, `hcl`, `gray`.

Examples

```

rgb(0,1,0)

rgb((0:15)/15, green=0, blue=0, names=paste("red",0:15,sep="."))

rgb(0, 0:12, 0, max = 255)# integer input

ramp <- colorRamp(c("red", "white"))
rgb( ramp(seq(0, 1, length = 5)), max = 255)

```

 rgb2hsv

RGB to HSV Conversion

Description

rgb2hsv transforms colors from RGB space (red/green/blue) into HSV space (hue/saturation/value).

Usage

```
rgb2hsv(r, g = NULL, b = NULL, gamma = 1, maxColorValue = 255)
```

Arguments

r vector of 'red' values in $[0, M]$, ($M = \text{maxColorValue}$) or 3-row rgb matrix.
g vector of 'green' values, or `NULL` when **r** is a matrix.
b vector of 'blue' values, or `NULL` when **r** is a matrix.
gamma a gamma-correction (supposedly applied to the r,g,b values previously), see `hsv(..., gamma)`.
maxColorValue number giving the maximum of the RGB color values range. The default 255 corresponds to the typical 0:255 RGB coding as in `col2rgb()`.

Details

Value (brightness) gives the amount of light in the color.
 Hue describes the dominant wavelength.
 Saturation is the amount of Hue mixed into the color.

Value

A matrix with a column for each color. The three rows of the matrix indicate hue, saturation and value and are named "h", "s", and "v" accordingly.

Author(s)

R interface by Wolfram Fischer <wolfram@fischer-zim.ch>;
 C code mainly by Nicholas Lewin-Koh <nikko@hailmail.net>.

Examples

```
## These (saturated, bright ones) only differ by hue
(rc <- col2rgb(c("red", "yellow","green","cyan", "blue", "magenta")))
(hc <- rgb2hsv(rc))
6 * hc["h",] # the hues are equispaced

(rgb3 <- floor(256 * matrix(stats::runif(3*12), 3,12)))
(hsv3 <- rgb2hsv(rgb3))
## Consistency :
stopifnot(rgb3 == col2rgb(hsv(h=hsv3[1,], s=hsv3[2,], v=hsv3[3,])),
           all.equal(hsv3, rgb2hsv(rgb3/255, maxColorValue = 1)))

## A (simplified) pure R version -- originally by Wolfram Fischer --
## showing the exact algorithm:
rgb2hsvR <- function(rgb, gamma = 1, maxColorValue = 255)
{
  if(!is.numeric(rgb)) stop("rgb matrix must be numeric")
  d <- dim(rgb)
  if(d[1] != 3) stop("rgb matrix must have 3 rows")
  n <- d[2]
  if(n == 0) return(cbind(c(h=1,s=1,v=1))[,0])
  rgb <- rgb/maxColorValue
  if(gamma != 1) rgb <- rgb ^ (1/gamma)

  ## get the max and min
  v <- apply( rgb, 2, max)
  s <- apply( rgb, 2, min)
  D <- v - s # range

  ## set hue to zero for undefined values (gray has no hue)
  h <- numeric(n)
  notgray <- ( s != v )

  ## blue hue
  idx <- (v == rgb[3,] & notgray )
  if (any (idx))
    h[idx] <- 2/3 + 1/6 * (rgb[1,idx] - rgb[2,idx]) / D[idx]
  ## green hue
  idx <- (v == rgb[2,] & notgray )
  if (any (idx))
    h[idx] <- 1/3 + 1/6 * (rgb[3,idx] - rgb[1,idx]) / D[idx]
  ## red hue
  idx <- (v == rgb[1,] & notgray )
  if (any (idx))
    h[idx] <- 1/6 * (rgb[2,idx] - rgb[3,idx]) / D[idx]

  ## correct for negative red
  idx <- (h < 0)
  h[idx] <- 1+h[idx]

  ## set the saturation
  s[! notgray] <- 0;
  s[notgray] <- 1 - s[notgray] / v[notgray]

  rbind( h=h, s=s, v=v )
}
```

```
}  
  
## confirm the equivalence:  
all.equal(rgb2hsv (rgb3),  
          rgb2hsvR(rgb3), tol=1e-14) # TRUE
```

savePlot

Save Cairo X11 Plot to File

Description

Save the current page of a cairo [X11](#) () device to a file.

Usage

```
savePlot(filename = paste("Rplot", type, sep="."),  
         type = c("png", "jpeg", "tiff", "bmp"),  
         device = dev.cur())
```

Arguments

filename	filename to save to.
type	file type: only "png" will be accepted for cairo version 1.0.
device	the device to save from.

Details

Only X11 devices of types "cairo" and "nbcairo" are supported.

This works by copying the image surface to a file. For PNG will always be a 24-bit per pixel PNG 'DirectClass' file, for JPEG the quality is 75% and for TIFF there is no compression.

At present the plot is saved after rendering onto the canvas (default opaque white), so for the default `bg = "transparent"` the effective background colour is the canvas colour.

Value

Invisible NULL.

trans3d

3D to 2D Transformation for Perspective Plots

Description

Projection of 3-dimensional to 2-dimensional points using a 4x4 viewing transformation matrix. Mainly for adding to perspective plots such as [persp](#).

Usage

```
trans3d(x, y, z, pmat)
```

Arguments

`x`, `y`, `z` numeric vectors of equal length, specifying points in 3D space.

`pmat` a 4×4 viewing transformation matrix, suitable for projecting the 3D coordinates (x, y, z) into the 2D plane using homogeneous 4D coordinates (x, y, z, t) ; such matrices are returned by [persp\(\)](#).

Value

a list with two components

`x`, `y` the projected 2d coordinates of the 3d input (x, y, z) .

Type1Font

Type 1 and CID Fonts

Description

These functions are used to define the translation of a R graphics font family name to a Type 1 or CID font descriptions, used by both the [postscript](#) and [pdf](#) graphics devices.

Usage

```
Type1Font(family, metrics, encoding = "default")
```

```
CIDFont(family, cmap, cmapEncoding, pdfresource = "")
```

Arguments

<code>family</code>	a character string giving the name to be used internally for a Type 1 or CID-keyed font family. This needs to uniquely identify each family, so if you modify a family which is in use (see postscriptFonts) you need to change the family name.
<code>metrics</code>	a character vector of four or five strings giving paths to the afm (Adobe Font Metric) files for the font.
<code>cmap</code>	the name of a CMap file for a CID-keyed font.
<code>encoding</code>	for <code>Type1Font</code> , the name of an encoding file. Defaults to "default", which maps on this platform to "ISOLatin1.enc". Otherwise, a file name in the 'enc' directory of the grDevices package, which is used if the path does not contain a path separator. An extension ".enc" can be omitted.
<code>cmapEncoding</code>	The name of a character encoding to be used with the named CMap file: strings will be translated to this encoding when written to the file.
<code>pdfresource</code>	A chunk of PDF code; only required for using a CID-keyed font on pdf; users should not be expected to provide this.

Details

For `Type1Fonts`, if four '.afm' files are supplied the fifth is taken to be "Symbol.afm". Relative paths are taken relative to the directory '*R_HOME*/library/grDevices/afm'. The fifth (symbol) font must be in AdobeSym encoding. However, the glyphs in the first four fonts are referenced by name and any encoding given within the '.afm' files is not used.

Glyphs in CID-keyed fonts are accessed by ID (number) and not by name. The CMap file maps encoded strings (usually in a MBCS) to IDs, so `cmap` and `cmapEncoding` specifications must match. There are no real bold or italic versions of CID fonts (bold/italic were very rarely used in traditional CJK typography), and for the `pdf` device all four font faces will be identical. However, for the `postscript` device, bold and italic (and bold italic) are emulated.

CID-keyed fonts are intended only for use for the glyphs of CJK languages, which are all monospaced and are all treated as filling the same bounding box. (Thus `plotmath` will work with such characters, but the spacing will be less carefully controlled than with Western glyphs.) The CID-keyed fonts do contain other characters, including a Latin alphabet: non-CJK glyphs are regarded as monospaced with half the width of CJK glyphs. This is often the case, but sometimes Latin glyphs designed for proportional spacing are used (and may look odd). We strongly recommend that CID-keyed fonts are **only** used for CJK glyphs.

Value

A list of class "Type1Font" or "CIDFont".

See Also

[postscript](#), [pdf](#), [postscriptFonts](#), and [pdfFonts](#).

Examples

```
## This duplicates "ComputerModernItalic".
CMitalic <- Type1Font("ComputerModern2",
  c("CM_regular_10.afm", "CM_boldx_10.afm",
    "cmti10.afm", "cmbxti10.afm",
    "CM_symbol_10.afm"),
```

```

        encoding = "TeXtext.enc")

## Not run:
## This could be used by
postscript(family = CMitalic)
## or
postscriptFonts(CMitalic = CMitalic) # once in a session
postscript(family = "CMitalic", encoding = "TeXtext.enc")
## End(Not run)

```

x11

X Window System Graphics

Description

X11 starts a graphics device driver for the X Window System (version 11). This can only be done on machines/accounts that have access to an X server.

x11 is recognized as a synonym for X11.

Usage

```

X11(display = "", width, height, pointsize, gamma, bg, canvas,
     fonts, xpos, ypos, title, type, antialias)

```

```

X11.options(..., reset = FALSE)

```

Arguments

display	the display on which the graphics window will appear. The default is to use the value in the user's environment variable <code>DISPLAY</code> . This is ignored (with a warning) if an X11 device is already open on another display.
width, height	the width and height of the plotting window, in inches. If NA, taken from the resources and if not specified there defaults to 7 inches. See also 'Resources'.
pointsize	the default pointsize to be used. Defaults to 12.
gamma	the gamma correction factor. This value is used to help ensure that the colours perceived are linearly related to RGB values (see hsv). By default 1 (default correction).
bg	colour, the initial background colour. Default "transparent".
canvas	colour. The colour of the canvas, which is visible only when the background colour is transparent. Should be a solid colour (and any alpha value will be ignored). Default "white".
fonts	X11 font description strings into which weight, slant and size will be substituted. There are two, the first for fonts 1 to 4 and the second for font 5, the symbol font. See section 'Fonts'.
xpos, ypos	integer: initial position of the top left corner of the window, in pixels. Negative values are from the opposite corner, e.g. <code>xpos=-100</code> says the top right corner should be 100 pixels from the right edge of the screen. If NA (the default), successive devices are cascaded in 20 pixel steps from the top left. See also 'Resources'.

<code>title</code>	character string, up to 100 bytes. With the default, "", a suitable title is created internally. A C-style format for an integer will be substituted by the device number (see the <code>file</code> argument to <code>postscript</code> for further details). How non-ASCII titles are handled is implementation-dependent.
<code>type</code>	character string, one of "Xlib" (the only type prior to R 2.7.0) or "cairo" or "nbcairo". The latter two will only be available if the system was compiled with support for cairo. Default "cairo" where available, otherwise "Xlib".
<code>antialias</code>	for cairo types, the type of anti-aliasing (if any) to be used. One of <code>c("default", "none", "gray", "subpixel")</code> .
<code>reset</code>	logical: should the defaults be reset to their defaults?
<code>...</code>	Any of the arguments to X11, plus <code>colortype</code> and <code>maxcubesize</code> (see section 'Colour Rendering').

Details

The defaults for all of the arguments of X11 are set by `X11.options`: the 'Arguments' section gives the 'factory-fresh' defaults.

The initial size and position are only hints, and may not be acted on by the window manager. Also, some systems (especially laptops) are set up to appear to have a screen of a different size to the physical screen.

Option `type` selects between two separate devices: R can be built with support for neither, `type = "Xlib"` or both. Where both are available, types "cairo" and "nbcairo" offer

- antialiasing of text and lines.
- translucent colours.
- scalable text, including to sizes like 4.5 pt.
- full support for UTF-8, so on systems with suitable fonts you can plot in many languages on a single figure (and this will work even in non-UTF-8 locales). The output should be locale-independent.

`type = "nbcairo"` is the same device as `type="cairo"` without buffering: which is faster will depend on the X11 connection. Both will be slower than `type = "Xlib"`, especially on a slow X11 connection as all the rendering is done on the machine running R rather than in the X server.

All devices which use an X11 server (including the `type = "Xlib"` versions of bitmap devices such as `png`) share internal structures, which means that they must use the same `display` and `visual`. If you want to change display, first close all such devices.

X11 Fonts

This section applies only to `type = "Xlib"`.

An initial/default font family for the device can be specified via the `fonts` argument, but if a device-independent R graphics font family is specified (e.g., via `par(family=)` in the graphics package), the X11 device makes use of the X11 font database (see `X11Fonts`) to convert the R graphics font family to an X11-specific font family description.

X11 chooses fonts by matching to a pattern, and it is quite possible that it will choose a font in the wrong encoding or which does not contain glyphs for your language (particularly common in `iso10646-1` fonts).

The `fonts` argument is a two-element character vector, and the first element will be crucial in successfully using non-Western-European fonts. Settings that have proved useful include

"*-mincho-%s-%s-***%d-***-***-***-***" for CJK languages and "-cronyx-helvetica-%s-%s-***%d-***-***-***-***" for Russian.

For UTF-8 locales, the XLC_LOCALE databases provide mappings between character encodings, and you may need to add an entry for your locale (e.g. Fedora Core 3 lacked one for ru_RU.utf8).

Cairo Fonts

The cairo-based device works directly with font family names such as "Helvetica" which should be selected by `par` or `gpar`. There are mappings for the three device-independent font families, "sans" for a sans-serif font (to "Helvetica"), "serif" for a serif font (to "Times") and "mono" for a monospaced font (to "Courier").

The font selection is handled by `Pango` (usually) or `cairo` (on Mac OS X and perhaps elsewhere). Both make use of `fontconfig` (<http://www.fontconfig.org>) to select fonts and so the results depend on the fonts installed on the system running `R` – setting the environment variable `FC_DEBUG` to 1 allows some tracing of the selection process.

This works best when high-quality scalable fonts are installed, usually in Type 1 or TrueType formats: see the “R Installation and Administration Manual” for advice on how to obtain and install such fonts.

Resources

The standard X11 resource `geometry` can be used to specify the window position and/or size, but will be overridden by values specified as arguments or non-NA defaults set in `X11.options`. The class looked for is `R_x11`. Note that the resource specifies the width and height in pixels and not in inches. See for example http://web.mit.edu/answers/xwindows/xwindows_resources.html and perhaps ‘man X’ (or <http://www.xfree86.org/current/X.7.html>). An example line in ‘`.Xresources`’ might be

```
R_x11*geometry: 900x900-0+0
```

which specifies a 900 x 900 pixel window at the top right of the screen.

Colour Rendering

X11 supports several ‘visual’ types, and nowadays almost all systems support ‘truecolor’ which X11 will use by default. This uses a direct specification of any RGB colour up to the depth supported (usually 8 bits per colour). Other visuals make use of a palette to support fewer colours, only grays or even only black/white. The palette is shared between all X11 clients, so it can be necessary to limit the number of colours used by `R`.

Cairo-based devices currently support only ‘truecolor’ visuals. (Cairo 1.6 will support other visuals.)

The default for `type="Xlib"` is to use the best possible colour model for the visual of the X11 server. This can be overridden by the `colortype` argument of `X11.options`. **Note:** All X11 and `type = "Xlib"` `bmp`, `jpeg`, `png` and `tiff` devices share a `colortype` which is set when the first device to be opened. To change the `colortype` you need to close *all* open such devices, and then use `X11.options(colortype=)`.

The `colortype` types are tried in the order "true", "pseudo", "gray" and "mono" (black or white only). The values "pseudo" and "pseudo.cube" provide colour strategies for a pseudocolor visual. The first strategy provides on-demand colour allocation which produces exact colours until the colour resources of the display are exhausted (when plotting will fail). The second allocates (if possible) a standard colour cube, and requested colours are approximated by the closest value in the cube.

With `colortype` equal to `"pseudo.cube"` or `"gray"` successively smaller palettes are tried until one is completely allocated. If allocation of the smallest attempt fails the device will revert to `"mono"`. For `"gray"` the search starts at 256 grays for a display with depth greater than 8, otherwise with half the available colours. For `"pseudo.cube"` the maximum cube size is set by `X11.options(maxcolorsize=)` and defaults to 256. With that setting the largest cube tried is 4 levels each for RGB, using 64 colours in the palette.

Anti-aliasing

Anti-aliasing is only supported for cairo-based devices, and applies to graphics and to fonts. It is generally preferable for lines and text, but can lead to undesirable effects for fills, e.g. for `image` plots, and so is never used for fills.

`antialias = "default"` is in principle platform-dependent, but seems most often equivalent to `antialias = "gray"`.

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is 7 inches square.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths in 1/96 inch, minimum one pixel for `type = "Xlib"`, 0.01 otherwise.
- For `type = "Xlib"` circle radii are in pixels with minimum one.
- Colours are interpreted by the X11 server, normally in a fair approximation to sRGB.

Examples

```
## Not run:
## put something this is your .Rprofile to customize the defaults
setHook(packageEvent("grDevices", "onLoad"),
        function(...) grDevices::X11.options(width=8, height=6, xpos=0,
                                                pointsize=10))
## End(Not run)
```

X11Fonts

X11 Fonts

Description

These functions handle the translation of a device-independent R graphics font family name to an X11 font description.

Usage

```
X11Font(font)

X11Fonts(...)
```

Arguments

<code>font</code>	a character string containing an X11 font description.
<code>...</code>	either character strings naming mappings to display, or new (named) mappings to define.

Details

These functions apply only to an [X11](#) device with `type = "Xlib"` - [X11](#) (`type = "Cairo"` uses a different mechanism to select fonts).

Such a device is created with a default font (see the documentation for [X11](#)), but it is also possible to specify a font family when drawing to the device (for example, see the documentation for "family" in [par](#) and for "fontfamily" in [gpar](#) in the **grid** package).

The font family sent to the device is a simple string name, which must be mapped to something more specific to X11 fonts. A list of mappings is maintained and can be modified by the user.

The `X11Fonts` function can be used to list existing mappings and to define new mappings. The `X11Font` function can be used to create a new mapping.

Default mappings are provided for three device-independent font family names: "sans" for a sans-serif font, "serif" for a serif font and "mono" for a monospaced font.

See Also

[X11](#)

Examples

```
X11Fonts()
X11Fonts("mono")
utopia <- X11Font("--utopia-*****-*****-*****")
X11Fonts(utopia=utopia)
```

Description

`xfig` starts the graphics device driver for producing XFig (version 3.2) graphics.

The auxiliary function `ps.options` can be used to set and view (if called without arguments) default values for the arguments to `xfig` and `postscript`.

Usage

```
xfig(file = ifelse(onefile, "Rplots.fig", "Rplot%03d.fig"),
     onefile = FALSE, encoding = "none",
     paper = "default", horizontal = TRUE,
     width = 0, height = 0, family = "Helvetica",
     pointsize = 12, bg = "transparent", fg = "black",
     pagecentre = TRUE)
```

Arguments

file	a character string giving the name of the file. For use with <code>onefile = FALSE</code> give a C integer format such as "Rplot%03d.fig" (the default in that case). (See postscript for further details.)
onefile	logical: if true allow multiple figures in one file. If false, assume only one page per file and generate a file number containing the page number.
encoding	The encoding in which to write text strings. The default is not to re-encode. This can be any encoding recognized by <code>iconv</code> : in a Western UTF-8 locale you probably want to select an 8-bit encoding such as <code>latin1</code> , and in an East Asian locale an EUC encoding. If re-encoding fails, the text strings will be written in the current encoding with a warning.
paper	the size of paper region. The choices are "A4", "Letter" and "Legal" (and these can be lowercase). A further choice is "default", which is the default. If this is selected, the <code>papersize</code> is taken from the option "papersize" if that is set to a non-empty value, otherwise "A4".
horizontal	the orientation of the printed image, a logical. Defaults to true, that is landscape orientation.
width, height	the width and height of the graphics region in inches. The default is to use the entire page less a 0.5 inch overall margin in each direction. (See postscript for further details.)
family	the font family to be used. This must be one of "AvantGarde", "Bookman", "Courier", "Helvetica" (the default), "Helvetica-Narrow", "NewCenturySchoolbook", "Palatino" or "Times". Any other value is replaced by "Helvetica", with a warning.
pointsize	the default point size to be used.
bg	the initial background color to be used.
fg	the initial foreground color to be used.
pagecentre	logical: should the device region be centred on the page?

Details

Although `xfig` can produce multiple plots in one file, the XFig format does not say how to separate or view them. So `onefile = FALSE` is the default.

The `file` argument is interpreted as a C integer format as used by `sprintf`, with integer argument the page number. The default gives files 'Rplot001.fig', ..., 'Rplot999.fig', 'Rplot1000.fig',

Line widths as controlled by `par(lwd=)` are in multiples of $5/6 * 1/72$ inch. Multiples less than 1 are allowed. `pch="."` with `cex = 1` corresponds to a square of side $1/72$ inch.

Windows users can make use of WinFIG (<http://www.schmidt-web-berlin.de/WinFIG.htm>, shareware).

Conventions

This section describes the implementation of the conventions for graphics devices set out in the “R Internals Manual”.

- The default device size is the paper size with a 0.25 inch border on all sides.
- Font sizes are in big points.
- The default font family is Helvetica.
- Line widths are integers, multiples of 5/432 inch.
- Circle radii are multiples of 1/1200 inch.
- Colours are interpreted by the viewing/printing application.

Note

Only some line textures ($0 \leq \text{lt}_y < 4$) are used. Eventually this may be partially remedied, but the XFig file format does not allow as general line textures as the R model. Unimplemented line textures are displayed as *dash-double-dotted*.

There is a limit of 512 colours (plus white and black) per file.

[Devices](#), [postscript](#), [ps.options](#).

xy.coords

Extracting Plotting Structures

Description

`xy.coords` is used by many functions to obtain x and y coordinates for plotting. The use of this common mechanism across all relevant R functions produces a measure of consistency.

Usage

```
xy.coords(x, y = NULL, xlab = NULL, ylab = NULL, log = NULL,  
          recycle = FALSE)
```

Arguments

<code>x, y</code>	the x and y coordinates of a set of points. Alternatively, a single argument <code>x</code> can be provided.
<code>xlab, ylab</code>	names for the x and y variables to be extracted.
<code>log</code>	character, "x", "y" or both, as for <code>plot</code> . Sets negative values to <code>NA</code> and gives a warning.
<code>recycle</code>	logical; if <code>TRUE</code> , recycle (rep) the shorter of <code>x</code> or <code>y</code> if their lengths differ.

Details

An attempt is made to interpret the arguments `x` and `y` in a way suitable for bivariate plotting (or other bivariate procedures).

If `y` is `NULL` and `x` is a

formula: of the form `yvar ~ xvar`. `xvar` and `yvar` are used as `x` and `y` variables.

list: containing components `x` and `y`, these are used to define plotting coordinates.

time series: the `x` values are taken to be `time(x)` and the `y` values to be the time series.

matrix or data.frame with two or more columns: the first is assumed to contain the `x` values and the second the `y` values. *Note* that is also true if `x` has columns named `"x"` and `"y"`; these names will be irrelevant here.

In any other case, the `x` argument is coerced to a vector and returned as `y` component where the resulting `x` is just the index vector `1:n`. In this case, the resulting `xlab` component is set to `"Index"`.

If `x` (after transformation as above) inherits from class `"POSIXt"` it is coerced to class `"POSIXct"`.

Value

A list with the components

<code>x</code>	numeric (i.e., "double") vector of abscissa values.
<code>y</code>	numeric vector of the same length as <code>x</code> .
<code>xlab</code>	character(1) or <code>NULL</code> , the 'label' of <code>x</code> .
<code>ylab</code>	character(1) or <code>NULL</code> , the 'label' of <code>y</code> .

See Also

`plot.default`, `lines`, `points` and `lowess` are examples of functions which use this mechanism.

Examples

```
xy.coords(stats::fft(c(1:10)), NULL)

with(cars, xy.coords(dist ~ speed, NULL)$xlab ) # = "speed"

xy.coords(1:3, 1:2, recycle=TRUE)
xy.coords(-2:10, NULL, log="y")
##> warning: 3 y values <=0 omitted ..
```

xyTable	<i>Multiplicities of (x,y) Points, e.g., for a Sunflower Plot</i>
---------	---

Description

Given (x,y) points, determine their multiplicity – checking for equality only up to some (crude kind of) noise. Note that this is special kind of 2D binning.

Usage

```
xyTable(x, y = NULL, digits)
```

Arguments

x, y	numeric vectors of the same length; alternatively other (x,y) argument combinations as allowed by <code>xy.coords(x, y)</code> .
digits	integer specifying the significant digits to be used for determining equality of coordinates. These are compared after rounding them via <code>signif(*, digits)</code> .

Value

A list with three components of same length,

x	x coordinates, rounded and sorted.
y	y coordinates, rounded (and sorted within x).
number	multiplicities (positive integers); i.e., <code>number[i]</code> is the multiplicity of <code>(x[i], y[i])</code> .

See Also

[sunflowerplot](#) which typically uses `xyTable()`; [signif](#).

Examples

```
xyTable(iris[,3:4], digits = 6)

## Discretized uncorrelated Gaussian:

require(stats)
xy <- data.frame(x = round(sort(rnorm(100))), y = rnorm(100))
xyTable(xy, digits = 1)
```

xyz.coords

*Extracting Plotting Structures***Description**

Utility for obtaining consistent x, y and z coordinates and labels for three dimensional (3D) plots.

Usage

```
xyz.coords(x, y = NULL, z = NULL,
           xlab = NULL, ylab = NULL, zlab = NULL,
           log = NULL, recycle = FALSE)
```

Arguments

<code>x, y, z</code>	the x, y and z coordinates of a set of points. Both y and z can be left at NULL. In this case, an attempt is made to interpret x in a way suitable for plotting. If the argument is a formula <code>zvar ~ xvar + yvar</code> , <code>xvar</code> , <code>yvar</code> and <code>zvar</code> are used as x, y and z variables; if the argument is a list containing components x, y and z, these are assumed to define plotting coordinates; if the argument is a matrix or <code>data.frame</code> with three or more columns, the first is assumed to contain the x values, the 2nd the y ones, and the 3rd the z ones – independently of any column names that x may have. Alternatively two arguments x and y can be provided (leaving <code>z = NULL</code>). One may be real, the other complex; in any other case, the arguments are coerced to vectors and the values plotted against their indices.
<code>xlab, ylab, zlab</code>	names for the x, y and z variables to be extracted.
<code>log</code>	character, "x", "y", "z" or combinations. Sets negative values to NA and gives a warning.
<code>recycle</code>	logical; if TRUE, recycle (<code>rep</code>) the shorter ones of x, y or z if their lengths differ.

Value

A list with the components

<code>x</code>	numeric (i.e., <code>double</code>) vector of abscissa values.
<code>y</code>	numeric vector of the same length as x.
<code>z</code>	numeric vector of the same length as x.
<code>xlab</code>	character(1) or NULL, the axis label of x.
<code>ylab</code>	character(1) or NULL, the axis label of y.
<code>zlab</code>	character(1) or NULL, the axis label of z.

Chapter 4

The graphics package

graphics-package *The R Graphics Package*

Description

R functions for base graphics

Details

This package contains functions for base graphics. Base graphics are traditional S graphics, as opposed to the newer [grid](#) graphics.

For a complete list of functions with individual help pages, use `library(help="graphics")`.

Author(s)

R Development Core Team and contributors worldwide

Maintainer: R Core Team <R-core@r-project.org>

Murrell, P. (2005) *R Graphics*. Chapman & Hall/CRC Press.

abline *Add Straight Lines to a Plot*

Description

This function adds one or more straight lines through the current plot.

Usage

```
abline(a = NULL, b = NULL, h = NULL, v = NULL, reg = NULL,  
       coef = NULL, untf = FALSE, ...)
```

Arguments

<code>a, b</code>	the intercept and slope, single values.
<code>untf</code>	logical asking whether to <i>untransform</i> . See ‘Details’.
<code>h</code>	the y-value(s) for horizontal line(s).
<code>v</code>	the x-value(s) for vertical line(s).
<code>coef</code>	a vector of length two giving the intercept and slope.
<code>reg</code>	an object with a <code>coef</code> method. See ‘Details’.
<code>...</code>	graphical parameters such as <code>col</code> , <code>lty</code> and <code>lwd</code> (possibly as vectors: see ‘Details’) and the line characteristics <code>lend</code> , <code>ljoin</code> and <code>lmitre</code> .

Details

Typical usages are

```
abline(a, b, untf = FALSE, ...)
abline(h=, untf = FALSE, ...)
abline(v=, untf = FALSE, ...)
abline(coef=, untf = FALSE, ...)
abline(reg=, untf = FALSE, ...)
```

The first form specifies the line in intercept/slope form (alternatively `a` can be specified on its own and is taken to contain the slope and intercept in vector form).

The `h=` and `v=` forms draw horizontal and vertical lines at the specified coordinates.

The `coef` form specifies the line by a vector containing the slope and intercept.

`reg` is a regression object with a `coef` method. If this returns a vector of length 1 then the value is taken to be the slope of a line through the origin, otherwise, the first 2 values are taken to be the intercept and slope.

If `untf` is true, and one or both axes are log-transformed, then a curve is drawn corresponding to a line in original coordinates, otherwise a line is drawn in the transformed coordinate system. The `h` and `v` parameters always refer to original coordinates.

The graphical parameters `col`, `lty` and `lwd` can be specified; see [par](#) for details. For the `h=` and `v=` usages they can be vectors of length greater than one, recycled as necessary.

See Also

[lines](#) and [segments](#) for connected and arbitrary lines given by their *endpoints*. [par](#).

Examples

```
## Setup up coordinate system (with x==y aspect ratio):
plot(c(-2,3), c(-1,5), type = "n", xlab="x", ylab="y", asp = 1)
## the x- and y-axis, and an integer grid
abline(h=0, v=0, col = "gray60")
text(1,0, "abline( h = 0 )", col = "gray60", adj = c(0, -.1))
```

```

abline(h = -1:5, v = -2:3, col = "lightgray", lty=3)
abline(a=1, b=2, col = 2)
text(1,3, "abline( 1, 2 )", col=2, adj=c(-.1,-.1))

## Simple Regression Lines:
require(stats)
sale5 <- c(6, 4, 9, 7, 6, 12, 8, 10, 9, 13)
plot(sale5)
abline(lsfit(1:10,sale5))
abline(lsfit(1:10,sale5, intercept = FALSE), col= 4) # less fitting

z <- lm(dist ~ speed, data = cars)
plot(cars)
abline(z) # equivalent to abline(reg = z) or
abline(coef = coef(z))

## trivial intercept model
abline(mC <- lm(dist ~ 1, data = cars)) ## the same as
abline(a = coef(mC), b = 0, col = "blue")

```

arrows

*Add Arrows to a Plot***Description**

Draw arrows between pairs of points.

Usage

```

arrows(x0, y0, x1, y1, length = 0.25, angle = 30, code = 2,
       col = par("fg"), lty = par("lty"), lwd = par("lwd"),
       ...)

```

Arguments

<code>x0, y0</code>	coordinates of points from which to draw.
<code>x1, y1</code>	coordinates of points to which to draw.
<code>length</code>	length of the edges of the arrow head (in inches).
<code>angle</code>	angle from the shaft of the arrow to the edge of the arrow head.
<code>code</code>	integer code, determining <i>kind</i> of arrows to be drawn.
<code>col, lty, lwd</code>	graphical parameters, possible vectors. NA values in <code>col</code> cause the arrow to be omitted.
<code>...</code>	graphical parameters such as <code>xpd</code> and the line characteristics <code>lend</code> , <code>ljoin</code> and <code>lmitre</code> : see par .

Details

For each i , an arrow is drawn between the point $(x0[i], y0[i])$ and the point $(x1[i], y1[i])$. The coordinate vectors will be recycled to the length of the longest.

If `code=1` an arrowhead is drawn at $(x0[i], y0[i])$ and if `code=2` an arrowhead is drawn at $(x1[i], y1[i])$. If `code=3` a head is drawn at both ends of the arrow. Unless `length = 0`, when no head is drawn.

The graphical parameters `col`, `lty` and `lwd` can be vectors of length greater than one and will be recycled if necessary.

The direction of a zero-length arrow is indeterminate, and hence so is the direction of the arrowheads. To allow for rounding error, arrowheads are omitted (with a warning) on any arrow of length less than 1/1000 inch.

Note

The first four arguments in the comparable S function are named $x1, y1, x2, y2$.

[segments](#) to draw segments.

Examples

```
x <- stats::runif(12); y <- stats::rnorm(12)
i <- order(x,y); x <- x[i]; y <- y[i]
plot(x,y, main="arrows(.) and segments(.)")
## draw arrows from point to point :
s <- seq(length(x)-1)# one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col= 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col= 'pink')
```

 assocplot

Association Plots

Description

Produce a Cohen-Friendly association plot indicating deviations from independence of rows and columns in a 2-dimensional contingency table.

Usage

```
assocplot(x, col = c("black", "red"), space = 0.3,
          main = NULL, xlab = NULL, ylab = NULL)
```

Arguments

<code>x</code>	a two-dimensional contingency table in matrix form.
<code>col</code>	a character vector of length two giving the colors used for drawing positive and negative Pearson residuals, respectively.
<code>space</code>	the amount of space (as a fraction of the average rectangle width and height) left between each rectangle.
<code>main</code>	overall title for the plot.
<code>xlab</code>	a label for the x axis. Defaults to the name (if any) of the row dimension in <code>x</code> .
<code>ylab</code>	a label for the y axis. Defaults to the name (if any) of the column dimension in <code>x</code> .

Details

For a two-way contingency table, the signed contribution to Pearson's χ^2 for cell i, j is $d_{ij} = (f_{ij} - e_{ij})/\sqrt{e_{ij}}$, where f_{ij} and e_{ij} are the observed and expected counts corresponding to the cell. In the Cohen-Friendly association plot, each cell is represented by a rectangle that has (signed) height proportional to d_{ij} and width proportional to $\sqrt{e_{ij}}$, so that the area of the box is proportional to the difference in observed and expected frequencies. The rectangles in each row are positioned relative to a baseline indicating independence ($d_{ij} = 0$). If the observed frequency of a cell is greater than the expected one, the box rises above the baseline and is shaded in the color specified by the first element of `col`, which defaults to black; otherwise, the box falls below the baseline and is shaded in the color specified by the second element of `col`, which defaults to red.

A more flexible and extensible implementation of association plots written in the grid graphics system is provided in the function `assoc` in the contributed package `vcd` (Meyer, Zeileis and Hornik, 2005).

x <- margin.table(HairEyeColor, c(1, 2))
x
assocplot(x, main = "Relation between hair and eye color")
```

Axis

Generic function to add an Axis to a Plot

Description

Generic function to add a suitable axis to the current plot.

Usage

```
Axis(x = NULL, at = NULL, ..., side, labels = NULL)
```

Arguments

<code>x</code>	an object which indicates the range over which an axis should be drawn
<code>at</code>	the points at which tick-marks are to be drawn.
<code>side</code>	an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
<code>labels</code>	this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tickpoints. If this is specified as a character or expression vector, <code>at</code> should be supplied and they should be the same length.
<code>...</code>	Arguments to be passed to methods and perhaps then to axis .

Details

This is a generic function. It works in a slightly non-standard way: if `x` is supplied and non-NULL it dispatches on `x`, otherwise if `at` is supplied and non-NULL it dispatches on `at`, and the default action is to call [axis](#), omitting argument `x`.

The idea is that for plots for which either or both of the axes are numerical but with a special interpretation, the standard plotting functions (including [boxplot](#), [contour](#), [coplot](#), [filled.contour](#), [pairs](#), [plot.default](#), [rug](#) and [stripchart](#)) will set up user coordinates and `Axis` will be called to label them appropriately.

There are "Date", "POSIXct" and "POSIXlt" methods which can pass an argument `format` onto the appropriate `axis` method (see [axis.POSIXct](#)).

Value

The numeric locations on the axis scale at which tick marks were drawn when the plot was first drawn (see 'Details').

This function is usually invoked for its side effect, which is to add an axis to an already existing plot.

See Also

[axis](#).

axis

*Add an Axis to a Plot***Description**

Adds an axis to the current plot, allowing the specification of the side, position, labels, and other options.

Usage

```
axis(side, at = NULL, labels = TRUE, tick = TRUE, line = NA,
      pos = NA, outer = FALSE, font = NA, lty = "solid",
      lwd = 1, lwd.ticks = lwd, col = NULL, col.ticks = NULL,
      hadj = NA, padj = NA, ...)
```

Arguments

side	an integer specifying which side of the plot the axis is to be drawn on. The axis is placed as follows: 1=below, 2=left, 3=above and 4=right.
at	the points at which tick-marks are to be drawn. Non-finite (infinite, NaN or NA) values are omitted. By default (when NULL) tickmark locations are computed, see ‘Details’ below.
labels	this can either be a logical value specifying whether (numerical) annotations are to be made at the tickmarks, or a character or expression vector of labels to be placed at the tickpoints. (Other objects are coerced by <code>as.graphicsAnnot()</code> .) If this is not logical, <code>at</code> should also be supplied and of the same length. If <code>labels</code> is of length zero after coercion, it has the same effect as supplying TRUE.
tick	a logical value specifying whether tickmarks and an axis line should be drawn
line	the number of lines into the margin at which the axis line will be drawn, if not NA.
pos	the coordinate at which the axis line is to be drawn: if not NA this overrides the value of <code>line</code> .
outer	a logical value indicating whether the axis should be drawn in the outer plot margin, rather than the standard plot margin.
font	font for text. Defaults to <code>par("font")</code> .
lty	line type for both the axis line and the tick marks.
lwd, lwd.ticks	line widths for the axis line and the tick marks. Zero or negative values will suppress the line or ticks.
col, col.ticks	colors for the axis line and the tick marks respectively. <code>col = NULL</code> means to use <code>par("fg")</code> , possibly specified inline, and <code>col=NULL</code> means to use whatever color <code>col</code> resolved to.
hadj	adjustment (see <code>par("adj")</code>) for all labels <i>parallel</i> (‘horizontal’) to the reading direction. If this is not a finite value, the default is used (centring for strings parallel to the axis, justification of the end nearest the axis otherwise).

`padj` adjustment for each tick label *perpendicular* to the reading direction. For labels parallel to the axes, `padj=0` means right or top alignment, and `padj=1` means left or bottom alignment. This can be a vector given a value for each string, and will be recycled as necessary.

If `padj` is not a finite value (the default), the value of `par("las")` determines the adjustment. For strings plotted perpendicular to the axis the default is to centre the string.

... other graphical parameters may also be passed as arguments to this function, particularly, `cex.axis`, `col.axis` and `font.axis` for axis annotation, `mgp` and `xaxp` or `yaxp` for positioning, `tck` or `tcl` for tick mark length and direction, `las` for vertical/horizontal label orientation, or `fg` instead of `col`, and `xpd` for clipping. See [par](#) on these.

Parameters `xaxt` (sides 1 and 3) and `yaxt` (sides 2 and 4) control if the axis is plotted at all.

Note that `lab` will partial match to argument `labels` unless the latter is also supplied. (Since the default axes have already been set up by `plot.window`, `lab` will not be acted on by `axis`.)

Details

The axis line is drawn from the lowest to the highest value of `at`, but will be clipped at the plot region. By default, only ticks which are drawn from points within the plot region (up to a tolerance for rounding error) are plotted, but the ticks and their labels may well extend outside the plot region. Use `xpd=TRUE` or `xpd=NA` to allow axes to extend further.

When `at = NULL`, pretty tick mark locations are computed internally (the same way `axTicks(side)` would) from `par("xaxp")` or `"yaxp"` and `par("xlog")` (or `"ylog"`). Note that these locations may change if an on-screen plot is resized (for example, if the `plot` argument `asp` (see `plot.window`) is set.)

If `labels` is not specified, the numeric values supplied or calculated for `at` are converted to character strings as if they were a numeric vector printed by `print.default(digits=7)`.

The code tries hard not to draw overlapping tick labels, and so will omit labels where they would abut or overlap previously drawn labels. This can result in, for example, every other tick being labelled. (The ticks are drawn left to right or bottom to top, and space at least the size of an 'm' is left between labels.)

If either `line` or `pos` is set, they (rather than `par("mgp")[3]`) determine the position of the axis line and tick marks, and the tick labels are placed `par("mgp")[2]` further lines into (or towards for `pos`) the margin.

Several of the graphics parameters affect the way axes are drawn. The vertical (for sides 1 and 3) positions of the axis and the tick labels are controlled by `mgp[2:3]` and `mex`, the size and direction of the ticks is controlled by `tck` and `tcl` and the appearance of the tick labels by `cex.axis`, `col.axis` and `font.axis` with orientation controlled by `las` (but not `srt`, unlike S which uses `srt` if `at` is supplied and `las` if it is not). Note that `adj` is not supported and labels are always centered. See [par](#) for details.

Value

The numeric locations on the axis scale at which tick marks were drawn when the plot was first drawn (see 'Details').

This function is usually invoked for its side effect, which is to add an axis to an already existing plot.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[Axis](#) for a generic interface.

[axTicks](#) returns the axis tick locations corresponding to `at=NULL`; [pretty](#) is more flexible for computing pretty tick coordinates and does *not* depend on (nor adapt to) the coordinate system in use.

Several graphics parameters affecting the appearance are documented in [par](#).

Examples

```
require(stats) # for rnorm
plot(1:4, rnorm(4), axes = FALSE)
axis(1, 1:4, LETTERS[1:4])
axis(2)
box() #- to make it look "as usual"

plot(1:7, rnorm(7), main = "axis() examples",
     type = "s", xaxt = "n", frame = FALSE, col = "red")
axis(1, 1:7, LETTERS[1:7], col.axis = "blue")
# unusual options:
axis(4, col = "violet", col.axis="dark violet", lwd = 2)
axis(3, col = "gold", lty = 2, lwd = 0.5)

# one way to have a custom x axis
plot(1:10, xaxt = "n")
axis(1, xaxp=c(2, 9, 7))
```

axis.POSIXct

Date and Date-time Plotting Functions

Description

Functions to plot objects of classes "POSIXlt", "POSIXct" and "Date" representing calendar dates and times.

Usage

```
axis.POSIXct(side, x, at, format, labels = TRUE, ...)
axis.Date(side, x, at, format, labels = TRUE, ...)

## S3 method for class 'POSIXct':
plot(x, y, xlab = "", ...)
## S3 method for class 'POSIXlt':
plot(x, y, xlab = "", ...)
## S3 method for class 'Date':
plot(x, y, xlab = "", ...)
```

Arguments

<code>x</code> , <code>at</code>	A date-time or date object.
<code>y</code>	numeric values to be plotted against <code>x</code> .
<code>xlab</code>	a character string giving the label for the x axis.
<code>side</code>	See axis .
<code>format</code>	See strptime .
<code>labels</code>	Either a logical value specifying whether annotations are to be made at the tick-marks, or a vector of character strings to be placed at the tickpoints.
<code>...</code>	Further arguments to be passed from or to other methods, typically graphical parameters or arguments of plot.default . For the <code>plot</code> methods, also <code>format</code> .

Details

The functions plot against an x-axis of date-times. `axis.POSIXct` and `axis.Date` work quite hard to choose suitable time units (years, months, days, hours, minutes or seconds) and a sensible output format, but this can be overridden by supplying a `format` specification.

If `at` is supplied it specifies the locations of the ticks and labels whereas if `x` is specified a suitable grid of labels is chosen. Printing of tick labels can be suppressed by using `labels = FALSE`.

Value

The locations on the axis scale at which tick marks were drawn.

See Also

[DateTimeClasses](#), [Dates](#) for details of the classes.

Examples

```
with(beaver1, {
  time <- strptime(paste(1990, day, time %% 100, time %% 100),
                  "%Y %j %H %M")
  plot(time, temp, type="l") # axis at 4-hour intervals.
  # now label every hour on the time axis
  plot(time, temp, type="l", xaxt="n")
  r <- as.POSIXct(round(range(time), "hours"))
  axis.POSIXct(1, at=seq(r[1], r[2], by="hour"), format="%H")
})

plot(.leap.seconds, 1:23, type="n", yaxt="n",
     xlab="leap seconds", ylab="", bty="n")
rug(.leap.seconds)
## or as dates
lps <- as.Date(.leap.seconds)
plot(lps, 1:23, type = "n", yaxt = "n", xlab = "leap seconds",
     ylab = "", bty = "n")
rug(lps)

## 100 random dates in a 10-week period
random.dates <- as.Date("2001/1/1") + 70*sort(stats::runif(100))
plot(random.dates, 1:100)
# or for a better axis labelling
```

```
plot(random.dates, 1:100, xaxt="n")
axis.Date(1, at=seq(as.Date("2001/1/1"), max(random.dates)+6, "weeks"))
axis.Date(1, at=seq(as.Date("2001/1/1"), max(random.dates)+6, "days"),
  labels = FALSE, tcl = -0.2)
```

axTicks

Compute Axis Tickmark Locations

Description

Compute pretty tickmark locations, the same way as R does internally. This is only non-trivial when `log` coordinates are active. By default, gives the `at` values which `axis(side)` would use.

Usage

```
axTicks(side, axp = NULL, usr = NULL, log = NULL)
```

Arguments

<code>side</code>	integer in 1:4, as for <code>axis</code> .
<code>axp</code>	numeric vector of length three, defaulting to <code>par("xaxp")</code> or <code>par("yaxp")</code> depending on the <code>side</code> argument.
<code>usr</code>	numeric vector of length four, defaulting to <code>par("usr")</code> giving horizontal ('x') and vertical ('y') user coordinate limits.
<code>log</code>	logical indicating if log coordinates are active; defaults to <code>par("xlog")</code> or <code>par("ylog")</code> .

Details

The `axp`, `usr`, and `log` arguments must be consistent as their default values (the `par(...)` results) are. If you specify all three (as non-NULL), the graphics environment is not used at all. Note that the meaning of `axp` alters very much when `log` is TRUE, see the documentation on `par(xaxp=.)`.

`axTicks()` can be regarded as an R implementation of the C function `CreateAtVector()` in `'.../src/main/plot.c'` which is called by `axis(side,*)` when no argument `at` is specified.

Value

numeric vector of coordinate values at which axis tickmarks can be drawn. By default, when only the first argument is specified, these values should be identical to those that `axis(side)` would use or has used.

See Also

`axis`, `par`. `pretty` uses the same algorithm (but independently of the graphics environment) and has more options. However it is not available for `log = TRUE`.

Examples

```

plot(1:7, 10*21:27)
axTicks(1)
axTicks(2)
stopifnot(identical(axTicks(1), axTicks(3)),
           identical(axTicks(2), axTicks(4)))

## Show how axTicks() and axis() correspond :
op <- par(mfrow = c(3,1))
for(x in 9999*c(1,2,8)) {
  plot(x, 9, log = "x")
  cat(formatC(par("xaxp"), width=5), ";", T <- axTicks(1), "\n")
  rug(T, col="red")
}
par(op)

```

barplot

*Bar Plots***Description**

Creates a bar plot with vertical or horizontal bars.

Usage

```

barplot(height, ...)

## Default S3 method:
barplot(height, width = 1, space = NULL,
        names.arg = NULL, legend.text = NULL, beside = FALSE,
        horiz = FALSE, density = NULL, angle = 45,
        col = NULL, border = par("fg"),
        main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
        xlim = NULL, ylim = NULL, xpd = TRUE, log = "",
        axes = TRUE, axisnames = TRUE,
        cex.axis = par("cex.axis"), cex.names = par("cex.axis"),
        inside = TRUE, plot = TRUE, axis.lty = 0, offset = 0,
        add = FALSE, ...)

```

Arguments

height	either a vector or matrix of values describing the bars which make up the plot. If height is a vector, the plot consists of a sequence of rectangular bars with heights given by the values in the vector. If height is a matrix and beside is FALSE then each bar of the plot corresponds to a column of height, with the values in the column giving the heights of stacked sub-bars making up the bar. If height is a matrix and beside is TRUE, then the values in each column are juxtaposed rather than stacked.
width	optional vector of bar widths. Re-cycled to length the number of bars drawn. Specifying a single value will have no visible effect unless xlim is specified.

space	the amount of space (as a fraction of the average bar width) left before each bar. May be given as a single number or one number per bar. If <code>height</code> is a matrix and <code>beside</code> is <code>TRUE</code> , <code>space</code> may be specified by two numbers, where the first is the space between bars in the same group, and the second the space between the groups. If not given explicitly, it defaults to <code>c(0, 1)</code> if <code>height</code> is a matrix and <code>beside</code> is <code>TRUE</code> , and to <code>0.2</code> otherwise.
<code>names.arg</code>	a vector of names to be plotted below each bar or group of bars. If this argument is omitted, then the names are taken from the <code>names</code> attribute of <code>height</code> if this is a vector, or the column names if it is a matrix.
<code>legend.text</code>	a vector of text used to construct a legend for the plot, or a logical indicating whether a legend should be included. This is only useful when <code>height</code> is a matrix. In that case given legend labels should correspond to the rows of <code>height</code> ; if <code>legend.text</code> is true, the row names of <code>height</code> will be used as labels if they are non-null.
<code>beside</code>	a logical value. If <code>FALSE</code> , the columns of <code>height</code> are portrayed as stacked bars, and if <code>TRUE</code> the columns are portrayed as juxtaposed bars.
<code>horiz</code>	a logical value. If <code>FALSE</code> , the bars are drawn vertically with the first bar to the left. If <code>TRUE</code> , the bars are drawn horizontally with the first at the bottom.
<code>density</code>	a vector giving the density of shading lines, in lines per inch, for the bars or bar components. The default value of <code>NULL</code> means that no shading lines are drawn. Non-positive values of <code>density</code> also inhibit the drawing of shading lines.
<code>angle</code>	the slope of shading lines, given as an angle in degrees (counter-clockwise), for the bars or bar components.
<code>col</code>	a vector of colors for the bars or bar components. By default, grey is used if <code>height</code> is a vector, and a gamma-corrected grey palette if <code>height</code> is a matrix.
<code>border</code>	the color to be used for the border of the bars. Use <code>border = NA</code> to omit borders. If there are shading lines, <code>border = TRUE</code> means use the same colour for the border as for the shading lines.
<code>main, sub</code>	overall and sub title for the plot.
<code>xlab</code>	a label for the x axis.
<code>ylab</code>	a label for the y axis.
<code>xlim</code>	limits for the x axis.
<code>ylim</code>	limits for the y axis.
<code>xpd</code>	logical. Should bars be allowed to go outside region?
<code>log</code>	string specifying if axis scales should be logarithmic; see <code>plot.default</code> .
<code>axes</code>	logical. If <code>TRUE</code> , a vertical (or horizontal, if <code>horiz</code> is true) axis is drawn.
<code>axisnames</code>	logical. If <code>TRUE</code> , and if there are <code>names.arg</code> (see above), the other axis is drawn (with <code>lty=0</code>) and labeled.
<code>cex.axis</code>	expansion factor for numeric axis labels.
<code>cex.names</code>	expansion factor for axis names (bar labels).
<code>inside</code>	logical. If <code>TRUE</code> , the lines which divide adjacent (non-stacked!) bars will be drawn. Only applies when <code>space = 0</code> (which it partly is when <code>beside = TRUE</code>).
<code>plot</code>	logical. If <code>FALSE</code> , nothing is plotted.
<code>axis.lty</code>	the graphics parameter <code>lty</code> applied to the axis and tick marks of the categorical (default horizontal) axis. Note that by default the axis is suppressed.

offset a vector indicating how much the bars should be shifted relative to the x axis.

add logical specifying if bars should be added to an already existing plot; defaults to FALSE.

... arguments to be passed to/from other methods. For the default method these can include further arguments (such as `axes`, `asp` and `main`) and graphical parameters (see `par`) which are passed to `plot.window()`, `title()` and `axis`.

Details

This is a generic function, it currently only has a default method. A formula interface may be added eventually.

Value

A numeric vector (or matrix, when `beside = TRUE`), say `mp`, giving the coordinates of *all* the bar midpoints drawn, useful for adding to the graph.

If `beside` is true, use `colMeans(mp)` for the midpoints of each *group* of bars, see example.

barplot(tN, col=gray.colors(20), log = "xy")

```

box

Draw a Box around a Plot

Description

This function draws a box around the current plot in the given color and linetype. The `bty` parameter determines the type of box drawn. See [par](#) for details.

Usage

```
box(which = "plot", lty = "solid", ...)
```

Arguments

<code>which</code>	character, one of "plot", "figure", "inner" and "outer".
<code>lty</code>	line type of the box.
<code>...</code>	further graphical parameters, such as <code>bty</code> , <code>col</code> , or <code>lwd</code> , see par . Note that <code>xpd</code> is not accepted as clipping is always to the device region.

Details

The choice of colour is complicated. If `col` was supplied and is not `NA`, it is used. Otherwise, if `fg` was supplied and is not `NA`, it is used. The final default is `par("col")`.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

[rect](#) for drawing of arbitrary rectangles.

Examples

```
plot(1:7, abs(stats::rnorm(7)), type = 'h', axes = FALSE)
axis(1, at = 1:7, labels = letters[1:7])
box(lty = '1373', col = 'red')
```

boxplot

*Box Plots***Description**

Produce box-and-whisker plot(s) of the given (grouped) values.

Usage

```
boxplot(x, ...)

## S3 method for class 'formula':
boxplot(formula, data = NULL, ..., subset, na.action = NULL)

## Default S3 method:
boxplot(x, ..., range = 1.5, width = NULL, varwidth = FALSE,
        notch = FALSE, outline = TRUE, names, plot = TRUE,
        border = par("fg"), col = NULL, log = "",
        pars = list(boxwex = 0.8, staplewex = 0.5, outwex = 0.5),
        horizontal = FALSE, add = FALSE, at = NULL)
```

Arguments

<code>formula</code>	a formula, such as $y \sim \text{grp}$, where y is a numeric vector of data values to be split into groups according to the grouping variable <code>grp</code> (usually a factor).
<code>data</code>	a data.frame (or list) from which the variables in <code>formula</code> should be taken.
<code>subset</code>	an optional vector specifying a subset of observations to be used for plotting.
<code>na.action</code>	a function which indicates what should happen when the data contain <code>NA</code> s. The default is to ignore missing values in either the response or the group.
<code>x</code>	for specifying data from which the boxplots are to be produced. Either a numeric vector, or a single list containing such vectors. Additional unnamed arguments specify further data as separate vectors (each corresponding to a component boxplot). <code>NA</code> s are allowed in the data.
<code>...</code>	For the <code>formula</code> method, named arguments to be passed to the default method. For the default method, unnamed arguments are additional data vectors (unless <code>x</code> is a list when they are ignored), and named arguments are arguments and graphical parameters to be passed to <code>bxp</code> in addition to the ones given by argument <code>pars</code> (and override those in <code>pars</code>).

range	this determines how far the plot whiskers extend out from the box. If <code>range</code> is positive, the whiskers extend to the most extreme data point which is no more than <code>range</code> times the interquartile range from the box. A value of zero causes the whiskers to extend to the data extremes.
width	a vector giving the relative widths of the boxes making up the plot.
varwidth	if <code>varwidth</code> is TRUE, the boxes are drawn with widths proportional to the square-roots of the number of observations in the groups.
notch	if <code>notch</code> is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap this is 'strong evidence' that the two medians differ (Chambers <i>et al.</i> , 1983, p. 62). See <code>boxplot.stats</code> for the calculations used.
outline	if <code>outline</code> is not true, the outliers are not drawn (as points whereas S+ uses lines).
names	group labels which will be printed under each boxplot. Can be a character vector or an expression (see <code>plotmath</code>).
boxwex	a scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower.
staplewex	staple line width expansion, proportional to box width.
outwex	outlier line width expansion, proportional to box width.
plot	if TRUE (the default) then a boxplot is produced. If not, the summaries which the boxplots are based on are returned.
border	an optional vector of colors for the outlines of the boxplots. The values in <code>border</code> are recycled if the length of <code>border</code> is less than the number of plots.
col	if <code>col</code> is non-null it is assumed to contain colors to be used to colour the bodies of the box plots. By default they are in the background colour.
log	character indicating if x or y or both coordinates should be plotted in log scale.
pars	a list of (potentially many) more graphical parameters, e.g., <code>boxwex</code> or <code>outpch</code> ; these are passed to <code>bxp</code> (if <code>plot</code> is true); for details, see there .
horizontal	logical indicating if the boxplots should be horizontal; default FALSE means vertical boxes.
add	logical, if true <code>add</code> boxplot to current plot.
at	numeric vector giving the locations where the boxplots should be drawn, particularly when <code>add = TRUE</code> ; defaults to <code>1:n</code> where <code>n</code> is the number of boxes.

Details

The generic function `boxplot` currently has a default method (`boxplot.default`) and a formula interface (`boxplot.formula`).

If multiple groups are supplied either as multiple arguments or via a formula, parallel boxplots will be plotted, in the order of the arguments or the order of the levels of the factor (see [factor](#)).

Missing values are ignored when forming boxplots.

Value

List with the following components:

<code>stats</code>	a matrix, each column contains the extreme of the lower whisker, the lower hinge, the median, the upper hinge and the extreme of the upper whisker for one group/plot. If all the inputs have the same class attribute, so will this component.
--------------------	---

n	a vector with the number of observations in each group.
conf	a matrix where each column contains the lower and upper extremes of the notch.
out	the values of any data points which lie beyond the extremes of the whiskers.
group	a vector of the same length as out whose elements indicate to which group the outlier belongs.
names	a vector of names for the groups.

Examples

```
## boxplot on a formula:
boxplot(count ~ spray, data = InsectSprays, col = "lightgray")
# *add* notches (somewhat funny here):
boxplot(count ~ spray, data = InsectSprays,
        notch = TRUE, add = TRUE, col = "blue")

boxplot(decrease ~ treatment, data = OrchardSprays,
        log = "y", col = "bisque")

rb <- boxplot(decrease ~ treatment, data = OrchardSprays, col="bisque")
title("Comparing boxplot()s and non-robust mean +/- SD")

mn.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, mean)
sd.t <- tapply(OrchardSprays$decrease, OrchardSprays$treatment, sd)
xi <- 0.3 + seq(rb$n)
points(xi, mn.t, col = "orange", pch = 18)
arrows(xi, mn.t - sd.t, xi, mn.t + sd.t,
       code = 3, col = "pink", angle = 75, length = .1)

## boxplot on a matrix:
mat <- cbind(Uni05 = (1:100)/21, Norm = rnorm(100),
            `5T` = rt(100, df = 5), Gam2 = rgamma(100, shape = 2))
boxplot(as.data.frame(mat),
        main = "boxplot(as.data.frame(mat), main = ...)")
par(las=1)# all axis labels horizontal
boxplot(as.data.frame(mat), main = "boxplot(*, horizontal = TRUE)",
        horizontal = TRUE)

## Using 'at = ' and adding boxplots -- example idea by Roger Bivand :

boxplot(len ~ dose, data = ToothGrowth,
```

```

boxwex = 0.25, at = 1:3 - 0.2,
subset = supp == "VC", col = "yellow",
main = "Guinea Pigs' Tooth Growth",
xlab = "Vitamin C dose mg",
ylab = "tooth length",
xlim = c(0.5, 3.5), ylim = c(0, 35), yaxs = "i")
boxplot(len ~ dose, data = ToothGrowth, add = TRUE,
        boxwex = 0.25, at = 1:3 + 0.2,
        subset = supp == "OJ", col = "orange")
legend(2, 9, c("Ascorbic acid", "Orange juice"),
      fill = c("yellow", "orange"))

## more examples in help(bxp)

```

bxp

*Draw Box Plots from Summaries***Description**

bxp draws box plots based on the given summaries in `z`. It is usually called from within `boxplot`, but can be invoked directly.

Usage

```

bxp(z, notch = FALSE, width = NULL, varwidth = FALSE,
    outline = TRUE, notch.frac = 0.5, log = "",
    border = par("fg"), pars = NULL, frame.plot = axes,
    horizontal = FALSE, add = FALSE, at = NULL, show.names = NULL,
    ...)

```

Arguments

<code>z</code>	a list containing data summaries to be used in constructing the plots. These are usually the result of a call to <code>boxplot</code> , but can be generated in any fashion.
<code>notch</code>	if <code>notch</code> is TRUE, a notch is drawn in each side of the boxes. If the notches of two plots do not overlap then the medians are significantly different at the 5 percent level.
<code>width</code>	a vector giving the relative widths of the boxes making up the plot.
<code>varwidth</code>	if <code>varwidth</code> is TRUE, the boxes are drawn with widths proportional to the square-roots of the number of observations in the groups.
<code>outline</code>	if <code>outline</code> is not true, the outliers are not drawn.
<code>notch.frac</code>	numeric in (0,1). When <code>notch=TRUE</code> , the fraction of the box width that the notches should use.
<code>border</code>	character or numeric (vector), the color of the box borders. Is recycled for multiple boxes. Is used as default for the <code>boxcol</code> , <code>medcol</code> , <code>whiskcol</code> , <code>staplecol</code> , and <code>outcol</code> options (see below).
<code>log</code>	character, indicating if any axis should be drawn in logarithmic scale, as in <code>plot.default</code> .
<code>frame.plot</code>	logical, indicating if a 'frame' (<code>box</code>) should be drawn; defaults to TRUE, unless <code>axes = FALSE</code> is specified.

<code>horizontal</code>	logical indicating if the boxplots should be horizontal; default <code>FALSE</code> means vertical boxes.
<code>add</code>	logical, if true <i>add</i> boxplot to current plot.
<code>at</code>	numeric vector giving the locations where the boxplots should be drawn, particularly when <code>add = TRUE</code> ; defaults to <code>1:n</code> where <code>n</code> is the number of boxes.
<code>show.names</code>	Set to <code>TRUE</code> or <code>FALSE</code> to override the defaults on whether an x-axis label is printed for each group.
<code>pars, ...</code>	graphical parameters (etc) can be passed as arguments to this function, either as a list (<code>pars</code>) or normally(<code>...</code>), see the following. (Those in <code>...</code> take precedence over those in <code>pars</code> .)

Currently, `yaxs` and `ylim` are used 'along the boxplot', i.e., vertically, when `horizontal` is false, and `xlim` horizontally. `xaxt`, `yaxt`, `las`, `cex.axis`, and `col.axis` are passed to `axis`, and `main`, `cex.main`, `col.main`, `sub`, `cex.sub`, `col.sub`, `xlab`, `ylab`, `cex.lab`, and `col.lab` are passed to `title`.

In addition, `axes` is accepted (see `plot.window`), with default `TRUE`.

The following arguments (or `pars` components) allow further customization of the boxplot graphics. Their defaults are typically determined from the non-prefixed version (e.g., `boxlty` from `lty`), either from the specified argument or `pars` component or the corresponding `par` one.

boxwex: a scale factor to be applied to all boxes. When there are only a few groups, the appearance of the plot can be improved by making the boxes narrower. The default depends on `at` and typically is 0.8.

staplewex, outwex: staple and outlier line width expansion, proportional to box width; both default to 0.5.

boxlty, boxlwd, boxcol, boxfill: box outline type, width, color, and fill color (which currently defaults to `col` and will in future default to `par("bg")`).

medlty, medlwd, medpch, medcex, medcol, medbg: median line type, line width, point character, point size expansion, color, and background color. The default `medpch = NA` suppresses the point, and `medlty = "blank"` does so for the line. Note that `medlwd` defaults to $3 \times$ the default `lwd`.

whisklty, whisklwd, whiskcol: whisker line type (default: `"dashed"`), width, and color.

staplelty, staplelwd, staplecol: staple (= end of whisker) line type, width, and color.

outlty, outlwd, outpch, outcex, outcol, outbg: outlier line type, line width, point character, point size expansion, color, and background color. The default `outlty = "blank"` suppresses the lines and `outpch = NA` suppresses points.

Value

An invisible vector, actually identical to the `at` argument, with the coordinates ("x" if horizontal is false, "y" otherwise) of box centers, useful for adding to the plot.

Note

if `add = FALSE`, the default is `xlim = c(0.5, n + 0.5)`. It will usually be a good idea to specify the latter if the "x" axis has a log scale or `at` is specified or `width` is far from uniform.

 cdplot

Conditional Density Plots

Description

Computes and plots conditional densities describing how the conditional distribution of a categorical variable y changes over a numerical variable x .

Usage

```
cdplot(x, ...)

## Default S3 method:
cdplot(x, y,
       plot = TRUE, tol.ylab = 0.05, ylevels = NULL,
       bw = "nrd0", n = 512, from = NULL, to = NULL,
       col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL,
       yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), ...)

## S3 method for class 'formula':
cdplot(formula, data = list(),
       plot = TRUE, tol.ylab = 0.05, ylevels = NULL,
       bw = "nrd0", n = 512, from = NULL, to = NULL,
       col = NULL, border = 1, main = "", xlab = NULL, ylab = NULL,
       yaxlabels = NULL, xlim = NULL, ylim = c(0, 1), ...,
       subset = NULL)
```

Arguments

<code>x</code>	an object, the default method expects either a single numerical variable.
<code>y</code>	a "factor" interpreted to be the dependent variable
<code>formula</code>	a "formula" of type $y \sim x$ with a single dependent "factor" and a single numerical explanatory variable.
<code>data</code>	an optional data frame.
<code>plot</code>	logical. Should the computed conditional densities be plotted?
<code>tol.ylab</code>	convenience tolerance parameter for y-axis annotation. If the distance between two labels drops under this threshold, they are plotted equidistantly.
<code>ylevels</code>	a character or numeric vector specifying in which order the levels of the dependent variable should be plotted.
<code>bw, n, from, to, ...</code>	arguments passed to density
<code>col</code>	a vector of fill colors of the same length as <code>levels(y)</code> . The default is to call gray.colors .
<code>border</code>	border color of shaded polygons.
<code>main, xlab, ylab</code>	character strings for annotation

yaxlabels character vector for annotation of y axis, defaults to levels(y).
 xlim, ylim the range of x and y values with sensible defaults.
 subset an optional vector specifying a subset of observations to be used for plotting.

Details

cdplot computes the conditional densities of x given the levels of y weighted by the marginal distribution of y . The densities are derived cumulatively over the levels of y .

This visualization technique is similar to spinograms (see [spineplot](#)) and plots $P(y|x)$ against x . The conditional probabilities are not derived by discretization (as in the spinogram), but using a smoothing approach via [density](#).

Note, that the estimates of the conditional densities are more reliable for high-density regions of x . Conversely, they are less reliable in regions with only few x observations.

Value

The conditional density functions (cumulative over the levels of y) are returned invisibly.

clip

Set Clipping Region

Description

Set clipping region in user coordinates

Usage

```
clip(x1, x2, y1, y2)
```

Arguments

```
x1, x2, y1, y2
      user coordinates of clipping rectangle
```

Details

How the clipping rectangle is set depends on the setting of `par("xpd")`: this function changes the current setting until the next high-level plotting command resets it.

Exactly when the clipping region will be reset can be hard to predict. `plot.new` always resets it. Functions such as `lines` and `text` only reset it if `par("xpd")` has been changed. However, functions such as `box`, `mtext`, `title` and `plot.dendrogram` can manipulate the `xpd` setting.

[par](#)

Examples

```
x <- rnorm(1000)
hist(x, xlim=c(-4,4))
usr <- par("usr")
clip(usr[1], -2, usr[3], usr[4])
hist(x, col = 'red', add = TRUE)
clip(2, usr[2], usr[3], usr[4])
hist(x, col = 'blue', add = TRUE)
do.call("clip", as.list(usr)) # reset to plot region
```

contour

*Display Contours***Description**

Create a contour plot, or add contour lines to an existing plot.

Usage

```
contour(x, ...)

## Default S3 method:
contour(x = seq(0, 1, length.out = nrow(z)),
        y = seq(0, 1, length.out = ncol(z)),
        z,
        nlevels = 10, levels = pretty(zlim, nlevels),
        labels = NULL,
        xlim = range(x, finite = TRUE),
        ylim = range(y, finite = TRUE),
        zlim = range(z, finite = TRUE),
        labcex = 0.6, drawlabels = TRUE, method = "flattest",
        vfont, axes = TRUE, frame.plot = axes,
        col = par("fg"), lty = par("lty"), lwd = par("lwd"),
        add = FALSE, ...)
```

Arguments

<code>x, y</code>	locations of grid lines at which the values in <code>z</code> are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If <code>x</code> is a list, its components <code>x\$x</code> and <code>x\$y</code> are used for <code>x</code> and <code>y</code> , respectively. If the list has component <code>z</code> this is used for <code>z</code> .
<code>z</code>	a matrix containing the values to be plotted (NAs are allowed). Note that <code>x</code> can be used instead of <code>z</code> for convenience.
<code>nlevels</code>	number of contour levels desired iff <code>levels</code> is not supplied.
<code>levels</code>	numeric vector of levels at which to draw contour lines.
<code>labels</code>	a vector giving the labels for the contour lines. If <code>NULL</code> then the levels are used as labels, otherwise this is coerced by <code>as.character</code> .
<code>labcex</code>	<code>cex</code> for contour labelling. This is an absolute size, not a multiple of <code>par("cex")</code> .
<code>drawlabels</code>	logical. Contours are labelled if <code>TRUE</code> .
<code>method</code>	character string specifying where the labels will be located. Possible values are "simple", "edge" and "flattest" (the default). See the 'Details' section.
<code>vfont</code>	if <code>NULL</code> , the current font family and face are used for the contour labels. If a character vector of length 2 then Hershey vector fonts are used for the contour labels. The first element of the vector selects a typeface and the second element selects a fontindex (see <code>text</code> for more information). The default is <code>NULL</code> on graphics devices with high-quality rotation of text and <code>c("sans serif", "plain")</code> otherwise.

<code>xlim, ylim, zlim</code>	x-, y- and z-limits for the plot.
<code>axes, frame.plot</code>	logical indicating whether axes or a box should be drawn, see plot.default .
<code>col</code>	color for the lines drawn.
<code>lty</code>	line type for the lines drawn.
<code>lwd</code>	line width for the lines drawn.
<code>add</code>	logical. If TRUE, add to a current plot.
<code>...</code>	additional arguments to plot.window , title , Axis and box , typically graphical parameters such as <code>cex.axis</code> .

Details

`contour` is a generic function with only a default method in base R.

The methods for positioning the labels on contours are "simple" (draw at the edge of the plot, overlaying the contour line), "edge" (draw at the edge of the plot, embedded in the contour line, with no labels overlapping) and "flattest" (draw on the flattest section of the contour, embedded in the contour line, with no labels overlapping). The second and third may not draw a label on every contour line.

For information about vector fonts, see the help for [text](#) and [Hershey](#).

Notice that `contour` interprets the `z` matrix as a table of $f(x[i], y[j])$ values, so that the `x` axis corresponds to row number and the `y` axis to column number, with column 1 at the bottom, i.e. a 90 degree clockwise rotation of the conventional textual layout.

Alternatively, use [contourplot](#) from the **lattice** package where the `formula` notation allows to use vectors `x, y, z` of the same length.

There is limited control over the axes and frame as arguments `col`, `lwd` and `lty` refer to the contour lines (rather than being general graphical parameters). For more control, add contours to a plot, or add axes and frame to a contour plot.

convertXY

Convert between Graphics Coordinate Systems

Description

Convert between graphics coordinate systems.

Usage

```

grconvertX(x, from = "user", to = "user")
grconvertY(y, from = "user", to = "user")

```

Arguments

`x, y` numeric vector of coordinates.
`from, to` character strings giving the coordinate systems to convert between.

Details

The coordinate systems are

"user" user coordinates.

"inches" inches.

"device" the device coordinate system.

"ndc" normalized device coordinates.

"nfc" normalized figure coordinates.

"npc" normalized plot coordinates.

"nic" normalized inner region coordinates. (The 'inner region' is that inside the outer margins.)

(These names can be partially matched.) For the 'normalized' coordinate systems the lower left has value 0 and the top right value 1.

Device coordinates are those in which the device works: they are usually in pixels where that makes sense and in big points (1/72 inch) otherwise (e.g. `pdf` and `postscript`).

Value

A numeric vector of the same length as the input.

Examples

```
op <- par(omd=c(0.1, 0.9, 0.1, 0.9), mfrow = c(1, 2))
plot(1:4)
for(tp in c("in", "dev", "ndc", "nfc", "npc", "nic"))
  print(grconvertX(c(1.0, 4.0), "user", tp))
par(op)
```

 coplot

Conditioning Plots

Description

This function produces two variants of the **conditioning plots** discussed in the reference below.

Usage

```
coplot(formula, data, given.values, panel = points, rows, columns,
       show.given = TRUE, col = par("fg"), pch = par("pch"),
       bar.bg = c(num = gray(0.8), fac = gray(0.95)),
       xlab = c(x.name, paste("Given :", a.name)),
       ylab = c(y.name, paste("Given :", b.name)),
       subscripts = FALSE,
       axlabels = function(f) abbreviate(levels(f)),
       number = 6, overlap = 0.5, xlim, ylim, ...)
co.intervals(x, number = 6, overlap = 0.5)
```

Arguments

formula	<p>a formula describing the form of conditioning plot. A formula of the form $y \sim x \mid a$ indicates that plots of y versus x should be produced conditional on the variable a. A formula of the form $y \sim x \mid a * b$ indicates that plots of y versus x should be produced conditional on the two variables a and b.</p> <p>All three or four variables may be either numeric or factors. When x or y are factors, the result is almost as if <code>as.numeric()</code> was applied, whereas for factor a or b, the conditioning (and its graphics if <code>show.given</code> is true) are adapted.</p>
data	a data frame containing values for any variables in the formula. By default the environment where <code>coplot</code> was called from is used.
given.values	<p>a value or list of two values which determine how the conditioning on a and b is to take place.</p> <p>When there is no b (i.e., conditioning only on a), usually this is a matrix with two columns each row of which gives an interval, to be conditioned on, but it can also be a single vector of numbers or a set of factor levels (if the variable being conditioned on is a factor). In this case (no b), the result of <code>co.intervals</code> can be used directly as <code>given.values</code> argument.</p>
panel	a <code>function(x, y, col, pch, ...)</code> which gives the action to be carried out in each panel of the display. The default is <code>points</code> .
rows	the panels of the plot are laid out in a <code>rows</code> by <code>columns</code> array. <code>rows</code> gives the number of rows in the array.
columns	the number of columns in the panel layout array.
show.given	logical (possibly of length 2 for 2 conditioning variables): should conditioning plots be shown for the corresponding conditioning variables (default TRUE)
col	a vector of colors to be used to plot the points. If too short, the values are recycled.
pch	a vector of plotting symbols or characters. If too short, the values are recycled.
bar.bg	a named vector with components "num" and "fac" giving the background colors for the (shingle) bars, for numeric and factor conditioning variables respectively.
xlab	character; labels to use for the x axis and the first conditioning variable. If only one label is given, it is used for the x axis and the default label is used for the conditioning variable.
ylab	character; labels to use for the y axis and any second conditioning variable.
subscripts	logical: if true the panel function is given an additional (third) argument <code>subscripts</code> giving the subscripts of the data passed to that panel.
axlabels	function for creating axis (tick) labels when x or y are factors.
number	integer; the number of conditioning intervals, for a and b , possibly of length 2. It is only used if the corresponding conditioning variable is not a <code>factor</code> .
overlap	numeric < 1 ; the fraction of overlap of the conditioning variables, possibly of length 2 for x and y direction. When <code>overlap</code> < 0 , there will be <i>gaps</i> between the data slices.
xlim	the range for the x axis.
ylim	the range for the y axis.
...	additional arguments to the panel function.
x	a numeric vector.

Details

In the case of a single conditioning variable `a`, when both `rows` and `columns` are unspecified, a ‘close to square’ layout is chosen with `columns >= rows`.

In the case of multiple `rows`, the *order* of the panel plots is from the bottom and from the left (corresponding to increasing `a`, typically).

A panel function should not attempt to start a new plot, but just plot within a given coordinate system: thus `plot` and `boxplot` are not panel functions.

The rendering of arguments `xlab` and `ylab` is not controlled by `par` arguments `cex.lab` and `font.lab` even though they are plotted by `mtext` rather than `title`.

Value

`co.intervals(., number, .)` returns a $(\text{number} \times 2)$ *matrix*, say `ci`, where `ci[k,]` is the *range* of `x` values for the `k`-th interval.

Examples

```
## Tonga Trench Earthquakes
coplot(lat ~ long | depth, data = quakes)
given.depth <- co.intervals(quakes$depth, number=4, overlap=.1)
coplot(lat ~ long | depth, data = quakes, given.v=given.depth, rows=1)

## Conditioning on 2 variables:
ll.dm <- lat ~ long | depth * mag
coplot(ll.dm, data = quakes)
coplot(ll.dm, data = quakes, number=c(4,7), show.given=c(TRUE,FALSE))
coplot(ll.dm, data = quakes, number=c(3,7),
       overlap=c(-.5,.1)) # negative overlap DROPS values

## given two factors
Index <- seq(length=nrow(warpbreaks)) # to get nicer default labels
coplot(breaks ~ Index | wool * tension, data = warpbreaks,
       show.given = 0:1)
coplot(breaks ~ Index | wool * tension, data = warpbreaks,
       col = "red", bg = "pink", pch = 21,
       bar.bg = c(fac = "light blue"))

## Example with empty panels:
with(data.frame(state.x77), {
  coplot(Life.Exp ~ Income | Illiteracy * state.region, number = 3,
        panel = function(x, y, ...) panel.smooth(x, y, span = .8, ...))
  ## y ~ factor -- not really sensible, but 'show off':
  coplot(Life.Exp ~ state.region | Income * state.division,
        panel = panel.smooth)
```

```
  })
```

```
curve
```

Draw Function Plots

Description

Draws a curve corresponding to the given function or, for `curve()` also an expression (in `x`) over the interval `[from, to]`.

Usage

```
curve(expr, from = NULL, to = NULL, n = 101, add = FALSE,
      type = "l", ylab = NULL, log = NULL, xlim = NULL, ...)

## S3 method for class 'function':
plot(x, y = 0, to = 1, from = y, xlim = NULL, ...)
```

Arguments

<code>expr</code>	an expression written as a function of <code>x</code> , or alternatively the name of a function which will be plotted.
<code>x</code>	a ‘vectorizing’ numeric R function.
<code>from, to</code>	the range over which the function will be plotted.
<code>n</code>	integer; the number of <code>x</code> values at which to evaluate.
<code>add</code>	logical; if TRUE add to already existing plot.
<code>xlim</code>	numeric of length 2; if specified, it serves as default for <code>c(from, to)</code> .
<code>type</code>	plot type: see <code>plot.default</code> .
<code>y</code>	alias for <code>from</code> for compatibility with <code>plot()</code>
<code>ylab, log, ...</code>	labels and graphical parameters can also be specified as arguments. <code>plot.function</code> passes all these to <code>curve</code> .

Details

The evaluation of `expr` is at `n` points equally spaced over the range `[from, to]`, possibly adapted to log scale. The points determined in this way are then joined with straight lines. `x(t)` or `expr` (with `x` inside) must return a numeric of the same length as the argument `t` or `x`.

For `curve()`, if either of `from` or `to` is `NULL`, it defaults to the corresponding element of `xlim`, and `xlim` defaults to the `x`-limits of the current plot. For `plot(<function>, ...)`, the defaults for `(from, to)` are `(0, 1)`.

`log` is taken from the current plot only when `add` is true, and otherwise defaults to "" indicating linear scales on both axes.

This used to be a quick hack which now seems to serve a useful purpose, but can give bad results for functions which are not smooth.

For expensive-to-compute expressions, you should use smarter tools.

See Also

[splinefun](#) for spline interpolation, [lines](#).

Examples

```
plot(qnorm)
plot(qlogis, main = "The Inverse Logit : qlogis()")
abline(h=0, v=0:2/2, lty=3, col="gray")

curve(sin, -2*pi, 2*pi)
curve(tan, main = "curve(tan) --> same x-scale as previous plot")

op <- par(mfrow=c(2,2))
curve(x^3-3*x, -2, 2)
curve(x^2-2, add = TRUE, col = "violet")

## simple and sophisticated, quite similar:
plot(cos, -pi, 3*pi)
plot(cos, xlim = c(-pi,3*pi), n = 1001, col = "blue", add=TRUE)

chippy <- function(x) sin(cos(x)*exp(-x/2))
curve(chippy, -8, 7, n=2001)
plot(chippy, -8, -5)

for(ll in c("", "x", "y", "xy"))
  curve(log(1+x), 1,100, log=ll, sub=paste("log= ",ll,"",sep=""))
par(op)
```

dotchart

Cleveland Dot Plots

Description

Draw a Cleveland dot plot.

Usage

```
dotchart(x, labels = NULL, groups = NULL, gdata = NULL,
         cex = par("cex"), pch = 21, gpch = 21, bg = par("bg"),
         color = par("fg"), gcolor = par("fg"), lcolor = "gray",
         xlim = range(x[is.finite(x)]),
         main = NULL, xlab = NULL, ylab = NULL, ...)
```

Arguments

<code>x</code>	either a vector or matrix of numeric values (NAs are allowed). If <code>x</code> is a matrix the overall plot consists of juxtaposed dotplots for each row.
<code>labels</code>	a vector of labels for each point. For vectors the default is to use names(<code>x</code>) and for matrices the row labels <code>dimnames(x)[[1]]</code> .
<code>groups</code>	an optional factor indicating how the elements of <code>x</code> are grouped. If <code>x</code> is a matrix, <code>groups</code> will default to the columns of <code>x</code> .

gdata	data values for the groups. This is typically a summary such as the median or mean of each group.
cex	the character size to be used. Setting <code>cex</code> to a value smaller than one can be a useful way of avoiding label overlap. Unlike many other graphics functions, this sets the actual size, not a multiple of <code>par("cex")</code> .
pch	the plotting character or symbol to be used.
gpch	the plotting character or symbol to be used for group values.
bg	the background color of plotting characters or symbols to be used; use <code>par(bg=*)</code> to set the background color of the whole plot.
color	the color(s) to be used for points and labels.
gcolor	the single color to be used for group labels and values.
lcolor	the color(s) to be used for the horizontal lines.
xlim	horizontal range for the plot, see <code>plot.window</code> , e.g.
main	overall title for the plot, see <code>title</code> .
xlab, ylab	axis annotations as in <code>title</code> .
...	graphical parameters can also be specified as arguments.

Value

This function is invoked for its side effect, which is to produce two variants of dotplots as described in Cleveland (1985).

Dot plots are a reasonable substitute for bar plots.

         main = "Death Rates in Virginia - 1940")
par(op)
```

filled.contour *Level (Contour) Plots*

Description

This function produces a contour plot with the areas between the contours filled in solid color (Cleveland calls this a level plot). A key showing how the colors map to z values is shown to the right of the plot.

Usage

```
filled.contour(x = seq(0, 1, length.out = nrow(z)),
              y = seq(0, 1, length.out = ncol(z)),
              z,
              xlim = range(x, finite=TRUE),
              ylim = range(y, finite=TRUE),
              zlim = range(z, finite=TRUE),
              levels = pretty(zlim, nlevels), nlevels = 20,
              color.palette = cm.colors,
              col = color.palette(length(levels) - 1),
              plot.title, plot.axes, key.title, key.axes,
              asp = NA, xaxs = "i", yaxs = "i", las = 1,
              axes = TRUE, frame.plot = axes, ...)
```

Arguments

<code>x, y</code>	locations of grid lines at which the values in <code>z</code> are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If <code>x</code> is a list, its components <code>x\$x</code> and <code>x\$y</code> are used for <code>x</code> and <code>y</code> , respectively. If the list has component <code>z</code> this is used for <code>z</code> .
<code>z</code>	a matrix containing the values to be plotted (NAs are allowed). Note that <code>x</code> can be used instead of <code>z</code> for convenience.
<code>xlim</code>	<code>x</code> limits for the plot.
<code>ylim</code>	<code>y</code> limits for the plot.
<code>zlim</code>	<code>z</code> limits for the plot.
<code>levels</code>	a set of levels which are used to partition the range of <code>z</code> . Must be strictly increasing (and finite). Areas with <code>z</code> values between consecutive levels are painted with the same color.
<code>nlevels</code>	if <code>levels</code> is not specified, the range of <code>z</code> , values is divided into approximately this many levels.
<code>color.palette</code>	a color palette function to be used to assign colors in the plot.
<code>col</code>	an explicit set of colors to be used in the plot. This argument overrides any palette function specification.
<code>plot.title</code>	statements which add titles to the main plot.
<code>plot.axes</code>	statements which draw axes (and a <code>box</code>) on the main plot. This overrides the default axes.
<code>key.title</code>	statements which add titles for the plot key.
<code>key.axes</code>	statements which draw axes on the plot key. This overrides the default axis.
<code>asp</code>	the y/x aspect ratio, see <code>plot.window</code> .
<code>xaxs</code>	the <code>x</code> axis style. The default is to use internal labeling.
<code>yaxs</code>	the <code>y</code> axis style. The default is to use internal labeling.
<code>las</code>	the style of labeling to be used. The default is to use horizontal labeling.
<code>axes, frame.plot</code>	logicals indicating if axes and a box should be drawn, as in <code>plot.default</code> .
<code>...</code>	additional graphical parameters, currently only passed to <code>title()</code> .

Note

This function currently uses the `layout` function and so is restricted to a full page display. As an alternative consider the `levelplot` and `contourplot` functions from the **lattice** package which work in multipanel displays.

The output produced by `filled.contour` is actually a combination of two plots; one is the filled contour and one is the legend. Two separate coordinate systems are set up for these two plots, but they are only used internally - once the function has returned these coordinate systems are lost. If you want to annotate the main contour plot, for example to add points, you can specify graphics commands in the `plot.axes` argument. An example is given below.

Examples

```
require(grDevices) # for colours
filled.contour(volcano, color = terrain.colors, asp = 1)# simple

x <- 10*1:nrow(volcano)
y <- 10*1:ncol(volcano)
filled.contour(x, y, volcano, color = terrain.colors,
  plot.title = title(main = "The Topography of Maunga Whau",
    xlab = "Meters North", ylab = "Meters West"),
  plot.axes = { axis(1, seq(100, 800, by = 100))
    axis(2, seq(100, 600, by = 100)) },
  key.title = title(main="Height\n(meters)"),
  key.axes = axis(4, seq(90, 190, by = 10))# maybe also asp=1
mtext(paste("filled.contour(.) from", R.version.string),
  side = 1, line = 4, adj = 1, cex = .66)

# Annotating a filled contour plot
a <- expand.grid(1:20, 1:20)
b <- matrix(a[,1] + a[,2], 20)
filled.contour(x = 1:20, y = 1:20, z = b,
  plot.axes={ axis(1); axis(2); points(10,10) })

## Persian Rug Art:
x <- y <- seq(-4*pi, 4*pi, len = 27)
r <- sqrt(outer(x^2, y^2, "+"))
filled.contour(cos(r^2)*exp(-r/(2*pi)), axes = FALSE)
## rather, the key *should* be labeled:
filled.contour(cos(r^2)*exp(-r/(2*pi)), frame.plot = FALSE,
  plot.axes = {})
```

fourfoldplot

*Fourfold Plots***Description**

Creates a fourfold display of a 2 by 2 by k contingency table on the current graphics device, allowing for the visual inspection of the association between two dichotomous variables in one or several populations (strata).

Usage

```
fourfoldplot(x, color = c("#99CCFF", "#6699CC"),
             conf.level = 0.95,
             std = c("margins", "ind.max", "all.max"),
             margin = c(1, 2), space = 0.2, main = NULL,
             mfrow = NULL, mfcol = NULL)
```

Arguments

<code>x</code>	a 2 by 2 by k contingency table in array form, or as a 2 by 2 matrix if k is 1.
<code>color</code>	a vector of length 2 specifying the colors to use for the smaller and larger diagonals of each 2 by 2 table.
<code>conf.level</code>	confidence level used for the confidence rings on the odds ratios. Must be a single nonnegative number less than 1; if set to 0, confidence rings are suppressed.
<code>std</code>	a character string specifying how to standardize the table. Must be one of "margins", "ind.max", or "all.max", and can be abbreviated by the initial letter. If set to "margins", each 2 by 2 table is standardized to equate the margins specified by <code>margin</code> while preserving the odds ratio. If "ind.max" or "all.max", the tables are either individually or simultaneously standardized to a maximal cell frequency of 1.
<code>margin</code>	a numeric vector with the margins to equate. Must be one of 1, 2, or <code>c(1, 2)</code> (the default), which corresponds to standardizing the row, column, or both margins in each 2 by 2 table. Only used if <code>std</code> equals "margins".
<code>space</code>	the amount of space (as a fraction of the maximal radius of the quarter circles) used for the row and column labels.
<code>main</code>	character string for the fourfold title.
<code>mfrow</code>	a numeric vector of the form <code>c(nr, nc)</code> , indicating that the displays for the 2 by 2 tables should be arranged in an <code>nr</code> by <code>nc</code> layout, filled by rows.
<code>mfcol</code>	a numeric vector of the form <code>c(nr, nc)</code> , indicating that the displays for the 2 by 2 tables should be arranged in an <code>nr</code> by <code>nc</code> layout, filled by columns.

Details

The fourfold display is designed for the display of 2 by 2 by k tables.

Following suitable standardization, the cell frequencies f_{ij} of each 2 by 2 table are shown as a quarter circle whose radius is proportional to $\sqrt{f_{ij}}$ so that its area is proportional to the cell frequency. An association (odds ratio different from 1) between the binary row and column variables is indicated by the tendency of diagonally opposite cells in one direction to differ in size from those

in the other direction; color is used to show this direction. Confidence rings for the odds ratio allow a visual test of the null of no association; the rings for adjacent quadrants overlap if and only if the observed counts are consistent with the null hypothesis.

Typically, the number k corresponds to the number of levels of a stratifying variable, and it is of interest to see whether the association is homogeneous across strata. The fourfold display visualizes the pattern of association. Note that the confidence rings for the individual odds ratios are not adjusted for multiple testing.

frame

Create / Start a New Plot Frame

Description

This function (`frame` is an alias for `plot.new`) causes the completion of plotting in the current plot (if there is one) and an advance to a new graphics frame. This is used in all high-level plotting functions and also useful for skipping plots when a multi-figure region is in use.

Usage

```
plot.new()
frame()
```

Details

The new page is painted with the background colour (`par("bg")`), which is often transparent. For devices with a *canvas* colour (the on-screen devices `X11`, `windows` and `quartz`), the window is first painted with the canvas colour and then the background colour.

There is a hook called `"plot.new"` (see `setHook`) called immediately after advancing the frame, which is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, `get` is called on it from within the **graphics** name space.)

`plot.window`, `plot.default`.

 grid

Add Grid to a Plot

Description

`grid` adds an `nx` by `ny` rectangular grid to an existing plot.

Usage

```
grid(nx = NULL, ny = nx, col = "lightgray", lty = "dotted",
     lwd = par("lwd"), equilogs = TRUE)
```

Arguments

<code>nx, ny</code>	number of cells of the grid in x and y direction. When <code>NULL</code> , as per default, the grid aligns with the tick marks on the corresponding <i>default</i> axis (i.e., tick-marks as computed by <code>axTicks</code>). When <code>NA</code> , no grid lines are drawn in the corresponding direction.
<code>col</code>	character or (integer) numeric; color of the grid lines.
<code>lty</code>	character or (integer) numeric; line type of the grid lines.
<code>lwd</code>	non-negative numeric giving line width of the grid lines.
<code>equilogs</code>	logical, only used when <i>log</i> coordinates and alignment with the axis tick marks are active. Setting <code>equilogs = FALSE</code> in that case gives <i>non equidistant</i> tick aligned grid lines.

Note

If more fine tuning is required, use `abline(h = ., v = .)` directly.

`plot`, `abline`, `lines`, `points`.

Examples

```
plot(1:3)
grid(NA, 5, lwd = 2) # grid only in y-direction

## maybe change the desired number of tick marks: par(lab=c(mx,my,7))
op <- par(mfcol = 1:2)
with(iris,
  {
    plot(Sepal.Length, Sepal.Width, col = as.integer(Species),
         xlim = c(4, 8), ylim = c(2, 4.5), panel.first = grid(),
         main = "with(iris, plot(..., panel.first = grid(), ..) )")
    plot(Sepal.Length, Sepal.Width, col = as.integer(Species),
         panel.first = grid(3, lty=1,lwd=2),
         main = "... panel.first = grid(3, lty=1,lwd=2), ..")
  }
)
par(op)
```

 hist

Histograms

Description

The generic function `hist` computes a histogram of the given data values. If `plot=TRUE`, the resulting object of class "histogram" is plotted by `plot.histogram`, before it is returned.

Usage

```
hist(x, ...)
```

Default S3 method:

```
hist(x, breaks = "Sturges",
     freq = NULL, probability = !freq,
     include.lowest = TRUE, right = TRUE,
     density = NULL, angle = 45, col = NULL, border = NULL,
     main = paste("Histogram of" , xname),
     xlim = range(breaks), ylim = NULL,
     xlab = xname, ylab,
     axes = TRUE, plot = TRUE, labels = FALSE,
     nclass = NULL, ...)
```

Arguments

<code>x</code>	a vector of values for which the histogram is desired.
<code>breaks</code>	one of: <ul style="list-style-type: none"> • a vector giving the breakpoints between histogram cells, • a single number giving the number of cells for the histogram, • a character string naming an algorithm to compute the number of cells (see ‘Details’), • a function to compute the number of cells. <p>In the last three cases the number is a suggestion only.</p>
<code>freq</code>	logical; if TRUE, the histogram graphic is a representation of frequencies, the counts component of the result; if FALSE, probability densities, component density, are plotted (so that the histogram has a total area of one). Defaults to TRUE <i>if and only if</i> breaks are equidistant (and probability is not specified).
<code>probability</code>	an <i>alias</i> for ! <code>freq</code> , for S compatibility.
<code>include.lowest</code>	logical; if TRUE, an <code>x[i]</code> equal to the <code>breaks</code> value will be included in the first (or last, for <code>right = FALSE</code>) bar. This will be ignored (with a warning) unless <code>breaks</code> is a vector.
<code>right</code>	logical; if TRUE, the histograms cells are right-closed (left open) intervals.
<code>density</code>	the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. Non-positive values of <code>density</code> also inhibit the drawing of shading lines.
<code>angle</code>	the slope of shading lines, given as an angle in degrees (counter-clockwise).
<code>col</code>	a colour to be used to fill the bars. The default of NULL yields unfilled bars.
<code>border</code>	the color of the border around the bars. The default is to use the standard foreground color.
<code>main, xlab, ylab</code>	these arguments to <code>title</code> have useful defaults here.
<code>xlim, ylim</code>	the range of x and y values with sensible defaults. Note that <code>xlim</code> is <i>not</i> used to define the histogram (breaks), but only for plotting (when <code>plot = TRUE</code>).
<code>axes</code>	logical. If TRUE (default), axes are draw if the plot is drawn.
<code>plot</code>	logical. If TRUE (default), a histogram is plotted, otherwise a list of breaks and counts is returned. In the latter case, a warning is used if (typically graphical) arguments are specified that only apply to the <code>plot = TRUE</code> case.
<code>labels</code>	logical or character. Additionally draw labels on top of bars, if not FALSE; see plot.histogram .
<code>nclass</code>	numeric (integer). For S(-PLUS) compatibility only, <code>nclass</code> is equivalent to <code>breaks</code> for a scalar or character argument.
<code>...</code>	further arguments and graphical parameters passed to plot.histogram and thence to <code>title</code> and <code>axis</code> (if <code>plot=TRUE</code>).

Details

The definition of *histogram* differs by source (with country-specific biases). R's default with equi-spaced breaks (also the default) is to plot the counts in the cells defined by `breaks`. Thus the height of a rectangle is proportional to the number of points falling into the cell, as is the area *provided* the breaks are equally-spaced.

The default with non-equi-spaced breaks is to give a plot of area one, in which the *area* of the rectangles is the fraction of the data points falling in the cells.

If `right = TRUE` (default), the histogram cells are intervals of the form $(a, b]$, i.e., they include their right-hand endpoint, but not their left one, with the exception of the first cell when `include.lowest` is `TRUE`.

For `right = FALSE`, the intervals are of the form $[a, b)$, and `include.lowest` means 'include highest'.

A numerical tolerance of 10^{-7} times the median bin size is applied when counting entries on the edges of bins.

The default for `breaks` is "Sturges": see `nclass.Sturges`. Other names for which algorithms are supplied are "Scott" and "FD" / "Freedman-Diaconis" (with corresponding functions `nclass.scott` and `nclass.FD`). Case is ignored and partial matching is used. Alternatively, a function can be supplied which will compute the intended number of breaks as a function of x .

Value

an object of class "histogram" which is a list with components:

<code>breaks</code>	the $n + 1$ cell boundaries (= <code>breaks</code> if that was a vector).
<code>counts</code>	n integers; for each cell, the number of <code>x[]</code> inside.
<code>density</code>	values $\hat{f}(x_i)$, as estimated density values. If <code>all(diff(breaks) == 1)</code> , they are the relative frequencies <code>counts/n</code> and in general satisfy $\sum_i \hat{f}(x_i)(b_{i+1} - b_i) = 1$, where $b_i = \text{breaks}[i]$.
<code>intensities</code>	same as <code>density</code> . Deprecated, but retained for compatibility.
<code>mids</code>	the n cell midpoints.
<code>xname</code>	a character string with the actual <code>x</code> argument name.
<code>equidist</code>	logical, indicating if the distances between <code>breaks</code> are all the same.

Typical plots with vertical bars are *not* histograms. Consider `barplot` or `plot(*, type = "h")` for such bar plots.

Examples

```

op <- par(mfrow=c(2, 2))
hist(islands)
utils::str(hist(islands, col="gray", labels = TRUE))

hist(sqrt(islands), breaks = 12, col="lightblue", border="pink")
##-- For non-equidistant breaks, counts should NOT be graphed unscaled:
r <- hist(sqrt(islands), breaks = c(4*0:5, 10*3:5, 70, 100, 140),
          col='blue1')
text(r$mids, r$density, r$counts, adj=c(.5, -.5), col='blue3')
sapply(r[2:3], sum)
sum(r$density * diff(r$breaks)) # == 1
lines(r, lty = 3, border = "purple") # -> lines.histogram(*)
par(op)

require(utils) # for str
str(hist(islands, breaks=12, plot= FALSE)) #-> 10 (~= 12) breaks
str(hist(islands, breaks=c(12,20,36,80,200,1000,17000), plot = FALSE))

hist(islands, breaks=c(12,20,36,80,200,1000,17000), freq = TRUE,
      main = "WRONG histogram") # and warning

require(stats)
set.seed(14)
x <- rchisq(100, df = 4)

## Comparing data with a model distribution should be done with qqplot(!)
qqplot(x, qchisq(ppoints(x), df = 4)); abline(0,1, col = 2, lty = 2)

## if you really insist on using hist() ... :
hist(x, freq = FALSE, ylim = c(0, 0.2))
curve(dchisq(x, df = 4), col = 2, lty = 2, lwd = 2, add = TRUE)

```

hist.POSIXt

*Histogram of a Date or Date-Time Object***Description**

Method for `hist` applied to date or date-time objects.

Usage

```

## S3 method for class 'POSIXt':
hist(x, breaks, ...,
      xlab = deparse(substitute(x)),
      plot = TRUE, freq = FALSE,
      start.on.monday = TRUE, format)

## S3 method for class 'Date':
hist(x, breaks, ...,
      xlab = deparse(substitute(x)),
      plot = TRUE, freq = FALSE,
      start.on.monday = TRUE, format)

```

Arguments

<code>x</code>	an object inheriting from class "POSIXt" or "Date".
<code>breaks</code>	a vector of cut points <i>or</i> number giving the number of intervals which <code>x</code> is to be cut into <i>or</i> an interval specification, one of "days", "weeks", "months", "quarters" or "years", plus "secs", "mins", "hours" for date-time objects.
<code>...</code>	graphical parameters, or arguments to <code>hist.default</code> such as <code>include.lowest</code> , <code>right</code> and <code>labels</code> .
<code>xlab</code>	a character string giving the label for the x axis, if plotted.
<code>plot</code>	logical. If TRUE (default), a histogram is plotted, otherwise a list of breaks and counts is returned.
<code>freq</code>	logical; if TRUE, the histogram graphic is a representation of frequencies, i.e. the counts component of the result; if FALSE, <i>relative</i> frequencies (probabilities) are plotted.
<code>start.on.monday</code>	logical. If <code>breaks = "weeks"</code> , should the week start on Mondays or Sundays?
<code>format</code>	for the x-axis labels. See <code>strptime</code> .

Details

Using `breaks = "quarters"` will create intervals of 3 calendar months, with the intervals beginning on January 1, April 1, July 1 or October 1, based upon `min(x)` as appropriate.

Value

An object of class "histogram": see `hist`.

See Also

`seq.POSIXt`, `axis.POSIXct`, `hist`

Examples

```
hist(.leap.seconds, "years", freq = TRUE)
hist(.leap.seconds,
      seq(ISoDate(1970, 1, 1), ISoDate(2010, 1, 1), "5 years"))

## 100 random dates in a 10-week period
random.dates <- as.Date("2001/1/1") + 70*stats::runif(100)
hist(random.dates, "weeks", format = "%d %b")
```

 identify

Identify Points in a Scatter Plot

Description

`identify` reads the position of the graphics pointer when the (first) mouse button is pressed. It then searches the coordinates given in `x` and `y` for the point closest to the pointer. If this point is close enough to the pointer, its index will be returned as part of the value of the call.

Usage

```
identify(x, ...)

## Default S3 method:
identify(x, y = NULL, labels = seq_along(x), pos = FALSE,
         n = length(x), plot = TRUE, atpen = FALSE, offset = 0.5,
         tolerance = 0.25, ...)
```

Arguments

<code>x, y</code>	coordinates of points in a scatter plot. Alternatively, any object which defines coordinates (a plotting structure, time series etc: see <code>xy.coords</code>) can be given as <code>x</code> , and <code>y</code> left missing.
<code>labels</code>	an optional character vector giving labels for the points. Will be coerced using <code>as.character</code> , and recycled if necessary to the length of <code>x</code> . Excess labels will be discarded, with a warning.
<code>pos</code>	if <code>pos</code> is <code>TRUE</code> , a component is added to the return value which indicates where text was plotted relative to each identified point: see <code>Value</code> .
<code>n</code>	the maximum number of points to be identified.
<code>plot</code>	logical: if <code>plot</code> is <code>TRUE</code> , the labels are printed near the points and if <code>FALSE</code> they are omitted.
<code>atpen</code>	logical: if <code>TRUE</code> and <code>plot = TRUE</code> , the lower-left corners of the labels are plotted at the points clicked rather than relative to the points.
<code>offset</code>	the distance (in character widths) which separates the label from identified points. Negative values are allowed. Not used if <code>atpen = TRUE</code> .
<code>tolerance</code>	the maximal distance (in inches) for the pointer to be 'close enough' to a point.
<code>...</code>	further arguments passed to <code>par</code> such as <code>cex</code> , <code>col</code> and <code>font</code> .

Details

`identify` is a generic function, and only the default method is described here.

`identify` is only supported on screen devices such as `X11`, `windows` and `quartz`. On other devices the call will do nothing.

Clicking near (as defined by `tolerance`) a point adds it to the list of identified points. Points can be identified only once, and if the point has already been identified or the click is not near any of the points a message is printed immediately on the R console.

If `plot` is `TRUE`, the point is labelled with the corresponding element of `labels`. If `atpen` is `false` (the default) the labels are placed below, to the left, above or to the right of the identified point,

depending on where the pointer was relative to the point. If `atpen` is true, the labels are placed with the bottom left of the string's box at the pointer.

For the usual `X11` device the identification process is terminated by pressing any mouse button other than the first. For the `quartz` device the process is terminated by pressing either the pop-up menu equivalent (usually second mouse button or `Ctrl-click`) or the `ESC` key.

On most devices which support `identify`, successful selection of a point is indicated by a bell sound unless `options(locatorBell = FALSE)` has been set.

If the window is resized or hidden and then exposed before the identification process has terminated, any labels drawn by `identify` will disappear. These will reappear once the identification process has terminated and the window is resized or hidden and exposed again. This is because the labels drawn by `identify` are not recorded in the device's display list until the identification process has terminated.

If you interrupt the `identify` call this leaves the graphics device in an undefined state, with points labelled but labels not recorded in the display list. Copying a device in that state will give unpredictable results.

Value

If `pos` is `FALSE`, an integer vector containing the indices of the identified points, in the order they were identified.

If `pos` is `TRUE`, a list containing a component `ind`, indicating which points were identified and a component `pos`, indicating where the labels were placed relative to the identified points (1=below, 2=left, 3=above, 4=right and 0=no offset, used if `atpen = TRUE`).

Technicalities

The algorithm used for placing labels is the same as used by `text` if `pos` is specified there, the difference being that the position of the pointer relative the identified point determines `pos` in `identify`.

For labels placed to the left of a point, the right-hand edge of the string's box is placed `offset` units to the left of the point, and analogously for points to the right. The baseline of the text is placed below the point so as to approximately centre string vertically. For labels placed above or below a point, the string is centered horizontally on the point. For labels placed above, the baseline of the text is placed `offset` units above the point, and for those placed below, the baseline is placed so that the top of the string's box is approximately `offset` units below the point. If you want more precise placement (e.g. centering) use `plot = FALSE` and plot via `text` or `points`: see the examples.

identifyPch <- function(x, y=NULL, n=length(x), pch=19, ...)
```

```

{
  xy <- xy.coords(x, y); x <- xy$x; y <- xy$y
  sel <- rep(FALSE, length(x)); res <- integer(0)
  while(sum(sel) < n) {
    ans <- identify(x[!sel], y[!sel], n=1, plot=FALSE, ...)
    if(!length(ans)) break
    ans <- which(!sel)[ans]
    points(x[ans], y[ans], pch = pch)
    sel[ans] <- TRUE
    res <- c(res, ans)
  }
  res
}

```

image

Display a Color Image

Description

Creates a grid of colored or gray-scale rectangles with colors corresponding to the values in *z*. This can be used to display three-dimensional or spatial data aka *images*. This is a generic function.

The functions `heat.colors`, `terrain.colors` and `topo.colors` create heat-spectrum (red to white) and topographical color schemes suitable for displaying ordered data, with *n* giving the number of colors desired.

Usage

```

image(x, ...)

## Default S3 method:
image(x, y, z, zlim, xlim, ylim, col = heat.colors(12),
      add = FALSE, xaxs = "i", yaxs = "i", xlab, ylab,
      breaks, oldstyle = FALSE, ...)

```

Arguments

<code>x, y</code>	locations of grid lines at which the values in <i>z</i> are measured. These must be finite, non-missing and in (strictly) ascending order. By default, equally spaced values from 0 to 1 are used. If <i>x</i> is a <code>list</code> , its components <code>x\$x</code> and <code>x\$y</code> are used for <i>x</i> and <i>y</i> , respectively. If the list has component <i>z</i> this is used for <i>z</i> .
<code>z</code>	a matrix containing the values to be plotted (NAs are allowed). Note that <i>x</i> can be used instead of <i>z</i> for convenience.
<code>zlim</code>	the minimum and maximum <i>z</i> values for which colors should be plotted, defaulting to the range of the finite values of <i>z</i> . Each of the given colors will be used to color an equispaced interval of this range. The <i>midpoints</i> of the intervals cover the range, so that values just outside the range will be plotted.
<code>xlim, ylim</code>	ranges for the plotted <i>x</i> and <i>y</i> values, defaulting to the ranges of <i>x</i> and <i>y</i> .
<code>col</code>	a list of colors such as that generated by <code>rainbow</code> , <code>heat.colors</code> , <code>topo.colors</code> , <code>terrain.colors</code> or similar functions.
<code>add</code>	logical; if TRUE, add to current plot (and disregard the following arguments). This is rarely useful because <code>image</code> ‘paints’ over existing graphics.

<code>xaxis, yaxis</code>	style of x and y axis. The default "i" is appropriate for images. See par .
<code>xlab, ylab</code>	each a character string giving the labels for the x and y axis. Default to the 'call names' of x or y, or to "" if these were unspecified.
<code>breaks</code>	a set of breakpoints for the colours: must give one more breakpoint than colour.
<code>oldstyle</code>	logical. If true the midpoints of the colour intervals are equally spaced, and <code>zlim[1]</code> and <code>zlim[2]</code> were taken to be midpoints. The default is to have colour intervals of equal lengths between the limits.
<code>...</code>	graphical parameters for plot may also be passed as arguments to this function, as can the plot aspect ratio <code>asp</code> and <code>axes</code> (see plot.window).

Details

The length of `x` should be equal to the `nrow(z)+1` or `nrow(z)`. In the first case `x` specifies the boundaries between the cells: in the second case `x` specifies the midpoints of the cells. Similar reasoning applies to `y`. It probably only makes sense to specify the midpoints of an equally-spaced grid. If you specify just one row or column and a length-one `x` or `y`, the whole user area in the corresponding direction is filled.

Rectangles corresponding to missing values are not plotted (and so are transparent and (unless `add=TRUE`) the default background painted in `par("bg")` will show though and if that is transparent, the canvas colour will be seen).

If `breaks` is specified then `zlim` is unused and the algorithm used follows [cut](#), so intervals are closed on the right and open on the left except for the lowest interval.

Notice that `image` interprets the `z` matrix as a table of $f(x[i], y[j])$ values, so that the x axis corresponds to row number and the y axis to column number, with column 1 at the bottom, i.e. a 90 degree counter-clockwise rotation of the conventional printed layout of a matrix.

Note

Based on a function by Thomas Lumley (tlumley@u.washington.edu).

Examples

```
require(grDevices) # for colours
x <- y <- seq(-4*pi, 4*pi, len=27)
r <- sqrt(outer(x^2, y^2, "+"))
image(z = z <- cos(r^2)*exp(-r/6), col=gray((0:32)/32))
image(z, axes = FALSE, main = "Math can be beautiful ...",
      xlab = expression(cos(r^2) * e^{-r/6}))
contour(z, add = TRUE, drawlabels = FALSE)

# Volcano data visualized as matrix. Need to transpose and flip
# matrix horizontally.
image(t(volcano)[ncol(volcano):1,])

# A prettier display of the volcano
x <- 10*(1:nrow(volcano))
```

```

y <- 10*(1:ncol(volcano))
image(x, y, volcano, col = terrain.colors(100), axes = FALSE)
contour(x, y, volcano, levels = seq(90, 200, by = 5),
        add = TRUE, col = "peru")
axis(1, at = seq(100, 800, by = 100))
axis(2, at = seq(100, 600, by = 100))
box()
title(main = "Maunga Whau Volcano", font.main = 4)

```

 layout

Specifying Complex Plot Arrangements

Description

`layout` divides the device up into as many rows and columns as there are in matrix `mat`, with the column-widths and the row-heights specified in the respective arguments.

Usage

```

layout(mat, widths = rep(1, ncol(mat)),
        heights = rep(1, nrow(mat)), respect = FALSE)

layout.show(n = 1)
lcm(x)

```

Arguments

<code>mat</code>	a matrix object specifying the location of the next N figures on the output device. Each value in the matrix must be 0 or a positive integer. If N is the largest positive integer in the matrix, then the integers $\{1, \dots, N - 1\}$ must also appear at least once in the matrix.
<code>widths</code>	a vector of values for the widths of columns on the device. Relative widths are specified with numeric values. Absolute widths (in centimetres) are specified with the <code>lcm()</code> function (see examples).
<code>heights</code>	a vector of values for the heights of rows on the device. Relative and absolute heights can be specified, see <code>widths</code> above.
<code>respect</code>	either a logical value or a matrix object. If the latter, then it must have the same dimensions as <code>mat</code> and each value in the matrix must be either 0 or 1.
<code>n</code>	number of figures to plot.
<code>x</code>	a dimension to be interpreted as a number of centimetres.

Details

Figure i is allocated a region composed from a subset of these rows and columns, based on the rows and columns in which i occurs in `mat`.

The `respect` argument controls whether a unit column-width is the same physical measurement on the device as a unit row-height.

There is a limit (currently 50) for the numbers of rows and columns in the layout, and also for the total number of cells (500).

`layout.show(n)` plots (part of) the current layout, namely the outlines of the next n figures.
`lcm` is a trivial function, to be used as *the* interface for specifying absolute dimensions for the widths and heights arguments of `layout()`.

Value

`layout` returns the number of figures, N , see above.

Warnings

These functions are totally incompatible with the other mechanisms for arranging plots on a device: `par(mfrow)`, `par(mfcol)` and `split.screen`.

barplot(yhist$counts, axes=FALSE, xlim=c(0, top), space=0, horiz=TRUE)

par(def.par)#- reset to default

```

legend

Add Legends to Plots

Description

This function can be used to add legends to plots. Note that a call to the function `locator(1)` can be used in place of the `x` and `y` arguments.

Usage

```

legend(x, y = NULL, legend, fill = NULL, col = par("col"),
       lty, lwd, pch,
       angle = 45, density = NULL, bty = "o", bg = par("bg"),
       box.lwd = par("lwd"), box.lty = par("lty"), box.col = par("fg"),
       pt.bg = NA, cex = 1, pt.cex = cex, pt.lwd = lwd,
       xjust = 0, yjust = 1, x.intersp = 1, y.intersp = 1,
       adj = c(0, 0.5), text.width = NULL, text.col = par("col"),
       merge = do.lines && has.pch, trace = FALSE,
       plot = TRUE, ncol = 1, horiz = FALSE, title = NULL,
       inset = 0, xpd, title.col = text.col)

```

Arguments

<code>x, y</code>	the <code>x</code> and <code>y</code> co-ordinates to be used to position the legend. They can be specified by keyword or in any way which is accepted by <code>xy.coords</code> : See ‘Details’.
<code>legend</code>	a character or <code>expression</code> vector. of length ≥ 1 to appear in the legend. Other objects will be coerced by <code>as.graphicsAnnot</code> .
<code>fill</code>	if specified, this argument will cause boxes filled with the specified colors (or shaded in the specified colors) to appear beside the legend text.
<code>col</code>	the color of points or lines appearing in the legend.
<code>lty, lwd</code>	the line types and widths for lines appearing in the legend. One of these two <i>must</i> be specified for line drawing.
<code>pch</code>	the plotting symbols appearing in the legend, either as vector of 1-character strings, or one (multi character) string. <i>Must</i> be specified for symbol drawing.
<code>angle</code>	angle of shading lines.

<code>density</code>	the density of shading lines, if numeric and positive. If <code>NULL</code> or negative or <code>NA</code> color filling is assumed.
<code>bty</code>	the type of box to be drawn around the legend. The allowed values are <code>"o"</code> (the default) and <code>"n"</code> .
<code>bg</code>	the background color for the legend box. (Note that this is only used if <code>bty != "n"</code> .)
<code>box.lty</code> , <code>box.lwd</code> , <code>box.col</code>	the line type, width and color for the legend box (if <code>bty = "o"</code>).
<code>pt.bg</code>	the background color for the <code>points</code> , corresponding to its argument <code>bg</code> .
<code>cex</code>	character expansion factor relative to current <code>par("cex")</code> . Used for text, and provides the default for <code>pt.cex</code> and <code>title.cex</code> .
<code>pt.cex</code>	expansion factor(s) for the points.
<code>pt.lwd</code>	line width for the points, defaults to the one for lines, or if that is not set, to <code>par("lwd")</code> .
<code>xjust</code>	how the legend is to be justified relative to the legend x location. A value of 0 means left justified, 0.5 means centered and 1 means right justified.
<code>yjust</code>	the same as <code>xjust</code> for the legend y location.
<code>x.intersp</code>	character interspacing factor for horizontal (x) spacing.
<code>y.intersp</code>	the same for vertical (y) line distances.
<code>adj</code>	numeric of length 1 or 2; the string adjustment for legend text. Useful for y-adjustment when <code>labels</code> are <code>plotmath</code> expressions.
<code>text.width</code>	the width of the legend text in x (<code>"user"</code>) coordinates. (Should be positive even for a reversed x axis.) Defaults to the proper value computed by <code>strwidth(legend)</code> .
<code>text.col</code>	the color used for the legend text.
<code>merge</code>	logical; if <code>TRUE</code> , merge points and lines but not filled boxes. Defaults to <code>TRUE</code> if there are points and lines.
<code>trace</code>	logical; if <code>TRUE</code> , shows how <code>legend</code> does all its magical computations.
<code>plot</code>	logical. If <code>FALSE</code> , nothing is plotted but the sizes are returned.
<code>ncol</code>	the number of columns in which to set the legend items (default is 1, a vertical legend).
<code>horiz</code>	logical; if <code>TRUE</code> , set the legend horizontally rather than vertically (specifying <code>horiz</code> overrides the <code>ncol</code> specification).
<code>title</code>	a character string or length-one expression giving a title to be placed at the top of the legend. Other objects will be coerced by <code>as.graphicsAnnot</code> .
<code>inset</code>	inset distance(s) from the margins as a fraction of the plot region when legend is placed by keyword.
<code>xpd</code>	if supplied, a value of the graphical parameter <code>xpd</code> to be used while the legend is being drawn.
<code>title.col</code>	color for <code>title</code> .

Details

Arguments `x`, `y`, `legend` are interpreted in a non-standard way to allow the coordinates to be specified *via* one or two arguments. If `legend` is missing and `y` is not numeric, it is assumed that the second argument is intended to be `legend` and that the first argument specifies the coordinates.

The coordinates can be specified in any way which is accepted by `xy.coords`. If this gives the coordinates of one point, it is used as the top-left coordinate of the rectangle containing the legend. If it gives the coordinates of two points, these specify opposite corners of the rectangle (either pair of corners, in any order).

The location may also be specified by setting `x` to a single keyword from the list "bottomright", "bottom", "bottomleft", "left", "topleft", "top", "topright", "right" and "center". This places the legend on the inside of the plot frame at the given location. Partial argument matching is used. The optional `inset` argument specifies how far the legend is inset from the plot margins. If a single value is given, it is used for both margins; if two values are given, the first is used for `x`- distance, the second for `y`-distance.

Attribute arguments such as `col`, `pch`, `lty`, etc, are recycled if necessary: `merge` is not.

Points are drawn *after* lines in order that they can cover the line with their background color `pt.bg`, if applicable.

See the examples for how to right-justify labels.

Value

A list with list components

<code>rect</code>	a list with components w , h positive numbers giving w idth and h eight of the legend's box. left , top <code>x</code> and <code>y</code> coordinates of upper left corner of the box.
<code>text</code>	a list with components x , y numeric vectors of length <code>length(legend)</code> , giving the <code>x</code> and <code>y</code> coordinates of the legend's text(s).

returned invisibly.

      inset = .02)
legend("right", "(x,y)", pch=1, title="right")
legend("center", "(x,y)", pch=1, title="center")

```

lines

Add Connected Line Segments to a Plot

Description

A generic function taking coordinates given in various ways and joining the corresponding points with line segments.

Usage

```
lines(x, ...)  
  
## Default S3 method:  
lines(x, y = NULL, type = "l", ...)
```

Arguments

<code>x</code> , <code>y</code>	coordinate vectors of points to join.
<code>type</code>	character indicating the type of plotting; actually any of the <code>types</code> as in <code>plot.default</code> .
<code>...</code>	Further graphical parameters (see <code>par</code>) may also be supplied as arguments, particularly, line type, <code>lty</code> , line width, <code>lwd</code> , color, <code>col</code> and for <code>type = "b"</code> , <code>pch</code> . Also the line characteristics <code>lend</code> , <code>ljoin</code> and <code>lmitre</code> .

Details

The coordinates can be passed in a plotting structure (a list with `x` and `y` components), a two-column matrix, a time series, See `xy.coords`. If supplied separately, they must be of the same length.

The coordinates can contain NA values. If a point contains NA in either its `x` or `y` value, it is omitted from the plot, and lines are not drawn to or from such points. Thus missing values can be used to achieve breaks in lines.

For `type = "h"`, `col` can be a vector and will be recycled as needed.

`lwd` can be a vector: its first element will apply to lines but the whole vector to symbols (recycled as necessary).

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

See Also

`points`, particularly for `type %in% c("p", "b", "o")`, `plot`, and the workhorse function `plot.xy`.

`abline` for drawing (single) straight lines.

`par` for how to specify colors.

Examples

```
# draw a smooth line through a scatter plot  
plot(cars, main="Stopping Distance versus Speed")  
lines(stats::lowess(cars))
```

locator

*Graphical Input***Description**

Reads the position of the graphics cursor when the (first) mouse button is pressed.

Usage

```
locator(n = 512, type = "n", ...)
```

Arguments

<code>n</code>	the maximum number of points to locate. Valid values start at 1.
<code>type</code>	One of "n", "p", "l" or "o". If "p" or "o" the points are plotted; if "l" or "o" they are joined by lines.
<code>...</code>	additional graphics parameters used if <code>type != "n"</code> for plotting the locations.

Details

`locator` is only supported on screen devices such as `X11`, `windows` and `quartz`. On other devices the call will do nothing.

Unless the process is terminated prematurely by the user (see below) at most `n` positions are determined.

For the usual `X11` device the identification process is terminated by pressing any mouse button other than the first. For the `quartz` device the process is terminated by pressing the ESC key.

The current graphics parameters apply just as if `plot.default` has been called with the same value of `type`. The plotting of the points and lines is subject to clipping, but locations outside the current clipping rectangle will be returned.

On most devices which support `locator`, successful selection of a point is indicated by a bell sound unless `options(locatorBell=FALSE)` has been set.

If the window is resized or hidden and then exposed before the input process has terminated, any lines or points drawn by `locator` will disappear. These will reappear once the input process has terminated and the window is resized or hidden and exposed again. This is because the points and lines drawn by `locator` are not recorded in the device's display list until the input process has terminated.

Value

A list containing `x` and `y` components which are the coordinates of the identified points in the user coordinate system, i.e., the one specified by `par("usr")`.

`identify`

matplot

*Plot Columns of Matrices***Description**

Plot the columns of one matrix against the columns of another.

Usage

```
matplot(x, y, type = "p", lty = 1:5, lwd = 1, pch = NULL,
        col = 1:6, cex = NULL, bg = NA,
        xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL,
        ..., add = FALSE, verbose = getOption("verbose"))

matpoints(x, y, type = "p", lty = 1:5, lwd = 1, pch = NULL,
          col = 1:6, ...)
```

```
matlines(x, y, type = "l", lty = 1:5, lwd = 1, pch = NULL,
         col = 1:6, ...)
```

Arguments

<code>x, y</code>	vectors or matrices of data for plotting. The number of rows should match. If one of them are missing, the other is taken as <code>y</code> and an <code>x</code> vector of <code>1:n</code> is used. Missing values (NAs) are allowed.
<code>type</code>	character string (length 1 vector) or vector of 1-character strings indicating the type of plot for each column of <code>y</code> , see plot for all possible types. The first character of <code>type</code> defines the first plot, the second character the second, etc. Characters in <code>type</code> are cycled through; e.g., "pl" alternately plots points and lines.
<code>lty, lwd</code>	vector of line types and widths. The first element is for the first column, the second element for the second column, etc., even if lines are not plotted for all columns. Line types will be used cyclically until all plots are drawn.
<code>pch</code>	character string or vector of 1-characters or integers for plotting characters, see points . The first character is the plotting-character for the first plot, the second for the second, etc. The default is the digits (1 through 9, 0) then the lowercase and uppercase letters.
<code>col</code>	vector of colors. Colors are used cyclically.
<code>cex</code>	vector of character expansion sizes, used cyclically. This works as a multiple of <code>par("cex")</code> . <code>NULL</code> is equivalent to <code>1.0</code> .
<code>bg</code>	vector of background (fill) colors for the open plot symbols given by <code>pch=21:25</code> as in points . The default <code>NA</code> corresponds to the one of the underlying function <code>plot.xy</code> .
<code>xlab, ylab</code>	titles for <code>x</code> and <code>y</code> axes, as in plot .
<code>xlim, ylim</code>	ranges of <code>x</code> and <code>y</code> axes, as in plot .
<code>...</code>	Graphical parameters (see par) and any further arguments of <code>plot</code> , typically <code>plot.default</code> , may also be supplied as arguments to this function. Hence, the high-level graphics control arguments described under par and the arguments to title may be supplied to this function.

add logical. If TRUE, plots are added to current one, using `points` and `lines`.
 verbose logical. If TRUE, write one line of what is done.

Details

Points involving missing values are not plotted.

The first column of `x` is plotted against the first column of `y`, the second column of `x` against the second column of `y`, etc. If one matrix has fewer columns, plotting will cycle back through the columns again. (In particular, either `x` or `y` may be a vector, against which all columns of the other argument will be plotted.)

The first element of `col`, `cex`, `lty`, `lwd` is used to plot the axes as well as the first line.

Because plotting symbols are drawn with lines and because these functions may be changing the line style, you should probably specify `lty=1` when using plotting symbols.

Side Effects

Function `matplot` generates a new plot; `matpoints` and `matlines` add to the current one.

```

mosaicplot

Mosaic Plots

Description

Plots a mosaic on the current graphics device.

Usage

```

mosaicplot(x, ...)

## Default S3 method:
mosaicplot(x, main = deparse(substitute(x)),
           sub = NULL, xlab = NULL, ylab = NULL,
           sort = NULL, off = NULL, dir = NULL,
           color = NULL, shade = FALSE, margin = NULL,
           cex.axis = 0.66, las = par("las"),
           type = c("pearson", "deviance", "FT"), ...)

## S3 method for class 'formula':
mosaicplot(formula, data = NULL, ...,
           main = deparse(substitute(data)), subset,
           na.action = stats::na.omit)

```

Arguments

<code>x</code>	a contingency table in array form, with optional category labels specified in the <code>dimnames(x)</code> attribute. The table is best created by the <code>table()</code> command.
<code>main</code>	character string for the mosaic title.
<code>sub</code>	character string for the mosaic sub-title (at bottom).
<code>xlab, ylab</code>	x- and y-axis labels used for the plot; by default, the first and second element of <code>names(dimnames(X))</code> (i.e., the name of the first and second variable in <code>X</code>).
<code>sort</code>	vector ordering of the variables, containing a permutation of the integers <code>1:length(dim(x))</code> (the default).

<code>off</code>	vector of offsets to determine percentage spacing at each level of the mosaic (appropriate values are between 0 and 20, and the default is 20 times the number of splits for 2-dimensional tables, and 10 otherwise. Rescaled to maximally 50, and recycled if necessary).
<code>dir</code>	vector of split directions (" <code>v</code> " for vertical and " <code>h</code> " for horizontal) for each level of the mosaic, one direction for each dimension of the contingency table. The default consists of alternating directions, beginning with a vertical split.
<code>color</code>	logical or (recycling) vector of colors for color shading, used only when <code>shade</code> is <code>FALSE</code> , or <code>NULL</code> (default). By default, grey boxes are drawn. <code>color=TRUE</code> uses a gamma-corrected grey palette. <code>color=FALSE</code> gives empty boxes with no shading.
<code>shade</code>	a logical indicating whether to produce extended mosaic plots, or a numeric vector of at most 5 distinct positive numbers giving the absolute values of the cut points for the residuals. By default, <code>shade</code> is <code>FALSE</code> , and simple mosaics are created. Using <code>shade = TRUE</code> cuts absolute values at 2 and 4.
<code>margin</code>	a list of vectors with the marginal totals to be fit in the log-linear model. By default, an independence model is fitted. See loglin for further information.
<code>cex.axis</code>	The magnification to be used for axis annotation, as a multiple of <code>par("cex")</code> .
<code>las</code>	numeric; the style of axis labels, see par .
<code>type</code>	a character string indicating the type of residual to be represented. Must be one of " <code>pearson</code> " (giving components of Pearson's χ^2), " <code>deviance</code> " (giving components of the likelihood ratio χ^2), or " <code>FT</code> " for the Freeman-Tukey residuals. The value of this argument can be abbreviated.
<code>formula</code>	a formula, such as <code>y ~ x</code> .
<code>data</code>	a data frame (or list), or a contingency table from which the variables in <code>formula</code> should be taken.
<code>...</code>	further arguments to be passed to or from methods.
<code>subset</code>	an optional vector specifying a subset of observations in the data frame to be used for plotting.
<code>na.action</code>	a function which indicates what should happen when the data contains variables to be cross-tabulated, and these variables contain NAs. The default is to omit cases which have an NA in any variable. Since the tabulation will omit all cases containing missing values, this will only be useful if the <code>na.action</code> function replaces missing values.

Details

This is a generic function. It currently has a default method (`mosaicplot.default`) and a formula interface (`mosaicplot.formula`).

Extended mosaic displays visualize standardized residuals of a loglinear model for the table by color and outline of the mosaic's tiles. (Standardized residuals are often referred to a standard normal distribution.) Negative residuals are drawn in shaded of red and with broken outlines; positive ones are drawn in blue with solid outlines.

For the formula method, if `data` is an object inheriting from classes "`table`" or "`fTable`", or an array with more than 2 dimensions, it is taken as a contingency table, and hence all entries should be nonnegative. In this case, the left-hand side of `formula` should be empty, and the variables on the right-hand side should be taken from the names of the `dimnames` attribute of the contingency table. A marginal table of these variables is computed, and a mosaic of this table is produced.

Otherwise, data should be a data frame or matrix, list or environment containing the variables to be cross-tabulated. In this case, after possibly selecting a subset of the data as specified by the `subset` argument, a contingency table is computed from the variables given in `formula`, and a mosaic is produced from this.

See Emerson (1998) for more information and a case study with television viewer data from Nielsen Media Research.

Missing values are not supported except via an `na.action` function when data contains variables to be cross-tabulated.

A more flexible and extensible implementation of mosaic plots written in the grid graphics system is provided in the function `mosaic` in the contributed package `vcd` (Meyer, Zeileis and Hornik, 2005).

```

mtext

Write Text into the Margins of a Plot

Description

Text is written in one of the four margins of the current figure region or one of the outer margins of the device region.

Usage

```

mtext(text, side = 3, line = 0, outer = FALSE, at = NA,
      adj = NA, padj = NA, cex = NA, col = NA, font = NA, ...)

```

Arguments

text	a character or expression vector specifying the <i>text</i> to be written. Other objects are coerced by as.graphicsAnnot .
side	on which side of the plot (1=bottom, 2=left, 3=top, 4=right).
line	on which MARgin line, starting at 0 counting outwards.
outer	use outer margins if available.
at	give location in user coordinates. If <code>length(at)==0</code> (the default), the location will be determined by <code>adj</code> .
adj	adjustment for each string in reading direction. For strings parallel to the axes, <code>adj = 0</code> means left or bottom alignment, and <code>adj = 1</code> means right or top alignment. If <code>adj</code> is not a finite value (the default), the value of <code>par("las")</code> determines the adjustment. For strings plotted parallel to the axis the default is to centre the string.
padj	adjustment for each string perpendicular to the reading direction (which is controlled by <code>adj</code>). For strings parallel to the axes, <code>padj = 0</code> means right or top alignment, and <code>padj = 1</code> means left or bottom alignment. If <code>padj</code> is not a finite value (the default), the value of <code>par("las")</code> determines the adjustment. For strings plotted perpendicular to the axis the default is to centre the string.

cex	character expansion factor. NULL and NA are equivalent to 1.0. This is an absolute measure, not scaled by <code>par("cex")</code> or by setting <code>par("mfrow")</code> or <code>par("mfcol")</code> . Can be a vector.
col	color to use. Can be a vector. NA values (the default) mean use <code>par("col")</code> .
font	font for text. Can be a vector. NA values (the default) mean use <code>par("font")</code> .
...	Further graphical parameters (see par), including <code>family</code> , <code>las</code> and <code>xpd</code> . (The latter defaults to the figure region unless <code>outer = TRUE</code> , otherwise the device region. It can only be increased.)

Details

The user coordinates in the outer margins always range from zero to one, and are not affected by the user coordinates in the figure region(s) — R differs here from other implementations of S.

All of the named arguments can be vectors, and recycling will take place to plot as many strings as the longest of the vector arguments.

Note that a vector `adj` has a different meaning from `text`. `adj = 0.5` will centre the string, but for `outer=TRUE` on the device region rather than the plot region.

Parameter `las` will determine the orientation of the string(s). For strings plotted perpendicular to the axis the default justification is to place the end of the string nearest the axis on the specified line. (Note that this differs from S, which uses `srt` if `at` is supplied and `las` if it is not. Parameter `srt` is ignored in R.)

Note that if the text is to be plotted perpendicular to the axis, `adj` determines the justification of the string *and* the position along the axis unless `at` is specified.

Side Effects

The given text is written onto the current plot.

plot(1:10, (-4:5)^2, main="Parabola Points", xlab="xlab")
mtext("10 of them")
for(s in 1:4)
  mtext(paste("mtext(..., line= -1, {side, col, font} = ", s,
            ", cex = ", (1+s)/2, ")"), line = -1,
        side=s, col=s, font=s, cex= (1+s)/2)
mtext("mtext(..., line= -2)", line = -2)
mtext("mtext(..., line= -2, adj = 0)", line = -2, adj = 0)
##--- log axis :
plot(1:10, exp(1:10), log='y', main="log='y'", xlab="xlab")
for(s in 1:4) mtext(paste("mtext(...,side=",s,")"), side=s)
```

 pairs

Scatterplot Matrices

Description

A matrix of scatterplots is produced.

Usage

```

pairs(x, ...)

## S3 method for class 'formula':
pairs(formula, data = NULL, ..., subset,
       na.action = stats::na.pass)

## Default S3 method:
pairs(x, labels, panel = points, ...,
      lower.panel = panel, upper.panel = panel,
      diag.panel = NULL, text.panel = textPanel,
      label.pos = 0.5 + has.diag/3,
      cex.labels = NULL, font.labels = 1,
      rowlattice = TRUE, gap = 1)

```

Arguments

x	the coordinates of points given as numeric columns of a matrix or dataframe. Logical and factor columns are converted to numeric in the same way that <code>data.matrix</code> does.
formula	a formula, such as $\sim x + y + z$. Each term will give a separate variable in the pairs plot, so terms should be numeric vectors. (A response will be interpreted as another variable, but not treated specially, so it is confusing to use one.)
data	a <code>data.frame</code> (or list) from which the variables in <code>formula</code> should be taken.
subset	an optional vector specifying a subset of observations to be used for plotting.
na.action	a function which indicates what should happen when the data contain NAs. The default is to pass missing values on to the panel functions, but <code>na.action = na.omit</code> will cause cases with missing values in any of the variables to be omitted entirely.
labels	the names of the variables.
panel	<code>function(x, y, ...)</code> which is used to plot the contents of each panel of the display.
...	arguments to be passed to or from methods. Also, graphical parameters can be given as arguments to <code>plot</code> such as <code>main.par("oma")</code> will be set appropriately unless specified.
lower.panel, upper.panel	separate panel functions to be used below and above the diagonal respectively.
diag.panel	optional <code>function(x, ...)</code> to be applied on the diagonals.

<code>text.panel</code>	optional function(<code>x</code> , <code>y</code> , <code>labels</code> , <code>cex</code> , <code>font</code> , ...) to be applied on the diagonals.
<code>label.pos</code>	<code>y</code> position of labels in the text panel.
<code>cex.labels</code> , <code>font.labels</code>	graphics parameters for the text panel.
<code>rowlattice</code>	logical. Should the layout be matrix-like with row 1 at the top, or graph-like with row 1 at the bottom?
<code>gap</code>	Distance between subplots, in margin lines.

Details

The ij th scatterplot contains $x[,i]$ plotted against $x[,j]$. The scatterplot can be customised by setting panel functions to appear as something completely different. The off-diagonal panel functions are passed the appropriate columns of x as x and y : the diagonal panel function (if any) is passed a single column, and the `text.panel` function is passed a single (x, y) location and the column name.

The graphical parameters `pch` and `col` can be used to specify a vector of plotting symbols and colors to be used in the plots.

The graphical parameter `oma` will be set by `pairs.default` unless supplied as an argument.

A panel function should not attempt to start a new plot, but just plot within a given coordinate system: thus `plot` and `boxplot` are not panel functions.

By default, missing values are passed to the panel functions and will often be ignored within a panel. However, for the formula method and `na.action = na.omit`, all cases which contain a missing values for any of the variables are omitted completely (including when the scales are selected).

```

panel.smooth

Simple Panel Plot

Description

An example of a simple useful panel function to be used as argument in e.g., [coplot](#) or [pairs](#).

Usage

```

panel.smooth(x, y, col = par("col"), bg = NA, pch = par("pch"),
             cex = 1, col.smooth = "red", span = 2/3, iter = 3,
             ...)

```

Arguments

<code>x, y</code>	numeric vectors of the same length
<code>col, bg, pch, cex</code>	numeric or character codes for the color(s), point type and size of points ; see also par .
<code>col.smooth</code>	color to be used by lines for drawing the smooths.
<code>span</code>	smoothing parameter f for lowess , see there.
<code>iter</code>	number of robustness iterations for lowess .
<code>...</code>	further arguments to lines .

See Also

[coplot](#) and [pairs](#) where `panel.smooth` is typically used; [lowess](#) which does the smoothing.

Examples

```
pairs(swiss, panel = panel.smooth, pch = ".")# emphasize the smooths
pairs(swiss, panel = panel.smooth, lwd = 2, cex= 1.5, col="blue")# hmm...
```

 par

Set or Query Graphical Parameters

Description

par can be used to set or query graphical parameters. Parameters can be set by specifying them as arguments to par in tag = value form, or by passing them as a list of tagged values.

Usage

```
par(..., no.readonly = FALSE)

<highlevel plot> (... , <tag> = <value>)
```

Arguments

... arguments in tag = value form, or a list of tagged values. The tags must come from the graphical parameters described below.

no.readonly logical; if TRUE and there are no other arguments, only parameters are returned which can be set by a subsequent par() call *on the same device*.

Details

Each device has its own set of graphical parameters. If the current device is the null device, par will open a new device before querying/setting parameters. (What device is controlled by options("device").)

Parameters are queried by giving one or more character vectors to par.

par() (no arguments) or par(no.readonly=TRUE) is used to get *all* the graphical parameters (as a named list). Their names are currently taken from the unexported variable .Pars.

R.O. indicates *read-only arguments*: These may only be used in queries and cannot be set. ("cin", "cra", "csi", "cxy" and "din" are always read-only.)

There are several parameters can only be set by a call to par():

- "ask",
- "fig", "fin",
- "lheight",
- "mai", "mar", "mex", "mfcol", "mfrow", "mfg",
- "new",
- "oma", "omd", "omi",
- "pin", "plt", "ps", "pty",
- "usr",
- "xlog", "ylog"

The remaining parameters can also be set as arguments (often via `...`) to high-level plot functions such as `plot.default`, `plot.window`, `points`, `lines`, `abline`, `axis`, `title`, `text`, `mtext`, `segments`, `symbols`, `arrows`, `polygon`, `rect`, `box`, `contour`, `filled.contour` and `image`. Such settings will be active during the execution of the function, only. However, see the comments on `bg` and `cex`, which may be taken as arguments to certain plot functions rather than as graphical parameters.

The meaning of ‘character size’ is not well-defined: this is set up for the device taking `pointsize` into account but often not the actual font family in use. Internally the corresponding pars (`cra`, `cin`, `cxy` and `csi`) are used only to set the inter-line spacing used to convert `mar` and `oma` to physical margins. (The same inter-line spacing multiplied by `lheight` is used for multi-line strings in `text` and `strheight`.)

Value

When parameters are set, their former values are returned in an invisible named list. Such a list can be passed as an argument to `par` to restore the parameter values. Use `par(no.readonly = TRUE)` for the full list of parameters that can be restored. However, restoring all of these is not wise since they contain several ways to set the same quantities, and these can have conflicting effects if the graphics device has been resized since the parameters were saved. You will reset all of `mfgrow`, `mfgcol` and `mfg` and will find `mfgrow` wins.

When just one parameter is queried, the value of that parameter is returned as (atomic) vector. When two or more parameters are queried, their values are returned in a list, with the list names giving the parameters.

Note the inconsistency: setting one parameter returns a list, but querying one parameter returns a vector.

Graphical Parameters

adj The value of `adj` determines the way in which text strings are justified in `text`, `mtext` and `title`. A value of 0 produces left-justified text, 0.5 (the default) centered text and 1 right-justified text. (Any value in $[0, 1]$ is allowed, and on most devices values outside that interval will also work.) Note that the `adj` argument of `text` also allows `adj = c(x, y)` for different adjustment in x- and y- directions. Note that whereas for `text` it refers to positioning of text about a point, for `mtext` and `title` it controls placement within the plot or device region.

ann If set to `FALSE`, high-level plotting functions calling `plot.default` do not annotate the plots they produce with axis titles and overall titles. The default is to do annotation.

ask logical. If `TRUE` (and the R session is interactive) the user is asked for input, before a new figure is drawn. As this applies to the device, it also affects output by packages **grid** and **lattice**. It can be set even on non-screen devices but may have no effect there.

This not really a graphics parameter, and its use is deprecated in favour of `devAskNewPage`.

bg The color to be used for the background of the device region. When called from `par()` it also sets `new=FALSE`. See section ‘Color Specification’ for suitable values. For many devices the initial value is set from the `bg` argument of the device, and for the rest it is normally `"white"`.

Note that some graphics functions such as `plot.default` and `points` have an *argument* of this name with a different meaning.

bty A character string which determined the type of `box` which is drawn about plots. If `bty` is one of `"o"` (the default), `"l"`, `"7"`, `"c"`, `"u"`, or `"|"` the resulting box resembles the corresponding upper case letter. A value of `"n"` suppresses the box.

cex A numerical value giving the amount by which plotting text and symbols should be magnified relative to the default. Note that some graphics functions such as `plot.default` have an *argument* of this name which *multiplies* this graphical parameter, and some functions such as `points` accept a vector of values which are recycled. Other uses will take just the first value if a vector of length greater than one is supplied.

This starts as 1 when a device is opened, and is reset when the layout is changed, e.g. by setting `mflow`.

cex.axis The magnification to be used for axis annotation relative to the current setting of `cex`.

cex.lab The magnification to be used for x and y labels relative to the current setting of `cex`.

cex.main The magnification to be used for main titles relative to the current setting of `cex`.

cex.sub The magnification to be used for sub-titles relative to the current setting of `cex`.

cin *R.O.*; character size (*width*, *height*) in inches. These are the same measurements as `cra`, expressed in different units.

col A specification for the default plotting color. See section ‘Color Specification’. (Some functions such as `lines` accept a vector of values which are recycled. Other uses will take just the first value if a vector of length greater than one is supplied.)

col.axis The color to be used for axis annotation. Defaults to "black".

col.lab The color to be used for x and y labels. Defaults to "black".

col.main The color to be used for plot main titles. Defaults to "black".

col.sub The color to be used for plot sub-titles. Defaults to "black".

cra *R.O.*; size of default character (*width*, *height*) in ‘rasters’ (pixels). Some devices have no concept of pixels and so assume an arbitrary pixel size, usually 1/72 inch. These are the same measurements as `cin`, expressed in different units.

crt A numerical value specifying (in degrees) how single characters should be rotated. It is unwise to expect values other than multiples of 90 to work. Compare with `srt` which does string rotation.

csi *R.O.*; height of (default-sized) characters in inches. The same as `par("cin")[2]`.

cxy *R.O.*; size of default character (*width*, *height*) in user coordinate units. `par("cxy")` is `par("cin")/par("pin")` scaled to user coordinates. Note that `c(strwidth(ch), strwidth(ch))` for a given string `ch` is usually much more precise.

din *R.O.*; the device dimensions, (*width*, *height*), in inches.

err (*Unimplemented*; R is silent when points outside the plot region are *not* plotted.) The degree of error reporting desired.

family The name of a font family for drawing text. The maximum allowed length is 200 bytes. This name gets mapped by each graphics device to a device-specific font description. The default value is "" which means that the default device fonts will be used (and what those are should be listed on the help page for the device). Standard values are "serif", "sans" and "mono", and the [Hershey](#) font families are also available. (Different devices may define others, and some devices will ignore this setting completely.) This can be specified inline for `text`.

fg The color to be used for the foreground of plots. This is the default color used for things like axes and boxes around plots. When called from `par()` this also sets parameter `col` to the same value. See section ‘Color Specification’. A few devices have an argument to set the initial value, which is otherwise "black".

fig A numerical vector of the form `c(x1, x2, y1, y2)` which gives the (NDC) coordinates of the figure region in the display region of the device. If you set this, unlike S, you start a new plot, so to add to an existing plot use `new=TRUE` as well.

fin The figure region dimensions, $(width, height)$, in inches. If you set this, unlike `S`, you start a new plot.

font An integer which specifies which font to use for text. If possible, device drivers arrange so that 1 corresponds to plain text (the default), 2 to bold face, 3 to italic and 4 to bold italic. Also, font 5 is expected to be the symbol font, in Adobe symbol encoding. On some devices font families can be selected by `family` to choose different sets of 5 fonts.

font.axis The font to be used for axis annotation.

font.lab The font to be used for x and y labels.

font.main The font to be used for plot main titles.

font.sub The font to be used for plot sub-titles.

lab A numerical vector of the form $c(x, y, len)$ which modifies the default way that axes are annotated. The values of `x` and `y` give the (approximate) number of tickmarks on the x and y axes and `len` specifies the label length. The default is $c(5, 5, 7)$. Note that this only affects the way the parameters `xaxp` and `yaxp` are set when the user coordinate system is set up, and is not consulted when axes are drawn. `len` is *unimplemented* in R.

las numeric in $\{0,1,2,3\}$; the style of axis labels.

0: always parallel to the axis [*default*],

1: always horizontal,

2: always perpendicular to the axis,

3: always vertical.

Also supported by `mtext`. Note that other string/character rotation (via argument `srt` to `par`) does *not* affect the axis labels.

lend The line end style. This can be specified as an integer or string:

0 and "round" mean rounded line caps [*default*];

1 and "butt" mean butt line caps;

2 and "square" mean square line caps.

lheight The line height multiplier. The height of a line of text (used to vertically space multi-line text) is found by multiplying the character height both by the current character expansion and by the line height multiplier. Default value is 1. Used in `text` and `strheight`.

ljoin The line join style. This can be specified as an integer or string:

0 and "round" mean rounded line joins [*default*];

1 and "mitre" mean mitred line joins;

2 and "bevel" mean bevelled line joins.

lmitre The line mitre limit. This controls when mitred line joins are automatically converted into bevelled line joins. The value must be larger than 1 and the default is 10. Not all devices will honour this setting.

lty The line type. Line types can either be specified as an integer (0=blank, 1=solid (default), 2=dashed, 3=dotted, 4=dotdash, 5=longdash, 6=twodash) or as one of the character strings "blank", "solid", "dashed", "dotted", "dotdash", "longdash", or "twodash", where "blank" uses 'invisible lines' (i.e., does not draw them).

Alternatively, a string of up to 8 characters (from $c(1:9, "A": "F")$) may be given, giving the length of line segments which are alternatively drawn and skipped. See section 'Line Type Specification'.

Some functions such as `lines` accept a vector of values which are recycled. Other uses will take just the first value if a vector of length greater than one is supplied.

- lwd** The line width, a *positive* number, defaulting to 1. The interpretation is device-specific, and some devices do not implement line widths less than one. (See the help on the device for details of the interpretation.)
Some functions such as `lines` accept a vector of values which are recycled. Other uses will take just the first value if a vector of length greater than one is supplied.
- mai** A numerical vector of the form `c(bottom, left, top, right)` which gives the margin size specified in inches.
- mar** A numerical vector of the form `c(bottom, left, top, right)` which gives the number of lines of margin to be specified on the four sides of the plot. The default is `c(5, 4, 4, 2) + 0.1`.
- mex** `mex` is a character size expansion factor which is used to describe coordinates in the margins of plots. Note that this does not change the font size, rather specifies the size of font (as a multiple of `csi`) used to convert between `mar` and `mai`, and between `oma` and `omi`.
This starts as 1 when the device is opened, and is reset when the layout is changed (alongside resetting `cex`).
- mfc** A vector of the form `c(nr, nc)`. Subsequent figures will be drawn in an `nr`-by-`nc` array on the device by *columns* (`mfc`), or *rows* (`mfrow`), respectively.
In a layout with exactly two rows and columns the base value of "`cex`" is reduced by a factor of 0.83: if there are three or more of either rows or columns, the reduction factor is 0.66.
Setting a layout resets the base value of `cex` and that of `mex` to 1.
If either of these is queried it will give the current layout, so querying cannot tell you the order the array will be filled.
Consider the alternatives, `layout` and `split.screen`.
- mfg** A numerical vector of the form `c(i, j)` where `i` and `j` indicate which figure in an array of figures is to be drawn next (if setting) or is being drawn (if enquiring). The array must already have been set by `mfc` or `mfrow`.
For compatibility with S, the form `c(i, j, nr, nc)` is also accepted, when `nr` and `nc` should be the current number of rows and number of columns. Mismatches will be ignored, with a warning.
- mgp** The margin line (in `mex` units) for the axis title, axis labels and axis line. Note that `mgp[1]` affects `title` whereas `mgp[2:3]` affect `axis`. The default is `c(3, 1, 0)`.
- mkh** The height in inches of symbols to be drawn when the value of `pch` is an integer. *Completely ignored currently.*
- new** logical, defaulting to FALSE. If set to TRUE, the next high-level plotting command (actually `plot.new`) should *not clean* the frame before drawing *as if it was on a new device*. It is an error (ignored with a warning) to try to use `new=TRUE` on a device that does not currently contain a high-level plot.
- oma** A vector of the form `c(bottom, left, top, right)` giving the size of the outer margins in lines of text.
- omd** A vector of the form `c(x1, x2, y1, y2)` giving the region *inside* outer margins in NDC (= normalized device coordinates), i.e., as fraction (in `[0, 1]`) of the device region.
- omi** A vector of the form `c(bottom, left, top, right)` giving the size of the outer margins in inches.
- pch** Either an integer specifying a symbol or a single character to be used as the default in plotting points. See `points` for possible values and their interpretation. Note that only integers and single-character strings can be set as a graphics parameter (and not NA nor NULL).
- pin** The current plot dimensions, `(width, height)`, in inches.

- plt** A vector of the form $c(x1, x2, y1, y2)$ giving the coordinates of the plot region as fractions of the current figure region.
- ps** integer; the point size of text (but not symbols). Unlike the `pointsize` argument of most devices, this does not change the relationship between `mar` and `mai` (nor `oma` and `omi`). What is meant by ‘point size’ is device-specific, but most devices mean a multiple of 1bp, that is 1/72 of an inch.
- pty** A character specifying the type of plot region to be used; "s" generates a square plotting region and "m" generates the maximal plotting region.
- smo** (*Unimplemented*) a value which indicates how smooth circles and circular arcs should be.
- srt** The string rotation in degrees. See the comment about `crt`. Only supported by `text`.
- tck** The length of tick marks as a fraction of the smaller of the width or height of the plotting region. If `tck` ≥ 0.5 it is interpreted as a fraction of the relevant side, so if `tck` = 1 grid lines are drawn. The default setting (`tck` = NA) is to use `tcl` = -0.5.
- tcl** The length of tick marks as a fraction of the height of a line of text. The default value is -0.5; setting `tcl` = NA sets `tck` = -0.01 which is S' default.
- usr** A vector of the form $c(x1, x2, y1, y2)$ giving the extremes of the user coordinates of the plotting region. When a logarithmic scale is in use (i.e., `par("xlog")` is true, see below), then the x-limits will be $10^{\text{par}("usr")[1:2]}$. Similarly for the y-axis.
- xaxp** A vector of the form $c(x1, x2, n)$ giving the coordinates of the extreme tick marks and the number of intervals between tick-marks when `par("xlog")` is false. Otherwise, when *log* coordinates are active, the three values have a different meaning: For a small range, *n* is *negative*, and the ticks are as in the linear case, otherwise, *n* is in 1:3, specifying a case number, and *x1* and *x2* are the lowest and highest power of 10 inside the user coordinates, $10^{\text{par}("usr")[1:2]}$. (The "usr" coordinates are log10-transformed here!)
- n=1** will produce tick marks at 10^j for integer *j*,
- n=2** gives marks $k10^j$ with $k \in \{1, 5\}$,
- n=3** gives marks $k10^j$ with $k \in \{1, 2, 5\}$.
- See `axTicks()` for a pure R implementation of this.
- This parameter is reset when a user coordinate system is set up, for example by starting a new page or by calling `plot.window` or setting `par("usr"):n` is taken from `par("lab")`. It affects the default behaviour of subsequent calls to `axis` for sides 1 or 3.
- xaxs** The style of axis interval calculation to be used for the x-axis. Possible values are "r", "i", "e", "s", "d". The styles are generally controlled by the range of data or `xlim`, if given. Style "r" (regular) first extends the data range by 4 percent at each end and then finds an axis with pretty labels that fits within the extended range. Style "i" (internal) just finds an axis with pretty labels that fits within the original data range. Style "s" (standard) finds an axis with pretty labels within which the original data range fits. Style "e" (extended) is like style "s", except that it also ensures that there is room for plotting symbols within the bounding box. Style "d" (direct) specifies that the current axis should be used on subsequent plots. (*Only "r" and "i" styles are currently implemented*)
- xaxt** A character which specifies the x axis type. Specifying "n" suppresses plotting of the axis. The standard value is "s": for compatibility with S values "l" and "t" are accepted but are equivalent to "s": any value other than "n" implies plotting.
- xlog** A logical value (see `log` in `plot.default`). If TRUE, a logarithmic scale is in use (e.g., after `plot(*, log = "x")`). For a new device, it defaults to FALSE, i.e., linear scale.
- xpd** A logical value or NA. If FALSE, all plotting is clipped to the plot region, if TRUE, all plotting is clipped to the figure region, and if NA, all plotting is clipped to the device region. See also `clip`.

yaxp A vector of the form `c(y1, y2, n)` giving the coordinates of the extreme tick marks and the number of intervals between tick-marks unless for log coordinates, see `xaxp` above.

yaxs The style of axis interval calculation to be used for the y-axis. See `xaxs` above.

yaxt A character which specifies the y axis type. Specifying "n" suppresses plotting.

ylog A logical value; see `xlog` above.

Color Specification

Colors can be specified in several different ways. The simplest way is with a character string giving the color name (e.g., "red"). A list of the possible colors can be obtained with the function `colors`. Alternatively, colors can be specified directly in terms of their RGB components with a string of the form "#RRGGBB" where each of the pairs RR, GG, BB consist of two hexadecimal digits giving a value in the range 00 to FF. Colors can also be specified by giving an index into a small table of colors, the `palette`. This provides compatibility with S. Index 0 corresponds to the background color. (Because apparently some people have been assuming it, it is also possible to specify integers as character strings, e.g. "3".)

Additionally, "transparent" or (integer) NA is *transparent*, useful for filled areas (such as the background!), and just invisible for things like lines or text. Semi-transparent colors are available for use on devices that support them.

The functions `rgb`, `hsv`, `hcl`, `gray` and `rainbow` provide additional ways of generating colors.

Line Type Specification

Line types can either be specified by giving an index into a small built-in table of line types (1 = solid, 2 = dashed, etc, see `lty` above) or directly as the lengths of on/off stretches of line. This is done with a string of an even number (up to eight) of characters, namely *non-zero* (hexadecimal) digits which give the lengths in consecutive positions in the string. For example, the string "33" specifies three units on followed by three off and "3313" specifies three units on followed by three off followed by one on and finally three off. The 'units' here are (on most devices) proportional to `lwd`, and with `lwd = 1` are in pixels or points or 1/96 inch.

The five standard dash-dot line types (`lty = 2:6`) correspond to `c("44", "13", "1343", "73", "2262")`.

Note that NA is not a valid value for `lty`.

Note

The effect of restoring all the (settable) graphics parameters as in the examples is hard to predict if the device has been resized. Several of them are attempting to set the same things in different ways, and those last in the alphabet will win. In particular, the settings of `mai`, `mar`, `pin`, `plt` and `pty` interact, as do the outer margin settings, the figure layout and figure region size.

Examples

```

op <- par(mfrow = c(2, 2), # 2 x 2 pictures on one plot
          pty = "s")      # square plotting region,
                          # independent of device size

## At end of plotting, reset to previous settings:
par(op)

## Alternatively,
op <- par(no.readonly = TRUE) # the whole list of settable par's.
## do lots of plotting and par(.) calls, then reset:
par(op)
## Note this is not in general good practice

par("ylog") # FALSE
plot(1 : 12, log = "y")
par("ylog") # TRUE

plot(1:2, xaxs = "i") # 'inner axis' w/o extra space
par(c("usr", "xaxp"))

( nr.prof <-
  c(prof.pilots=16,lawyers=11,farmers=10,salesmen=9,physicians=9,
    mechanics=6,policemen=6,managers=6,engineers=5,teachers=4,
    housewives=3,students=3,armed.forces=1))
par(las = 3)
barplot(rbind(nr.prof)) # R 0.63.2: shows alignment problem
par(las = 0) # reset to default

require(grDevices) # for gray
## 'fg' use:
plot(1:12, type = "b", main="'fg' : axes, ticks and box in gray",
      fg = gray(0.7), bty="7" , sub=R.version.string)

ex <- function() {
  old.par <- par(no.readonly = TRUE) # all par settings which
                                     # could be changed.

  on.exit(par(old.par))
  ## ...
  ## ... do lots of par() settings and plots
  ## ...
  invisible() #-- now, par(old.par) will be executed
}
ex()

persp

Perspective Plots

Description

This function draws perspective plots of surfaces over the x–y plane. `persp` is a generic function.

Usage

```
persp(x, ...)

## Default S3 method:
persp(x = seq(0, 1, length.out = nrow(z)),
      y = seq(0, 1, length.out = ncol(z)),
      z, xlim = range(x), ylim = range(y),
      zlim = range(z, na.rm = TRUE),
      xlab = NULL, ylab = NULL, zlab = NULL,
      main = NULL, sub = NULL,
      theta = 0, phi = 15, r = sqrt(3), d = 1,
      scale = TRUE, expand = 1,
      col = "white", border = NULL, ltheta = -135, lphi = 0,
      shade = NA, box = TRUE, axes = TRUE, nticks = 5,
      ticktype = "simple", ...)
```

Arguments

<code>x, y</code>	locations of grid lines at which the values in <code>z</code> are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If <code>x</code> is a list, its components <code>x\$x</code> and <code>x\$y</code> are used for <code>x</code> and <code>y</code> , respectively.
<code>z</code>	a matrix containing the values to be plotted (NAs are allowed). Note that <code>x</code> can be used instead of <code>z</code> for convenience.
<code>xlim, ylim, zlim</code>	<code>x</code> -, <code>y</code> - and <code>z</code> -limits. The plot is produced so that the rectangular volume defined by these limits is visible.
<code>xlab, ylab, zlab</code>	titles for the axes. N.B. These must be character strings; expressions are not accepted. Numbers will be coerced to character strings.
<code>main, sub</code>	main and sub title, as for <code>title</code> .
<code>theta, phi</code>	angles defining the viewing direction. <code>theta</code> gives the azimuthal direction and <code>phi</code> the colatitude.
<code>r</code>	the distance of the eyepoint from the centre of the plotting box.
<code>d</code>	a value which can be used to vary the strength of the perspective transformation. Values of <code>d</code> greater than 1 will lessen the perspective effect and values less and 1 will exaggerate it.
<code>scale</code>	before viewing the <code>x</code> , <code>y</code> and <code>z</code> coordinates of the points defining the surface are transformed to the interval [0,1]. If <code>scale</code> is <code>TRUE</code> the <code>x</code> , <code>y</code> and <code>z</code> coordinates are transformed separately. If <code>scale</code> is <code>FALSE</code> the coordinates are scaled so that aspect ratios are retained. This is useful for rendering things like DEM information.
<code>expand</code>	a expansion factor applied to the <code>z</code> coordinates. Often used with $0 < \text{expand} < 1$ to shrink the plotting box in the <code>z</code> direction.
<code>col</code>	the color(s) of the surface facets. Transparent colours are ignored. This is recycled to the $(nx - 1)(ny - 1)$ facets.
<code>border</code>	the color of the line drawn around the surface facets. The default, <code>NULL</code> , corresponds to <code>par("fg")</code> . A value of <code>NA</code> will disable the drawing of borders: this is sometimes useful when the surface is shaded.

<code>ltheta, lphi</code>	if finite values are specified for <code>ltheta</code> and <code>lphi</code> , the surface is shaded as though it was being illuminated from the direction specified by azimuth <code>ltheta</code> and colatitude <code>lphi</code> .
<code>shade</code>	the shade at a surface facet is computed as $(1+d)/2$ raised to the power of <code>shade</code> , where <code>d</code> is the dot product of a unit vector normal to the facet and a unit vector in the direction of a light source. Values of <code>shade</code> close to one yield shading similar to a point light source model and values close to zero produce no shading. Values in the range 0.5 to 0.75 provide an approximation to daylight illumination.
<code>box</code>	should the bounding box for the surface be displayed. The default is <code>TRUE</code> .
<code>axes</code>	should ticks and labels be added to the box. The default is <code>TRUE</code> . If <code>box</code> is <code>FALSE</code> then no ticks or labels are drawn.
<code>ticktype</code>	character: <code>"simple"</code> draws just an arrow parallel to the axis to indicate direction of increase; <code>"detailed"</code> draws normal ticks as per 2D plots.
<code>nticks</code>	the (approximate) number of tick marks to draw on the axes. Has no effect if <code>ticktype</code> is <code>"simple"</code> .
<code>...</code>	additional graphical parameters (see par).

Details

The plots are produced by first transforming the coordinates to the interval $[0,1]$. The surface is then viewed by looking at the origin from a direction defined by `theta` and `phi`. If `theta` and `phi` are both zero the viewing direction is directly down the negative `y` axis. Changing `theta` will vary the azimuth and changing `phi` the colatitude.

There is a hook called `"persp"` (see [setHook](#)) called after the plot is completed, which is used in the testing code to annotate the plot page. The hook function(s) are called with no argument.

Notice that `persp` interprets the `z` matrix as a table of $f(x[i], y[j])$ values, so that the `x` axis corresponds to row number and the `y` axis to column number, with column 1 at the bottom, so that with the standard rotation angles, the top left corner of the matrix is displayed at the left hand side, closest to the user.

The sizes and fonts of the axis labels and the annotations for `ticktype="detailed"` are controlled by graphics parameters `"cex.lab"/"font.lab"` and `"cex.axis"/"font.axis"` respectively. (This changed in R 2.5.0.)

Value

`persp()` returns the *viewing transformation matrix*, say `VT`, a 4×4 matrix suitable for projecting 3D coordinates (x, y, z) into the 2D plane using homogeneous 4D coordinates (x, y, z, t) . It can be used to superimpose additional graphical elements on the 3D plot, by [lines\(\)](#) or [points\(\)](#), using the simple function [trans3d\(\)](#).

# Create a function interpolating colors in the range of specified colors
jet.colors <- colorRampPalette( c("blue", "green") )
# Generate the desired number of colors from this palette
nbc <- 100

```

```

color <- jet.colors(nbc)
# Compute the z-value at the facet centres
zfacet <- z[-1, -1] + z[-1, -ncz] + z[-nrz, -1] + z[-nrz, -ncz]
# Recode facet z-values into color indices
facetcol <- cut(zfacet, nbc)
persp(x, y, z, col=color[facetcol], phi=30, theta=-30)

par(op)

```

pie

Pie Charts

Description

Draw a pie chart.

Usage

```

pie(x, labels = names(x), edges = 200, radius = 0.8,
    clockwise = FALSE, init.angle = if(clockwise) 90 else 0,
    density = NULL, angle = 45, col = NULL, border = NULL,
    lty = NULL, main = NULL, ...)

```

Arguments

<code>x</code>	a vector of non-negative numerical quantities. The values in <code>x</code> are displayed as the areas of pie slices.
<code>labels</code>	one or more expressions or character strings giving names for the slices. Other objects are coerced by <code>as.graphicsAnnot</code> . For empty or NA (after coercion to character) labels, no label nor pointing line is drawn.
<code>edges</code>	the circular outline of the pie is approximated by a polygon with this many edges.
<code>radius</code>	the pie is drawn centered in a square box whose sides range from -1 to 1 . If the character strings labeling the slices are long it may be necessary to use a smaller radius.
<code>clockwise</code>	logical indicating if slices are drawn clockwise or counter clockwise (i.e., mathematically positive direction), the latter is default.
<code>init.angle</code>	number specifying the <i>starting angle</i> (in degrees) for the slices. Defaults to 0 (i.e., '3 o'clock') unless <code>clockwise</code> is true where <code>init.angle</code> defaults to 90 (degrees), (i.e., '12 o'clock').
<code>density</code>	the density of shading lines, in lines per inch. The default value of <code>NULL</code> means that no shading lines are drawn. Non-positive values of <code>density</code> also inhibit the drawing of shading lines.
<code>angle</code>	the slope of shading lines, given as an angle in degrees (counter-clockwise).
<code>col</code>	a vector of colors to be used in filling or shading the slices. If missing a set of 6 pastel colours is used, unless <code>density</code> is specified when <code>par("fg")</code> is used.
<code>border, lty</code>	(possibly vectors) arguments passed to <code>polygon</code> which draws each slice.
<code>main</code>	an overall title for the plot.
<code>...</code>	graphical parameters can be given as arguments to <code>pie</code> . They will affect the main title and labels only.

Note

Pie charts are a very bad way of displaying information. The eye is good at judging linear measures and bad at judging relative areas. A bar chart or dot chart is a preferable way of displaying this type of data.

Cleveland (1985), page 264: "Data that can be shown by pie charts always can be shown by a dot chart. This means that judgements of position along a common scale can be made instead of the less accurate angle judgements." This statement is based on the empirical investigations of Cleveland and McGill as well as investigations by perceptual psychologists.

Examples

```
require(grDevices)
pie(rep(1, 24), col = rainbow(24), radius = 0.9)

pie.sales <- c(0.12, 0.3, 0.26, 0.16, 0.04, 0.12)
names(pie.sales) <- c("Blueberry", "Cherry",
  "Apple", "Boston Cream", "Other", "Vanilla Cream")
pie(pie.sales) # default colours
pie(pie.sales,
  col = c("purple", "violetred1", "green3", "cornsilk", "cyan", "white"))
pie(pie.sales, col = gray(seq(0.4,1.0,length=6)))
pie(pie.sales, density = 10, angle = 15 + 10 * 1:6)
pie(pie.sales, clockwise=TRUE, main="pie(*, clockwise=TRUE)")
segments(0,0, 0,1, col= "red", lwd = 2)
text(0,1, "init.angle = 90", col= "red")

n <- 200
pie(rep(1,n), labels="", col=rainbow(n), border=NA,
  main = "pie(*, labels=\"\", col=rainbow(n), border=NA,..")
```

 plot

Generic X-Y Plotting

Description

Generic function for plotting of R objects. For more details about the graphical parameter arguments, see [par](#).

Usage

```
plot(x, y, ...)
```

Arguments

<code>x</code>	the coordinates of points in the plot. Alternatively, a single plotting structure, function or <i>any R object with a plot method</i> can be provided.
<code>y</code>	the y coordinates of points in the plot, <i>optional</i> if <code>x</code> is an appropriate structure.
<code>...</code>	Arguments to be passed to methods, such as graphical parameters (see par). Many methods will accept the following arguments:

type what type of plot should be drawn. Possible types are

- "p" for **p**oints,
- "l" for **l**ines,
- "b" for **b**oth,
- "c" for the lines part alone of "b",
- "o" for both 'overplotted',
- "h" for 'histogram' like (or 'high-density') vertical lines,
- "s" for stair steps,
- "S" for other steps, see 'Details' below,
- "n" for no plotting.

All other types give a warning or an error; using, e.g., `type = "punkte"` being equivalent to `type = "p"` for S compatibility.

main an overall title for the plot: see [title](#).

sub a sub title for the plot: see [title](#).

xlab a title for the x axis: see [title](#).

ylab a title for the y axis: see [title](#).

asp the y/x aspect ratio, see [plot.window](#).

Details

For simple scatter plots, [plot.default](#) will be used. However, there are `plot` methods for many R objects, including [functions](#), [data.frames](#), [density](#) objects, etc. Use `methods(plot)` and the documentation for these.

The two step types differ in their x-y preference: Going from (x_1, y_1) to (x_2, y_2) with $x_1 < x_2$, `type = "s"` moves first horizontal, then vertical, whereas `type = "S"` moves the other way around.

See Also

[plot.default](#), [plot.formula](#) and other methods; [points](#), [lines](#), [par](#).

Examples

```
require(stats)
plot(cars)
lines(lowess(cars))

plot(sin, -pi, 2*pi)

## Discrete Distribution Plot:
plot(table(rpois(100,5)), type = "h", col = "red", lwd=10,
      main="rpois(100,lambda=5)")

## Simple quantiles/ECDF, see ecdf() {library(stats)} for a better one:
```

```
plot(x <- sort(rnorm(47)), type = "s", main = "plot(x, type = \"s\")")
points(x, cex = .5, col = "dark red")
```

plot.data.frame *Plot Method for Data Frames*

Description

plot.data.frame, a method for the `plot` generic. It is designed for a quick look at numeric data frames.

Usage

```
## S3 method for class 'data.frame':
plot(x, ...)
```

Arguments

`x` object of class `data.frame`.
`...` further arguments to `stripchart`, `plot.default` or `pairs`.

Details

This is intended for data frames with *numeric* columns. For more than two columns it first calls `data.matrix` to convert the data frame to a numeric matrix and then calls `pairs` to produce a scatterplot matrix). This can fail and may well be inappropriate: for example numerical conversion of dates will lose their special meaning and a warning will be given.

For a two-column data frame it plots the second column against the first by the most appropriate method for the first column.

For a single numeric column it uses `stripchart`, and for other single-column data frames tries to find a plot method for the single column.

See Also

[data.frame](#)

Examples

```
plot(OrchardSprays[1], method="jitter")
plot(OrchardSprays[c(4,1)])
plot(OrchardSprays)

plot(iris)
plot(iris[5:4])
plot(women)
```

plot.default

*The Default Scatterplot Function***Description**

Draw a scatter plot with decorations such as axes and titles in the active graphics window.

Usage

```
## Default S3 method:
plot(x, y = NULL, type = "p", xlim = NULL, ylim = NULL,
     log = "", main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
     ann = par("ann"), axes = TRUE, frame.plot = axes,
     panel.first = NULL, panel.last = NULL, asp = NA, ...)
```

Arguments

<code>x</code> , <code>y</code>	the <code>x</code> and <code>y</code> arguments provide the <code>x</code> and <code>y</code> coordinates for the plot. Any reasonable way of defining the coordinates is acceptable. See the function xy.coords for details. If supplied separately, they must be of the same length.
<code>type</code>	1-character string giving the type of plot desired. The following values are possible, for details, see plot : "p" for points, "l" for lines, "o" for overplotted points and lines, "b", "c" for (empty if "c") points joined by lines, "s" and "S" for stair steps and "h" for histogram-like vertical lines. Finally, "n" does not produce any points or lines.
<code>xlim</code>	the <code>x</code> limits (<code>x1</code> , <code>x2</code>) of the plot. Note that <code>x1 > x2</code> is allowed and leads to a 'reversed axis'.
<code>ylim</code>	the <code>y</code> limits of the plot.
<code>log</code>	a character string which contains "x" if the <code>x</code> axis is to be logarithmic, "y" if the <code>y</code> axis is to be logarithmic and "xy" or "yx" if both axes are to be logarithmic.
<code>main</code>	a main title for the plot, see also title .
<code>sub</code>	a sub title for the plot.
<code>xlab</code>	a label for the <code>x</code> axis, defaults to a description of <code>x</code> .
<code>ylab</code>	a label for the <code>y</code> axis, defaults to a description of <code>y</code> .
<code>ann</code>	a logical value indicating whether the default annotation (title and <code>x</code> and <code>y</code> axis labels) should appear on the plot.
<code>axes</code>	a logical value indicating whether both axes should be drawn on the plot. Use graphical parameter "xaxt" or "yaxt" to suppress just one of the axes.
<code>frame.plot</code>	a logical indicating whether a box should be drawn around the plot.
<code>panel.first</code>	an expression to be evaluated after the plot axes are set up but before any plotting takes place. This can be useful for drawing background grids or scatterplot smooths.
<code>panel.last</code>	an expression to be evaluated after plotting has taken place.
<code>asp</code>	the <code>y/x</code> aspect ratio, see plot.window .
<code>...</code>	other graphical parameters (see par and section 'Details' below).

Details

Commonly used graphical parameters are:

col The colors for lines and points. Multiple colors can be specified so that each point can be given its own color. If there are fewer colors than points they are recycled in the standard fashion. Lines will all be plotted in the first colour specified.

bg a vector of background colors for open plot symbols, see [points](#). Note: this is **not** the same setting as `par("bg")`.

pch a vector of plotting characters or symbols: see [points](#).

cex a numerical vector giving the amount by which plotting characters and symbols should be scaled relative to the default. This works as a multiple of `par("cex")`. NULL and NA are equivalent to 1.0. Note that this does not affect annotation: see below.

lty the line type, see [par](#).

cex.main, **col.lab**, **font.sub**, **etc** settings for main- and sub-title and axis annotation, see [title](#) and [par](#).

lwd the line width, see [par](#).

Speed <- cars$speed
Distance <- cars$dist
plot(Speed, Distance, panel.first = grid(8,8),
     pch = 0, cex = 1.2, col = "blue")
plot(Speed, Distance,
     panel.first = lines(stats::lowess(Speed, Distance), lty = "dashed"),
     pch = 0, cex = 1.2, col = "blue")

## Show the different plot types
x <- 0:12
y <- sin(pi/5 * x)
op <- par(mfrow = c(3,3), mar = .1+ c(2,2,3,1))
for (tp in c("p","l","b", "c","o","h", "s","S","n")) {
  plot(y ~ x, type = tp,
       main = paste("plot(*, type = \"",tp,"\"",sep=""))
  if(tp == "S") {
    lines(x,y, type = "s", col = "red", lty = 2)
    mtext("lines(*, type = \"s\\", ...)", col = "red", cex=.8)
  }
}
par(op)
```

```
##--- Log-Log Plot with custom axes
lx <- seq(1,5, length=41)
yl <- expression(e^{-frac(1,2) * {log[10](x)}^2})
y <- exp(-.5*lx^2)
op <- par(mfrow=c(2,1), mar=par("mar")+c(0,1,0,0))
plot(10^lx, y, log="xy", type="l", col="purple",
     main="Log-Log plot", ylab=yl, xlab="x")
plot(10^lx, y, log="xy", type="o", pch='.', col="forestgreen",
     main="Log-Log plot with custom axes", ylab=yl, xlab="x",
     axes = FALSE, frame.plot = TRUE)
my.at <- 10^(1:5)
axis(1, at = my.at, labels = formatC(my.at, format="fg"))
at.y <- 10^(-5:-1)
axis(2, at = at.y, labels = formatC(at.y, format="fg"), col.axis="red")
par(op)
```

plot.design

Plot Univariate Effects of a 'Design' or Model

Description

Plot univariate effects of one or more [factors](#), typically for a designed experiment as analyzed by [aov\(\)](#). Further, in S this is a method of the [plot](#) generic function for [design](#) objects.

Usage

```
plot.design(x, y = NULL, fun = mean, data = NULL, ...,
           ylim = NULL, xlab = "Factors", ylab = NULL,
           main = NULL, ask = NULL, xaxt = par("xaxt"),
           axes = TRUE, xtick = FALSE)
```

Arguments

x	either a data frame containing the design factors and optionally the response, or a formula or terms object.
y	the response, if not given in x.
fun	a function (or name of one) to be applied to each subset. It must return one number for a numeric (vector) input.
data	data frame containing the variables referenced by x when that is formula like.
...	graphical arguments such as col , see par .
ylim	range of y values, as in plot.default .
xlab	x axis label, see title .
ylab	y axis label with a 'smart' default.
main	main title, see title .
ask	logical indicating if the user should be asked before a new page is started – in the case of multiple y's.
xaxt	character giving the type of x axis.
axes	logical indicating if axes should be drawn.
xtick	logical indicating if ticks (one per factor) should be drawn on the x axis.

Details

The supplied function will be called once for each level of each factor in the design and the plot will show these summary values. The levels of a particular factor are shown along a vertical line, and the overall value of `fun()` for the response is drawn as a horizontal line.

This is a new R implementation which will not be completely compatible to the earlier S implementations. This is not a bug but might still change.

Note

A big effort was taken to make this closely compatible to the S version. However, `col` (and `fg`) specification has different effects.

See Also

[interaction.plot](#) for a ‘standard graphic’ of designed experiments.

Examples

```
require(stats)
plot.design(warpbreaks)# automatic for data frame with one numeric var.

Form <- breaks ~ wool + tension
summary(fml <- aov(Form, data = warpbreaks))
plot.design(      Form, data = warpbreaks, col = 2)# same as above

## More than one y :
utils::str(esoph)
plot.design(esoph) ## two plots; if interactive you are "ask"ed

## or rather, compare mean and median:
op <- par(mfcol = 1:2)
plot.design(ncases/ncontrols ~ ., data = esoph, ylim = c(0, 0.8))
plot.design(ncases/ncontrols ~ ., data = esoph, ylim = c(0, 0.8),
            fun = median)
par(op)
```

plot.factor	<i>Plotting Factor Variables</i>
-------------	----------------------------------

Description

This functions implements a scatterplot method for `factor` arguments of the generic `plot` function. Actually, `boxplot` is used when `y` is numeric and a `spineplot` when `y` is a factor. For a single factor `x` (i.e., with `y` missing) a simple `barplot` is produced.

Usage

```
## S3 method for class 'factor':
plot(x, y, legend.text = NULL, ...)
```

Arguments

<code>x, y</code>	numeric or factor. <code>y</code> may be missing.
<code>legend.text</code>	character vector for annotation of <code>y</code> axis, defaults to <code>levels(y)</code> . Can be used instead of <code>yaxlabels</code> (for backward compatibility).
<code>...</code>	Further arguments to <code>plot</code> , see also <code>par</code> .

See Also

[plot.default](#), [plot.formula](#), [barplot](#), [boxplot](#), [spineplot](#).

Examples

```
require(grDevices)
plot(PlantGrowth) # -> plot.data.frame
plot(weight ~ group, data = PlantGrowth) # numeric vector ~ factor
plot(cut(weight, 2) ~ group, data = PlantGrowth) # factor ~ factor
## passing "..." to spineplot() eventually:
plot(cut(weight, 3) ~ group, data = PlantGrowth,
     col = hcl(c(0, 120, 240), 50, 70))

plot(PlantGrowth$group, axes=FALSE, main="no axes")# extremely silly
```

plot.formula	<i>Formula Notation for Scatterplots</i>
--------------	--

Description

Specify a scatterplot or add points or lines via a formula.

Usage

```
## S3 method for class 'formula':
plot(formula, data = parent.frame(), ..., subset,
      ylab = varnames[response], ask = dev.interactive())

## S3 method for class 'formula':
points(formula, data = parent.frame(), ..., subset)

## S3 method for class 'formula':
lines(formula, data = parent.frame(), ..., subset)
```

Arguments

formula	a formula , such as $y \sim x$.
data	a <code>data.frame</code> (or list) from which the variables in <code>formula</code> should be taken.
...	Arguments to be passed to or from other methods. <code>horizontal = TRUE</code> is also accepted.
subset	an optional vector specifying a subset of observations to be used in the fitting process.
ylab	the y label of the plot(s).
ask	logical, see par .

Details

Both the terms in the formula and the ... arguments are evaluated in `data` enclosed in `parent.frame()` if `data` is a list or a data frame. The terms of the formula and those arguments in ... that are of the same length as `data` are subjected to the subsetting specified in `subset`. If the formula in `plot.formula` contains more than one non-response term, a series of plots of y against each term is given. A plot against the running index can be specified as `plot(y ~ 1)`.

Missing values are not considered in these methods, and in particular cases with missing values are not removed.

If y is an object (i.e. has a `class` attribute) then `plot.formula` looks for a plot method for that class first. Otherwise, the class of x will determine the type of the plot. For factors this will be a parallel boxplot, and argument `horizontal = TRUE` can be used (see [boxplot](#)).

Value

These functions are invoked for their side effect of drawing in the active graphics device.

See Also

[plot.default](#), [points](#), [lines](#), [plot.factor](#).

Examples

```
op <- par(mfrow=c(2,1))
plot(Ozone ~ Wind, data = airquality, pch=as.character(Month))
plot(Ozone ~ Wind, data = airquality, pch=as.character(Month),
      subset = Month != 7)
par(op)
```

plot.histogram *Plot Histograms*

Description

These are methods for objects of class "histogram", typically produced by [hist](#).

Usage

```
## S3 method for class 'histogram':
plot(x, freq = equidist, density = NULL, angle = 45,
     col = NULL, border = par("fg"), lty = NULL,
     main = paste("Histogram of",
                  paste(x$xname, collapse="\n")),
     sub = NULL, xlab = x$xname, ylab,
     xlim = range(x$breaks), ylim = NULL,
     axes = TRUE, labels = FALSE, add = FALSE, ann = TRUE, ...)

## S3 method for class 'histogram':
lines(x, ...)
```

Arguments

x	a histogram object, or a list with components density, mid, etc, see hist for information about the components of x.
freq	logical; if TRUE, the histogram graphic is to present a representation of frequencies, i.e. x\$counts; if FALSE, <i>relative</i> frequencies (probabilities), i.e., x\$density, are plotted. The default is true for equidistant breaks and false otherwise.
col	a colour to be used to fill the bars. The default of NULL yields unfilled bars.
border	the color of the border around the bars.
angle, density	select shading of bars by lines: see rect .
lty	the line type used for the bars, see also lines .
main, sub, xlab, ylab	these arguments to <code>title</code> have useful defaults here.
xlim, ylim	the range of x and y values with sensible defaults.
axes	logical, indicating if axes should be drawn.
labels	logical or character. Additionally draw labels on top of bars, if not FALSE; if TRUE, draw the counts or rounded densities; if labels is a character, draw itself.
add	logical. If TRUE, only the bars are added to the current plot. This is what <code>lines.histogram(*)</code> does.
ann	logical. Should annotations (titles and axis titles) be plotted?
...	further graphical parameters to <code>title</code> and <code>axis</code> .

Details

`lines.histogram(*)` is the same as `plot.histogram(*, add = TRUE)`.

See Also

[hist](#), [stem](#), [density](#).

Examples

```
(wwt <- hist(women$weight, nclass = 7, plot = FALSE))
plot(wwt, labels = TRUE) # default main & xlab using wwt$xname
plot(wwt, border = "dark blue", col = "light blue",
     main = "Histogram of 15 women's weights", xlab = "weight [pounds]")

## Fake "lines" example, using non-default labels:
w2 <- wwt; w2$counts <- w2$counts - 1
lines(w2, col = "Midnight Blue", labels = ifelse(w2$counts, "> 1", "1"))
```

plot.table

Plot Methods for 'table' Objects

Description

This is a method of the generic `plot` function for (contingency) [table](#) objects. Whereas for two- and more dimensional tables, a [mosaicplot](#) is drawn, one-dimensional ones are plotted as bars.

Usage

```
## S3 method for class 'table':
plot(x, type = "h", ylim = c(0, max(x)), lwd = 2,
     xlab = NULL, ylab = NULL, frame.plot = is.num, ...)
```

Arguments

<code>x</code>	a table (like) object.
<code>type</code>	plotting type.
<code>ylim</code>	range of y-axis.
<code>lwd</code>	line width for bars when <code>type = "h"</code> is used in the 1D case.
<code>xlab, ylab</code>	x- and y-axis labels.
<code>frame.plot</code>	logical indicating if a frame (box) should be drawn in the 1D case. Defaults to true when <code>x</code> has dimnames coerce-able to numbers.
<code>...</code>	further graphical arguments, see plot.default .

See Also

[plot.factor](#), the `plot` method for factors.

Examples

```
## 1-d tables
(Poiss.tab <- table(N = stats::rpois(200, lambda = 5)))
plot(Poiss.tab, main = "plot(table(rpois(200, lambda = 5)))")

plot(table(state.division))

## 4-D :
plot(Titanic, main = "plot(Titanic, main= *)")
```

plot.window

Set up World Coordinates for Graphics Window

Description

This function sets up the world coordinate system for a graphics window. It is called by higher level functions such as `plot.default` (after `plot.new`).

Usage

```
plot.window(xlim, ylim, log = "", asp = NA, ...)
```

Arguments

<code>xlim</code> , <code>ylim</code>	numeric vectors of length 2, giving the x and y coordinates ranges.
<code>log</code>	character; indicating which axes should be in log scale.
<code>asp</code>	numeric, giving the aspect ratio y/x, see below.
<code>...</code>	further graphical parameters as in <code>par</code> . The relevant ones are <code>xaxs</code> , <code>yaxs</code> and <code>lab</code> .

Details

asp: If `asp` is a finite positive value then the window is set up so that one data unit in the x direction is equal in length to `asp` × one data unit in the y direction.

Note that in this case, `par("usr")` is no longer determined by, e.g., `par("xaxs")`, but rather by `asp` and the device's aspect ratio. (See what happens if you interactively resize the plot device after running the example below!)

The special case `asp == 1` produces plots where distances between points are represented accurately on screen. Values with `asp > 1` can be used to produce more accurate maps when using latitude and longitude.

To reverse an axis, use `xlim` or `ylim` of the form `c(hi, lo)`.

The function attempts to produce a plausible set of scales if one or both of `xlim` and `ylim` is of length one or the two values given are identical, but it is better to avoid that case.

Usually, one should rather use the higher level functions such as `plot`, `hist`, `image`, ..., instead and refer to their help pages for explanation of the arguments.

A side-effect of the call is to set up the `usr`, `xaxp` and `yaxp` graphical parameters. (It is for the latter two that `lab` is used.)

See Also

[xy.coords](#), [plot.xy](#), [plot.default](#).

Examples

```
##--- An example for the use of 'asp' :
require(stats) # normally loaded
loc <- cmdscale(eurodist)
rx <- range(x <- loc[,1])
ry <- range(y <- -loc[,2])
plot(x, y, type="n", asp=1, xlab="", ylab="")
abline(h = pretty(rx, 10), v = pretty(ry, 10), col = "lightgray")
text(x, y, labels(eurodist), cex=0.8)
```

plot.xy

Basic Internal Plot Function

Description

This is *the* internal function that does the basic plotting of points and lines. Usually, one should rather use the higher level functions instead and refer to their help pages for explanation of the arguments.

Usage

```
plot.xy(xy, type, pch = par("pch"), lty = par("lty"),
        col = par("col"), bg = NA,
        cex = 1, lwd = par("lwd"), ...)
```

Arguments

xy	A four-element list as results from xy.coords .
type	1 character code: see plot.default . NULL is accepted as a synonym for "p".
pch	character or integer code for kind of points, see points.default .
lty	line type code, see lines .
col	color code or name, see colors , palette . Here NULL means colour 0.
bg	background (fill) color for the open plot symbols 21:25: see points.default .
cex	character expansion.
lwd	line width, also used for (non-filled) plot symbols, see lines and points .
...	further graphical parameters such as xpd , lend , ljoin and lmitre .

Details

The arguments [pch](#), [col](#), [bg](#), [cex](#), [lwd](#) may be vectors and may be recycled, depending on [type](#): see [points](#) and [lines](#) for specifics. In particular note that [lwd](#) is treated as a vector for points and as a single (first) value for lines.

[cex](#) is a numeric factor in addition to `par("cex")` which affects symbols and characters as drawn by type "p", "o", "b" and "c".

See Also

[plot](#), [plot.default](#), [points](#), [lines](#).

Examples

```
points.default # to see how it calls "plot.xy(xy.coords(x, y), ...)"
```

points

Add Points to a Plot

Description

`points` is a generic function to draw a sequence of points at the specified coordinates. The specified character(s) are plotted, centered at the coordinates.

Usage

```
points(x, ...)

## Default S3 method:
points(x, y = NULL, type = "p", ...)
```

Arguments

`x`, `y` coordinate vectors of points to plot.

`type` character indicating the type of plotting; actually any of the `types` as in [plot.default](#).

`...` Further graphical parameters may also be supplied as arguments. See ‘Details’.

Details

The coordinates can be passed in a plotting structure (a list with `x` and `y` components), a two-column matrix, a time series, See [xy.coords](#). If supplied separately, they must be of the same length. Graphical parameters commonly used are

pch plotting ‘character’, i.e., symbol to use. This can either be a single character or an integer code for one of a set of graphics symbols. The full set of S symbols is available with `pch=0:18`, see the examples below.

Value `pch="."` (equivalently `pch = 46`) is handled specially. It is a rectangle of side 0.01 inch (scaled by `cex`). In addition, if `cex = 1` (the default), each side is at least one pixel (1/72 inch on the [pdf](#), [postscript](#) and [xfig](#) devices).

For other text symbols, `cex = 1` corresponds to the default fontsize of the device, often specified by an argument `pointsize`. For `pch` in `0:25` the default size is about 75% of the character height (see `par("cin")`).

col color code or name, see [par](#).

bg background (fill) color for the open plot symbols given by `pch=21:25`.

cex character (or symbol) expansion: a numerical vector. This works as a multiple of `par("cex")`.

lwd line width for drawing symbols see [par](#).

Others less commonly used are `lty` and `lwd` for types such as "b" and "l".

Graphical parameters `pch`, `col`, `bg`, `cex` and `lwd` can be vectors (which will be recycled as needed) giving a value for each point plotted. If lines are to be plotted (e.g. for `type = "b"`/ the first element of `lwd` is used.

Points whose `x`, `y`, `pch`, `col` or `cex` value is `NA` are omitted from the plot.

'pch' values

Values of `pch` are stored internally as integers. The interpretation is

- `NA_integer_`: no symbol.
- `0:18`: S-compatible vector symbols.
- `0:25`: R vector symbols.
- `26:31`: unused (and ignored).
- `32:127`: ASCII characters.
- `128:255` native characters *only in a single-byte locale and for the symbol font*. (`128:159` are only used on Windows.)
- `-32 . . .` Unicode point (where supported).

Note that unlike S (which uses octagons), symbols 1, 10, 13 and 16 use circles. The filled shapes do not include a border.

The following R plotting symbols are can be obtained with `pch=19:25`: those with `21:25` can be colored and filled with different colors: `col` gives the border color and `bg` the background color.

- `pch=19`: solid circle,
- `pch=20`: bullet (smaller circle),
- `pch=21`: filled circle,
- `pch=22`: filled square,
- `pch=23`: filled diamond,
- `pch=24`: filled triangle point-up,
- `pch=25`: filled triangle point down.

Note that all of these both fill the shape and draw a border. Some care in interpretation is needed when semi-transparent colours are used for both fill and border (and the result might be device-specific and even viewer-specific for [pdf](#)).

Values `pch=26:31` are currently unused and `pch=32:127` give the ASCII characters. In a single-byte locale `pch=128:255` give the corresponding character (if any) in the locale's character set. Where supported by the OS, negative values specify a Unicode point, so e.g. `-0x2642L` is a 'male sign' and `-0x20ACL` is the Euro.

A character string consisting of a single character is converted to an integer: `32:127` for ASCII characters, and usually to the Unicode point number otherwise. (In non-Latin-1 single-byte locales, `128:255` will be used for 8-bit characters.)

If `pch` supplied is a logical, integer or character `NA` or an empty character string the point is omitted from the plot.

If `pch` is `NULL` or otherwise of length 0, `par("pch")` is used.

If the symbol font (`par(font = 5)`) is used, numerical values should be used for `pch`: the range is `c(32:126, 160:254)` in all locales (but 240 is not defined (used for 'apple' on Mac OS) and 160, Euro, may not be present).

Note

A single-byte encoding may include the characters in `pch=128:255`, and if it does, a font may not include all (or even any) of them.

Not all negative numbers are valid as Unicode points, and no check is done. A display device is likely to use a rectangle for (or omit) Unicode points that do not exist or which it does not have a glyph.

```

polygon

Polygon Drawing

Description

`polygon` draws the polygons whose vertices are given in `x` and `y`.

Usage

```

polygon(x, y = NULL, density = NULL, angle = 45,
        border = NULL, col = NA, lty = par("lty"), ...)

```

Arguments

<code>x, y</code>	vectors containing the coordinates of the vertices of the polygon.
<code>density</code>	the density of shading lines, in lines per inch. The default value of <code>NULL</code> means that no shading lines are drawn. A zero value of <code>density</code> means no shading nor filling whereas negative values (and <code>NA</code>) suppress shading (and so allow color filling).
<code>angle</code>	the slope of shading lines, given as an angle in degrees (counter-clockwise).
<code>col</code>	the color for filling the polygon. The default, <code>NA</code> , is to leave polygons unfilled, unless <code>density</code> is specified. (For back-compatibility, <code>NULL</code> is equivalent to <code>NA</code> .) If <code>density</code> is specified with a positive value this gives the color of the shading lines.

<code>border</code>	the color to draw the border. The default, <code>NULL</code> , means to use <code>par("fg")</code> . Use <code>border = NA</code> to omit borders. For compatibility with <code>S</code> , <code>border</code> can also be logical, in which case <code>FALSE</code> is equivalent to <code>NA</code> (borders omitted) and <code>TRUE</code> is equivalent to <code>NULL</code> (use the foreground colour),
<code>lty</code>	the line type to be used, as in <code>par</code> .
<code>...</code>	graphical parameters such as <code>xpd</code> , <code>lend</code> , <code>ljoin</code> and <code>lmitre</code> can be given as arguments.

Details

The coordinates can be passed in a plotting structure (a list with `x` and `y` components), a two-column matrix, See `xy.coords`.

It is assumed that the polygon is to be closed by joining the last point to the first point.

The coordinates can contain missing values. The behaviour is similar to that of `lines`, except that instead of breaking a line into several lines, `NA` values break the polygon into several complete polygons (including closing the last point to the first point). See the examples below.

When multiple polygons are produced, the values of `density`, `angle`, `col`, `border`, and `lty` are recycled in the usual manner.

Bugs

The present shading algorithm can produce incorrect results for self-intersecting polygons.

Author(s)

The code implementing polygon shading was donated by Kevin Buhr (`buhr@stat.wisc.edu`).

# and recycling of col, border, and lty
op <- par(mfrow=c(2,1))
plot(c(1,9), 1:2, type="n")
polygon(1:9, c(2,1,2,1,1,2,1,2,1),
        col=c("red", "blue"),
        border=c("green", "yellow"),
        lwd=3, lty=c("dashed", "solid"))
plot(c(1,9), 1:2, type="n")
polygon(1:9, c(2,1,2,1,NA,2,1,2,1),
        col=c("red", "blue"),
        border=c("green", "yellow"),
        lwd=3, lty=c("dashed", "solid"))
par(op)

# Line-shaded polygons
plot(c(1,9), 1:2, type="n")
polygon(1:9, c(2,1,2,1,NA,2,1,2,1),
        density=c(10, 20), angle=c(-45, 45))

```

rect

Draw One or More Rectangles

Description

rect draws a rectangle (or sequence of rectangles) with the given coordinates, fill and border colors.

Usage

```

rect(xleft, ybottom, xright, ytop, density = NULL, angle = 45,
     col = NA, border = NULL, lty = par("lty"), lwd = par("lwd"),
     ...)

```

Arguments

xleft	a vector (or scalar) of left x positions.
ybottom	a vector (or scalar) of bottom y positions.
xright	a vector (or scalar) of right x positions.
ytop	a vector (or scalar) of top y positions.
density	the density of shading lines, in lines per inch. The default value of NULL means that no shading lines are drawn. A zero value of density means no shading lines whereas negative values (and NA) suppress shading (and so allow color filling).
angle	angle (in degrees) of the shading lines.

col	color(s) to fill or shade the rectangle(s) with. The default NA (or also NULL) means do not fill, i.e., draw transparent rectangles, unless density is specified.
border	color for rectangle border(s). The default means <code>par("fg")</code> . Use <code>border = NA</code> to omit borders. If there are shading lines, <code>border = TRUE</code> means use the same colour for the border as for the shading lines.
lty	line type for borders and shading; defaults to "solid".
lwd	line width for borders and shading.
...	graphical parameters such as <code>xpd</code> , <code>lend</code> , <code>ljoin</code> and <code>lmitre</code> can be given as arguments.

Details

The positions supplied, i.e., `xleft`, ... are relative to the current plotting region. If the x-axis goes from 100 to 200 then `xleft` must be larger than 100 and `xright` must be less than 200. The position vectors will be recycled to the length of the longest.

It is a graphics primitive used in [hist](#), [barplot](#), [legend](#), etc.

      density=c(NA, NA, 10, 30), angle=c(NA, NA, 30, -30))

par(op)
```

`rug`*Add a Rug to a Plot*

Description

Adds a *rug* representation (1-d plot) of the data to the plot.

Usage

```
rug(x, ticksize = 0.03, side = 1, lwd = 0.5, col = par("fg"),
    quiet = getOption("warn") < 0, ...)
```

Arguments

<code>x</code>	A numeric vector
<code>ticksize</code>	The length of the ticks making up the ‘rug’. Positive lengths give inwards ticks.
<code>side</code>	On which side of the plot box the rug will be plotted. Normally 1 (bottom) or 3 (top).
<code>lwd</code>	The line width of the ticks. Some devices will round the default width up to 1.
<code>col</code>	The colour the ticks are plotted in.
<code>quiet</code>	logical indicating if there should be a warning about clipped values.
<code>...</code>	further arguments, passed to <code>axis</code> , such as <code>line</code> or <code>pos</code> for specifying the location of the rug.

Details

Because of the way `rug` is implemented, only values of `x` that fall within the plot region are included. There will be a warning if any finite values are omitted, but non-finite values are omitted silently.

Prior to R 2.8.0 `rug` re-drew the axis like: it no longer does so.

See Also

`jitter` which you may want for ties in `x`.

Examples

```
require(stats)# both 'density' and its default method
with(faithful, {
  plot(density(eruptions, bw = 0.15))
  rug(eruptions)
  rug(jitter(eruptions, amount = 0.01), side = 3, col = "light blue")
})
```

Description

`split.screen` defines a number of regions within the current device which can, to some extent, be treated as separate graphics devices. It is useful for generating multiple plots on a single device. Screens can themselves be split, allowing for quite complex arrangements of plots.

`screen` is used to select which screen to draw in.

`erase.screen` is used to clear a single screen, which it does by filling with the background colour.

`close.screen` removes the specified screen definition(s).

Usage

```
split.screen(figs, screen, erase = TRUE)
screen(n = , new = TRUE)
erase.screen(n = )
close.screen(n, all.screens = FALSE)
```

Arguments

<code>figs</code>	A two-element vector describing the number of rows and the number of columns in a screen matrix <i>or</i> a matrix with 4 columns. If a matrix, then each row describes a screen with values for the left, right, bottom, and top of the screen (in that order) in NDC units, that is 0 at the lower left corner of the device surface, and 1 at the upper right corner.
<code>screen</code>	A number giving the screen to be split. It defaults to the current screen if there is one, otherwise the whole device region.
<code>erase</code>	logical: should selected screen be cleared?
<code>n</code>	A number indicating which screen to prepare for drawing (<code>screen</code>), erase (<code>erase.screen</code>), or close (<code>close.screen</code>). (<code>close.screen</code> will accept a vector of screen numbers.)
<code>new</code>	A logical value indicating whether the screen should be erased as part of the preparation for drawing in the screen.
<code>all.screens</code>	A logical value indicating whether all of the screens should be closed.

Details

The first call to `split.screen` places **R** into split-screen mode. The other split-screen functions only work within this mode. While in this mode, certain other commands should be avoided (see the Warnings section below). Split-screen mode is exited by the command `close.screen(all = TRUE)`.

If the current screen is closed, `close.screen` sets the current screen to be the next larger screen number if there is one, otherwise to the first available screen.

Value

`split.screen` returns a vector of screen numbers for the newly-created screens. With no arguments, `split.screen` returns a vector of valid screen numbers.

`screen` invisibly returns the number of the selected screen. With no arguments, `screen` returns the number of the current screen.

`close.screen` returns a vector of valid screen numbers.

`screen`, `erase.screen`, and `close.screen` all return `FALSE` if `R` is not in split-screen mode.

Warnings

The recommended way to use these functions is to completely draw a plot and all additions (i.e. points and lines) to the base plot, prior to selecting and plotting on another screen. The behavior associated with returning to a screen to add to an existing plot is unpredictable and may result in problems that are not readily visible.

These functions are totally incompatible with the other mechanisms for arranging plots on a device: `par(mfrow)`, `par(mfcol)` and `layout()`.

The functions are also incompatible with some plotting functions, such as `coplot`, which make use of these other mechanisms.

`erase.screen` will appear not to work if the background colour is transparent (as it is by default on most devices).

axis(4)                    # add tic marks to right-hand axis
title("Plot 1")
close.screen(all = TRUE)   # exit split-screen mode
}

```

segments

Add Line Segments to a Plot

Description

Draw line segments between pairs of points.

Usage

```

segments(x0, y0, x1, y1,
         col = par("fg"), lty = par("lty"), lwd = par("lwd"),
         ...)

```

Arguments

`x0`, `y0` coordinates of points **from** which to draw.

`x1`, `y1` coordinates of points **to** which to draw.

`col`, `lty`, `lwd` usual graphical parameters as in [par](#), possibly vectors. NA values in `col` cause the segment to be omitted.

`...` further graphical parameters (from [par](#)), such as `xpd` and the line characteristics `lend`, `ljoin` and `lmitre`.

Details

For each `i`, a line segment is drawn between the point $(x0[i], y0[i])$ and the point $(x1[i], y1[i])$. The coordinate vectors will be recycled to the length of the longest.

The graphical parameters `col`, `lty` and `lwd` can be vectors of length greater than one and will be recycled if necessary.

Examples

```
x <- stats::runif(12); y <- stats::rnorm(12)
i <- order(x,y); x <- x[i]; y <- y[i]
plot(x, y, main="arrows(.) and segments(.)")
## draw arrows from point to point :
s <- seq(length(x)-1)# one shorter than data
arrows(x[s], y[s], x[s+1], y[s+1], col= 1:3)
s <- s[-length(s)]
segments(x[s], y[s], x[s+2], y[s+2], col= 'pink')
```

spineplot

*Spine Plots and Spinograms***Description**

Spine plots are a special cases of mosaic plots, and can be seen as a generalization of stacked (or highlighted) bar plots. Analogously, spinograms are an extension of histograms.

Usage

```
spineplot(x, ...)
```

Default S3 method:

```
spineplot(x, y = NULL,
          breaks = NULL, tol.ylab = 0.05, off = NULL,
          ylevels = NULL, col = NULL,
          main = "", xlab = NULL, ylab = NULL,
          xaxlabels = NULL, yaxlabels = NULL,
          xlim = NULL, ylim = c(0, 1), ...)
```

S3 method for class 'formula':

```
spineplot(formula, data = list(),
          breaks = NULL, tol.ylab = 0.05, off = NULL,
          ylevels = NULL, col = NULL,
          main = "", xlab = NULL, ylab = NULL,
          xaxlabels = NULL, yaxlabels = NULL,
          xlim = NULL, ylim = c(0, 1), ...,
          subset = NULL)
```

Arguments

x	an object, the default method expects either a single variable (interpreted to be the explanatory variable) or a 2-way table. See details.
y	a "factor" interpreted to be the dependent variable
formula	a "formula" of type $y \sim x$ with a single dependent "factor" and a single explanatory variable.
data	an optional data frame.
breaks	if the explanatory variable is numeric, this controls how it is discretized. breaks is passed to <code>hist</code> and can be a list of arguments.

<code>tol.ylab</code>	convenience tolerance parameter for y-axis annotation. If the distance between two labels drops under this threshold, they are plotted equidistantly.
<code>off</code>	vertical offset between the bars (in per cent). It is fixed to 0 for spinograms and defaults to 2 for spine plots.
<code>ylevels</code>	a character or numeric vector specifying in which order the levels of the dependent variable should be plotted.
<code>col</code>	a vector of fill colors of the same length as <code>levels(y)</code> . The default is to call <code>gray.colors</code> .
<code>main, xlab, ylab</code>	character strings for annotation
<code>xaxlabels, yaxlabels</code>	character vectors for annotation of x and y axis. Default to <code>levels(y)</code> and <code>levels(x)</code> , respectively for the spine plot. For <code>xaxlabels</code> in the spinogram, the breaks are used.
<code>xlim, ylim</code>	the range of x and y values with sensible defaults.
<code>...</code>	additional arguments passed to <code>rect</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used for plotting.

Details

`spineplot` creates either a spinogram or a spine plot. It can be called via `spineplot(x, y)` or `spineplot(y ~ x)` where `y` is interpreted to be the dependent variable (and has to be categorical) and `x` the explanatory variable. `x` can be either categorical (then a spine plot is created) or numerical (then a spinogram is plotted). Additionally, `spineplot` can also be called with only a single argument which then has to be a 2-way table, interpreted to correspond to `table(x, y)`.

Both, spine plots and spinograms, are essentially mosaic plots with special formatting of spacing and shading. Conceptually, they plot $P(y|x)$ against $P(x)$. For the spine plot (where both x and y are categorical), both quantities are approximated by the corresponding empirical relative frequencies. For the spinogram (where x is numerical), x is first discretized (by calling `hist` with `breaks` argument) and then empirical relative frequencies are taken.

Thus, spine plots can also be seen as a generalization of stacked bar plots where not the heights but the widths of the bars corresponds to the relative frequencies of x . The heights of the bars then correspond to the conditional relative frequencies of y in every x group. Analogously, spinograms extend stacked histograms.

Value

The table visualized is returned invisibly.

stars

Star (Spider/Radar) Plots and Segment Diagrams

Description

Draw star plots or segment diagrams of a multivariate data set. With one single location, also draws ‘spider’ (or ‘radar’) plots.

Usage

```
stars(x, full = TRUE, scale = TRUE, radius = TRUE,
      labels = dimnames(x)[[1]], locations = NULL,
      nrow = NULL, ncol = NULL, len = 1,
      key.loc = NULL, key.labels = dimnames(x)[[2]],
      key.xpd = TRUE,
      xlim = NULL, ylim = NULL, flip.labels = NULL,
      draw.segments = FALSE,
      col.segments = 1:n.seg, col.stars = NA,
      axes = FALSE, frame.plot = axes,
      main = NULL, sub = NULL, xlab = "", ylab = "",
      cex = 0.8, lwd = 0.25, lty = par("lty"), xpd = FALSE,
      mar = pmin(par("mar"),
                 1.1+ c(2*axes+ (xlab != ""),
                       2*axes+ (ylab != ""), 1, 0)),
      add = FALSE, plot = TRUE, ...)
```

Arguments

<code>x</code>	matrix or data frame of data. One star or segment plot will be produced for each row of <code>x</code> . Missing values (NA) are allowed, but they are treated as if they were 0 (after scaling, if relevant).
<code>full</code>	logical flag: if TRUE, the segment plots will occupy a full circle. Otherwise, they occupy the (upper) semicircle only.
<code>scale</code>	logical flag: if TRUE, the columns of the data matrix are scaled independently so that the maximum value in each column is 1 and the minimum is 0. If FALSE, the presumption is that the data have been scaled by some other algorithm to the range [0, 1].
<code>radius</code>	logical flag: in TRUE, the radii corresponding to each variable in the data will be drawn.
<code>labels</code>	vector of character strings for labeling the plots. Unlike the S function <code>stars</code> , no attempt is made to construct labels if <code>labels = NULL</code> .
<code>locations</code>	Either two column matrix with the <code>x</code> and <code>y</code> coordinates used to place each of the segment plots; or numeric of length 2 when all plots should be superimposed (for a 'spider plot'). By default, <code>locations = NULL</code> , the segment plots will be placed in a rectangular grid.
<code>nrow, ncol</code>	integers giving the number of rows and columns to use when <code>locations</code> is NULL. By default, <code>nrow == ncol</code> , a square layout will be used.
<code>len</code>	scale factor for the length of radii or segments.
<code>key.loc</code>	vector with <code>x</code> and <code>y</code> coordinates of the unit key.
<code>key.labels</code>	vector of character strings for labeling the segments of the unit key. If omitted, the second component of <code>dimnames(x)</code> is used, if available.
<code>key.xpd</code>	clipping switch for the unit key (drawing and labeling), see <code>par("xpd")</code> .
<code>xlim</code>	vector with the range of <code>x</code> coordinates to plot.
<code>ylim</code>	vector with the range of <code>y</code> coordinates to plot.
<code>flip.labels</code>	logical indicating if the label locations should flip up and down from diagram to diagram. Defaults to a somewhat smart heuristic.

<code>draw.segments</code>	logical. If TRUE draw a segment diagram.
<code>col.segments</code>	color vector (integer or character, see <code>par</code>), each specifying a color for one of the segments (variables). Ignored if <code>draw.segments = FALSE</code> .
<code>col.stars</code>	color vector (integer or character, see <code>par</code>), each specifying a color for one of the stars (cases). Ignored if <code>draw.segments = TRUE</code> .
<code>axes</code>	logical flag: if TRUE axes are added to the plot.
<code>frame.plot</code>	logical flag: if TRUE, the plot region is framed.
<code>main</code>	a main title for the plot.
<code>sub</code>	a sub title for the plot.
<code>xlab</code>	a label for the x axis.
<code>ylab</code>	a label for the y axis.
<code>cex</code>	character expansion factor for the labels.
<code>lwd</code>	line width used for drawing.
<code>lty</code>	line type used for drawing.
<code>xpd</code>	logical or NA indicating if clipping should be done, see <code>par</code> (<code>xpd = .</code>).
<code>mar</code>	argument to <code>par</code> (<code>mar = *</code>), typically choosing smaller margins than by default.
<code>...</code>	further arguments, passed to the first call of <code>plot()</code> , see <code>plot.default</code> and to <code>box()</code> if <code>frame.plot</code> is true.
<code>add</code>	logical, if TRUE <i>add</i> stars to current plot.
<code>plot</code>	logical, if FALSE, nothing is plotted.

Details

Missing values are treated as 0.

Each star plot or segment diagram represents one row of the input x . Variables (columns) start on the right and wind counterclockwise around the circle. The size of the (scaled) column is shown by the distance from the center to the point on the star or the radius of the segment representing the variable.

Only one page of output is produced.

Note

This code started life as spatial star plots by David A. Andrews. See <http://www.udallas.edu:8080/~andrews/software/software.html>.

Prior to 1.4.1, scaling only shifted the maximum to 1, although documented as here.

      main="US Judges 1-10 ")
palette("default")
stars(cbind(1:16,10*(16:1)),draw.segments=TRUE,
      main = "A Joke -- do *not* use symbols on 2D data!")
```

Description

`stem` produces a stem-and-leaf plot of the values in `x`. The parameter `scale` can be used to expand the scale of the plot. A value of `scale=2` will cause the plot to be roughly twice as long as the default.

Usage

```
stem(x, scale = 1, width = 80, atom = 1e-08)
```

Arguments

<code>x</code>	a numeric vector.
<code>scale</code>	This controls the plot length.
<code>width</code>	The desired width of plot.
<code>atom</code>	a tolerance.

References

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole.

Examples

```
stem(islands)
stem(log10(islands))
```

stripchart	<i>1-D Scatter Plots</i>
------------	--------------------------

Description

`stripchart` produces one dimensional scatter plots (or dot plots) of the given data. These plots are a good alternative to `boxplots` when sample sizes are small.

Usage

```
stripchart(x, ...)

## S3 method for class 'formula':
stripchart(x, data = NULL, dlab = NULL, ...,
           subset, na.action = NULL)

## Default S3 method:
stripchart(x, method = "overplot", jitter = 0.1, offset = 1/3,
           vertical = FALSE, group.names, add = FALSE,
           at = NULL, xlim = NULL, ylim = NULL,
           ylab=NULL, xlab=NULL, dlab="", glab="",
           log = "", pch = 0, col = par("fg"), cex = par("cex"),
           axes = TRUE, frame.plot = axes, ...)
```

Arguments

<code>x</code>	the data from which the plots are to be produced. In the default method the data can be specified as a single numeric vector, or as list of numeric vectors, each corresponding to a component plot. In the <code>formula</code> method, a symbolic specification of the form $y \sim g$ can be given, indicating the observations in the vector <code>y</code> are to be grouped according to the levels of the factor <code>g</code> . NAs are allowed in the data.
<code>data</code>	a <code>data.frame</code> (or list) from which the variables in <code>x</code> should be taken.
<code>subset</code>	an optional vector specifying a subset of observations to be used for plotting.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. The default is to ignore missing values in either the response or the group.
<code>...</code>	additional parameters passed to the default method, or by it to <code>plot</code> , <code>axis</code> and <code>title</code> to control the appearance of the plot.
<code>method</code>	the method to be used to separate coincident points. The default method "overplot" causes such points to be overplotted, but it is also possible to specify "jitter" to jitter the points, or "stack" have coincident points stacked. The last method only makes sense for very granular data.
<code>jitter</code>	when <code>method="jitter"</code> is used, <code>jitter</code> gives the amount of jittering applied.
<code>offset</code>	when stacking is used, points are stacked this many line-heights (symbol widths) apart.
<code>vertical</code>	when <code>vertical</code> is TRUE the plots are drawn vertically rather than the default horizontal.
<code>group.names</code>	group labels which will be printed alongside (or underneath) each plot.
<code>add</code>	logical, if true <code>add</code> the chart to the current plot.
<code>at</code>	numeric vector giving the locations where the charts should be drawn, particularly when <code>add = TRUE</code> ; defaults to <code>1:n</code> where <code>n</code> is the number of boxes.
<code>ylab, xlab</code>	labels: see <code>title</code> .
<code>dlab, glab</code>	alternate way to specify axis labels: see 'Details'.
<code>xlim, ylim</code>	plot limits: see <code>plot.window</code> .
<code>log</code>	on which axes to use a log scale: see <code>plot.default</code>
<code>pch, col, cex</code>	Graphical parameters: see <code>par</code> .
<code>axes, frame.plot</code>	Axis control: see <code>plot.default</code>

Details

Extensive examples of the use of this kind of plot can be found in Box, Hunter and Hunter or Seber and Wild.

The `dlab` and `glab` labels may be used instead of `xlab` and `ylab` if those are not specified. `dlab` applies to the continuous data axis (the X axis unless `vertical` is TRUE), `glab` to the group axis.

Examples

```
x <- stats::rnorm(50)
xr <- round(x, 1)
stripchart(x) ; m <- mean(par("usr")[1:2])
text(m, 1.04, "stripchart(x, \"overplot\")")
stripchart(xr, method = "stack", add = TRUE, at = 1.2)
text(m, 1.35, "stripchart(round(x,1), \"stack\")")
stripchart(xr, method = "jitter", add = TRUE, at = 0.7)
text(m, 0.85, "stripchart(round(x,1), \"jitter\")")

stripchart(decrease ~ treatment,
  main = "stripchart(OrchardSprays)",
  vertical = TRUE, log = "y", data = OrchardSprays)

stripchart(decrease ~ treatment, at = c(1:8)^2,
  main = "stripchart(OrchardSprays)",
  vertical = TRUE, log = "y", data = OrchardSprays)
```

strwidth

*Plotting Dimensions of Character Strings and Math Expressions***Description**

These functions compute the width or height, respectively, of the given strings or mathematical expressions `s[i]` on the current plotting device in *user* coordinates, *inches* or as fraction of the figure width `par("fin")`.

Usage

```
strwidth(s, units = "user", cex = NULL, font = NULL, vfont = NULL, ...)
strheight(s, units = "user", cex = NULL, font = NULL, vfont = NULL, ...)
```

Arguments

<code>s</code>	a character or expression vector whose dimensions are to be determined. Other objects are coerced by <code>as.graphicsAnnot</code> .
<code>units</code>	character indicating in which units <code>s</code> is measured; should be one of "user", "inches", "figure"; partial matching is performed.
<code>cex</code>	numeric character expansion factor ; multiplied by <code>par("cex")</code> yields the final character size; the default NULL is equivalent to 1.
<code>font, vfont, ...</code>	additional information about the font, possibly including the graphics parameter "family": see text .

Details

Where an element of `s` is a multi-line string (that is, contains newlines `\n`), the width and height are of an enclosing rectangle of the string as plotted by [text](#). The inter-line spacing is controlled by `cex`, `par("lheight")` and the 'point size' (but not the actual font in use).

Measurements in "user" units (the default) are only available after `plot.new` has been called – otherwise an error is thrown.

Value

Numeric vector with the same length as `s`, giving the width or height for each `s[i]`. NA strings are given width and height 0 (as they are not plotted).

See Also

`text`, `nchar`

Examples

```
str.ex <- c("W", "w", "I", ".", "WwI.")
op <- par(pty='s'); plot(1:100, 1:100, type="n")
sw <- strwidth(str.ex); sw
all.equal(sum(sw[1:4]), sw[5])
#- since the last string contains the others

sw.i <- strwidth(str.ex, "inches"); 25.4 * sw.i # width in [mm]
unique(sw / sw.i)
# constant factor: 1 value
mean(sw.i / strwidth(str.ex, "fig")) / par('fin')[1] # = 1: are the same

## See how letters fall in classes
## -- depending on graphics device and font!
all.lett <- c(letters, LETTERS)
shL <- strheight(all.lett, units = "inches") * 72 # 'big points'
table(shL) # all have same heights ...
mean(shL)/par("cin")[2] # around 0.6

(swL <- strwidth(all.lett, units="inches") * 72) # 'big points'
split(all.lett, factor(round(swL, 2)))

sumex <- expression(sum(x[i], i=1,n), e^{i * pi} == -1)
strwidth(sumex)
strheight(sumex)

par(op)#- reset to previous setting
```

sunflowerplot

Produce a Sunflower Scatter Plot

Description

Multiple points are plotted as ‘sunflowers’ with multiple leaves (‘petals’) such that overplotting is visualized instead of accidental and invisible.

Usage

```
sunflowerplot(x, y = NULL, number, log = "", digits = 6,
              xlab = NULL, ylab = NULL, xlim = NULL, ylim = NULL,
              add = FALSE, rotate = FALSE,
              pch = 16, cex = 0.8, cex.fact = 1.5,
              col = par("col"), bg = NA, size = 1/8, seg.col = 2,
              seg.lwd = 1.5, ...)
```

Arguments

<code>x</code>	numeric vector of x-coordinates of length <code>n</code> , say, or another valid plotting structure, as for <code>plot.default</code> , see also <code>xy.coords</code> .
<code>y</code>	numeric vector of y-coordinates of length <code>n</code> .
<code>number</code>	integer vector of length <code>n</code> . <code>number[i]</code> = number of replicates for $(x[i], y[i])$, may be 0. Default (<code>missing(number)</code>): compute the exact multiplicity of the points <code>x[]</code> , <code>y[]</code> , via <code>xyTable()</code> .
<code>log</code>	character indicating log coordinate scale, see <code>plot.default</code> .
<code>digits</code>	when <code>number</code> is computed (i.e., not specified), <code>x</code> and <code>y</code> are rounded to <code>digits</code> significant digits before multiplicities are computed.
<code>xlab, ylab</code>	character label for x-, or y-axis, respectively.
<code>xlim, ylim</code>	<code>numeric(2)</code> limiting the extents of the x-, or y-axis.
<code>add</code>	logical; should the plot be added on a previous one? Default is <code>FALSE</code> .
<code>rotate</code>	logical; if <code>TRUE</code> , randomly rotate the sunflowers (preventing artefacts).
<code>pch</code>	plotting character to be used for points (<code>number[i]==1</code>) and center of sunflowers.
<code>cex</code>	numeric; character size expansion of center points (s. <code>pch</code>).
<code>cex.fact</code>	numeric <i>shrinking</i> factor to be used for the center points <i>when there are flower leaves</i> , i.e., <code>cex / cex.fact</code> is used for these.
<code>col, bg</code>	colors for the plot symbols, passed to <code>plot.default</code> .
<code>size</code>	of sunflower leaves in inches, <code>1[in] := 2.54[cm]</code> . Default: <code>1/8</code> ; approximately 3.2mm.
<code>seg.col</code>	color to be used for the segments which make the sunflowers leaves, see <code>par(col=)</code> ; <code>col = "gold"</code> reminds of real sunflowers.
<code>seg.lwd</code>	numeric; the line width for the leaves' segments.
<code>...</code>	further arguments to <code>plot</code> [if <code>add=FALSE</code>].

Details

For `number[i]==1`, a (slightly enlarged) usual plotting symbol (`pch`) is drawn. For `number[i] > 1`, a small plotting symbol is drawn and `number[i]` equi-angular 'rays' emanate from it.

If `rotate=TRUE` and `number[i] >= 2`, a random direction is chosen (instead of the y-axis) for the first ray. The goal is to `jitter` the orientations of the sunflowers in order to prevent artefactual visual impressions.

Value

A list with three components of same length,

<code>x</code>	x coordinates
<code>y</code>	y coordinates
<code>number</code>	number

Use `xyTable()` (from package `grDevices`) if you are only interested in this return value.

Side Effects

A scatter plot is drawn with ‘sunflowers’ as symbols.

Examples

```
require(stats)
require(grDevices)

## 'number' is computed automatically:
sunflowerplot(iris[, 3:4])
## Imitating Chambers et al., p.109, closely:
sunflowerplot(iris[, 3:4], cex=.2, cex.fact=1, size=.035, seg.lwd=.8)

sunflowerplot(x=sort(2*round(rnorm(100))), y= round(rnorm(100),0),
              main = "Sunflower Plot of Rounded N(0,1)")
## Similarly using a "xyTable" argument:
xyT <- xyTable(x=sort(2*round(rnorm(100))), y= round(rnorm(100),0),
              digits=3)
utils::str(xyT, vec.len=20)
sunflowerplot(xyT, main = "2nd Sunflower Plot of Rounded N(0,1)")

## A 'marked point process' {explicit 'number' argument}:
sunflowerplot(rnorm(100), rnorm(100), number = rpois(n=100,lambda=2),
              main="Sunflower plot (marked point process)",
              rotate=TRUE, col = "blue4")
```

symbols

Draw Symbols (Circles, Squares, Stars, Thermometers, Boxplots) on a Plot

Description

This function draws symbols on a plot. One of six symbols; *circles*, *squares*, *rectangles*, *stars*, *thermometers*, and *boxplots*, can be plotted at a specified set of x and y coordinates. Specific aspects of the symbols, such as relative size, can be customized by additional parameters.

Usage

```
symbols(x, y = NULL, circles, squares, rectangles, stars,
        thermometers, boxplots, inches = TRUE, add = FALSE,
        fg = par("col"), bg = NA,
        xlab = NULL, ylab = NULL, main = NULL,
        xlim = NULL, ylim = NULL, ...)
```

Arguments

<code>x, y</code>	the x and y co-ordinates for the centres of the symbols. They can be specified in any way which is accepted by <code>xy.coords</code> .
<code>circles</code>	a vector giving the radii of the circles.
<code>squares</code>	a vector giving the length of the sides of the squares.
<code>rectangles</code>	a matrix with two columns. The first column gives widths and the second the heights of rectangles.
<code>stars</code>	a matrix with three or more columns giving the lengths of the rays from the center of the stars. NA values are replaced by zeroes.
<code>thermometers</code>	a matrix with three or four columns. The first two columns give the width and height of the thermometer symbols. If there are three columns, the third is taken as a proportion: the thermometers are filled (using colour <code>fg</code>) from their base to this proportion of their height. If there are four columns, the third and fourth columns are taken as proportions and the thermometers are filled between these two proportions of their heights. The part of the box not filled in <code>fg</code> will be filled in the background colour (default transparent) given by <code>bg</code> .
<code>boxplots</code>	a matrix with five columns. The first two columns give the width and height of the boxes, the next two columns give the lengths of the lower and upper whiskers and the fifth the proportion (with a warning if not in [0,1]) of the way up the box that the median line is drawn.
<code>inches</code>	TRUE, FALSE or a positive number. See ‘Details’.
<code>add</code>	if <code>add</code> is TRUE, the symbols are added to an existing plot, otherwise a new plot is created.
<code>fg</code>	colour(s) the symbols are to be drawn in.
<code>bg</code>	if specified, the symbols are filled with colour(s), the vector <code>bg</code> being recycled to the number of symbols. The default is to leave the symbols unfilled.
<code>xlab</code>	the x label of the plot if <code>add</code> is not true. Defaults to the <code>deparsed</code> expression used for <code>x</code> .
<code>ylab</code>	the y label of the plot. Unused if <code>add = TRUE</code> .
<code>main</code>	a main title for the plot. Unused if <code>add = TRUE</code> .
<code>xlim</code>	numeric vector of length 2 giving the x limits for the plot. Unused if <code>add = TRUE</code> .
<code>ylim</code>	numeric vector of length 2 giving the y limits for the plot. Unused if <code>add = TRUE</code> .
<code>...</code>	graphics parameters can also be passed to this function, as can the plot aspect ratio <code>asp</code> (see <code>plot.window</code>).

Details

Observations which have missing coordinates or missing size parameters are not plotted. The exception to this is *stars*. In that case, the length of any ray which is NA is reset to zero.

Argument `inches` controls the sizes of the symbols. If `TRUE` (the default), the symbols are scaled so that the largest dimension of any symbol is one inch. If a positive number is given the symbols are scaled to make largest dimension this size in inches (so `TRUE` and `1` are equivalent). If `inches` is `FALSE`, the units are taken to be those of the appropriate axes. (For circles, squares and stars the units of the `x` axis are used. For boxplots, the lengths of the whiskers are regarded as dimensions alongside width and height when scaling by `inches`, and are otherwise interpreted in the units of the `y` axis.)

Circles of radius zero are plotted at radius one pixel (which is device-dependent).

See Also

[stars](#) for drawing *stars* with a bit more flexibility.

If you are thinking about doing ‘bubble plots’ by `symbols(*, circles=*)`, you should *really* consider using [sunflowerplot](#) instead.

Examples

```
require(stats); require(grDevices)
x <- 1:10
y <- sort(10*runif(10))
z <- runif(10)
z3 <- cbind(z, 2*runif(10), runif(10))
symbols(x, y, thermometers=cbind(.5, 1, z), inches=.5, fg = 1:10)
symbols(x, y, thermometers = z3, inches=FALSE)
text(x,y, apply(format(round(z3, digits=2)), 1, paste, collapse = ","),
      adj = c(-.2,0), cex = .75, col = "purple", xpd=NA)

## Note that example(trees) shows more sensible plots!
N <- nrow(trees)
with(trees, {
  ## Girth is diameter in inches
  symbols(Height, Volume, circles=Girth/24, inches=FALSE,
          main="Trees' Girth")# xlab and ylab automatically
  ## Colours too:
  palette(rainbow(N, end = 0.9))
  symbols(Height, Volume, circles=Girth/16, inches=FALSE, bg = 1:N,
          fg="gray30", main="symbols(*, circles=Girth/16, bg = 1:N)")
  palette("default")
})
```

text *Add Text to a Plot*

Description

`text` draws the strings given in the vector `labels` at the coordinates given by `x` and `y`. `y` may be missing since `xy.coords(x, y)` is used for construction of the coordinates.

Usage

```
text(x, ...)

## Default S3 method:
text(x, y = NULL, labels = seq_along(x), adj = NULL,
      pos = NULL, offset = 0.5, vfont = NULL,
      cex = 1, col = NULL, font = NULL, ...)
```

Arguments

<code>x, y</code>	numeric vectors of coordinates where the text <code>labels</code> should be written. If the length of <code>x</code> and <code>y</code> differs, the shorter one is recycled.
<code>labels</code>	a character vector or expression specifying the <i>text</i> to be written. An attempt is made to coerce other language objects (names and calls) to expressions, and vectors and other classed objects to character vectors by <code>as.character</code> . If <code>labels</code> is longer than <code>x</code> and <code>y</code> , the coordinates are recycled to the length of <code>labels</code> .
<code>adj</code>	one or two values in $[0, 1]$ which specify the <code>x</code> (and optionally <code>y</code>) adjustment of the labels. On most devices values outside that interval will also work.
<code>pos</code>	a position specifier for the text. If specified this overrides any <code>adj</code> value given. Values of 1, 2, 3 and 4, respectively indicate positions below, to the left of, above and to the right of the specified coordinates.
<code>offset</code>	when <code>pos</code> is specified, this value gives the offset of the label from the specified coordinate in fractions of a character width.
<code>vfont</code>	NULL for the current font family, or a character vector of length 2 for Hershey vector fonts. The first element of the vector selects a typeface and the second element selects a style. Ignored if <code>labels</code> is an expression.
<code>cex</code>	numeric character expansion factor; multiplied by <code>par("cex")</code> yields the final character size. NULL and NA are equivalent to 1.0.
<code>col, font</code>	the color and (if <code>vfont = NULL</code>) font to be used, possibly vectors. These default to the values of the global graphical parameters in <code>par()</code> .
<code>...</code>	further graphical parameters (from <code>par</code>), such as <code>srt</code> , <code>family</code> and <code>xpd</code> .

Details

`labels` must be of type `character` or `expression` (or be coercible to such a type). In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, greek letters, fractions, etc.

`adj` allows *adjustment* of the text with respect to (x, y) . Values of 0, 0.5, and 1 specify left/bottom, middle and right/top alignment, respectively. The default is for centered text, i.e., `adj`

= `c(0.5, 0.5)`. Accurate vertical centering needs character metric information on individual characters which is only available on some devices. Vertical alignment is done slightly differently for character strings and for expressions: `adj=c(0,0)` means to left-justify and to align on the baseline for strings but on the bottom of the bounding box for expressions. This also affects vertical centering: for strings the centering excludes any descenders whereas for expressions it includes them.

The `pos` and `offset` arguments can be used in conjunction with values returned by `identify` to recreate an interactively labelled plot.

Text can be rotated by using graphical parameters `srt` (see [par](#)); this rotates about the centre set by `adj`.

Graphical parameters `col`, `cex` and `font` can be vectors and will then be applied cyclically to the labels (and extra values will be ignored). NA values of `font` are replaced by `par("font")`.

Labels whose `x`, `y`, `labels`, `cex` or `col` value is NA are omitted from the plot.

What happens when `font = 5` (the symbol font) is selected can be both device- and locale-dependent. Most often labels will be interpreted in the Adobe symbol encoding, so e.g. "d" is delta, and "\300" is aleph.

Euro symbol

The Euro symbol was introduced relatively recently and may not be available in older fonts. In recent versions of Adobe symbol fonts it is character 160, so `text(x, y, "\xA0", font = 5)` may work. People using Western European locales on Unix-alikes can probably select ISO-8895-15 (Latin-9) which has the Euro as character 165: this can also be used for [postscript](#) and [pdf](#). It is `\u20ac` in Unicode, which can be used in UTF-8 locales.

The Euro should be rendered correctly by `X11` in UTF-8 locales, but the corresponding single-byte encoding in [postscript](#) and [pdf](#) will need to be selected as `ISOLatin9.enc`.

```

```

      adj = c(0,0))
text(4, 9, expression(hat(beta) == (X^t * X)^{-1} * X^t * y))
text(4, 8.4, "expression(hat(beta) == (X^t * X)^{-1} * X^t * y)",
      cex = .75)
text(4, 7, expression(bar(x) == sum(frac(x[i], n), i==1, n)))

## Two more latin1 examples
text(5,10.2,
      "Le français, c'est facile: Règles, Liberté, Egalité, Fraternité...")
text(5,9.8,
      "Jetzt no chli züritüütsch: (noch ein bißchen Zürcher deutsch)")

```

title

Plot Annotation

Description

This function can be used to add labels to a plot. Its first four principal arguments can also be used as arguments in most high-level plotting functions. They must be of type `character` or `expression`. In the latter case, quite a bit of mathematical notation is available such as sub- and superscripts, greek letters, fractions, etc: see [plotmath](#)

Usage

```

title(main = NULL, sub = NULL, xlab = NULL, ylab = NULL,
      line = NA, outer = FALSE, ...)

```

Arguments

<code>main</code>	The main title (on top) using font and size (<code>character expansion</code>) <code>par("font.main")</code> and color <code>par("col.main")</code> .
<code>sub</code>	Sub-title (at bottom) using font and size <code>par("font.sub")</code> and color <code>par("col.sub")</code> .
<code>xlab</code>	X axis label using font and character expansion <code>par("font.lab")</code> and color <code>par("col.lab")</code> .
<code>ylab</code>	Y axis label, same font attributes as <code>xlab</code> .
<code>line</code>	specifying a value for <code>line</code> overrides the default placement of labels, and places them this many lines outwards from the plot edge.
<code>outer</code>	a logical value. If <code>TRUE</code> , the titles are placed in the outer margins of the plot.
<code>...</code>	further graphical parameters from <code>par</code> . Use e.g., <code>col.main</code> or <code>cex.sub</code> instead of just <code>col</code> or <code>cex</code> . <code>adj</code> controls the justification of the titles. <code>xpd</code> can be used to set the clipping region: this defaults to the figure region unless <code>outer = TRUE</code> , otherwise the device region and can only be increased. <code>mgp</code> controls the default placing of the axis titles.

Details

The labels passed to `title` can be character strings or language objects (names, calls or expressions), or a list containing the string to be plotted, and a selection of the optional modifying graphical parameters `cex=`, `col=` and `font=`. Other objects will be coerced by `as.graphicsAnnot`.

The position of `main` defaults to being vertically centered in (outer) margin 3 and justified horizontally according to `par("adj")` on the plot region (device region for `outer=TRUE`).

The positions of `xlab`, `ylab` and `sub` are line (default for `xlab` and `ylab` being `par("mgp")[1]` and increased by 1 for `sub`) lines (of height `par("mex")`) into the appropriate margin, justified in the text direction according to `par("adj")` on the plot/device region.

`mtext`, `text`; `plotmath` for details on mathematical annotation.

Examples

```
plot(cars, main = "") # here, could use main directly
title(main = "Stopping Distance versus Speed")

plot(cars, main = "")
title(main = list("Stopping Distance versus Speed", cex=1.5,
                 col="red", font=3))

## Specifying "...":
plot(1, col.axis = "sky blue", col.lab = "thistle")
title("Main Title", sub = "sub title",
      cex.main = 2, font.main = 4, col.main = "blue",
      cex.sub = 0.75, font.sub = 3, col.sub = "red")

x <- seq(-4, 4, len = 101)
y <- cbind(sin(x), cos(x))
matplot(x, y, type = "l", xaxt = "n",
        main = expression(paste(plain(sin) * phi, " and ",
                                plain(cos) * phi)),
        ylab = expression("sin" * phi, "cos" * phi), # only 1st is taken
        xlab = expression(paste("Phase Angle ", phi)),
        col.main = "blue")
axis(1, at = c(-pi, -pi/2, 0, pi/2, pi),
     labels = expression(-pi, -pi/2, 0, pi/2, pi))
abline(h = 0, v = pi/2 * c(-1,1), lty = 2, lwd = .1, col = "gray70")
```

Description

`xinch` and `yinch` convert the specified number of inches given as their arguments into the correct units for plotting with graphics functions. Usually, this only makes sense when normal coordinates are used, i.e., *no* log scale (see the `log` argument to `par`).

`xyinch` does the same for a pair of numbers `xy`, simultaneously.

Usage

```
xinch(x = 1, warn.log = TRUE)
yinch(y = 1, warn.log = TRUE)
xyinch(xy = 1, warn.log = TRUE)
```

Arguments

<code>x, y</code>	numeric vector
<code>xy</code>	numeric of length 1 or 2.
<code>warn.log</code>	logical; if TRUE, a warning is printed in case of active log scale.

Examples

```
all(c(xinch(),yinch()) == xyinch()) # TRUE
xyinch()
xyinch #- to see that is really    delta{"usr"} / "pin"

## plot labels offset 0.12 inches to the right
## of plotted symbols in a plot
with(mtcars, {
  plot(mpg, disp, pch=19, main= "Motor Trend Cars")
  text(mpg + xinch(0.12), disp, row.names(mtcars),
       adj = 0, cex = .7, col = 'blue')
})
```

 xspline

Draw an X-spline

Description

Draw an X-spline, a curve drawn relative to control points.

Usage

```
xspline(x, y = NULL, shape = 0, open = TRUE, repEnds = TRUE, draw = TRUE,
        border = par("fg"), col = NA, ...)
```

Arguments

<code>x, y</code>	vectors containing the coordinates of the vertices of the polygon. See xy.coords for alternatives.
<code>shape</code>	A numeric vector of values between -1 and 1, which control the shape of the spline relative to the control points.
<code>open</code>	A logical value indicating whether the spline is an open or a closed shape.

<code>repEnds</code>	For open X-splines, a logical value indicating whether the first and last control points should be replicated for drawing the curve. Ignored for closed X-splines.
<code>draw</code>	logical: should the X-spline be drawn? If false, a set of line segments to draw the curve is returned, and nothing is drawn.
<code>border</code>	the color to draw the curve. Use <code>border = NA</code> to omit borders.
<code>col</code>	the color for filling the shape. The default, <code>NA</code> , is to leave unfilled.
<code>...</code>	graphical parameters such as <code>lty</code> , <code>xpd</code> , <code>lend</code> , <code>ljoin</code> and <code>lmitre</code> can be given as arguments.

Details

An X-spline is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.

If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1). If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open X-splines, the start and end control points must have a shape of 0 (and non-zero values are silently converted to zero).

For open X-splines, by default the start and end control points are replicated before the curve is drawn. A curve is drawn between (interpolating or approximating) the second and third of each set of four control points, so this default behaviour ensures that the resulting curve starts at the first control point you have specified and ends at the last control point. The default behaviour can be turned off via the `repEnds` argument.

Value

If `draw = TRUE`, `NULL` otherwise a list with elements `x` and `y` which could be passed to `lines`, `polygon` and so on.

Invisible in both cases.

Note

Two-dimensional splines need to be created in an isotropic coordinate system. Device coordinates are used (with an anisotropy correction if needed.)

Chapter 5

The grid package

grid-package

The Grid Graphics Package

Description

A rewrite of the graphics layout capabilities, plus some support for interaction.

Details

This package contains a graphics system which supplements S-style graphics (see the **graphics** package).

Further information is available in the following [vignettes](#):

grid	Introduction to grid (../doc/grid.pdf)
displaylist	Display Lists in grid (../doc/displaylist.pdf)
frame	Frames and packing grobs (../doc/frame.pdf)
grobs	Working with grid grobs (../doc/grobs.pdf)
interactive	Editing grid Graphics (../doc/interactive.pdf)
locndimn	Locations versus Dimensions (../doc/locndimn.pdf)
moveline	Demonstrating move-to and line-to (../doc/moveline.pdf)
nonfinite	How grid responds to non-finite values (../doc/nonfinite.pdf)
plotexample	Writing grid Code (../doc/plotexample.pdf)

Paul Murrell (paul@stat.auckland.ac.nz)

Maintainer: R Core Team (R-core@r-project.org)

References

Murrell, P. (2005) *R Graphics*. Chapman & Hall/CRC Press.

absolute.size	<i>Absolute Size of a Grob</i>
---------------	--------------------------------

Description

This function converts a unit object into absolute units. Absolute units are unaffected, but non-absolute units are converted into "null" units.

Usage

```
absolute.size(unit)
```

Arguments

unit An object of class "unit".

Details

Absolute units are things like "inches", "cm", and "lines". Non-absolute units are "npc" and "native".

This function is designed to be used in `widthDetails` and `heightDetails` methods.

Value

An object of class "unit".

Author(s)

Paul Murrell

See Also

[widthDetails](#) and [heightDetails](#) methods.

 arrow

Describe arrows to add to a line.

Description

Produces a description of what arrows to add to a line. The result can be passed to a function that draws a line, e.g., `grid.lines`.

Usage

```
arrow(angle = 30, length = unit(0.25, "inches"),
      ends = "last", type = "open")
```

Arguments

angle	The angle of the arrow head in degrees (smaller numbers produce narrower, pointier arrows). Essentially describes the width of the arrow head.
length	A unit specifying the length of the arrow head (from tip to base).
ends	One of "last", "first", or "both", indicating which ends of the line to draw arrow heads.
type	One of "open" or "closed" indicating whether the arrow head should be a closed triangle.

Examples

```
arrow()
```

 convertNative

Convert a Unit Object to Native units

Description

This function is deprecated in grid version 0.8 and will be made defunct in grid version 1.9

You should use the `convertUnit()` function or one of its close allies instead.

This function returns a numeric vector containing the specified x or y locations or dimensions, converted to "user" or "data" units, relative to the current viewport.

Usage

```
convertNative(unit, dimension="x", type="location")
```

Arguments

unit	A unit object.
dimension	Either "x" or "y".
type	Either "location" or "dimension".

Value

A numeric vector.

WARNING

If you draw objects based on output from these conversion functions, then resize your device, the objects will be drawn incorrectly – the base R display list will not recalculate these conversions. This means that you can only rely on the results of these calculations if the size of your device is fixed.

Author(s)

Paul Murrell

See Also

[grid.convert](#), [unit](#)

Examples

```
grid.newpage()
pushViewport(viewport(width=unit(.5, "npc"),
                      height=unit(.5, "npc")))

grid.rect()
w <- convertNative(unit(1, "inches"))
h <- convertNative(unit(1, "inches"), "y")
# This rectangle starts off life as 1in square, but if you
# resize the device it will no longer be 1in square
grid.rect(width=unit(w, "native"), height=unit(h, "native"),
          gp=gpar(col="red"))
popViewport(1)

# How to use grid.convert(), etc instead
convertNative(unit(1, "inches")) ==
  convertX(unit(1, "inches"), "native", valueOnly=TRUE)
convertNative(unit(1, "inches"), "y", "dimension") ==
  convertHeight(unit(1, "inches"), "native", valueOnly=TRUE)
```

dataViewport

Create a Viewport with Scales based on Data

Description

This is a convenience function for producing a viewport with x- and/or y-scales based on numeric values passed to the function.

Usage

```
dataViewport(xData = NULL, yData = NULL, xscale = NULL,
            yscale = NULL, extension = 0.05, ...)
```

Arguments

xData	A numeric vector of data.
yData	A numeric vector of data.
xscale	A numeric vector (length 2).
yscale	A numeric vector (length 2).
extension	A numeric. If length greater than 1, then first value is used to extend the xscale and second value is used to extend the yscale.
...	All other arguments will be passed to a call to the <code>viewport()</code> function.

Details

If `xscale` is not specified then the values in `x` are used to generate an x-scale based on the range of `x`, extended by the proportion specified in `extension`. Similarly for the y-scale.

Value

A grid viewport object.

[viewport](#) and [plotViewport](#).

drawDetails

Customising grid Drawing

Description

These generic hook functions are called whenever a grid grob is drawn. They provide an opportunity for customising the drawing of a new class derived from grob (or gTree).

Usage

```
drawDetails(x, recording)
draw.details(x, recording)
preDrawDetails(x)
postDrawDetails(x)
```

Arguments

x	A grid grob.
recording	A logical value indicating whether a grob is being added to the display list or redrawn from the display list.

Details

These functions are called by the `grid.draw` methods for grobs and `gTrees`.

`preDrawDetails` is called first during the drawing of a grob. This is where any additional viewports should be pushed (see, for example, `grid::preDrawDetails.frame`). Note that the default behaviour for grobs is to push any viewports in the `vp` slot, and for `gTrees` is to also push and up any viewports in the `childrenvp` slot so there is typically nothing to do here.

`drawDetails` is called next and is where any additional calculations and graphical output should occur (see, for example, `grid::drawDetails.xaxis`). Note that the default behaviour for `gTrees` is to draw all grobs in the `children` slot so there is typically nothing to do here.

`postDrawDetails` is called last and should reverse anything done in `preDrawDetails` (i.e., pop or up any viewports that were pushed; again, see, for example, `grid::postDrawDetails.frame`). Note that the default behaviour for grobs is to pop any viewports that were pushed so there is typically nothing to do here.

Note that `preDrawDetails` and `postDrawDetails` are also called in the calculation of "grobwidth" and "grobheight" units.

Value

None of these functions are expected to return a value.

Author(s)

Paul Murrell

[grid.draw](#)

editDetails

Customising grid Editing

Description

This generic hook function is called whenever a `grid` grob is edited via `grid.edit` or `editGrob`. This provides an opportunity for customising the editing of a new class derived from `grob` (or `gTree`).

Usage

```
editDetails(x, specs)
```

Arguments

<code>x</code>	A <code>grid</code> grob.
<code>specs</code>	A list of named elements. The names indicate the grob slots to modify and the values are the new values for the slots.

Details

This function is called by `grid.edit` and `editGrob`. A method should be written for classes derived from `grob` or `gTree` if a change in a slot has an effect on other slots in the `grob` or children of a `gTree` (e.g., see `grid:::editDetails.xaxis`).

Note that the slot already has the new value.

Value

The function **MUST** return the modified `grob`.

Author(s)

Paul Murrell

[grid.edit](#)

gEdit

Create and Apply Edit Objects

Description

The functions `gEdit` and `gEditList` create objects representing an edit operation (essentially a list of arguments to `editGrob`).

The functions `applyEdit` and `applyEdits` apply one or more edit operations to a graphical object.

These functions are most useful for developers creating new graphical functions and objects.

Usage

```
gEdit(...)
gEditList(...)
applyEdit(x, edit)
applyEdits(x, edits)
```

Arguments

<code>...</code>	one or more arguments to the <code>editGrob</code> function (for <code>gEdit</code>) or one or more "gEdit" objects (for <code>gEditList</code>).
<code>x</code>	a <code>grob</code> (grid graphical object).
<code>edit</code>	a "gEdit" object.
<code>edits</code>	either a "gEdit" object or a "gEditList" object.

Value

`gEdit` returns an object of class "gEdit".

`gEditList` returns an object of class "gEditList".

`applyEdit` and `applyEditList` return the modified `grob`.

Author(s)

Paul Murrell

See Also[grob editGrob](#)**Examples**

```
grid.rect(gp=gpar(col="red"))
# same thing, but more verbose
grid.draw(applyEdit(rectGrob(), gEdit(gp=gpar(col="red"))))
```

`getNames`*List the names of grobs on the display list*

Description

Returns a character vector containing the names of all top-level grobs on the display list.

Usage

```
getNames()
```

Value

A character vector.

Author(s)

Paul Murrell

Examples

```
grid.grill()
getNames()
```

`gpar`*Handling Grid Graphical Parameters*

Description

`gpar()` should be used to create a set of graphical parameter settings. It returns an object of class "gpar". This is basically a list of name-value pairs.

`get.gpar()` can be used to query the current graphical parameter settings.

Usage

```
gpar(...)
get.gpar(names = NULL)
```

Arguments

... Any number of named arguments.
 names A character vector of valid graphical parameter names.

Details

All grid viewports and (predefined) graphical objects have a slot called `gp`, which contains a "gpar" object. When a viewport is pushed onto the viewport stack and when a graphical object is drawn, the settings in the "gpar" object are enforced. In this way, the graphical output is modified by the `gp` settings until the graphical object has finished drawing, or until the viewport is popped off the viewport stack, or until some other viewport or graphical object is pushed or begins drawing.

Valid parameter names are:

<code>col</code>	Colour for lines and borders.
<code>fill</code>	Colour for filling rectangles, polygons, ...
<code>alpha</code>	Alpha channel for transparency
<code>lty</code>	Line type
<code>lwd</code>	Line width
<code>lex</code>	Multiplier applied to line width
<code>lineend</code>	Line end style (round, butt, square)
<code>linejoin</code>	Line join style (round, mitre, bevel)
<code>linemitre</code>	Line mitre limit (number greater than 1)
<code>fontsize</code>	The size of text (in points)
<code>cex</code>	Multiplier applied to fontsize
<code>fontfamily</code>	The font family
<code>fontface</code>	The font face (bold, italic, ...)
<code>lineheight</code>	The height of a line as a multiple of the size of text
<code>font</code>	Font face (alias for fontface; for backward compatibility)

Colours can be specified in one of the forms returned by `rgb`, as a name (see `colors`) or as a positive integer index into the current `palette` (with zero or negative values being taken as transparent).

The `alpha` setting is combined with the alpha channel for individual colours by multiplying (with both alpha settings normalised to the range 0 to 1).

The size of text is `fontsize*cex`. The size of a line is `fontsize*cex*lineheight`.

The `cex` setting is cumulative; if a viewport is pushed with a `cex` of 0.5 then another viewport is pushed with a `cex` of 0.5, the effective `cex` is 0.25.

The `alpha` and `lex` settings are also cumulative.

Changes to the `fontfamily` may be ignored by some devices, but is supported by PostScript, PDF, X11, Windows, and Quartz. The `fontfamily` may be used to specify one of the Hershey Font families (e.g., `HersheySerif`) and this specification will be honoured on all devices.

The specification of `fontface` can be an integer or a string. If an integer, then it follows the R base graphics standard: 1 = plain, 2 = bold, 3 = italic, 4 = bold italic. If a string, then valid values are: "plain", "bold", "italic", "oblique", and "bold.italic". For the special case of the `HersheySerif` font family, "cyrillic", "cyrillic.oblique", and "EUC" are also available.

Specifying the value `NULL` for a parameter is the same as not specifying any value for that parameter, except for `col` and `fill`, where `NULL` indicates not to draw a border or not to fill an area (respectively).

All parameter values can be vectors of multiple values. (This will not always make sense – for example, viewports will only take notice of the first parameter value.)

The `gamma` parameter is defunct since R 2.7.0.

`get.gpar()` returns all current graphical parameter settings.

Value

An object of class "gpar".

Author(s)

Paul Murrell

[Hershey](#).

Examples

```
gp <- get.gpar()
utils::str(gp)
## These *do* nothing but produce a "gpar" object:
gpar(col = "red")
gpar(col = "blue", lty = "solid", lwd = 3, fontsize = 16)
get.gpar(c("col", "lty"))
grid.newpage()
vp <- viewport(w = .8, h = .8, gp = gpar(col="blue"))
grid.draw(gTree(children=gList(rectGrob(gp = gpar(col="red")),
                               textGrob(paste("The rect is its own colour (red)",
                                               "but this text is the colour",
                                               "set by the gTree (green)",
                                               sep = "\n"))),
            gp = gpar(col="green"), vp = vp))
grid.text("This text is the colour set by the viewport (blue)",
          y = 1, just = c("center", "bottom"),
          gp = gpar(fontsize=20), vp = vp)
grid.newpage()
## example with multiple values for a parameter
pushViewport(viewport())
grid.points(1:10/11, 1:10/11, gp = gpar(col=1:10))
popViewport()
```

gPath

Concatenate Grob Names

Description

This function can be used to generate a grob path for use in `grid.edit` and friends.

A grob path is a list of nested grob names.

Usage

```
gPath(...)
```

Arguments

... Character values which are grob names.

Details

Grob names must only be unique amongst grobs which share the same parent in a gTree.

This function can be used to generate a specification for a grob that includes the grob's parent's name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

Value

A `gPath` object.

Grid

Grid Graphics

Description

General information about the grid graphics package.

Details

Grid graphics provides an alternative to the standard R graphics. The user is able to define arbitrary rectangular regions (called *viewports*) on the graphics device and define a number of coordinate systems for each region. Drawing can be specified to occur in any viewport using any of the available coordinate systems.

Grid graphics and standard R graphics do not mix!

Type `library(help = grid)` to see a list of (public) Grid graphics functions.

```
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
    heights=unit(rep(1, 4),
        c("lines", "lines", "lines", "null")),
    widths=unit(c(1, 1), "inches")))
## Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6,
    w=unit(1, "inches"), h=unit(1, "inches")))
## A flash plotting example
grid.multipanel(vp=viewport(0.5, 0.5, 0.8, 0.8))
```

Grid Viewports

*Create a Grid Viewport***Description**

These functions create viewports, which describe rectangular regions on a graphics device and define a number of coordinate systems within those regions.

Usage

```
viewport(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
    width = unit(1, "npc"), height = unit(1, "npc"),
    default.units = "npc", just = "centre",
    gp = gpar(), clip = "inherit",
    xscale = c(0, 1), yscale = c(0, 1),
    angle = 0,
    layout = NULL,
    layout.pos.row = NULL, layout.pos.col = NULL,
    name = NULL)
vpList(...)
vpStack(...)
vpTree(parent, children)
```

Arguments

<code>x</code>	A numeric vector or unit object specifying x-location.
<code>y</code>	A numeric vector or unit object specifying y-location.
<code>width</code>	A numeric vector or unit object specifying width.
<code>height</code>	A numeric vector or unit object specifying height.
<code>default.units</code>	A string indicating the default units to use if <code>x</code> , <code>y</code> , <code>width</code> , or <code>height</code> are only given as numeric vectors.
<code>just</code>	A string or numeric vector specifying the justification of the viewport relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.

<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>clip</code>	One of "on", "inherit", or "off", indicating whether to clip to the extent of this viewport, inherit the clipping region from the parent viewport, or turn clipping off altogether. For back-compatibility, a logical value of <code>TRUE</code> corresponds to "on" and <code>FALSE</code> corresponds to "inherit".
<code>xscale</code>	A numeric vector of length two indicating the minimum and maximum on the x-scale.
<code>yscale</code>	A numeric vector of length two indicating the minimum and maximum on the y-scale.
<code>angle</code>	A numeric value indicating the angle of rotation of the viewport. Positive values indicate the amount of rotation, in degrees, anticlockwise from the positive x-axis.
<code>layout</code>	A Grid layout object which splits the viewport into subregions.
<code>layout.pos.row</code>	A numeric vector giving the rows occupied by this viewport in its parent's layout.
<code>layout.pos.col</code>	A numeric vector giving the columns occupied by this viewport in its parent's layout.
<code>name</code>	A character value to uniquely identify the viewport once it has been pushed onto the viewport tree.
<code>...</code>	Any number of grid viewport objects.
<code>parent</code>	A grid viewport object.
<code>children</code>	A <code>vpList</code> object.

Details

The location and size of a viewport are relative to the coordinate systems defined by the viewport's parent (either a graphical device or another viewport). The location and size can be specified in a very flexible way by specifying them with unit objects. When specifying the location of a viewport, specifying both `layout.pos.row` and `layout.pos.col` as `NULL` indicates that the viewport ignores its parent's layout and specifies its own location and size (via its `locn`). If only one of `layout.pos.row` and `layout.pos.col` is `NULL`, this means occupy ALL of the appropriate row(s)/column(s). For example, `layout.pos.row = 1` and `layout.pos.col = NULL` means occupy all of row 1. Specifying non-`NULL` values for both `layout.pos.row` and `layout.pos.col` means occupy the intersection of the appropriate rows and columns. If a vector of length two is specified for `layout.pos.row` or `layout.pos.col`, this indicates a range of rows or columns to occupy. For example, `layout.pos.row = c(1, 3)` and `layout.pos.col = c(2, 4)` means occupy cells in the intersection of rows 1, 2, and 3, and columns, 2, 3, and 4.

Clipping obeys only the most recent viewport clip setting. For example, if you clip to viewport1, then clip to viewport2, the clipping region is determined wholly by viewport2, the size and shape of viewport1 is irrelevant (until viewport2 is popped of course).

If a viewport is rotated (because of its own `angle` setting or because it is within another viewport which is rotated) then the `clip` flag is ignored.

Viewport names need not be unique. When pushed, viewports sharing the same parent must have unique names, which means that if you push a viewport with the same name as an existing viewport, the existing viewport will be replaced in the viewport tree. A viewport name can be any string, but

grid uses the reserved name "ROOT" for the top-level viewport. Also, when specifying a viewport name in `downViewport` and `seekViewport`, it is possible to provide a viewport path, which consists of several names concatenated using the separator (currently `: :`). Consequently, it is not advisable to use this separator in viewport names.

The viewports in a `vpList` are pushed in parallel. The viewports in a `vpStack` are pushed in series. When a `vpTree` is pushed, the parent is pushed first, then the children are pushed in parallel.

Value

An R object of class `viewport`.

            gp=gpar(fontsize=8))
}

```

grid.add

Add a Grid Graphical Object

Description

Add a grob to a gTree or a descendant of a gTree.

Usage

```

grid.add(gPath, child, strict = FALSE, grep = FALSE,
         global = FALSE, allDevices = FALSE, redraw = TRUE)

addGrob(gTree, child, gPath = NULL, strict = FALSE, grep = FALSE,
        global = FALSE)

setChildren(x, children)

```

Arguments

gTree, x	A gTree object.
gPath	A gPath object. For grid.add this specifies a gTree on the display list. For addGrob this specifies a descendant of the specified gTree.
child	A grob object.
children	A gList object.
strict	A boolean indicating whether the gPath must be matched exactly.
grep	A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).

global	A boolean indicating whether the function should affect just the first match of the <code>gPath</code> , or whether all matches should be affected.
allDevices	A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
redraw	A logical value to indicate whether to redraw the grob.

Details

`addGrob` copies the specified grob and returns a modified grob.

`grid.add` destructively modifies a grob on the display list. If `redraw` is `TRUE` it then redraws everything to reflect the change.

`setChildren` is a basic function for setting all children of a `gTree` at once (instead of repeated calls to `addGrob`).

Value

`addGrob` returns a grob object; `grid.add` returns `NULL`.

grid.arrows

Draw Arrows

Description

Functions to create and draw arrows at either end of a line, or at either end of a `line.to`, `lines`, or `segments` grob.

These functions have been deprecated in favour of `arrow` arguments to the line-related primitives.

Usage

```
grid.arrows(x = c(0.25, 0.75), y = 0.5, default.units = "npc",
            grob = NULL,
            angle = 30, length = unit(0.25, "inches"),
            ends = "last", type = "open", name = NULL,
            gp = gpar(), draw = TRUE, vp = NULL)
```

```
arrowsGrob(x = c(0.25, 0.75), y = 0.5, default.units = "npc",
            grob = NULL,
            angle = 30, length = unit(0.25, "inches"),
            ends = "last", type = "open", name = NULL,
            gp = gpar(), vp = NULL)
```

Arguments

<code>x</code>	A numeric vector or unit object specifying x-values.
<code>y</code>	A numeric vector or unit object specifying y-values.
<code>default.units</code>	A string indicating the default units to use if <code>x</code> or <code>y</code> are only given as numeric vectors.
<code>grob</code>	A grob to add arrows to; currently can only be a <code>line.to</code> , <code>lines</code> , or <code>segments</code> grob.
<code>angle</code>	A numeric specifying (half) the width of the arrow head (in degrees).
<code>length</code>	A unit object specifying the length of the arrow head.
<code>ends</code>	One of "first", "last", or "both", indicating which end of the line to add arrow heads.
<code>type</code>	Either "open" or "closed" to indicate the type of arrow head.
<code>name</code>	A character identifier.
<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>draw</code>	A logical value indicating whether graphics output should be produced.
<code>vp</code>	A Grid viewport object (or NULL).

Details

Both functions create an arrows grob (a graphical object describing arrows), but only `grid.arrows()` draws the arrows (and then only if `draw` is TRUE).

If the `grob` argument is specified, this overrides any `x` and/or `y` arguments.

Value

An arrows grob. `grid.arrows()` returns the value invisibly.

gs <- segmentsGrob(x0=unit(1:4/5, "npc"),
                  x1=unit(1:4/5, "npc"))
grid.arrows(grob=gs, length=unit(0.1, "npc"),
            type="closed", gp=gpar(fill="white"))
popViewport()
pushViewport(viewport(layout.pos.col=4,
                      layout.pos.row=2))
grid.rect(gp=gpar(col="grey"))
# Arrows on a lines grob
# Name these because going to grid.edit them later
gl <- linesGrob(name="curve", x=unit(0:80/100, "npc"),
               y=unit((0:80/100)^2, "npc"))
grid.arrows(name="arrowOnLine", grob=gl, angle=15, type="closed",
            gp=gpar(fill="black"))
popViewport()
pushViewport(viewport(layout.pos.col=1,
                      layout.pos.row=2))
grid.move.to(x=0.5, y=0.8)
popViewport()
pushViewport(viewport(layout.pos.col=4,
                      layout.pos.row=1))
# Arrows on a line.to grob
glt <- lineToGrob(x=0.5, y=0.2, gp=gpar(lwd=3))
grid.arrows(grob=glt, ends="first", gp=gpar(lwd=3))
popViewport(2)
grid.edit(gPath("arrowOnLine", "curve"), y=unit((0:80/100)^3, "npc"))
## End(Not run)

```

grid.circle	<i>Draw a Circle</i>
-------------	----------------------

Description

Functions to create and draw a circle.

Usage

```
grid.circle(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL,
            gp=gpar(), draw=TRUE, vp=NULL)
circleGrob(x=0.5, y=0.5, r=0.5, default.units="npc", name=NULL,
            gp=gpar(), vp=NULL)
```

Arguments

x	A numeric vector or unit object specifying x-locations.
y	A numeric vector or unit object specifying y-locations.
r	A numeric vector or unit object specifying radii.
default.units	A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name	A character identifier.
gp	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
draw	A logical value indicating whether graphics output should be produced.
vp	A Grid viewport object (or <code>NULL</code>).

Details

Both functions create a circle grob (a graphical object describing a circle), but only `grid.circle()` draws the circle (and then only if `draw` is `TRUE`).

The radius may be given in any units; if the units are *relative* (e.g., "npc" or "native") then the radius will be different depending on whether it is interpreted as a width or as a height. In such cases, the smaller of these two values will be the result. To see the effect, type `grid.circle()` and adjust the size of the window.

Value

A circle grob. `grid.circle()` returns the value invisibly.

Warning

Negative values for the radius are silently converted to their absolute value.

Author(s)

Paul Murrell

See Also[Grid, viewport](#)

`grid.clip`*Set the Clipping Region*

Description

These functions set the clipping region within the current viewport *without* altering the current coordinate system.

Usage

```
grid.clip(...)
clipGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
         width = unit(1, "npc"), height = unit(1, "npc"),
         just = "centre", hjust = NULL, vjust = NULL,
         default.units = "npc", name = NULL, vp = NULL)
```

Arguments

<code>x</code>	A numeric vector or unit object specifying x-location.
<code>y</code>	A numeric vector or unit object specifying y-location.
<code>width</code>	A numeric vector or unit object specifying width.
<code>height</code>	A numeric vector or unit object specifying height.
<code>just</code>	The justification of the clip rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
<code>hjust</code>	A numeric vector specifying horizontal justification. If specified, overrides the <code>just</code> setting.
<code>vjust</code>	A numeric vector specifying vertical justification. If specified, overrides the <code>just</code> setting.
<code>default.units</code>	A string indicating the default units to use if <code>x</code> , <code>y</code> , <code>width</code> , or <code>height</code> are only given as numeric vectors.
<code>name</code>	A character identifier.
<code>vp</code>	A Grid viewport object (or NULL).
<code>...</code>	Arguments passed to <code>clipGrob</code> .

Details

Both functions create a clip rectangle (a graphical object describing a clip rectangle), but only `grid.clip` enforces the clipping.

Pushing or popping a viewport *always* overrides the clip region set by a clip grob, regardless of whether that viewport explicitly enforces a clipping region.

Value

clipGrob returns a clip grob.

Examples

```
# draw across entire viewport, but clipped
grid.clip(x = 0.3, width = 0.1)
grid.lines(gp=gpar(col="green", lwd=5))
# draw across entire viewport, but clipped (in different place)
grid.clip(x = 0.7, width = 0.1)
grid.lines(gp=gpar(col="red", lwd=5))
# Viewport sets new clip region
pushViewport(viewport(width=0.5, height=0.5, clip=TRUE))
grid.lines(gp=gpar(col="grey", lwd=3))
# Return to original viewport; get
# clip region from previous grid.clip()
# (NOT from previous viewport clip region)
popViewport()
grid.lines(gp=gpar(col="black"))
```

grid.collection *Create a Coherent Group of Grid Graphical Objects*

Description

This function is deprecated; please use `gTree`.

This function creates a graphical object which contains several other graphical objects. When it is drawn, it draws all of its children.

It may be convenient to name the elements of the collection.

Usage

```
grid.collection(..., gp=gpar(), draw=TRUE, vp=NULL)
```

Arguments

...	Zero or more objects of class "grob".
gp	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
draw	A logical value to indicate whether to produce graphical output.
vp	A Grid viewport object (or <code>NULL</code>).

Value

A collection grob.

[grid.grob](#).

grid.convert

Convert Between Different grid Coordinate Systems

Description

These functions take a unit object and convert it to an equivalent unit object in a different coordinate system.

Usage

```

convertX(x, unitTo, valueOnly = FALSE)
convertY(x, unitTo, valueOnly = FALSE)
convertWidth(x, unitTo, valueOnly = FALSE)
convertHeight(x, unitTo, valueOnly = FALSE)
convertUnit(x, unitTo,
            axisFrom = "x", typeFrom = "location",
            axisTo = axisFrom, typeTo = typeFrom,
            valueOnly = FALSE)
grid.convertX(x, unitTo, valueOnly = FALSE)
grid.convertY(x, unitTo, valueOnly = FALSE)
grid.convertWidth(x, unitTo, valueOnly = FALSE)
grid.convertHeight(x, unitTo, valueOnly = FALSE)
grid.convert(x, unitTo,
            axisFrom = "x", typeFrom = "location",
            axisTo = axisFrom, typeTo = typeFrom,
            valueOnly = FALSE)

```

Arguments

x	A unit object.
unitTo	The coordinate system to convert the unit to. See the unit function for valid coordinate systems.
axisFrom	Either "x" or "y" to indicate whether the unit object represents a value in the x- or y-direction.
typeFrom	Either "location" or "dimension" to indicate whether the unit object represents a location or a length.
axisTo	Same as axisFrom, but applies to the unit object that is to be created.
typeTo	Same as typeFrom, but applies to the unit object that is to be created.
valueOnly	A logical indicating. If TRUE then the function does not return a unit object, but rather only the converted numeric values.

Details

The `convertUnit` function allows for general-purpose conversions. The other four functions are just more convenient front-ends to it for the most common conversions.

The conversions occur within the current viewport.

It is not currently possible to convert to all valid coordinate systems (e.g., "strwidth" or "grob-width"). I'm not sure if all of these are impossible, they just seem implausible at this stage.

In normal usage of grid, these functions should not be necessary. If you want to express a location or dimension in inches rather than user coordinates then you should simply do something like `unit(1, "inches")` rather than something like `unit(0.134, "native")`.

In some cases, however, it is necessary for the user to perform calculations on a unit value and this function becomes necessary. In such cases, please take note of the warning below.

The `grid.*` versions are just previous incarnations which have been deprecated.

Value

A unit object in the specified coordinate system (unless `valueOnly` is TRUE in which case the returned value is a numeric).

Warning

The conversion is only valid for the current device size. If the device is resized then at least some conversions will become invalid. For example, suppose that I create a unit object as follows: `oneinch <- convertUnit(unit(1, "inches"), "native")`. Now if I resize the device, the unit object in `oneinch` no longer corresponds to a physical length of 1 inch.

convertX(unit(1/(1157/1238*72.27), "inches"), "dida")
convertX(unit(1/(1/12*1157/1238*72.27), "inches"), "cicero")
```

```

convertX(unit(1/(65536*72.27), "inches"), "scaledpts")

pushViewport(viewport(width=unit(1, "inches"),
                      height=unit(2, "inches"),
                      xscale=c(0, 1),
                      yscale=c(1, 3)))
## Location versus dimension
convertY(unit(2, "native"), "inches")
convertHeight(unit(2, "native"), "inches")
## From "x" to "y" (the conversion is via "inches")
convertUnit(unit(1, "native"), "native",
            axisFrom="x", axisTo="y")
## Convert several values at once
convertX(unit(c(0.5, 2.54), c("npc", "cm")),
        c("inches", "native"))
popViewport()
## Convert a complex unit
convertX(unit(1, "strwidth", "Hello"), "native")

```

grid.copy

Make a Copy of a Grid Graphical Object

Description

This function is redundant and will disappear in future versions.

Usage

```
grid.copy(grob)
```

Arguments

grob A grob object.

Value

A copy of the grob object.

Author(s)

Paul Murrell

[grid.grob.](#)

grid.curve

*Draw a Curve Between Locations***Description**

These functions create and draw a curve from one location to another.

Usage

```
grid.curve(...)
curveGrob(x1, y1, x2, y2, default.units = "npc",
          curvature = 1, angle = 90, ncp = 1, shape = 0.5,
          square = TRUE, squareShape = 1,
          inflect = FALSE, arrow = NULL, open = TRUE,
          debug = FALSE,
          name = NULL, gp = gpar(), vp = NULL)
arcCurvature(theta)
```

Arguments

x1	A numeric vector or unit object specifying the x-location of the start point.
y1	A numeric vector or unit object specifying the y-location of the start point.
x2	A numeric vector or unit object specifying the x-location of the end point.
y2	A numeric vector or unit object specifying the y-location of the end point.
default.units	A string indicating the default units to use if x1, y1, x2 or y2 are only given as numeric values.
curvature	A numeric value giving the amount of curvature. Negative values produce left-hand curves, positive values produce right-hand curves, and zero produces a straight line.
angle	A numeric value between 0 and 180, giving an amount to skew the control points of the curve. Values less than 90 skew the curve towards the start point and values greater than 90 skew the curve towards the end point.
ncp	The number of control points used to draw the curve. More control points creates a smoother curve.
shape	A numeric vector of values between -1 and 1, which control the shape of the curve relative to its control points. See <code>grid.xspline</code> for more details.
square	A logical value that controls whether control points for the curve are created city-block fashion or obliquely. When <code>ncp</code> is 1 and <code>angle</code> is 90, this is typically <code>TRUE</code> , otherwise this should probably be set to <code>FALSE</code> (see Examples below).
squareShape	A shape value to control the behaviour of the curve relative to any additional control point that is inserted if <code>square</code> is <code>TRUE</code> .
inflect	A logical value specifying whether the curve should be cut in half and inverted (see Examples below).
arrow	A list describing arrow heads to place at either end of the curve, as produced by the <code>arrow</code> function.

open	A logical value indicating whether to close the curve (connect the start and end points).
debug	A logical value indicating whether debugging information should be drawn.
name	A character identifier.
gp	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
vp	A Grid viewport object (or NULL).
...	Arguments to be passed to <code>curveGrob</code> .
theta	An angle (in degrees).

Details

Both functions create a curve grob (a graphical object describing an curve), but only `grid.curve` draws the curve.

The `arcCurvature` function can be used to calculate a `curvature` such that control points are generated on an arc corresponding to angle `theta`. This is typically used in conjunction with a large `npc` to produce a curve corresponding to the desired arc.

Value

A grob object.

curveTest(2, 3, shape=0)
curveTest(3, 1, curvature=-1)
curveTest(3, 2, square=FALSE)
curveTest(3, 3, debug=TRUE)
popViewport(2)
```

grid.display.list *Control the Grid Display List*

Description

Turn the Grid display list on or off.

Usage

```
grid.display.list(on=TRUE)
engine.display.list(on=TRUE)
```

Arguments

`on` A logical value to indicate whether the display list should be on or off.

Details

All drawing and viewport-setting operations are (by default) recorded in the Grid display list. This allows redrawing to occur following an editing operation.

This display list could get very large so it may be useful to turn it off in some cases; this will of course disable redrawing.

All graphics output is also recorded on the main display list of the R graphics engine (by default). This supports redrawing following a device resize and allows copying between devices.

Turning off this display list means that grid will redraw from its own display list for device resizes and copies. This will be slower than using the graphics engine display list.

Value

None.

WARNING

Turning the display list on causes the display list to be erased!

Turning off both the grid display list and the graphics engine display list will result in no redrawing whatsoever.

Author(s)

Paul Murrell

`grid.draw`*Draw a grid grob*

Description

Produces graphical output from a graphical object.

Usage

```
grid.draw(x, recording=TRUE)
```

Arguments

<code>x</code>	An object of class "grob" or NULL.
<code>recording</code>	A logical value to indicate whether the drawing operation should be recorded on the Grid display list.

Details

This is a generic function with methods for grob and gTree objects.

The grob and gTree methods automatically push any viewports in a vp slot and automatically apply any gpar settings in a gp slot. In addition, the gTree method pushes and ups any viewports in a childrenvp slot and automatically calls `grid.draw` for any grobs in a children slot.

The methods for grob and gTree call the generic hook functions `preDrawDetails`, `drawDetails`, and `postDrawDetails` to allow classes derived from grob or gTree to perform additional viewport pushing/popping and produce additional output beyond the default behaviour for grobs and gTrees.

Value

None.

Author(s)

Paul Murrell

See Also

[grob](#).

Examples

```
grid.newpage()
## Create a graphical object, but don't draw it
l <- linesGrob()
## Draw it
grid.draw(l)
```

grid.edit

Edit the Description of a Grid Graphical Object

Description

Changes the value of one of the slots of a grob and redraws the grob.

Usage

```
grid.edit(gPath, ..., strict = FALSE, grep = FALSE,
          global = FALSE, allDevices = FALSE, redraw = TRUE)

grid.gedit(..., grep = TRUE, global = TRUE)

editGrob(grob, gPath = NULL, ..., strict = FALSE, grep = FALSE,
         global = FALSE)
```

Arguments

grob	A grob object.
...	Zero or more named arguments specifying new slot values.
gPath	A gPath object. For <code>grid.edit</code> this specifies a grob on the display list. For <code>editGrob</code> this specifies a descendant of the specified grob.
strict	A boolean indicating whether the gPath must be matched exactly.
grep	A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., <code>c(TRUE, FALSE)</code> means that every odd element of the gPath will be treated as a regular expression).
global	A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
allDevices	A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
redraw	A logical value to indicate whether to redraw the grob.

Details

`editGrob` copies the specified grob and returns a modified grob.

`grid.edit` destructively modifies a grob on the display list. If `redraw` is `TRUE` it then redraws everything to reflect the change.

Both functions call `editDetails` to allow a grob to perform custom actions and `validDetails` to check that the modified grob is still coherent.

`grid.gedit` (g for global) is just a convenience wrapper for `grid.edit` with different defaults.

Value

`editGrob` returns a grob object; `grid.edit` returns `NULL`.

Author(s)

Paul Murrell

See Also[grob](#), [getGrob](#), [addGrob](#), [removeGrob](#).**Examples**

```

grid.newpage()
grid.xaxis(name = "xa", vp = viewport(width=.5, height=.5))
grid.edit("xa", gp = gpar(col="red"))
# won't work because no ticks (at is NULL)
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))
grid.edit("xa", at = 1:4/5)
# Now it should work
try(grid.edit(gPath("xa", "ticks"), gp = gpar(col="green")))

```

grid.frame

*Create a Frame for Packing Objects***Description**

These functions, together with `grid.pack`, `grid.place`, `packGrob`, and `placeGrob` are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with this function then use `grid.pack` or whatever to pack/place objects into the frame.

Usage

```

grid.frame(layout=NULL, name=NULL, gp=gpar(), vp=NULL, draw=TRUE)
frameGrob(layout=NULL, name=NULL, gp=gpar(), vp=NULL)

```

Arguments

<code>layout</code>	A Grid layout, or NULL. This can be used to initialise the frame with a number of rows and columns, with initial widths and heights, etc.
<code>name</code>	A character identifier.
<code>vp</code>	An object of class <code>viewport</code> , or NULL.
<code>gp</code>	An object of class <code>gpar</code> ; typically the output from a call to the function <code>gpar</code> .
<code>draw</code>	Should the frame be drawn.

Details

Both functions create a frame `grob` (a graphical object describing a frame), but only `grid.frame()` draws the frame (and then only if `draw` is `TRUE`). Nothing will actually be drawn, but it will put the frame on the display list, which means that the output will be dynamically updated as objects are packed into the frame. Possibly useful for debugging.

Value

A frame `grob`. `grid.frame()` returns the value invisibly.

Author(s)

Paul Murrell

See Also[grid.pack](#)**Examples**

```
grid.newpage()
grid.frame(name="gf", draw=TRUE)
grid.pack("gf", rectGrob(gp=gpar(fill="grey")), width=unit(1, "null"))
grid.pack("gf", textGrob("hi there"), side="right")
```

grid.get

*Get a Grid Graphical Object***Description**

Retrieve a grob or a descendant of a grob.

Usage

```
grid.get(gPath, strict = FALSE, grep = FALSE, global = FALSE,
         allDevices = FALSE)

grid.gget <- function(..., grep = TRUE, global = TRUE)

getGrob(gTree, gPath, strict = FALSE, grep = FALSE, global = FALSE)
```

Arguments

gTree	A gTree object.
gPath	A gPath object. For grid.get this specifies a grob on the display list. For getGrob this specifies a descendant of the specified gTree.
strict	A boolean indicating whether the gPath must be matched exactly.
grep	A boolean indicating whether the gPath should be treated as a regular expression. Values are recycled across elements of the gPath (e.g., c(TRUE, FALSE) means that every odd element of the gPath will be treated as a regular expression).
global	A boolean indicating whether the function should affect just the first match of the gPath, or whether all matches should be affected.
allDevices	A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.

Details

grid.gget (g for global) is just a convenience wrapper for grid.get with different defaults.

Value

A grob object.

Author(s)

Paul Murrell

See Also

[grob](#), [getGrob](#), [addGrob](#), [removeGrob](#).

Examples

```
grid.xaxis(name="xa")
grid.get("xa")
grid.get(gPath("xa", "ticks"))

grid.draw(gTree(name="gt", children=gList(xaxisGrob(name="axis"))))
grid.get(gPath("gt", "axis", "ticks"))
```

grid.grab

Grab the current grid output

Description

Creates a gTree object from the current grid display list or from a scene generated by user-specified code.

Usage

```
grid.grab(warn = 2, wrap = FALSE, ...)
grid.grabExpr(expr, warn = 2, wrap = FALSE, ...)
```

Arguments

<code>expr</code>	An expression to be evaluated. Typically, some calls to grid drawing functions.
<code>warn</code>	An integer specifying the amount of warnings to emit. 0 means no warnings, 1 means warn when it is certain that the grab will not faithfully represent the original scene. 2 means warn if there's any possibility that the grab will not faithfully represent the original scene.
<code>wrap</code>	A logical indicating how the output should be captured. If TRUE, each non-grob element on the display list is captured by wrapping it in a grob.
<code>...</code>	arguments passed to gTree, for example, a name and/or class for the gTree that is created.

Details

There are four ways to capture grid output as a gTree.

There are two functions for capturing output: use `grid.grab` to capture an existing drawing and `grid.grabExpr` to capture the output from an expression (without drawing anything).

For each of these functions, the output can be captured in two ways. One way tries to be clever and make a gTree with a `childrenvp` slot containing all viewports on the display list (including those that are popped) and every grob on the display list as a child of the new gTree; each child has a `vpPath` in the `vp` slot so that it is drawn in the appropriate viewport. In other words, the gTree contains all elements on the display list, but in a slightly altered form.

The other way, `wrap=TRUE`, is to create a grob for every element on the display list (and make all of those grobs children of the gTree).

The first approach creates a more compact and elegant gTree, which is more flexible to work with, but is not guaranteed to faithfully replicate all possible grid output. The second approach is more brute force, and harder to work with, but should always faithfully replicate the original output.

Value

A gTree object.

See Also

[gTree](#)

Examples

```
pushViewport(viewport(w=.5, h=.5))
grid.rect()
grid.points(stats::runif(10), stats::runif(10))
popViewport()
grab <- grid.grab()
grid.newpage()
grid.draw(grab)
```

grid.grill

Draw a Grill

Description

This function draws a grill within a Grid viewport.

Usage

```
grid.grill(h = unit(seq(0.25, 0.75, 0.25), "npc"),
           v = unit(seq(0.25, 0.75, 0.25), "npc"),
           default.units = "npc", gp=gpar(col = "grey"), vp = NULL)
```

Arguments

<code>h</code>	A numeric vector or unit object indicating the horizontal location of the vertical grill lines.
<code>v</code>	A numeric vector or unit object indicating the vertical location of the horizontal grill lines.
<code>default.units</code>	A string indicating the default units to use if <code>h</code> or <code>v</code> are only given as numeric vectors.
<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>vp</code>	A Grid viewport object.

Value

None.

grid.grob

Create a Grid Graphical Object

Description

These functions create grid graphical objects.

Usage

```
grid.grob(list.struct, cl = NULL, draw = TRUE)
grob(..., name = NULL, gp = NULL, vp = NULL, cl = NULL)
gTree(..., name = NULL, gp = NULL, vp = NULL, children = NULL,
       childrenvp = NULL, cl = NULL)
grobTree(..., name = NULL, gp = NULL, vp = NULL,
         childrenvp = NULL, cl = NULL)
childNames(gTree)
gList(...)
```

Arguments

<code>...</code>	For <code>grob</code> and <code>gTree</code> , the named slots describing important features of the graphical object. For <code>gList</code> and <code>grobTree</code> , a series of grob objects.
<code>list.struct</code>	A list (preferably with each element named).
<code>name</code>	A character identifier for the grob. Used to find the grob on the display list and/or as a child of another grob.

<code>children</code>	A <code>gList</code> object.
<code>childrenvp</code>	A viewport object (or <code>NULL</code>).
<code>gp</code>	A <code>gpar</code> object, typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>vp</code>	A viewport object (or <code>NULL</code>).
<code>cl</code>	A string giving the class attribute for the <code>list.struct</code>
<code>draw</code>	A logical value to indicate whether to produce graphical output.
<code>gTree</code>	A <code>gTree</code> object.

Details

These functions can be used to create a basic `grob`, `gTree`, or `gList` object, or a new class derived from one of these.

A grid graphical object (`grob`) is a description of a graphical item. These basic classes provide default behaviour for validating, drawing, and modifying graphical objects. Both call the function `validDetails` to check that the object returned is coherent.

A `gTree` can have other `grobs` as children; when a `gTree` is drawn, it draws all of its children. Before drawing its children, a `gTree` pushes its `childrenvp` slot and then navigates back up (calls `upViewport`) so that the children can specify their location within the `childrenvp` via a `vpPath`.

`Grob` names need not be unique in general, but all children of a `gTree` must have different names. A `grob` name can be any string, though it is not advisable to use the `gPath` separator (currently `:`) in `grob` names.

The function `childNames` returns the names of the `grobs` which are children of a `gTree`.

All grid primitives (`grid.lines`, `grid.rect`, ...) and some higher-level grid components (e.g., `grid.xaxis` and `grid.yaxis`) are derived from these classes.

`grobTree` is just a convenient wrapper for `gTree` when the only components of the `gTree` are `grobs` (so all unnamed arguments become children of the `gTree`).

`grid.grob` is deprecated.

Value

A `grob` object.

Paul Murrell

See Also

[grid.draw](#), [grid.edit](#), [grid.get](#).

 grid.layout

 Create a Grid Layout

Description

This function returns a Grid layout, which describes a subdivision of a rectangular region.

Usage

```
grid.layout(nrow = 1, ncol = 1,
            widths = unit(rep(1, ncol), "null"),
            heights = unit(rep(1, nrow), "null"),
            default.units = "null", respect = FALSE,
            just="centre")
```

Arguments

nrow	An integer describing the number of rows in the layout.
ncol	An integer describing the number of columns in the layout.
widths	A numeric vector or unit object describing the widths of the columns in the layout.
heights	A numeric vector or unit object describing the heights of the rows in the layout.
default.units	A string indicating the default units to use if widths or heights are only given as numeric vectors.
respect	A logical value or a numeric matrix. If a logical, this indicates whether row heights and column widths should respect each other. If a matrix, non-zero values indicate that the corresponding row and column should be respected (see examples below).
just	A string vector indicating how the layout should be justified if it is not the same size as its parent viewport. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible values are: "left", "right", "centre", "center", "bottom", and "top". NOTE that in this context, "left", for example, means align the left edge of the left-most layout column with the left edge of the parent viewport.

Details

The unit objects given for the widths and heights of a layout may use a special units that only has meaning for layouts. This is the "null" unit, which indicates what relative fraction of the available width/height the column/row occupies. See the reference for a better description of relative widths and heights in layouts.

Value

A Grid layout object.

WARNING

This function must NOT be confused with the base R graphics function `layout`. In particular, do not use `layout` in combination with Grid graphics. The documentation for `layout` may provide some useful information and this function should behave identically in comparable situations. The `grid.layout` function has *added* the ability to specify a broader range of units for row heights and column widths, and allows for nested layouts (see `viewport`).

```
## A variety of layouts (some a bit mid-bending ...)
layout.torture()
## Demonstration of layout justification
grid.newpage()
testlay <- function(just="centre") {
  pushViewport(viewport(layout=grid.layout(1, 1, widths=unit(1, "inches"),
    heights=unit(0.25, "npc"),
    just=just))
  pushViewport(viewport(layout.pos.col=1, layout.pos.row=1))
  grid.rect()
  grid.text(paste(just, collapse="-"))
  popViewport(2)
}
testlay()
testlay(c("left", "top"))
testlay(c("right", "top"))
testlay(c("right", "bottom"))
testlay(c("left", "bottom"))
testlay(c("left"))
testlay(c("right"))
testlay(c("bottom"))
testlay(c("top"))
```

grid.lines

Draw Lines in a Grid Viewport

Description

These functions create and draw a series of lines.

Usage

```

grid.lines(x = unit(c(0, 1), "npc"),
          y = unit(c(0, 1), "npc"),
          default.units = "npc",
          arrow = NULL, name = NULL,
          gp=gpar(), draw = TRUE, vp = NULL)
linesGrob(x = unit(c(0, 1), "npc"),
          y = unit(c(0, 1), "npc"),
          default.units = "npc",
          arrow = NULL, name = NULL,
          gp=gpar(), vp = NULL)
grid.polyline(...)
polylineGrob(x = unit(c(0, 1), "npc"),
             y = unit(c(0, 1), "npc"),
             id=NULL, id.lengths=NULL,
             default.units = "npc",
             arrow = NULL, name = NULL,
             gp=gpar(), vp = NULL)

```

Arguments

<code>x</code>	A numeric vector or unit object specifying x-values.
<code>y</code>	A numeric vector or unit object specifying y-values.
<code>default.units</code>	A string indicating the default units to use if <code>x</code> or <code>y</code> are only given as numeric vectors.
<code>arrow</code>	A list describing arrow heads to place at either end of the line, as produced by the <code>arrow</code> function.
<code>name</code>	A character identifier.
<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>draw</code>	A logical value indicating whether graphics output should be produced.
<code>vp</code>	A Grid viewport object (or <code>NULL</code>).
<code>id</code>	A numeric vector used to separate locations in <code>x</code> and <code>y</code> into multiple lines. All locations with the same <code>id</code> belong to the same line.
<code>id.lengths</code>	A numeric vector used to separate locations in <code>x</code> and <code>y</code> into multiple lines. Specifies consecutive blocks of locations which make up separate lines.
<code>...</code>	Arguments passed to <code>polylineGrob</code> .

Details

The first two functions create a lines grob (a graphical object describing lines), and `grid.lines` draws the lines (if `draw` is `TRUE`).

The second two functions create or draw a polyline grob, which is just like a lines grob, except that there can be multiple distinct lines drawn.

Value

A lines grob or a polyline grob. `grid.lines` returns a lines grob invisibly.

Author(s)

Paul Murrell

See Also[Grid](#), [viewport](#), [arrow](#)**Examples**

```
grid.lines()
# Using id (NOTE: locations are not in consecutive blocks)
grid.newpage()
grid.polyline(x=c((0:4)/10, rep(.5, 5), (10:6)/10, rep(.5, 5)),
             y=c(rep(.5, 5), (10:6/10), rep(.5, 5), (0:4)/10),
             id=rep(1:5, 4),
             gp=gpar(col=1:5, lwd=3))
# Using id.lengths
grid.newpage()
grid.polyline(x=outer(c(0, .5, 1, .5), 5:1/5),
             y=outer(c(.5, 1, .5, 0), 5:1/5),
             id.lengths=rep(4, 5),
             gp=gpar(col=1:5, lwd=3))
```

`grid.locator`*Capture a Mouse Click*

Description

Allows the user to click the mouse once within the current graphics device and returns the location of the mouse click within the current viewport, in the specified coordinate system.

Usage

```
grid.locator(unit = "native")
```

Arguments

`unit` The coordinate system in which to return the location of the mouse click. See the [unit](#) function for valid coordinate systems.

Details

This function is modal (like the graphics package function `locator`) so the command line and graphics drawing is blocked until the use has clicked the mouse in the current device.

Value

A unit object representing the location of the mouse click within the current viewport, in the specified coordinate system.

If the user did not click mouse button 1, the function (invisibly) returns `NULL`.

Examples

```
if (interactive()) {
  ## Need to write a more sophisticated unit as.character method
  unittrim <- function(unit) {
    sub("^[0-9]+|[0-9]+.[0-9]+|[0-9]*", "\\1", as.character(unit))
  }
  do.click <- function(unit) {
    click.locn <- grid.locator(unit)
    grid.segments(unit.c(click.locn$x, unit(0, "npc")),
                  unit.c(unit(0, "npc"), click.locn$y),
                  click.locn$x, click.locn$y,
                  gp=gpar(lty="dashed", col="grey"))
    grid.points(click.locn$x, click.locn$y, pch=16, size=unit(1, "mm"))
    clickx <- unittrim(click.locn$x)
    clicky <- unittrim(click.locn$y)
    grid.text(paste("(", clickx, ", ", clicky, ")", sep=""),
              click.locn$x + unit(2, "mm"), click.locn$y,
              just="left")
  }
  do.click("inches")
  pushViewport(viewport(width=0.5, height=0.5,
                        xscale=c(0, 100), yscale=c(0, 10)))

  grid.rect()
  grid.xaxis()
  grid.yaxis()
  do.click("native")
  popViewport()
}
```

grid.ls

*List the names of grobs or viewports***Description**

Returns a listing of the names of grobs or viewports.

This is a generic function with methods for grobs (including gTrees) and viewports (including vpTrees).

Usage

```
grid.ls(x=NULL, grobs=TRUE, viewports=FALSE, fullNames=FALSE,
        recursive=TRUE, print=TRUE, flatten=TRUE, ...)
```

```
nestedListing(x, gindent=" ", vpendent=gindent)
```

```
pathListing(x, gvpSep=" | ", gAlign=TRUE)
grobPathListing(x, ...)
```

Arguments

<code>x</code>	A grob or viewport or NULL. If NULL, the current grid display list is listed. For print functions, this should be the result of a call to <code>grid.ls</code> .
<code>grobs</code>	A logical value indicating whether to list grobs.
<code>viewports</code>	A logical value indicating whether to list viewports.
<code>fullNames</code>	A logical value indicating whether to embellish object names with information about the object type.
<code>recursive</code>	A logical value indicating whether recursive structures should also list their children.
<code>print</code>	A logical indicating whether to print the listing or a function that will print the listing.
<code>flatten</code>	A logical value indicating whether to flatten the listing. Otherwise a more complex hierarchical object is produced.
<code>gindent</code>	The indent used to show nesting in the output for grobs.
<code>vpindent</code>	The indent used to show nesting in the output for viewports.
<code>gvpSep</code>	The string used to separate viewport paths from grob paths.
<code>gAlign</code>	Logical indicating whether to align the left hand edge of all grob paths.
<code>...</code>	Arguments passed to the <code>print</code> function.

Details

If the argument `x` is NULL, the current contents of the grid display list are listed (both viewports and grobs). In other words, all objects representing the current scene are listed.

Otherwise, `x` should be a grob or a viewport.

The default behaviour of this function is to print information about the grobs in the current scene. It is also possible to add information about the viewports in the scene. By default, the listing is recursive, so all children of `gTrees` and all nested viewports are reported.

The format of the information can be controlled via the `print` argument, which can be given a function to perform the formatting. The `nestedListing` function produces a line per grob or viewport, with indenting used to show nesting. The `pathListing` function produces a line per grob or viewport, with viewport paths and grob paths used to show nesting. The `grobPathListing` is a simple derivation that only shows lines for grobs. The user can define new functions.

Value

The result of this function is either a "gridFlatListing" object (if `flatten` is TRUE) or a "gridListing" object.

The former is a simple (flat) list of vectors. This is convenient, for example, for working programmatically with the list of grob and viewport names, or for writing a new display function for the listing.

The latter is a more complex hierarchical object (list of lists), but it does contain more detailed information so may be of use for more advanced customisations.

Author(s)

Paul Murrell

See Also[grob viewport](#)**Examples**

```
# A gTree, called "parent", with childrenvp vpTree (vp2 within vp1)
# and child grob, called "child", with vp vpPath (down to vp2)
sampleGTree <- gTree(name="parent",
                    children=gList(grob(name="child", vp="vp1::vp2")),
                    childrenvp=vpTree(parent=viewport(name="vp1"),
                                       children=vpList(viewport(name="vp2"))))

grid.ls(sampleGTree)
# Show viewports too
grid.ls(sampleGTree, view=TRUE)
# Only show viewports
grid.ls(sampleGTree, view=TRUE, grob=FALSE)
# Alternate displays
# nested listing, custom indent
grid.ls(sampleGTree, view=TRUE, print=nestedListing, gindent="--")
# path listing
grid.ls(sampleGTree, view=TRUE, print=pathListing)
# path listing, without grobs aligned
grid.ls(sampleGTree, view=TRUE, print=pathListing, gAlign=FALSE)
# grob path listing
grid.ls(sampleGTree, view=TRUE, print=grobPathListing)
# path listing, grobs only
grid.ls(sampleGTree, print=pathListing)
# path listing, viewports only
grid.ls(sampleGTree, view=TRUE, grob=FALSE, print=pathListing)
# raw flat listing
str(grid.ls(sampleGTree, view=TRUE, print=FALSE))
```

grid.move.to

*Move or Draw to a Specified Position***Description**

Grid has the notion of a current location. These functions sets that location.

Usage

```
grid.move.to(x = 0, y = 0, default.units = "npc", name = NULL,
            draw = TRUE, vp = NULL)

moveToGrob(x = 0, y = 0, default.units = "npc", name = NULL, vp = NULL)

grid.line.to(x = 1, y = 1, default.units = "npc",
            arrow = NULL, name = NULL,
            gp = gpar(), draw = TRUE, vp = NULL)
```

```
lineToGrob(x = 1, y = 1, default.units = "npc", arrow = NULL,
           name = NULL, gp = gpar(), vp = NULL)
```

Arguments

<code>x</code>	A numeric value or a unit object specifying an x-value.
<code>y</code>	A numeric value or a unit object specifying a y-value.
<code>default.units</code>	A string indicating the default units to use if <code>x</code> or <code>y</code> are only given as numeric values.
<code>arrow</code>	A list describing arrow heads to place at either end of the line, as produced by the <code>arrow</code> function.
<code>name</code>	A character identifier.
<code>draw</code>	A logical value indicating whether graphics output should be produced.
<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>vp</code>	A Grid viewport object (or <code>NULL</code>).

Details

Both functions create a `move.to/line.to` grob (a graphical object describing a `move.to/line.to`), but only `grid.move.to/line.to()` draws the `move.to/line.to` (and then only if `draw` is `TRUE`).

Value

A `move.to/line.to` grob. `grid.move.to/line.to()` returns the value invisibly.

grid.move.to(0.5, 0.5)
grid.line.to(1, 1)
grid.line.to(0.5, 0)
pushViewport(viewport(x=0, y=0, w=0.25, h=0.25, just=c("left", "bottom")))
grid.rect()
grid.grill()
grid.line.to(0.5, 0.5)
popViewport()
```

grid.newpage	<i>Move to a New Page on a Grid Device</i>
--------------	--

Description

This function erases the current device or moves to a new page.

Usage

```
grid.newpage(recording = TRUE)
```

Arguments

recording	A logical value to indicate whether the new-page operation should be saved onto the Grid display list.
-----------	--

Details

The new page is painted with the fill colour (`gpar("fill")`), which is often transparent. For devices with a *canvas* colour (the on-screen devices `X11`, `windows` and `quartz`), the page is first painted with the canvas colour and then the background colour.

There is a hook called "grid.newpage" (see `setHook`) which is used in the testing code to annotate the new page. The hook function(s) are called with no argument. (If the value is a character string, `get` is called on it from within the **grid** name space.)

Value

None.

Author(s)

Paul Murrell

See Also

[Grid](#)

grid.null	<i>Null Graphical Object</i>
-----------	------------------------------

Description

These functions create a NULL graphical object, which has zero width, zero height, and draw nothing. It can be used as a place-holder or as an invisible reference point for other drawing.

Usage

```
nullGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
         default.units = "npc",
         name = NULL, vp = NULL)
grid.null(...)
```

Arguments

x	A numeric vector or unit object specifying x-location.
y	A numeric vector or unit object specifying y-location.
default.units	A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name	A character identifier.
vp	A Grid viewport object (or NULL).
...	Arguments passed to <code>nullGrob()</code> .

Value

A null grob.

Author(s)

Paul Murrell

See Also

[Grid, viewport](#)

Examples

```
grid.newpage()
grid.null(name="ref")
grid.rect(height=grobHeight("ref"))
grid.segments(0, 0, grobX("ref", 0), grobY("ref", 0))
```

grid.pack

Pack an Object within a Frame

Description

This functions, together with `grid.frame` and `frameGrob` are part of a GUI-builder-like interface to constructing graphical images. The idea is that you create a frame with `grid.frame` or `frameGrob` then use this functions to pack objects into the frame.

Usage

```
grid.pack(gPath, grob, redraw = TRUE, side = NULL,
          row = NULL, row.before = NULL, row.after = NULL,
          col = NULL, col.before = NULL, col.after = NULL,
          width = NULL, height = NULL,
          force.width = FALSE, force.height = FALSE, border = NULL,
          dynamic = FALSE)

packGrob(frame, grob, side = NULL,
          row = NULL, row.before = NULL, row.after = NULL,
          col = NULL, col.before = NULL, col.after = NULL,
```

```
width = NULL, height = NULL,
force.width = FALSE, force.height = FALSE, border = NULL,
dynamic = FALSE)
```

Arguments

<code>gPath</code>	A <code>gPath</code> object, which specifies a frame on the display list.
<code>frame</code>	An object of class <code>frame</code> , typically the output from a call to <code>grid.frame</code> .
<code>grob</code>	An object of class <code>grob</code> . The object to be packed.
<code>redraw</code>	A boolean indicating whether the output should be updated.
<code>side</code>	One of "left", "top", "right", "bottom" to indicate which side to pack the object on.
<code>row</code>	Which row to add the object to. Must be between 1 and the-number-of-rows-currently-in-the-frame + 1, or NULL in which case the object occupies all rows.
<code>row.before</code>	Add the object to a new row just before this row.
<code>row.after</code>	Add the object to a new row just after this row.
<code>col</code>	Which col to add the object to. Must be between 1 and the-number-of-cols-currently-in-the-frame + 1, or NULL in which case the object occupies all cols.
<code>col.before</code>	Add the object to a new col just before this col.
<code>col.after</code>	Add the object to a new col just after this col.
<code>width</code>	Specifies the width of the column that the object is added to (rather than allowing the width to be taken from the object).
<code>height</code>	Specifies the height of the row that the object is added to (rather than allowing the height to be taken from the object).
<code>force.width</code>	A logical value indicating whether the width of the column that the grob is being packed into should be EITHER the width specified in the call to <code>grid.pack</code> OR the maximum of that width and the pre-existing width.
<code>force.height</code>	A logical value indicating whether the height of the column that the grob is being packed into should be EITHER the height specified in the call to <code>grid.pack</code> OR the maximum of that height and the pre-existing height.
<code>border</code>	A <code>unit</code> object of length 4 indicating the borders around the object.
<code>dynamic</code>	If the width/height is taken from the grob being packed, this boolean flag indicates whether the grobwidth/height unit refers directly to the grob, or uses a <code>gPath</code> to the grob. In the latter case, changes to the grob will trigger a recalculation of the width/height.

Details

`packGrob` modifies the given frame `grob` and returns the modified frame `grob`.

`grid.pack` destructively modifies a frame `grob` on the display list (and redraws the display list if `redraw` is TRUE).

These are (meant to be) very flexible functions. There are many different ways to specify where the new object is to be added relative to the objects already in the frame. The function checks that the specification is not self-contradictory.

NOTE that the width/height of the row/col that the object is added to is taken from the object itself unless the `width/height` is specified.

Value

packGrob returns a frame grob, but grid.pack returns NULL.

Author(s)

Paul Murrell

See Also

[grid.frame](#), [grid.place](#), [grid.edit](#), and [gPath](#).

grid.place	<i>Place an Object within a Frame</i>
------------	---------------------------------------

Description

These functions provide a simpler (and faster) alternative to the `grid.pack()` and `packGrob` functions. They can be used to place objects within the existing rows and columns of a frame layout. They do not provide the ability to add new rows and columns nor do they affect the heights and widths of the rows and columns.

Usage

```
grid.place(gPath, grob, row = 1, col = 1, redraw = TRUE)
placeGrob(frame, grob, row = NULL, col = NULL)
```

Arguments

gPath	A gPath object, which specifies a frame on the display list.
frame	An object of class <code>frame</code> , typically the output from a call to <code>grid.frame</code> .
grob	An object of class <code>grob</code> . The object to be placed.
row	Which row to add the object to. Must be between 1 and the-number-of-rows-currently-in-the-frame.
col	Which col to add the object to. Must be between 1 and the-number-of-cols-currently-in-the-frame.
redraw	A boolean indicating whether the output should be updated.

Details

`placeGrob` modifies the given frame `grob` and returns the modified frame `grob`.

`grid.place` destructively modifies a frame `grob` on the display list (and redraws the display list if `redraw` is `TRUE`).

Value

`placeGrob` returns a frame `grob`, but `grid.place` returns NULL.

`grid.plot.and.legend`

A Simple Plot and Legend Demo

Description

This function is just a wrapper for a simple demonstration of how a basic plot and legend can be drawn from scratch using grid.

Usage

```
grid.plot.and.legend()
```

Author(s)

Paul Murrell

Examples

```
grid.plot.and.legend()
```

`grid.points`

Draw Data Symbols

Description

These functions create and draw data symbols.

Usage

```
grid.points(x = stats::runif(10),
            y = stats::runif(10),
            pch = 1, size = unit(1, "char"),
            default.units = "native", name = NULL,
            gp = gpar(), draw = TRUE, vp = NULL)
pointsGrob(x = stats::runif(10),
            y = stats::runif(10),
            pch = 1, size = unit(1, "char"),
            default.units = "native", name = NULL,
            gp = gpar(), vp = NULL)
```

Arguments

<code>x</code>	A numeric vector or unit object specifying x-values.
<code>y</code>	A numeric vector or unit object specifying y-values.
<code>pch</code>	A numeric or character vector indicating what sort of plotting symbol to use. See points for the interpretation of these values.
<code>size</code>	A unit object specifying the size of the plotting symbols.
<code>default.units</code>	A string indicating the default units to use if <code>x</code> or <code>y</code> are only given as numeric vectors.
<code>name</code>	A character identifier.
<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>draw</code>	A logical value indicating whether graphics output should be produced.
<code>vp</code>	A Grid viewport object (or NULL).

Details

Both functions create a points grob (a graphical object describing points), but only `grid.points` draws the points (and then only if `draw` is TRUE).

Value

A points grob. `grid.points` returns the value invisibly.

<code>grid.polygon</code>	<i>Draw a Polygon</i>
---------------------------	-----------------------

Description

These functions create and draw a polygon. The final point will automatically be connected to the initial point.

Usage

```
grid.polygon(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
             id=NULL, id.lengths=NULL,
             default.units="npc", name=NULL,
             gp=gpar(), draw=TRUE, vp=NULL)
polygonGrob(x=c(0, 0.5, 1, 0.5), y=c(0.5, 1, 0.5, 0),
            id=NULL, id.lengths=NULL,
            default.units="npc", name=NULL,
            gp=gpar(), vp=NULL)
```

Arguments

<code>x</code>	A numeric vector or unit object specifying x-locations.
<code>y</code>	A numeric vector or unit object specifying y-locations.
<code>id</code>	A numeric vector used to separate locations in <code>x</code> and <code>y</code> into multiple polygons. All locations with the same <code>id</code> belong to the same polygon.
<code>id.lengths</code>	A numeric vector used to separate locations in <code>x</code> and <code>y</code> into multiple polygons. Specifies consecutive blocks of locations which make up separate polygons.
<code>default.units</code>	A string indicating the default units to use if <code>x</code> , <code>y</code> , <code>width</code> , or <code>height</code> are only given as numeric vectors.
<code>name</code>	A character identifier.
<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>draw</code>	A logical value indicating whether graphics output should be produced.
<code>vp</code>	A Grid viewport object (or NULL).

Details

Both functions create a polygon `grob` (a graphical object describing a polygon), but only `grid.polygon` draws the polygon (and then only if `draw` is `TRUE`).

Value

A `grob` object.

```

grid.pretty	<i>Generate a Sensible Set of Breakpoints</i>
-------------	---

Description

Produces a pretty set of breakpoints within the range given.

Usage

```
grid.pretty(range)
```

Arguments

range	A numeric vector
-------	------------------

Value

A numeric vector of breakpoints.

Author(s)

Paul Murrell

grid.prompt	<i>Prompt before New Page</i>
-------------	-------------------------------

Description

This function can be used to control whether the user is prompted before starting a new page of output.

Usage

```
grid.prompt(ask)
```

Arguments

ask	a logical value. If TRUE, the user is prompted before a new page of output is started.
-----	--

Details

As from R 2.7.0 this is deprecated in favour of [devAskNewPage](#) as a single setting affects both the base and grid graphics systems.

The default value when a device is opened is taken from the setting of `options("device.ask.default")`.

Value

The current prompt setting *before* any new setting is applied.

Author(s)

Paul Murrell

See Also[grid.newpage](#)

`grid.record`*Encapsulate calculations and drawing*

Description

Evaluates an expression that includes both calculations and drawing that depends on the calculations so that both the calculations and the drawing will be rerun when the scene is redrawn (e.g., device resize or editing).

Intended *only* for expert use.

Usage

```
recordGrob(expr, list, name=NULL, gp=NULL, vp=NULL)
grid.record(expr, list, name=NULL, gp=NULL, vp=NULL)
```

Arguments

<code>expr</code>	object of mode expression or <code>call</code> or an unevaluated expression.
<code>list</code>	a list defining the environment in which <code>expr</code> is to be evaluated.
<code>name</code>	A character identifier.
<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>vp</code>	A Grid viewport object (or <code>NULL</code>).

Details

A grob is created of special class "recordedGrob" (and drawn, in the case of `grid.record`). The `drawDetails` method for this class evaluates the expression with the `list` as the evaluation environment (and the `grid` Namespace as the parent of that environment).

Note

This function *must* be used instead of the function `recordGraphics`; all of the dire warnings about using `recordGraphics` responsibly also apply here.

Author(s)

Paul Murrell

See Also[recordGraphics](#)

Examples

```
grid.record({
  w <- convertWidth(unit(1, "inches"), "npc")
  grid.rect(width=w)
},
list())
```

grid.rect

*Draw rectangles***Description**

These functions create and draw rectangles.

Usage

```
grid.rect(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
  width = unit(1, "npc"), height = unit(1, "npc"),
  just = "centre", hjust = NULL, vjust = NULL,
  default.units = "npc", name = NULL,
  gp=gpar(), draw = TRUE, vp = NULL)
rectGrob(x = unit(0.5, "npc"), y = unit(0.5, "npc"),
  width = unit(1, "npc"), height = unit(1, "npc"),
  just = "centre", hjust = NULL, vjust = NULL,
  default.units = "npc", name = NULL,
  gp=gpar(), vp = NULL)
```

Arguments

x	A numeric vector or unit object specifying x-location.
y	A numeric vector or unit object specifying y-location.
width	A numeric vector or unit object specifying width.
height	A numeric vector or unit object specifying height.
just	The justification of the rectangle relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
hjust	A numeric vector specifying horizontal justification. If specified, overrides the just setting.
vjust	A numeric vector specifying vertical justification. If specified, overrides the just setting.
default.units	A string indicating the default units to use if x, y, width, or height are only given as numeric vectors.
name	A character identifier.
gp	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
draw	A logical value indicating whether graphics output should be produced.
vp	A Grid viewport object (or NULL).

Details

Both functions create a `rect grob` (a graphical object describing rectangles), but only `grid.rect` draws the rectangles (and then only if `draw` is `TRUE`).

Value

A `rect grob`. `grid.rect` returns the value invisibly.

<code>grid.refresh</code>	<i>Refresh the current grid scene</i>
---------------------------	---------------------------------------

Description

Replays the current grid display list.

Usage

```
grid.refresh()
```

Author(s)

Paul Murrell

<code>grid.remove</code>	<i>Remove a Grid Graphical Object</i>
--------------------------	---------------------------------------

Description

Remove a `grob` from a `gTree` or a descendant of a `gTree`.

Usage

```
grid.remove(gPath, warn = TRUE, strict = FALSE, grep = FALSE,
            global = FALSE, allDevices = FALSE, redraw = TRUE)
```

```
grid.gremove <- function(..., grep = TRUE, global = TRUE)
```

```
removeGrob(gTree, gPath, strict = FALSE, grep = FALSE,
            global = FALSE, warn = TRUE)
```

Arguments

<code>gTree</code>	A <code>gTree</code> object.
<code>gPath</code>	A <code>gPath</code> object. For <code>grid.remove</code> this specifies a <code>gTree</code> on the display list. For <code>removeGrob</code> this specifies a descendant of the specified <code>gTree</code> .
<code>strict</code>	A boolean indicating whether the <code>gPath</code> must be matched exactly.
<code>grep</code>	A boolean indicating whether the <code>gPath</code> should be treated as a regular expression. Values are recycled across elements of the <code>gPath</code> (e.g., <code>c(TRUE, FALSE)</code> means that every odd element of the <code>gPath</code> will be treated as a regular expression).
<code>global</code>	A boolean indicating whether the function should affect just the first match of the <code>gPath</code> , or whether all matches should be affected.
<code>allDevices</code>	A boolean indicating whether all open devices should be searched for matches, or just the current device. NOT YET IMPLEMENTED.
<code>warn</code>	A logical to indicate whether failing to find the specified grob should trigger an error.
<code>redraw</code>	A logical value to indicate whether to redraw the grob.

Details

`removeGrob` copies the specified grob and returns a modified grob.

`grid.remove` destructively modifies a grob on the display list. If `redraw` is `TRUE` it then redraws everything to reflect the change.

`grid.gremove` (g for global) is just a convenience wrapper for `grid.remove` with different defaults.

Value

`removeGrob` returns a grob object; `grid.remove` returns `NULL`.

grid.segments

Draw Line Segments

Description

These functions create and draw line segments.

Usage

```

grid.segments(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
             x1 = unit(1, "npc"), y1 = unit(1, "npc"),
             default.units = "npc",
             arrow = NULL,
             name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
segmentsGrob(x0 = unit(0, "npc"), y0 = unit(0, "npc"),
            x1 = unit(1, "npc"), y1 = unit(1, "npc"),
            default.units = "npc",
            arrow = NULL, name = NULL, gp = gpar(), vp = NULL)

```

Arguments

<code>x0</code>	Numeric indicating the starting x-values of the line segments.
<code>y0</code>	Numeric indicating the starting y-values of the line segments.
<code>x1</code>	Numeric indicating the stopping x-values of the line segments.
<code>y1</code>	Numeric indicating the stopping y-values of the line segments.
<code>default.units</code>	A string.
<code>arrow</code>	A list describing arrow heads to place at either end of the line segments, as produced by the <code>arrow</code> function.
<code>name</code>	A character identifier.
<code>gp</code>	An object of class <code>gpar</code> .
<code>draw</code>	A logical value indicating whether graphics output should be produced.
<code>vp</code>	A Grid viewport object (or <code>NULL</code>).

Details

Both functions create a `segments grob` (a graphical object describing segments), but only `grid.segments` draws the segments (and then only if `draw` is `TRUE`).

Value

A `segments grob`. `grid.segments` returns the value invisibly.

`grid.set`*Set a Grid Graphical Object*

Description

Replace a grob or a descendant of a grob.

Usage

```
grid.set(gPath, newGrob, strict = FALSE, grep = FALSE,  
         redraw = TRUE)
```

```
setGrob(gTree, gPath, newGrob, strict = FALSE, grep = FALSE)
```

Arguments

<code>gTree</code>	A <code>gTree</code> object.
<code>gPath</code>	A <code>gPath</code> object. For <code>grid.set</code> this specifies a grob on the display list. For <code>setGrob</code> this specifies a descendant of the specified <code>gTree</code> .
<code>newGrob</code>	A grob object.
<code>strict</code>	A boolean indicating whether the <code>gPath</code> must be matched exactly.
<code>grep</code>	A boolean indicating whether the <code>gPath</code> should be treated as a regular expression. Values are recycled across elements of the <code>gPath</code> (e.g., <code>c(TRUE, FALSE)</code> means that every odd element of the <code>gPath</code> will be treated as a regular expression).
<code>redraw</code>	A logical value to indicate whether to redraw the grob.

Details

`setGrob` copies the specified grob and returns a modified grob.

`grid.set` destructively replaces a grob on the display list. If `redraw` is `TRUE` it then redraws everything to reflect the change.

These functions should not normally be called by the user.

Value

`setGrob` returns a grob object; `grid.set` returns `NULL`.

Author(s)

Paul Murrell

[grid.grob](#).

grid.show.layout *Draw a Diagram of a Grid Layout*

Description

This function uses Grid graphics to draw a diagram of a Grid layout.

Usage

```
grid.show.layout(l, newpage=TRUE, bg = "light grey",  
                cell.border = "blue", cell.fill = "light blue",  
                cell.label = TRUE, label.col = "blue",  
                unit.col = "red", vp = NULL)
```

Arguments

<code>l</code>	A Grid layout object.
<code>newpage</code>	A logical value indicating whether to move on to a new page before drawing the diagram.
<code>bg</code>	The colour used for the background.
<code>cell.border</code>	The colour used to draw the borders of the cells in the layout.
<code>cell.fill</code>	The colour used to fill the cells in the layout.
<code>cell.label</code>	A logical indicating whether the layout cells should be labelled.
<code>label.col</code>	The colour used for layout cell labels.
<code>unit.col</code>	The colour used for labelling the widths/heights of columns/rows.
<code>vp</code>	A Grid viewport object (or NULL).

Details

A viewport is created within `vp` to provide a margin for annotation, and the layout is drawn within that new viewport. The margin is filled with light grey, the new viewport is filled with white and framed with a black border, and the layout regions are filled with light blue and framed with a blue border. The diagram is annotated with the widths and heights (including units) of the columns and rows of the layout using red text. (All colours are defaults and may be customised via function arguments.)

Value

None.

Author(s)

Paul Murrell

See Also

[Grid](#), [viewport](#), [grid.layout](#)

Examples

```
## Diagram of a simple layout
grid.show.layout(grid.layout(4,2,
    heights=unit(rep(1, 4),
        c("lines", "lines", "lines", "null")),
    widths=unit(c(1, 1), "inches")))
```

grid.show.viewport *Draw a Diagram of a Grid Viewport*

Description

This function uses Grid graphics to draw a diagram of a Grid viewport.

Usage

```
grid.show.viewport(v, parent.layout = NULL, newpage = TRUE,
    border.fill="light grey",
    vp.col="blue", vp.fill="light blue",
    scale.col="red",
    vp = NULL)
```

Arguments

<code>v</code>	A Grid viewport object.
<code>parent.layout</code>	A grid layout object. If this is not NULL and the viewport given in <code>v</code> has its location specified relative to the layout, then the diagram shows the layout and which cells <code>v</code> occupies within the layout.
<code>newpage</code>	A logical value to indicate whether to move to a new page before drawing the diagram.
<code>border.fill</code>	Colour to fill the border margin.
<code>vp.col</code>	Colour for the border of the viewport region.
<code>vp.fill</code>	Colour to fill the viewport region.
<code>scale.col</code>	Colour to draw the viewport axes.
<code>vp</code>	A Grid viewport object (or NULL).

Details

A viewport is created within `vp` to provide a margin for annotation, and the diagram is drawn within that new viewport. By default, the margin is filled with light grey, the new viewport is filled with white and framed with a black border, and the viewport region is filled with light blue and framed with a blue border. The diagram is annotated with the width and height (including units) of the viewport, the (x, y) location of the viewport, and the x- and y-scales of the viewport, using red lines and text.

Value

None.

Author(s)

Paul Murrell

See Also[Grid](#), [viewport](#)**Examples**

```
## Diagram of a sample viewport
grid.show.viewport(viewport(x=0.6, y=0.6,
                            w=unit(1, "inches"), h=unit(1, "inches")))
grid.show.viewport(viewport(layout.pos.row=2, layout.pos.col=2:3),
                  grid.layout(3, 4))
```

grid.text

*Draw Text***Description**

These functions create and draw text and [plotmath](#) expressions.

Usage

```
grid.text(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
          just = "centre", hjust = NULL, vjust = NULL, rot = 0,
          check.overlap = FALSE, default.units = "npc",
          name = NULL, gp = gpar(), draw = TRUE, vp = NULL)
```

```
textGrob(label, x = unit(0.5, "npc"), y = unit(0.5, "npc"),
          just = "centre", hjust = NULL, vjust = NULL, rot = 0,
          check.overlap = FALSE, default.units = "npc",
          name = NULL, gp = gpar(), vp = NULL)
```

Arguments

label	A character or expression vector. Other objects are coerced by as.graphicsAnnot .
x	A numeric vector or unit object specifying x-values.
y	A numeric vector or unit object specifying y-values.
just	The justification of the text relative to its (x, y) location. If there are two values, the first value specifies horizontal justification and the second value specifies vertical justification. Possible string values are: "left", "right", "centre", "center", "bottom", and "top". For numeric values, 0 means left alignment and 1 means right alignment.
hjust	A numeric vector specifying horizontal justification. If specified, overrides the just setting.
vjust	A numeric vector specifying vertical justification. If specified, overrides the just setting.
rot	The angle to rotate the text.

<code>check.overlap</code>	A logical value to indicate whether to check for and omit overlapping text.
<code>default.units</code>	A string indicating the default units to use if <code>x</code> or <code>y</code> are only given as numeric vectors.
<code>name</code>	A character identifier.
<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>draw</code>	A logical value indicating whether graphics output should be produced.
<code>vp</code>	A Grid viewport object (or <code>NULL</code>).

Details

Both functions create a text grob (a graphical object describing text), but only `grid.text` draws the text (and then only if `draw` is `TRUE`).

If the `label` argument is an expression, the output is formatted as a mathematical annotation, as for base graphics text.

Value

A text grob. `grid.text` returns the value invisibly.

draw.text(c("centre"), 4, 4)

```

grid.xaxis

Draw an X-Axis

Description

These functions create and draw an x-axis.

Usage

```

grid.xaxis(at = NULL, label = TRUE, main = TRUE,
           edits = NULL, name = NULL,
           gp = gpar(), draw = TRUE, vp = NULL)

```

```

xaxisGrob(at = NULL, label = TRUE, main = TRUE,
           edits = NULL, name = NULL,
           gp = gpar(), vp = NULL)

```

Arguments

at	A numeric vector of x-value locations for the tick marks.
label	A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the at argument.
main	A logical value indicating whether to draw the axis at the bottom (TRUE) or at the top (FALSE) of the viewport.
edits	A gEdit or gEditList containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever at is NULL.
name	A character identifier.
gp	An object of class gpar, typically the output from a call to the function gpar. This is basically a list of graphical parameter settings.
draw	A logical value indicating whether graphics output should be produced.
vp	A Grid viewport object (or NULL).

Details

Both functions create an xaxis grob (a graphical object describing an axis), but only grid.xaxis draws the axis (and then only if draw is TRUE).

Value

An axis grob. `grid.xaxis` returns the value invisibly.

Children

If the `at` slot of an `xaxis` grob is not `NULL` then the `xaxis` will have the following children:

major representing the line at the base of the tick marks.

ticks representing the tick marks.

labels representing the tick labels.

If the `at` slot is `NULL` then there are no children and ticks are drawn based on the current viewport scale.

grid.xspline

Draw an Xspline

Description

These functions create and draw an `xspline`, a curve drawn relative to control points.

Usage

```
grid.xspline(...)
xsplineGrob(x = c(0, 0.5, 1, 0.5), y = c(0.5, 1, 0.5, 0),
            id = NULL, id.lengths = NULL,
            default.units = "npc",
            shape = 0, open = TRUE, arrow = NULL, repEnds = TRUE,
            name = NULL, gp = gpar(), vp = NULL)
```

Arguments

<code>x</code>	A numeric vector or unit object specifying x-locations of spline control points.
<code>y</code>	A numeric vector or unit object specifying y-locations of spline control points.
<code>id</code>	A numeric vector used to separate locations in <code>x</code> and <code>y</code> into multiple <code>xsplines</code> . All locations with the same <code>id</code> belong to the same <code>xspline</code> .
<code>id.lengths</code>	A numeric vector used to separate locations in <code>x</code> and <code>y</code> into multiple <code>xspline</code> . Specifies consecutive blocks of locations which make up separate <code>xsplines</code> .
<code>default.units</code>	A string indicating the default units to use if <code>x</code> or <code>y</code> are only given as numeric vectors.

shape	A numeric vector of values between -1 and 1, which control the shape of the spline relative to the control points.
open	A logical value indicating whether the spline is a line or a closed shape.
arrow	A list describing arrow heads to place at either end of the xspline, as produced by the <code>arrow</code> function.
repEnds	A logical value indicating whether the first and last control points should be replicated for drawing the curve (see Details below).
name	A character identifier.
gp	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
vp	A Grid viewport object (or NULL).
...	Arguments to be passed to <code>xsplineGrob</code> .

Details

Both functions create an `xspline grob` (a graphical object describing an `xspline`), but only `grid.xspline` draws the `xspline`.

An `xspline` is a line drawn relative to control points. For each control point, the line may pass through (interpolate) the control point or it may only approach (approximate) the control point; the behaviour is determined by a shape parameter for each control point.

If the shape parameter is greater than zero, the spline approximates the control points (and is very similar to a cubic B-spline when the shape is 1). If the shape parameter is less than zero, the spline interpolates the control points (and is very similar to a Catmull-Rom spline when the shape is -1). If the shape parameter is 0, the spline forms a sharp corner at that control point.

For open `xsplines`, the start and end control points must have a shape of 0 (and non-zero values are silently converted to zero without warning).

For open `xsplines`, by default the start and end control points are actually replicated before the curve is drawn. A curve is drawn between (interpolating or approximating) the second and third of each set of four control points, so this default behaviour ensures that the resulting curve starts at the first control point you have specified and ends at the last control point. The default behaviour can be turned off via the `repEnds` argument, in which case the curve that is drawn starts (approximately) at the second control point and ends (approximately) at the first and second-to-last control point.

The `repEnds` argument is ignored for closed `xsplines`.

Missing values are not allowed for `x` and `y` (i.e., it is not valid for a control point to be missing).

For closed `xsplines`, a curve is automatically drawn between the final control point and the initial control point.

Value

A grob object.

<code>grid.yaxis</code>	<i>Draw a Y-Axis</i>
-------------------------	----------------------

Description

These functions create and draw a y-axis.

Usage

```
grid.yaxis(at = NULL, label = TRUE, main = TRUE,
           edits = NULL, name = NULL,
           gp = gpar(), draw = TRUE, vp = NULL)
```

```
yaxisGrob(at = NULL, label = TRUE, main = TRUE,
           edits = NULL, name = NULL,
           gp = gpar(), vp = NULL)
```

Arguments

<code>at</code>	A numeric vector of y-value locations for the tick marks.
<code>label</code>	A logical value indicating whether to draw the labels on the tick marks, or an expression or character vector which specify the labels to use. If not logical, must be the same length as the <code>at</code> argument.
<code>main</code>	A logical value indicating whether to draw the axis at the left (<code>TRUE</code>) or at the right (<code>FALSE</code>) of the viewport.
<code>edits</code>	A <code>gEdit</code> or <code>gEditList</code> containing edit operations to apply (to the children of the axis) when the axis is first created and during redrawing whenever <code>at</code> is <code>NULL</code> .
<code>name</code>	A character identifier.
<code>gp</code>	An object of class <code>gpar</code> , typically the output from a call to the function <code>gpar</code> . This is basically a list of graphical parameter settings.
<code>draw</code>	A logical value indicating whether graphics output should be produced.
<code>vp</code>	A Grid viewport object (or <code>NULL</code>).

Details

Both functions create a `yaxis grob` (a graphical object describing a yaxis), but only `grid.yaxis` draws the yaxis (and then only if `draw` is `TRUE`).

Value

A `yaxis grob`. `grid.yaxis` returns the value invisibly.

Children

If the `at` slot of an `xaxis grob` is not `NULL` then the `xaxis` will have the following children:

major representing the line at the base of the tick marks.

ticks representing the tick marks.

labels representing the tick labels.

If the `at` slot is `NULL` then there are no children and ticks are drawn based on the current viewport scale.

grobName	<i>Generate a Name for a Grob</i>
----------	-----------------------------------

Description

This function generates a unique (within-session) name for a grob, based on the grob's class.

Usage

```
grobName(grob = NULL, prefix = "GRID")
```

Arguments

grob	A grob object or NULL.
prefix	The prefix part of the name.

Value

A character string of the form `prefix.class(grob).index`

Author(s)

Paul Murrell

grobWidth	<i>Create a Unit Describing the Width of a Grob</i>
-----------	---

Description

These functions create a unit object describing the width or height of a grob. They are generic.

Usage

```
grobWidth(x)
grobHeight(x)
```

Arguments

x	A grob object.
---	----------------

Value

A unit object.

Author(s)

Paul Murrell

See Also[unit](#) and [stringWidth](#)

grobX

*Create a Unit Describing a Grob Boundary Location***Description**

These functions create a unit object describing a location somewhere on the boundary of a grob. They are generic.

Usage

```
grobX(x, theta)
grobY(x, theta)
```

Arguments

<code>x</code>	A grob, or gList, or gTree, or gPath.
<code>theta</code>	An angle indicating where the location is on the grob boundary. Can be one of "east", "north", "west", or "south", which correspond to angles 0, 90, 180, and 270, respectively.

Details

The angle is anti-clockwise with zero corresponding to a line with an origin centred between the extreme points of the shape, and pointing at 3 o'clock.

If the grob describes a single shape, the boundary value should correspond to the exact edge of the shape.

If the grob describes multiple shapes, the boundary value will either correspond to the edge of a bounding box around all of the shapes described by the grob (for multiple rectangles, circles, xsplines, or text), or to a convex hull around all vertices of all shapes described by the grob (for multiple polygons, points, lines, polylines, and segments).

Points grobs are currently a special case because the convex hull is based on the data symbol *locations* and does not take into account the extent of the data symbols themselves.

The extents of any arrow heads are currently *not* taken into account.

Value

A unit object.

Author(s)

Paul Murrell

plotViewport	<i>Create a Viewport with a Standard Plot Layout</i>
--------------	--

Description

This is a convenience function for producing a viewport with the common S-style plot layout – i.e., a central plot region surrounded by margins given in terms of a number of lines of text.

Usage

```
plotViewport(margins=c(5.1, 4.1, 4.1, 2.1), ...)
```

Arguments

margins	A numeric vector interpreted in the same way as <code>par(mar)</code> in base graphics.
...	All other arguments will be passed to a call to the <code>viewport()</code> function.

Value

A grid viewport object.

Author(s)

Paul Murrell

See Also

pop.viewport	<i>Pop a Viewport off the Grid Viewport Stack</i>
--------------	---

Description

Grid maintains a viewport stack — a list of nested drawing contexts.

This function makes the parent of the specified viewport the new default viewport.

Usage

```
pop.viewport(n=1, recording=TRUE)
```

Arguments

n	An integer giving the number of viewports to pop. Defaults to 1.
recording	A logical value to indicate whether the set-viewport operation should be recorded on the Grid display list.

Value

None.

Warning

This function has been deprecated. Please use `popViewport` instead.

Author(s)

Paul Murrell

push.viewport

Push a Viewport onto the Grid Viewport Stack

Description

Grid maintains a viewport stack — a list of nested drawing contexts.

This function makes the specified viewport the default viewport and makes its parent the previous default viewport (i.e., nests the specified context within the previous default context).

Usage

```
push.viewport(..., recording=TRUE)
```

Arguments

<code>...</code>	One or more objects of class "viewport", or NULL.
<code>recording</code>	A logical value to indicate whether the set-viewport operation should be recorded on the Grid display list.

Value

None.

Warning

This function has been deprecated. Please use `pushViewport` instead.

Querying the Viewport Tree

Get the Current Grid Viewport (Tree)

Description

`current.viewport()` returns the viewport that Grid is going to draw into.
`current.vpTree` returns the entire Grid viewport tree.
`current.vpPath` returns the viewport path to the current viewport.
`current.transform` returns the transformation matrix for the current viewport.

Usage

```
current.viewport(vp=NULL)
current.vpTree(all=TRUE)
current.vpPath()
current.transform()
```

Arguments

<code>vp</code>	A Grid viewport object. Use of this argument has been deprecated.
<code>all</code>	A logical value indicating whether the entire viewport tree should be returned.

Details

If `all` is `FALSE` then `current.vpTree` only returns the subtree below the current viewport.

Value

A Grid viewport object from `current.viewport` or `current.vpTree`.
`current.transform` returns a 4x4 transformation matrix.
The viewport path returned by `current.vpPath` is `NULL` if the current viewport is the `ROOT` viewport

  just="left", name="B"))
upViewport(1)
pushViewport(viewport(x=0.5, width=0.4, height=0.8,
  just="left", name="C"))
```

```

pushViewport (viewport (width=0.8, height=0.8, name="D"))
current.vpPath ()
upViewport (1)
current.vpPath ()
current.vpTree ()
current.viewport ()
current.vpTree (all=FALSE)
popViewport (0)

```

stringWidth	<i>Create a Unit Describing the Width of a String</i>
-------------	---

Description

These functions create a unit object describing the width or height of a string.

Usage

```

stringWidth (string)
stringHeight (string)

```

Arguments

string A character vector.

Value

A unit object.

Author(s)

Paul Murrell

unit	<i>Function to Create a Unit Object</i>
------	---

Description

This function creates a unit object — a vector of unit values. A unit value is typically just a single numeric value with an associated unit.

Usage

```

unit (x, units, data=NULL)

```

Arguments

<code>x</code>	A numeric vector.
<code>units</code>	A character vector specifying the units for the corresponding numeric values.
<code>data</code>	This argument is used to supply extra information for special <code>unit</code> types.

Details

Unit objects allow the user to specify locations and dimensions in a large number of different coordinate systems. All drawing occurs relative to a viewport and the `units` specifies what coordinate system to use within that viewport.

Possible `units` (coordinate systems) are:

"npc" Normalised Parent Coordinates (the default). The origin of the viewport is (0, 0) and the viewport has a width and height of 1 unit. For example, (0.5, 0.5) is the centre of the viewport.

"cm" Centimetres.

"inches" Inches. 1 in = 2.54 cm.

"mm" Millimetres. 10 mm = 1 cm.

"points" Points. 72.27 pt = 1 in.

"picas" Picas. 1 pc = 12 pt.

"bigpts" Big Points. 72 bp = 1 in.

"dida" Dida. 1157 dd = 1238 pt.

"cicero" Cicero. 1 cc = 12 dd.

"scaledpts" Scaled Points. 65536 sp = 1 pt.

"lines" Lines of text. Locations and dimensions are in terms of multiples of the default text size of the viewport (as specified by the viewport's `fontsize` and `lineheight`).

"char" Multiples of nominal font height of the viewport (as specified by the viewport's `fontsize`).

"native" Locations and dimensions are relative to the viewport's `xscale` and `yscale`.

"snpc" Square Normalised Parent Coordinates. Same as Normalised Parent Coordinates, except gives the same answer for horizontal and vertical locations/dimensions. It uses the *lesser* of `npc-width` and `npc-height`. This is useful for making things which are a proportion of the viewport, but have to be square (or have a fixed aspect ratio).

"strwidth" Multiples of the width of the string specified in the `data` argument. The font size is determined by the `pointsize` of the viewport.

"strheight" Multiples of the height of the string specified in the `data` argument. The font size is determined by the `pointsize` of the viewport.

"grobwidth" Multiples of the width of the grob specified in the `data` argument.

"grobheight" Multiples of the height of the grob specified in the `data` argument.

A special `units` value of `"null"` is also allowed, but only makes sense when used in specifying widths of columns or heights of rows in grid layouts (see [grid.layout](#)).

The `data` argument must be a list when the `unit.length()` is greater than 1. For example, `unit(rep(1, 3), c("npc", "strwidth", "inches"), data=list(NULL, "my string", NULL))`.

It is possible to subset unit objects in the normal way (e.g., `unit(1:5, "npc")[2:4]`), but a special function `unit.c` is provided for combining unit objects.

Certain arithmetic and summary operations are defined for unit objects. In particular, it is possible to add and subtract unit objects (e.g., `unit(1, "npc") - unit(1, "inches")`), and to specify the minimum or maximum of a list of unit objects (e.g., `min(unit(0.5, "npc"), unit(1, "inches"))`).

Value

An object of class "unit".

WARNING

There is a special function `unit.c` for concatenating several unit objects.

The `c` function will not give the right answer.

There used to be "mylines", "mychar", "mystrwidth", "mystrheight" units. These will still be accepted, but work exactly the same as "lines", "char", "strwidth", "strheight".

Author(s)

Paul Murrell

See Also

[unit.c](#)

Examples

```
unit(1, "npc")
unit(1:3/4, "npc")
unit(1:3/4, "npc") + unit(1, "inches")
min(unit(0.5, "npc"), unit(1, "inches"))
unit.c(unit(0.5, "npc"), unit(2, "inches") + unit(1:3/4, "npc"),
        unit(1, "strwidth", "hi there"))
```

unit.c

Combine Unit Objects

Description

This function produces a new unit object by combining the unit objects specified as arguments.

Usage

```
unit.c(...)
```

Arguments

... An arbitrary number of unit objects.

Value

An object of class `unit`.

Author(s)

Paul Murrell

See Also[unit.](#)

unit.length	<i>Length of a Unit Object</i>
-------------	--------------------------------

Description

The length of a unit object is defined as the number of unit values in the unit object.

This function has been deprecated in favour of a unit method for the generic length function.

Usage

```
unit.length(unit)
```

Arguments

unit	A unit object.
------	----------------

Value

An integer value.

Author(s)

Paul Murrell

See Also[unit](#)**Examples**

```
length(unit(1:3, "npc"))
length(unit(1:3, "npc") + unit(1, "inches"))
length(max(unit(1:3, "npc") + unit(1, "inches")))
length(max(unit(1:3, "npc") + unit(1, "strwidth", "a"))*4)
length(unit(1:3, "npc") + unit(1, "strwidth", "a")*4)
```

 unit.pmin

Parallel Unit Minima and Maxima

Description

Returns a unit object whose *i*'th value is the minimum (or maximum) of the *i*'th values of the arguments.

Usage

```
unit.pmin(...)
unit.pmax(...)
```

Arguments

... One or more unit objects.

Details

The length of the result is the maximum of the lengths of the arguments; shorter arguments are recycled in the usual manner.

Value

A unit object.

Author(s)

Paul Murrell

Examples

```
max(unit(1:3, "cm"), unit(0.5, "npc"))
unit.pmax(unit(1:3, "cm"), unit(0.5, "npc"))
```

 unit.rep

Replicate Elements of Unit Objects

Description

Replicates the units according to the values given in `times` and `length.out`.

This function has been deprecated in favour of a unit method for the generic `rep` function.

Usage

```
unit.rep(x, ...)
```

Arguments

`x` An object of class "unit".
 ... arguments to be passed to `rep` such as `times` and `length.out`.

Value

An object of class "unit".

Author(s)

Paul Murrell

See Also

[rep](#)

Examples

```
rep(unit(1:3, "npc"), 3)
rep(unit(1:3, "npc"), 1:3)
rep(unit(1:3, "npc") + unit(1, "inches"), 3)
rep(max(unit(1:3, "npc") + unit(1, "inches")), 3)
rep(max(unit(1:3, "npc") + unit(1, "strwidth", "a"))*4, 3)
rep(unit(1:3, "npc") + unit(1, "strwidth", "a")*4, 3)
```

validDetails

Customising grid grob Validation

Description

This generic hook function is called whenever a grid grob is created or edited via `grob`, `gTree`, `grid.edit` or `editGrob`. This provides an opportunity for customising the validation of a new class derived from `grob` (or `gTree`).

Usage

```
validDetails(x)
```

Arguments

`x` A grid grob.

Details

This function is called by `grob`, `gTree`, `grid.edit` and `editGrob`. A method should be written for classes derived from `grob` or `gTree` to validate the values of slots specific to the new class. (e.g., see `grid::validDetails.axis`).

Note that the standard slots for grobs and gTrees are automatically validated (e.g., `vp`, `gp` slots for grobs and, in addition, `children`, and `childrenvp` slots for gTrees) so only slots specific to a new class need to be addressed.

Value

The function MUST return the validated grob.

Author(s)

Paul Murrell

See Also

[grid.edit](#)

vpPath

Concatenate Viewport Names

Description

This function can be used to generate a viewport path for use in `downViewport` or `seekViewport`.

A viewport path is a list of nested viewport names.

Usage

```
vpPath(...)
```

Arguments

... Character values which are viewport names.

Details

Viewport names must only be unique amongst viewports which share the same parent in the viewport tree.

This function can be used to generate a specification for a viewport that includes the viewport's parent's name (and the name of its parent and so on).

For interactive use, it is possible to directly specify a path, but it is strongly recommended that this function is used otherwise in case the path separator is changed in future versions of grid.

Value

A `vpPath` object.

See Also

[viewport](#), [pushViewport](#), [popViewport](#), [downViewport](#), [seekViewport](#), [upViewport](#)

Examples

```
vpPath("vp1", "vp2")
```

widthDetails	<i>Width and Height of a grid grob</i>
--------------	--

Description

These generic functions are used to determine the size of grid grobs.

Usage

```
widthDetails(x)
heightDetails(x)
```

Arguments

x A grid grob.

Details

These functions are called in the calculation of "grobwidth" and "grobheight" units. Methods should be written for classes derived from grob or gTree where the size of the grob can be determined (see, for example `grid:::widthDetails.frame`).

Value

A unit object.

Author(s)

Paul Murrell

See Also

[absolute.size](#).

Working with Viewports

Maintaining and Navigating the Grid Viewport Tree

Description

Grid maintains a tree of viewports — nested drawing contexts.

These functions provide ways to add or remove viewports and to navigate amongst viewports in the tree.

Usage

```
pushViewport(..., recording=TRUE)
popViewport(n, recording=TRUE)
downViewport(name, strict=FALSE, recording=TRUE)
seekViewport(name, recording=TRUE)
upViewport(n, recording=TRUE)
```

Arguments

<code>...</code>	One or more objects of class "viewport".
<code>n</code>	An integer value indicating how many viewports to pop or navigate up. The special value 0 indicates to pop or navigate viewports right up to the root viewport.
<code>name</code>	A character value to identify a viewport in the tree.
<code>strict</code>	A boolean indicating whether the <code>vpPath</code> must be matched exactly.
<code>recording</code>	A logical value to indicate whether the viewport operation should be recorded on the Grid display list.

Details

Objects created by the `viewport()` function are only descriptions of a drawing context. A viewport object must be pushed onto the viewport tree before it has any effect on drawing.

The viewport tree always has a single root viewport (created by the system) which corresponds to the entire device (and default graphical parameter settings). Viewports may be added to the tree using `pushViewport()` and removed from the tree using `popViewport()`.

There is only ever one current viewport, which is the current position within the viewport tree. All drawing and viewport operations are relative to the current viewport. When a viewport is pushed it becomes the current viewport. When a viewport is popped, the parent viewport becomes the current viewport. Use `upViewport` to navigate to the parent of the current viewport, without removing the current viewport from the viewport tree. Use `downViewport` to navigate to a viewport further down the viewport tree and `seekViewport` to navigate to a viewport anywhere else in the tree.

If a viewport is pushed and it has the same `name` as a viewport at the same level in the tree, then it replaces the existing viewport in the tree.

Value

`downViewport` returns the number of viewports it went down.

This can be useful for returning to your starting point by doing something like `depth <- downViewport()` then `upViewport(depth)`.

`xDetails`*Boundary of a grid grob*

Description

These generic functions are used to determine a location on the boundary of a grid grob.

Usage

```
xDetails(x, theta)
yDetails(x, theta)
```

Arguments

<code>x</code>	A grid grob.
<code>theta</code>	A numeric angle, in degrees, measured anti-clockwise from the 3 o'clock <i>or</i> one of the following character strings: "north", "east", "west", "south".

Details

The location on the grob boundary is determined by taking a line from the centre of the grob at the angle `theta` and intersecting it with the convex hull of the grob (for the basic grob primitives, the centre is determined as half way between the minimum and maximum values in x and y directions).

These functions are called in the calculation of "grobX" and "grobY" units as produced by the `grobX` and `grobY` functions. Methods should be written for classes derived from `grob` or `gTree` where the boundary of the grob can be determined.

Value

A unit object.

Chapter 6

The methods package

methods-package *Formal Methods and Classes*

Description

Formally defined methods and classes for R objects, plus other programming tools, as described in the references.

Details

This package provides the ‘S4’ or ‘S version 4’ approach to methods and classes in a functional language.

See the documentation entries [Classes](#), [Methods](#), and [GenericFunctions](#) for general discussion of these topics, at a fairly technical level. Links from those pages, and the documentation of [setClass](#) and [setMethod](#) cover the main programming tools needed.

For a complete list of functions and classes, use `library(help="methods")`.

`.BasicFunsList`*List of Builtin and Special Functions*

Description

A named list providing instructions for turning builtin and special functions into generic functions.

Functions in R that are defined as `.Primitive(<name>)` are not suitable for formal methods, because they lack the basic reflectance property. You can't find the argument list for these functions by examining the function object itself.

Future versions of R may fix this by attaching a formal argument list to the corresponding function. While generally the names of arguments are not checked by the internal code implementing the function, the number of arguments frequently is.

In any case, some definition of a formal argument list is needed if users are to define methods for these functions. In particular, if methods are to be merged from multiple packages, the different sets of methods need to agree on the formal arguments.

In the absence of reflectance, this list provides the relevant information via a dummy function associated with each of the known specials for which methods are allowed.

At the same, the list flags those specials for which methods are meaningless (e.g., `for`) or just a very bad idea (e.g., `.Primitive`).

A generic function created via `setMethod`, for example, for one of these special functions will have the argument list from `.BasicFunsList`. If no entry exists, the argument list (`x, ...`) is assumed.

`as`*Force an Object to Belong to a Class*

Description

These functions manage the relations that allow coercing an object to a given class.

Usage

```
as(object, Class, strict=TRUE, ext)
```

```
as(object, Class) <- value
```

```
setAs(from, to, def, replace, where = topenv(parent.frame()))
```

Arguments

`object` any R object.

`Class` the name of the class to which `object` should be coerced.

<code>strict</code>	logical flag. If <code>TRUE</code> , the returned object must be strictly from the target class (unless that class is a virtual class, in which case the object will be from the closest actual class, in particular the original object, if that class extends the virtual class directly). If <code>strict = FALSE</code> , any simple extension of the target class will be returned, without further change. A simple extension is, roughly, one that just adds slots to an existing class.
<code>value</code>	The value to use to modify <code>object</code> (see the discussion below). You should supply an object with class <code>Class</code> ; some coercion is done, but you're unwise to rely on it.
<code>from, to</code>	The classes between which the coerce methods <code>def</code> and <code>replace</code> perform coercion.
<code>def</code>	function of one argument. It will get an object from class <code>from</code> and had better return an object of class <code>to</code> . The convention is that the name of the argument is <code>from</code> ; if another argument name is used, <code>setAs</code> will attempt to substitute <code>from</code> .
<code>replace</code>	if supplied, the function to use as a replacement method, when <code>as</code> is used on the left of an assignment. Should be a function of two arguments, <code>from, value</code> , although <code>setAs</code> will attempt to substitute if the arguments differ.
<code>where</code>	the position or environment in which to store the resulting methods. For most applications, it is recommended to omit this argument and to include the call to <code>setAs</code> in source code that is evaluated at the top level; that is, either in an R session by something equivalent to a call to <code>source</code> , or as part of the R source code for a package.
<code>ext</code>	the optional object defining how <code>Class</code> is extended by the class of the object (as returned by <code>possibleExtends</code>). This argument is used internally (to provide essential information for non-public classes), but you are unlikely to want to use it directly.

Summary of Functions

as: Returns the version of this object coerced to be the given `Class`. When used in the replacement form on the left of an assignment, the portion of the object corresponding to `Class` is replaced by `value`.

The operation of `as()` in either form depends on the definition of coerce methods. Methods are defined automatically when the two classes are related by inheritance; that is, when one of the classes is a subclass of the other. See the section on inheritance below for details.

Coerce methods are also predefined for basic classes (including all the types of vectors, functions and a few others). See `showMethods(coerce)` for a list of these.

Beyond these two sources of methods, further methods are defined by calls to the `setAs` function.

setAs: Define methods for coercing an object of class `from` to be of class `to`; the `def` argument provides for direct coercing and the `replace` argument, if included, provides for replacement. See the "How" section below for details.

coerce, coerce<-: Coerce `from` to be of the same class as `to`.

These functions should not be called explicitly. The function `setAs` creates methods for them for the `as` function to use.

Inheritance and Coercion

Objects from one class can turn into objects from another class either automatically or by an explicit call to the `as` function. Automatic conversion is special, and comes from the designer of one class of objects asserting that this class extends another class. The most common case is that one or more class names are supplied in the `contains=` argument to `setClass`, in which case the new class extends each of the earlier classes (in the usual terminology, the earlier classes are *superclasses* of the new class and it is a *subclass* of each of them).

This form of inheritance is called *simple* inheritance in R. See `setClass` for details. Inheritance can also be defined explicitly by a call to `setIs`. The two versions have slightly different implications for coerce methods. Simple inheritance implies that inherited slots behave identically in the subclass and the superclass. Whenever two classes are related by simple inheritance, corresponding coerce methods are defined for both direct and replacement use of `as`. In the case of simple inheritance, these methods do the obvious computation: they extract or replace the slots in the object that correspond to those in the superclass definition.

The implicitly defined coerce methods may be overridden by a call to `setAs`; note, however, that the implicit methods are defined for each subclass-superclass pair, so that you must override each of these explicitly, not rely on inheritance.

When inheritance is defined by a call to `setIs`, the coerce methods are provided explicitly, not generated automatically. Inheritance will apply (to the `from` argument, as described in the section below). You could also supply methods via `setAs` for non-inherited relationships, and now these also can be inherited.

For further on the distinction between simple and explicit inheritance, see `setIs`.

How Functions ‘as’ and ‘setAs’ Work

The function `as` turns `object` into an object of class `Class`. In doing so, it applies a “coerce method”, using S4 classes and methods, but in a somewhat special way. Coerce methods are methods for the function `coerce` or, in the replacement case the function ``coerce<-``. These functions have two arguments in method signatures, `from` and `to`, corresponding to the class of the object and the desired coerce class. These functions must not be called directly, but are used to store tables of methods for the use of `as`, directly and for replacements. In this section we will describe the direct case, but except where noted the replacement case works the same way, using ``coerce<-`` and the `replace` argument to `setAs`, rather than `coerce` and the `def` argument.

Assuming the `object` is not already of the desired class, `as` first looks for a method in the table of methods for the function `coerce` for the signature `c(from = class(object), to = Class)`, in the same way method selection would do its initial lookup. To be precise, this means the table of both direct and inherited methods, but inheritance is used specially in this case (see below).

If no method is found, `as` looks for one. First, if either `Class` or `class(object)` is a superclass of the other, the class definition will contain the information needed to construct a coerce method. In the usual case that the subclass contains the superclass (i.e., has all its slots), the method is constructed either by extracting or replacing the inherited slots. Non-simple extensions (the result of a call to `setIs`) will usually contain explicit methods, though possibly not for replacement.

If no subclass/superclass relationship provides a method, `as` looks for an inherited method, but applying inheritance for the argument `from` only, not for the argument `to` (if you think about it, you’ll probably agree that you wouldn’t want the result to be from some class other than the `Class` specified). Thus, `selectMethod("coerce", sig, useInherited= c(from=TRUE, to= FALSE))` replicates the method selection used by `as()`.

In nearly all cases the method found in this way will be cached in the table of coerce methods (the exception being subclass relationships with a test, which are legal but discouraged). So the detailed

calculations should be done only on the first occurrence of a coerce from `class(object)` to `Class`.

With this explanation as background, the function `setAs` does a fairly obvious computation: It constructs and sets a method for the function `coerce` with signature `c(from, to)`, using the `def` argument to define the body of the method. The function supplied as `def` can have one argument (interpreted as an object to be coerced) or two arguments (the `from` object and the `to` class). Either way, `setAs` constructs a function of two arguments, with the second defaulting to the name of the `to` class. The method will be called from `as` with the object as the `from` argument and no `to` argument, with the default for this argument being the name of the intended `to` class, so the method can use this information in messages.

The direct version of the `as` function also has a `strict=` argument that defaults to `TRUE`. Calls during the evaluation of methods for other functions will set this argument to `FALSE`. The distinction is relevant when the object being coerced is from a simple subclass of the `to` class; if `strict=FALSE` in this case, nothing need be done. For most user-written `coerce` methods, when the two classes have no subclass/superclass, the `strict=` argument is irrelevant.

The `replace` argument to `setAs` provides a method for ``coerce<-``. As with all replacement methods, the last argument of the method must have the name `value` for the object on the right of the assignment. As with the `coerce` method, the first two arguments are `from, to`; there is no `strict=` option for the `replace` case.

The function `coerce` exists as a repository for such methods, to be selected as described above by the `as` function. Actually dispatching the methods using `standardGeneric` could produce incorrect inherited methods, by using inheritance on the `to` argument; as mentioned, this is not the logic used for `as`. To prevent selecting and caching invalid methods, calls to `coerce` are currently mapped into calls to `as`, with a warning message.

Basic Coercion Methods

Methods are pre-defined for coercing any object to one of the basic datatypes. For example, `as(x, "numeric")` uses the existing `as.numeric` function. These built-in methods can be listed by `showMethods("coerce")`.

See Also

If you think of using `try(as(x, cl))`, consider `canCoerce(x, cl)` instead.

Examples

```
## using the definition of class "track" from Classes

setAs("track", "numeric", function(from) from@y)

t1 <- new("track", x=1:20, y=(1:20)^2)

as(t1, "numeric")
```

```
## The next example shows:
## 1. A virtual class to define setAs for several classes at once.
## 2. as() using inherited information

setClass("ca", representation(a = "character", id = "numeric"))

setClass("cb", representation(b = "character", id = "numeric"))

setClass("id")
setIs("ca", "id")
setIs("cb", "id")

setAs("id", "numeric", function(from) from@id)

CA <- new("ca", a = "A", id = 1)
CB <- new("cb", b = "B", id = 2)

setAs("cb", "ca", function(from, to )new(to, a=from@b, id = from@id))

as(CB, "numeric")
```

BasicClasses

Classes Corresponding to Basic Data Types

Description

Formal classes exist corresponding to the basic R object types, allowing these types to be used in method signatures, as slots in class definitions, and to be extended by new classes.

Usage

```
### The following are all basic vector classes.
### They can appear as class names in method signatures,
### in calls to as(), is(), and new().
"character"
"complex"
"double"
"expression"
"integer"
"list"
"logical"
"numeric"
"single"
"raw"

### the class
"vector"
### is a virtual class, extended by all the above

### the class
"S4"
```

```
### is an object type for S4 objects that do not extend
### any of the basic vector classes. It is a virtual class.

### The following are additional basic classes
"NULL"      # NULL objects
"function"  # function objects, including primitives
"externalptr" # raw external pointers for use in C code

"ANY"      # virtual classes used by the methods package itself
"VIRTUAL"
"missing"
```

Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted class name, and the remaining arguments if any are objects to be interpreted as vectors of this class. Multiple arguments will be concatenated.

The class `"expression"` is slightly odd, in that the `...` arguments will *not* be evaluated; therefore, don't enclose them in a call to `quote()`.

Extends

Class `"vector"`, directly.

Methods

coerce Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, `as(x, "numeric")` calls `as.numeric(x)`.

callGeneric	<i>Call the Current Generic Function from a Method</i>
-------------	--

Description

A call to `callGeneric` can only appear inside a method definition. It then results in a call to the current generic function. The value of that call is the value of `callGeneric`. While it can be called from any method, it is useful and typically used in methods for group generic functions.

Usage

```
callGeneric(...)
```

Arguments

`...` Optionally, the arguments to the function in its next call.
 If no arguments are included in the call to `callGeneric`, the effect is to call the function with the current arguments. See the detailed description for what this really means.

Details

The name and package of the current generic function is stored in the environment of the method definition object. This name is looked up and the corresponding function called.

The statement that passing no arguments to `callGeneric` causes the generic function to be called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that "missing" is a valid class in a method signature). For a formal argument, say `x`, that appears in the original call, there is a corresponding argument in the generated call equivalent to `x = x`. In effect, this means that the generic function sees the same actual arguments, but arguments are evaluated only once.

Using `callGeneric` with no arguments is prone to creating infinite recursion, unless one of the arguments in the signature has been modified in the current method so that a different method is selected.

Value

The value returned by the new call.

## End(Not run)
```

callNextMethod	<i>Call an Inherited Method</i>
----------------	---------------------------------

Description

A call to `callNextMethod` can only appear inside a method definition. It then results in a call to the first inherited method after the current method, with the arguments to the current method passed down to the next method. The value of that method call is the value of `callNextMethod`.

Usage

```
callNextMethod(...)
```

Arguments

...

Optionally, the arguments to the function in its next call (but note that the dispatch is as in the detailed description below; the arguments have no effect on selecting the next method.)

If no arguments are included in the call to `callNextMethod`, the effect is to call the method with the current arguments. See the detailed description for what this really means.

Calling with no arguments is often the natural way to use `callNextMethod`; see the examples.

Details

The ‘next’ method (i.e., the first inherited method) is defined to be that method which *would* have been called if the current method did not exist. This is more-or-less literally what happens: The current method (to be precise, the method with signature given by the `defined` slot of the method from which `callNextMethod` is called) is deleted from a copy of the methods for the current generic, and `selectMethod` is called to find the next method (the result is cached in a special object, so the search only typically happens once per session per combination of argument classes).

Note that the preceding definition means that the next method is defined uniquely when `setMethod` inserts the method containing the `callNextMethod` call, given the definitions of the classes in the signature. The choice does not depend on the path that gets us to that method (for example, through inheritance or from another `callNextMethod` call). This definition was not enforced in versions of R prior to 2.3.0, where the method was selected based on the target signature, and so could vary depending on the actual arguments.

It is also legal, and often useful, for the method called by `callNextMethod` to itself have a call to `callNextMethod`. This generally works as you would expect, but for completeness be aware that it is possible to have ambiguous inheritance in the S structure, in the sense that the same two classes can appear as superclasses *in the opposite order* in two other class definitions. In this case the effect of a nested instance of `callNextMethod` is not well defined. Such inconsistent class hierarchies are both rare and nearly always the result of bad design, but they are possible, and currently undetected.

The statement that the method is called with the current arguments is more precisely as follows. Arguments that were missing in the current call are still missing (remember that “missing” is a valid class in a method signature). For a formal argument, say `x`, that appears in the original call, there is a corresponding argument in the next method call equivalent to `x = x`. In effect, this means that the next method sees the same actual arguments, but arguments are evaluated only once.

Value

The value returned by the selected method.

[callGeneric](#) to call the generic function with the current dispatch rules (typically for a group generic function); [Methods](#) for the general behavior of method dispatch

Examples

```
## some class definitions with simple inheritance
setClass("B0" , representation(b0 = "numeric"))

setClass("B1", representation(b1 = "character"), contains = "B0")

setClass("B2", representation(b2 = "logical"), contains = "B1")

## and a rather silly function to illustrate callNextMethod

f <- function(x) class(x)

setMethod("f", "B0", function(x) c(x@b0^2, callNextMethod()))
setMethod("f", "B1", function(x) c(paste(x@b1, ":"), callNextMethod()))
setMethod("f", "B2", function(x) c(x@b2, callNextMethod()))

b1 <- new("B1", b0 = 2, b1 = "Testing")

b2 <- new("B2", b2 = FALSE, b1 = "More testing", b0 = 10)

f(b2)
stopifnot(identical(f(b2), c(b2@b2, paste(b2@b1, ":"), b2@b0^2, "B2")))

f(b1)

## a sneakier method: the *changed* x is used:
setMethod("f", "B2", function(x) {x@b0 <- 111; c(x@b2, callNextMethod())})
f(b2)
stopifnot(identical(f(b2), c(b2@b2, paste(b2@b1, ":"), 111^2, "B2")))
```

Description

Test if an object can be coerced to a given S4 class. Maybe useful inside `if()` to ensure that calling `as(object, Class)` will find a method.

Usage

```
canCoerce(object, Class)
```

Arguments

`object` any R object, typically of a formal S4 class.
`Class` an S4 class (see `isClass`).

Value

a scalar logical, TRUE if there is a `coerce` method (as defined by `setAs`, e.g.) for the signature (`from = class(object)`, `to = Class`).

See Also

`as`, `setAs`, `selectMethod`, `setClass`,

Examples

```
m <- matrix(pi, 2, 3)
canCoerce(m, "numeric") # TRUE
canCoerce(m, "array")   # TRUE
```

cbind2

Combine two Objects by Columns or Rows

Description

Combine two matrix-like R objects by columns (`cbind2`) or rows (`rbind2`). These are (S4) generic functions with default methods.

Usage

```
cbind2(x, y)
rbind2(x, y)
```

Arguments

`x` any R object, typically matrix-like.
`y` any R object, typically similar to `x`, or missing completely.

Details

The main use of `cbind2` (`rbind2`) is to be called by `cbind()` (`rbind()`) if these are activated. This allows `cbind` (`rbind`) to work for formally classed (aka ‘S4’) objects by providing S4 methods for these objects. Currently, a call `methods:::bind_activation(TRUE)` is needed to install a `cbind2`-calling version of `cbind` (into the base name space) and the same for `rbind`. `methods:::bind_activation(FALSE)` reverts to the previous internal version of `cbind` which does not build on `cbind2`, see the examples.

Value

A matrix (or matrix like object) combining the columns (or rows) of `x` and `y`.

Methods

`x = "ANY", y = "ANY"` the default method using R’s internal code.

`x = "ANY", y = "missing"` the default method for one argument using R’s internal code.

See Also

`cbind`, `rbind`.

Examples

```
cbind2(1:3, 4)
m <- matrix(3:8, 2,3, dimnames=list(c("a","b"), LETTERS[1:3]))
cbind2(1:2, m) # keeps dimnames from m

### Note: Use the following activation if you want cbind() to work
### ---- on S4 objects -- be careful otherwise!

methods:::bind_activation(on = TRUE)
trace("cbind2")
cbind(a=1:3) # no call to cbind2()
cbind(a=1:3, four=4, 7:9) # calling cbind2() twice
untrace("cbind2")

## The following fails currently,
## since cbind() works recursively from the tail:
try( cbind(m, a=1, b=3) )

## turn off the `special cbind()` :
methods:::bind_activation(FALSE)
```

Description

Class definitions are objects that contain the formal definition of a class of R objects, usually referred to as an S4 class, to distinguish them from the informal S3 classes. This document gives an overview of S4 classes; for details of the class representation objects, see help for the class [classRepresentation](#).

Metadata Information

When a class is defined, an object is stored that contains the information about that class. The object, known as the *metadata* defining the class, is not stored under the name of the class (to allow programmers to write generating functions of that name), but under a specially constructed name. To examine the class definition, call [getClass](#). The information in the metadata object includes:

Slots: The data contained in an object from an S4 class is defined by the *slots* in the class definition.

Each slot in an object is a component of the object; like components (that is, elements) of a list, these may be extracted and set, using the function [slot\(\)](#) or more often the operator "@". However, they differ from list components in important ways. First, slots can only be referred to by name, not by position, and there is no partial matching of names as with list elements.

All the objects from a particular class have the same set of slot names; specifically, the slot names that are contained in the class definition. Each slot in each object always is an object of the class specified for this slot in the definition of the current class. The word “is” corresponds to the R function of the same name ([is](#)), meaning that the class of the object in the slot must be the same as the class specified in the definition, or some class that extends the one in the definition (a *subclass*).

One class name is special, `.Data`. This stands for the ‘data part’ of the object. Any class that contains one of the basic object types in R, has implicitly a corresponding `.Data` slot of that type, allowing computations to extract or replace the data part while leaving other slots unchanged. The `.Data` slot also determines the type of the object; if `x` has a `.Data` slot, the type of the slot is the type of the object (that is, the value of [typeof\(x\)](#)). Extending a basic type this way allows objects to use old-style code for the corresponding type as well as S4 methods. Any basic type can be used for `.Data`, with the exception of a few that do not behave like ordinary objects; namely, "NULL", environments, and external pointers.

There is one additional use of the data part, which is also an exception to the correspondence with the object’s type. The exception arises from the special treatment of [matrix](#) and [array](#) “classes” in R. Matrix and array objects are managed internally and recognized without regard to any class attribute; therefore, they can be used as the data part of a new class. In this case, the object type for the new class depends on the type of the data in the matrix or array.

If the new class does not have a data part as described above, the type of objects from the new class is "S4".

Superclasses: The definition of a class includes the *superclasses* —the classes that this class extends. A class `Fancy`, say, extends a class `Simple` if an object from the `Fancy` class has all the capabilities of the `Simple` class (and probably some more as well). In particular, and very usefully, any method defined to work for a `Simple` object can be applied to a `Fancy` object as well.

This relationship is expressed equivalently by saying that `Simple` is a superclass of `Fancy`, or that `Fancy` is a subclass of `Simple`.

The direct superclasses of a class are those superclasses explicitly defined. Direct superclasses can be defined in three ways. Most commonly, the superclasses are listed in the `contains=` argument in the call to `setClass` that creates the subclass. In this case the subclass will contain all the slots of the superclass, and the relation between the class is called *simple*, as it in fact is. Superclasses can also be defined explicitly by a call to `setIs`; in this case, the relation requires methods to be specified to go from subclass to superclass. Thirdly, a class union is a superclass of all the members of the union. In this case too the relation is *simple*, but notice that the relation is defined when the superclass is created, not when the subclass is created as with the `contains=` mechanism.

The definition of a superclass will also potentially contain its own direct superclasses. These are considered (and shown) as superclasses at distance 2 from the original class; their direct superclasses are at distance 3, and so on. All these are legitimate superclasses for purposes such as method selection.

When superclasses are defined by including the names of superclasses in the `contains=` argument to `setClass`, an object from the class will have all the slots defined for its own class *and* all the slots defined for all its superclasses as well.

The information about the relation between a class and a particular superclass is encoded as an object of class `SClassExtension`. A list of such objects for the superclasses (and sometimes for the subclasses) is included in the metadata object defining the class. If you need to compute with these objects (for example, to compare the distances), call the function `extends` with argument `fullInfo=TRUE`.

Prototype: The objects from a class, typically created by a call to `new` or by assigning another object from the class, are defined by the *prototype* object for the class and by additional arguments in the call to `new`, which are passed to a method for that class for the function `initialize`.

Each class definition contains a prototype object for the class. This must have values for all the slots defined by the class definition. By default, these are the prototypes of all the slot classes, if those are not virtual classes. However, the definition of the class can specify any valid object for any of the slots.

Virtual classes; Basic classes

Classes exist for which there are no actual objects, the *virtual* classes, in fact a very important programming tool. They are used to group together ordinary classes that want to share some programming behavior, without necessarily restricting how the behavior is implemented. Virtual class definitions may if you want include slots (to provide some common behavior without fully defining the object—see the class `traceable` for an example).

A simple and useful form of virtual class is the *class union*, a virtual class that is defined in a call to `setClassUnion` by listing one or more of subclasses (classes that extend the class union). Class unions can include as subclasses basic data types (whose definition is otherwise sealed).

There are a number of ‘basic’ classes, corresponding to the ordinary kinds of data occurring in R. For example, `"numeric"` is a class corresponding to numeric vectors. The other vector basic classes are `"logical"`, `"integer"`, `"complex"`, `"character"`, `"raw"`, `"list"` and `"expression"`. The prototypes for the vector classes are vectors of length 0 of the corresponding type. Notice that basic classes are unusual in that the prototype object is from the class itself.

In addition to the vector classes there are also basic classes corresponding to objects in the language, such as `"function"` and `"call"`. These classes are subclasses of the virtual class `"language"`. Finally, there are basic classes for specialized objects, such as `"environment"`

and "externalptr". The vector and language basic classes can be used as slots or as superclasses for any other class definitions. The classes corresponding to other object types can be used as slots but not always as superclasses, since many of them do not follow the functional behavior of the language; in particular, they are not copied and so cannot have attributes or slots defined locally.

S3 Classes

Earlier, informal classes of objects (usually referred to as ‘S3’ classes) are used by many R functions. It is natural to consider including them as the class for a slot in a formal class, or even as a class to be extended by the new class. This isn’t prohibited but there are some disadvantages, and if you do want to include S3 classes, they should be declared by including them in a call to `setOldClass`. Here are some considerations:

- Using S3 classes somewhat defeats the purpose of defining a formal class: An important advantage to your users is that a formal class provides guarantees of what the object contains (minimally, the classes of the slots and therefore what data they contain; optionally, any other requirements imposed by a validity method).

But there is no guarantee whatever about the data in an object from an S3 class. It’s entirely up to the functions that create or modify such objects. If you want to provide guarantees to your users, you will need a validity method that explicitly checks the contents of S3-class objects.

- To get the minimal guarantee (that the object in a slot has, or extends, the class for the slot) you should ensure that the S3 classes are known to *be* S3 classes, possibly with S inheritance. To do this, include a call to `setOldClass` for the S3 classes used.

Otherwise, the S3 class is undefined (and the code used by `setClass` will issue a warning). Slot assignments, for example, will not then check for possible errors.

- Current versions of R (beginning with 2.8.0) try to accommodate S4 classes that extend S3 classes, that is, those including an S3 class in the `contains=` argument to `setClass`. Specifically, objects from such classes will contain the S3 class as a slot, and some S3 computations will recognize the S3 class, including method dispatch and the function `inherits`. See `S3Class` for details. The S3 classes *must* have been registered by a call to `setOldClass`. The basic caution remains true however: There is no guarantee that all S3 computations will be compatible, and some are known not to be.

- These caveats apply to S3 classes; that is, objects with a class assigned by some R function but without a formal class definition. In contrast, the built-in vector types (`numeric`, `list`, etc.) are generally fine as slots or for `contains=` classes. These object types don’t have formal slots, but the base code in the system essentially forces them to contain the type of data they claim to have.

Objects with a “class” of `matrix` or `array` are somewhat in between. They do not have an explicit S3 class, but do have one or two attributes. There is no general problem in having these as slots, but because there is no guarantee of a `dimnames` slot, they don’t work as formal classes. The `ts` class, although also ancient in the S language, is implemented in R essentially as an S3 class, with the implications noted above—not suitable for a `contains=` argument—but with a few S4 methods defined. See the documentation for class `structure` for more details.

classRepresentation-class
Class Objects

Description

These are the objects that hold the definition of classes of objects. They are constructed and stored as meta-data by calls to the function [setClass](#). Don't manipulate them directly, except perhaps to look at individual slots.

Details

Class definitions are stored as metadata in various packages. Additional metadata supplies information on inheritance (the result of calls to [setIs](#)). Inheritance information implied by the class definition itself (because the class contains one or more other classes) is also constructed automatically.

When a class is to be used in an R session, this information is assembled to complete the class definition. The completion is a second object of class "classRepresentation", cached for the session or until something happens to change the information. A call to [getClass](#) returns the completed definition of a class; a call to [getClassDef](#) returns the stored definition (uncompleted).

In particular, completion fills in the upward- and downward-pointing inheritance information for the class, in slots `contains` and `subclasses` respectively. It's in principle important to note that this information can depend on which packages are installed, since these may define additional subclasses or superclasses.

Slots

slots: A named list of the slots in this class; the elements of the list are the classes to which the slots must belong (or extend), and the names of the list gives the corresponding slot names.

contains: A named list of the classes this class 'contains'; the elements of the list are objects of [SClassExtension](#). The list may be only the direct extensions or all the currently known extensions (see the details).

virtual: Logical flag, set to TRUE if this is a virtual class.

prototype: The object that represents the standard prototype for this class; i.e., the data and slots returned by a call to [new](#) for this class with no special arguments. Don't mess with the prototype object directly.

validity: Optionally, a function to be used to test the validity of objects from this class. See [validObject](#).

access: Access control information. Not currently used.

className: The character string name of the class.

package: The character string name of the package to which the class belongs. Nearly always the package on which the metadata for the class is stored, but in operations such as constructing inheritance information, the internal package name rules.

subclasses: A named list of the classes known to extend this class'; the elements of the list are objects of class `SClassExtension`. The list is currently only filled in when completing the class definition (see the details).

versionKey: Object of class "externalptr"; eventually will perhaps hold some versioning information, but not currently used.

sealed: Object of class "logical"; is this class sealed? If so, no modifications are allowed.

Description

Special documentation can be supplied to describe the classes and methods that are created by the software in the methods package. Techniques to access this documentation and to create it in R help files are described here.

Getting documentation on classes and methods

You can ask for on-line help for class definitions, for specific methods for a generic function, and for general discussion of methods for a generic function. These requests use the `?` operator (see [help](#) for a general description of the operator). Of course, you are at the mercy of the implementer as to whether there *is* any documentation on the corresponding topics.

Documentation on a class uses the argument `class` on the left of the `?`, and the name of the class on the right; for example,

```
class ? genericFunction
```

to ask for documentation on the class "genericFunction".

When you want documentation for the methods defined for a particular function, you can ask either for a general discussion of the methods or for documentation of a particular method (that is, the method that would be selected for a particular set of actual arguments).

Overall methods documentation is requested by calling the `?` operator with `methods` as the left-side argument and the name of the function as the right-side argument. For example,

```
methods ? initialize
```

asks for documentation on the methods for the `initialize` function.

Asking for documentation on a particular method is done by giving a function call expression as the right-hand argument to the `"?"` operator. There are two forms, depending on whether you prefer to give the class names for the arguments or expressions that you intend to use in the actual call.

If you planned to evaluate a function call, say `myFun(x, sqrt(wt))` and wanted to find out something about the method that would be used for this call, put the call on the right of the `"?"` operator:

```
?myFun(x, sqrt(wt))
```

A method will be selected, as it would be for the call itself, and documentation for that method will be requested. If `myFun` is not a generic function, ordinary documentation for the function will be requested.

If you know the actual classes for which you would like method documentation, you can supply these explicitly in place of the argument expressions. In the example above, if you want method documentation for the first argument having class `"maybeNumber"` and the second `"logical"`, call the `"?"` operator, this time with a left-side argument `method`, and with a function call on the right using the class names as arguments:

```
method ? myFun("maybeNumber", "logical")
```

Once again, a method will be selected, this time corresponding to the specified classes, and method documentation will be requested. This version only works with generic functions.

The two forms each have advantages. The version with actual arguments doesn't require you to figure out (or guess at) the classes of the arguments. On the other hand, evaluating the arguments may take some time, depending on the example. The version with class names does require you to pick classes, but it's otherwise unambiguous. It has a subtler advantage, in that the classes supplied may be virtual classes, in which case no actual argument will have specifically this class. The class `"maybeNumber"`, for example, might be a class union (see the example for `setClassUnion`).

In either form, methods will be selected as they would be in actual computation, including use of inheritance and group generic functions. See `selectMethod` for the details, since it is the function used to find the appropriate method.

Writing Documentation for Methods

The on-line documentation for methods and classes uses some extensions to the R documentation format to implement the requests for class and method documentation described above. See the document *Writing R Extensions* for the available markup commands (you should have consulted this document already if you are at the stage of documenting your software).

In addition to the specific markup commands to be described, you can create an initial, overall file with a skeleton of documentation for the methods defined for a particular generic function:

```
promptMethods("myFun")
```

will create a file, `'myFun-methods.Rd'` with a skeleton of documentation for the methods defined for function `myFun`. The output from `promptMethods` is suitable if you want to describe all or most of the methods for the function in one file, separate from the documentation of the generic function itself. Once the file has been filled in and moved to the `'man'` subdirectory of your source package, requests for methods documentation will use that file, both for specific methods documentation as described above, and for overall documentation requested by

```
methods ? myFun
```

You are not required to use `promptMethods`, and if you do, you may not want to use the entire file created:

- If you want to document the methods in the file containing the documentation for the generic function itself, you can cut-and-paste to move the `\alias` lines and the `Methods` section from the file created by `promptMethods` to the existing file.
- On the other hand, if these are auxiliary methods, and you only want to document the added or modified software, you should strip out all but the relevant `\alias` lines for the methods of interest, and remove all but the corresponding `\item` entries in the `Methods` section. Note that in this case you will usually remove the first `\alias` line as well, since that is the marker for general methods documentation on this function (in the example, `\alias{myfun-methods}`).

If you simply want to direct documentation for one or more methods to a particular R documentation file, insert the appropriate alias.

Description

The “...” argument in R functions is treated specially, in that it matches zero, one or more actual arguments (and so, objects). A mechanism has been added to R to allow “...” as the signature of a generic function. Methods defined for such functions will be selected and called when *all* the arguments matching “...” are from the specified class or from some subclass of that class.

Using "..." in a Signature

Beginning with version 2.8.0 of R, S4 methods can be dispatched (selected and called) corresponding to the special argument “...”. Currently, “...” cannot be mixed with other formal arguments: either the signature of the generic function is “...” only, or it does not contain “...”. (This restriction may be lifted in a future version.)

Given a suitable generic function, methods are specified in the usual way by a call to `setMethod`. The method definition must be written expecting all the arguments corresponding to “...” to be from the class specified in the method’s signature, or from a class that extends that class (i.e., a subclass of that class).

Typically the methods will pass “...” down to another function or will create a list of the arguments and iterate over that. See the examples below.

When you have a computation that is suitable for more than one existing class, a convenient approach may be to define a union of these classes by a call to `setClassUnion`. See the example below.

Method Selection and Dispatch for "..."

See [Methods](#) for a general discussion. The following assumes you have read the “Method Selection and Dispatch” section of that documentation.

A method selecting on “...” is specified by a single class in the call to `setMethod`. If all the actual arguments corresponding to “...” have this class, the corresponding method is selected directly.

Otherwise, the class of each argument and that class’ superclasses are computed, beginning with the first “...” argument. For the first argument, eligible methods are those for any of the classes. For each succeeding argument that introduces a class not considered previously, the eligible methods are further restricted to those matching the argument’s class or superclasses. If no further eligible classes exist, the iteration breaks out and the default method, if any, is selected.

At the end of the iteration, one or more methods may be eligible. If more than one, the selection looks for the method with the least distance to the actual arguments. For each argument, any inherited method corresponds to a distance, available from the `contains` slot of the class definition. Since the same class can arise for more than one argument, there may be several distances associated with it. Combining them is inevitably arbitrary: the current computation uses the minimum distance. Thus, for example, if a method matched one argument directly, one as first generation superclass and another as a second generation superclass, the distances are 0, 1 and 2. The current selection computation would use distance 0 for this method. In particular, this selection criterion tends to use a method that matches exactly one or more of the arguments’ class.

As with ordinary method selection, there may be multiple methods with the same distance. A warning message is issued and one of the methods is chosen (the first encountered, which in this case is rather arbitrary).

Notice that, while the computation examines all arguments, the essential cost of dispatch goes up with the number of *distinct* classes among the arguments, likely to be much smaller than the number of arguments when the latter is large.

Implementation Details

Methods dispatching on “...” were introduced in version 2.8.0 of R. The initial implementation of the corresponding selection and dispatch is in an R function, for flexibility while the new mechanism is being studied. In this implementation, a local version of `setGeneric` is inserted in the generic function’s environment. The local version selects a method according to the criteria above and calls that method, from the environment of the generic function. This is slightly different from the action taken by the C implementation when “...” is not involved. Aside from the extra computing time required, the method is evaluated in a true function call, as opposed to the special context constructed by the C version (which cannot be exactly replicated in R code.) However, situations in which different computational results would be obtained have not been encountered so far, and seem very unlikely.

Methods dispatching on arguments other than “...” are *cached* by storing the inherited method in the table of all methods, where it will be found on the next selection with the same combination of classes in the actual arguments (but not used for inheritance searches). Methods based on “...” are also cached, but not found quite as immediately. As noted, the selected method depends only on the set of classes that occur in the “...” arguments. Each of these classes can appear one or more times, so many combinations of actual argument classes will give rise to the same effective signature. The selection computation first computes and sorts the distinct classes encountered. This gives a label that will be cached in the table of all methods, avoiding any further search for inherited classes after the first occurrence. A call to `showMethods` will expose such inherited methods.

The intention is that the “...” features will be added to the standard C code when enough experience with them has been obtained. It is possible that at the same time, combinations of “...” with other arguments in signatures may be supported.

Examples

```
cc <- function(...)c(...)

setGeneric("cc")

setMethod("cc", "character", function(...)paste(...))

setClassUnion("Number", c("numeric", "complex"))

setMethod("cc", "Number", function(...) sum(...))
```

```

setClass("cdate", contains = "character", representation(date = "Date"))
setClass("vdate", contains = "vector", representation(date = "Date"))
cd1 = new("cdate", "abcdef", date = Sys.Date())
cd2 = new("vdate", "abcdef", date = Sys.Date())
stopifnot(identical(cc(letters, character(), cd1), paste(letters, character(), cd1))) # t
stopifnot(identical(cc(letters, character(), cd2), c(letters, character(), cd2))) # the c
stopifnot(identical(cc(1:10, 1+1i), sum(1:10, 1+1i))) # the "Number" method
stopifnot(identical(cc(1:10, 1+1i, TRUE), c(1:10, 1+1i, TRUE))) # the default
stopifnot(identical(cc(), c())) # no arguments implies the default method
setGeneric("numMax", function(...)standardGeneric("numMax"))
setMethod("numMax", "numeric", function(...)max(...)) # won't work for complex data
setMethod("numMax", "Number", function(...) paste(...)) # should not be selected w/o comp
stopifnot(identical(numMax(1:10, pi, 1+1i), paste(1:10, pi, 1+1i)))
stopifnot(identical(numMax(1:10, pi, 1), max(1:10, pi, 1)))
try(numMax(1:10, pi, TRUE)) # should be an error: no default method
## A generic version of paste(), dispatching on the "..." argument:
setGeneric("paste", signature = "...")
setMethod("paste", "Number", function(..., sep, collapse) c(...))
stopifnot(identical(paste(1:10, pi, 1), c(1:10, pi, 1)))

```

environment-class *Class "environment"*

Description

A formal class for R environments.

Objects from the Class

Objects can be created by calls of the form `new("environment", ...)`. The arguments in ..., if any, should be named and will be assigned to the newly created environment.

Methods

coerce signature(from = "ANY", to = "environment"): calls [as.environment](#).

initialize signature(object = "environment"): Implements the assignments in the new environment. Note that the object argument is ignored; a new environment is *always* created, since environments are not protected by copying.

[new.env](#)

findClass	<i>Computations with Classes</i>
-----------	----------------------------------

Description

Functions to find and manipulate class definitions.

Usage

```
removeClass(Class, where)

isClass(Class, formal=TRUE, where)

getClasses(where, inherits = missing(where))

findClass(Class, where, unique = "")

resetClass(Class, classDef, where)

sealClass(Class, where)
```

Arguments

Class	character string name for the class. The functions will usually take a class definition instead of the string. To restrict the class to those defined in a particular package, set the packageSlot of the character string.
where	The environment in which to modify or remove the definition. Defaults to the top-level environment of the calling function (the global environment for ordinary computations, but the environment or name space of a package in the source for a package). When searching for class definitions, <code>where</code> defines where to do the search, and the default is to search from the top-level environment or name space of the caller to this function.
unique	if <code>findClass</code> expects a unique location for the class, <code>unique</code> is a character string explaining the purpose of the search (and is used in warning and error messages). By default, multiple locations are possible and the function always returns a list.
inherits	in a call to <code>getClasses</code> , should the value returned include all parent environments of <code>where</code> , or that environment only? Defaults to <code>TRUE</code> if <code>where</code> is omitted, and to <code>FALSE</code> otherwise.
formal	Should a formal definition be required?
classDef	For <code>removeClass</code> , the optional class definition (but usually it's better for <code>Class</code> to be the class definition, and to omit <code>classDef</code>).

Details

These are the functions that test and manipulate formal class definitions. Brief documentation is provided below. See the references for an introduction and for more details.

removeClass: Remove the definition of this class, from the environment `where` if this argument is supplied; if not, `removeClass` will search for a definition, starting in the top-level environment of the call to `removeClass`, and remove the (first) definition found.

isClass: Is this the name of a formally defined class? (Argument `formal` is for compatibility and is ignored.)

getClassNames: The names of all the classes formally defined on `where`. If called with no argument, all the classes visible from the calling function (if called from the top-level, all the classes in any of the environments on the search list). The `inherits` argument can be used to search a particular environment and all its parents, but usually the default setting is what you want.

findClass: The list of environments or positions on the search list in which a class definition of `Class` is found. If `where` is supplied, this is an environment (or name space) from which the search takes place; otherwise the top-level environment of the caller is used. If `unique` is supplied as a character string, `findClass` returns a single environment or position. By default, it always returns a list. The calling function should select, say, the first element as a position or environment for functions such as `get`.

If `unique` is supplied as a character string, `findClass` will warn if there is more than one definition visible (using the string to identify the purpose of the call), and will generate an error if no definition can be found.

resetClass: Reset the internal definition of a class. Causes the complete definition of the class to be re-computed, from the representation and superclasses specified in the original call to `setClass`.

This function is called when aspects of the class definition are changed. You would need to call it explicitly if you changed the definition of a class that this class extends (but doing that in the middle of a session is living dangerously, since it may invalidate existing objects).

sealClass: Seal the current definition of the specified class, to prevent further changes. It is possible to seal a class in the call to `setClass`, but sometimes further changes have to be made (e.g., by calls to `setIs`). If so, call `sealClass` after all the relevant changes have been made.

findMethods

*Descriptions of the Methods Defined for a Generic Function***Description**

These functions convert the methods defined in a table for a generic function (as used for selection of methods) into a list, for study or display, or provide other information summarizing the methods.

The function `findMethods` returns a list of the method definitions currently existing for generic function `f`, limited to the methods defined in environment `where` if that argument is supplied and possibly limited to those including one or more of the specified `classes` in the method signature.

The function `findMethodSignatures` returns a character matrix whose rows are the class names from the signature of the corresponding methods; it operates either from a list returned by `findMethods`, or by computing such a list itself, given the same arguments as `findMethods`.

The function `hasMethods` returns `TRUE` or `FALSE` according to whether there is a non-empty table of methods for function `f` in the environment or search position `where` (or anywhere on the search list if `where` is missing).

The function `getMethods` is an older alternative to `findMethods`, returning information in the form of an object of class `MethodsList`, previously used for method dispatch. It is not recommended, since the object returned is usually less convenient than the value of `findMethods`.

Usage

```
findMethods(f, where, classes = character(), inherited = FALSE)
findMethodSignatures(..., target = TRUE, methods = )
```

```
hasMethods(f, where, package)
```

```
getMethods(f, where)
```

Arguments

<code>f</code>	A generic function or the character-string name of one.
<code>where</code>	Optionally, an environment or position on the search list to look for methods metadata. If <code>where</code> is missing, <code>findMethods</code> uses the current table of methods in the generic function itself, and <code>hasMethods</code> looks for metadata anywhere in the search list.
<code>classes</code>	If supplied, only methods whose signatures contain at least one of the supplied classes will be included in the value returned.
<code>inherited</code>	Logical flag; if <code>TRUE</code> , the table of all methods, inherited or defined directly, will be used; otherwise, only the methods explicitly defined. Option <code>TRUE</code> is meaningful only if <code>where</code> is missing.
<code>...</code>	In the call to <code>findMethodSignatures</code> , any arguments that might be given to <code>findMethods</code> .
<code>target</code>	Optional flag to <code>findMethodSignatures</code> ; if <code>TRUE</code> , the signatures used are the target signatures (the classes for which the method will be selected); if <code>FALSE</code> , they will be the signatures are defined. The difference is only meaningful if <code>inherited</code> is <code>TRUE</code> .

methods	In the call to <code>findMethodSignatures</code> , an optional list of methods, presumably returned by a previous call to <code>findMethods</code> . If missing, that function will be call with the ... arguments.
package	In a call to <code>hasMethods</code> , the package name for the generic function (e.g., "base" for primitives). If missing this will be inferred either from the "package" attribute of the function name, if any, or from the package slot of the generic function. See details below.

Details

The functions obtain a table of the defined methods, either from the generic function or from the stored metadata object in the environment specified by `where`. The information in the table is converted as described above to produce the returned value.

Note that the list returned may contain the primitive function itself, when the generic corresponds to a primitive. (Basically, because primitive functions are abnormal R objects, which cannot currently be extended as method definitions.) Computations that use the returned list to derive other information need to take account of this possibility. See the implementation of `findMethodSignatures` for an example.

Note that `hasMethods`, but not the other functions, can be used even if no generic function of this name is currently found. In this case `package` must either be supplied as an argument or included as an attribute of `f`, since the package name is part of the identification of the methods tables.

These functions should be used in searching for or summarizing methods, rather than using information about how the metadata for methods is stored.

Examples

```
mm <- findMethods("Ops")
findMethodSignatures(methods = mm)
```

fixPre1.8

Fix Objects Saved from R Versions Previous to 1.8

Description

Beginning with R version 1.8.0, the class of an object contains the identification of the package in which the class is defined. The function `fixPre1.8` fixes and re-assigns objects missing that information (typically because they were loaded from a file saved with a previous version of R.)

Usage

```
fixPre1.8(names, where)
```

Arguments

names	Character vector of the names of all the objects to be fixed and re-assigned.
where	The environment from which to look for the objects, and for class definitions. Defaults to the top environment of the call to <code>fixPre1.8</code> , the global environment if the function is used interactively.

Details

The named object will be saved where it was found. Its class attribute will be changed to the full form required by R 1.8; otherwise, the contents of the object should be unchanged.

Objects will be fixed and re-assigned only if all the following conditions hold:

1. The named object exists.
2. It is from a defined class (not a basic datatype which has no actual class attribute).
3. The object appears to be from an earlier version of R.
4. The class is currently defined.
5. The object is consistent with the current class definition.

If any condition except the second fails, a warning message is generated.

Note that `fixPre1.8` currently fixes *only* the change in class attributes. In particular, it will not fix binary versions of packages installed with earlier versions of R if these use incompatible features. Such packages must be re-installed from source, which is the wise approach always when major version changes occur in R.

Value

The names of all the objects that were in fact re-assigned.

genericFunction-class
Generic Function Objects

Description

Generic functions (objects from or extending class `genericFunction`) are extended function objects, containing information used in creating and dispatching methods for this function. They also identify the package associated with the function and its methods.

Objects from the Class

Generic functions are created and assigned by `setGeneric` or `setGroupGeneric` and, indirectly, by `setMethod`.

As you might expect `setGeneric` and `setGroupGeneric` create objects of class `"genericFunction"` and `"groupGenericFunction"` respectively.

Slots

.Data: Object of class `"function"`, the function definition of the generic, usually created automatically as a call to `standardGeneric`.

generic: Object of class `"character"`, the name of the generic function.

package: Object of class `"character"`, the name of the package to which the function definition belongs (and *not* necessarily where the generic function is stored). If the package is not specified explicitly in the call to `setGeneric`, it is usually the package on which the corresponding non-generic function exists.

group: Object of class `"list"`, the group or groups to which this generic function belongs. Empty by default.

valueClass: Object of class "character"; if not an empty character vector, identifies one or more classes. It is asserted that all methods for this function return objects from these class (or from classes that extend them).

signature: Object of class "character", the vector of formal argument names that can appear in the signature of methods for this generic function. By default, it is all the formal arguments, except for ... Order matters for efficiency: the most commonly used arguments in specifying methods should come first.

default: Object of class "OptionalMethods", the default method for this function. Generated automatically and used to initialize method dispatch.

skeleton: Object of class "call", a slot used internally in method dispatch. Don't expect to use it directly.

Extends

Class "function", from data part.

Class "OptionalMethods", by class "function".

Class "PossibleMethod", by class "function".

Methods

Generic function objects are used in the creation and dispatch of formal methods; information from the object is used to create methods list objects and to merge or update the existing methods for this generic.

GenericFunctions *Tools for Managing Generic Functions*

Description

The functions documented here manage collections of methods associated with a generic function, as well as providing information about the generic functions themselves.

Usage

```
isGeneric(f, where, fdef, getName = FALSE)
isGroup(f, where, fdef)
removeGeneric(f, where)

dumpMethod(f, signature, file, where, def)
findFunction(f, generic = TRUE, where = topenv(parent.frame()))
dumpMethods(f, file, signature, methods, where)
signature(...)

removeMethods(f, where = topenv(parent.frame()), all = missing(where))
setReplaceMethod(f, ..., where = topenv(parent.frame()))

getGenerics(where, searchForm = FALSE)
```

Arguments

<code>f</code>	The character string naming the function.
<code>where</code>	The environment, name space, or search-list position from which to search for objects. By default, start at the top-level environment of the calling function, typically the global environment (i.e., use the search list), or the name space of a package from which the call came. It is important to supply this argument when calling any of these functions indirectly. With package name spaces, the default is likely to be wrong in such calls.
<code>signature</code>	The class signature of the relevant method. A signature is a named or unnamed vector of character strings. If named, the names must be formal argument names for the generic function. If <code>signature</code> is unnamed, the default is to use the first <code>length(signature)</code> formal arguments of the function.
<code>file</code>	The file or connection on which to dump method definitions.
<code>def</code>	The function object defining the method; if omitted, the current method definition corresponding to the signature.
<code>...</code>	Named or unnamed arguments to form a signature.
<code>generic</code>	In testing or finding functions, should generic functions be included. Supply as <code>FALSE</code> to get only non-generic functions.
<code>fdef</code>	Optional, the generic function definition. Usually omitted in calls to <code>isGeneric</code>
<code>getName</code>	If <code>TRUE</code> , <code>isGeneric</code> returns the name of the generic. By default, it returns <code>TRUE</code> .
<code>methods</code>	The methods object containing the methods to be dumped. By default, the methods defined for this generic (optionally on the specified <code>where</code> location).
<code>all</code>	in <code>removeMethods</code> , logical indicating if all (default) or only the first method found should be removed.
<code>searchForm</code>	In <code>getGenerics</code> , if <code>TRUE</code> , the package slot of the returned result is in the form used by <code>search()</code> , otherwise as the simple package name (e.g. "package:base" vs "base").

Summary of Functions

isGeneric: Is there a function named `f`, and if so, is it a generic?

The `getName` argument allows a function to find the name from a function definition. If it is `TRUE` then the name of the generic is returned, or `FALSE` if this is not a generic function definition.

The behavior of `isGeneric` and `getGeneric` for primitive functions is slightly different. These functions don't exist as formal function objects (for efficiency and historical reasons), regardless of whether methods have been defined for them. A call to `isGeneric` tells you whether methods have been defined for this primitive function, anywhere in the current search list, or in the specified position `where`. In contrast, a call to `getGeneric` will return what the generic for that function would be, even if no methods have been currently defined for it.

removeGeneric, removeMethods: Remove all the methods for the generic function of this name. In addition, `removeGeneric` removes the function itself; `removeMethods` restores the non-generic function which was the default method. If there was no default method, `removeMethods` leaves a generic function with no methods.

standardGeneric: Dispatches a method from the current function call for the generic function `f`. It is an error to call `standardGeneric` anywhere except in the body of the corresponding generic function.

Note that `standardGeneric` is a primitive function in the `base` package for efficiency reasons, but rather documented here where it belongs naturally.

dumpMethod: Dump the method for this generic function and signature.

findFunction: return a list of either the positions on the search list, or the current top-level environment, on which a function object for `name` exists. The returned value is *always* a list, use the first element to access the first visible version of the function. See the example.

NOTE: Use this rather than `find` with `mode="function"`, which is not as meaningful, and has a few subtle bugs from its use of regular expressions. Also, `findFunction` works correctly in the code for a package when attaching the package via a call to `library`.

dumpMethods: Dump all the methods for this generic.

signature: Returns a named list of classes to be matched to arguments of a generic function.

getGenerics: returns the names of the generic functions that have methods defined on `where`; this argument can be an environment or an index into the search list. By default, the whole search list is used. (`allGenerics()` is a *deprecated* alias for `getGenerics()`.)

The methods definitions are stored with package qualifiers; for example, methods for function `"initialize"` might refer to two different functions of that name, on different packages. The package names corresponding to the method list object are contained in the slot `package` of the returned object. The form of the returned name can be plain (e.g., `"base"`), or in the form used in the search list (`"package:base"`) according to the value of `searchForm`

Details

setGeneric: If there is already a non-generic function of this name, it will be used to define the generic unless `def` is supplied, and the current function will become the default method for the generic.

If `def` is supplied, this defines the generic function, and no default method will exist (often a good feature, if the function should only be available for a meaningful subset of all objects).

Arguments `group` and `valueClass` are retained for consistency with S-Plus, but are currently not used.

isGeneric: If the `fdef` argument is supplied, take this as the definition of the generic, and test whether it is really a generic, with `f` as the name of the generic. (This argument is not available in S-Plus.)

removeGeneric: If `where` supplied, just remove the version on this element of the search list; otherwise, removes the first version encountered.

standardGeneric: Generic functions should usually have a call to `standardGeneric` as their entire body. They can, however, do any other computations as well.

The usual `setGeneric` (directly or through calling `setMethod`) creates a function with a call to `standardGeneric`.

dumpMethod: The resulting source file will recreate the method.

findFunction: If `generic` is `FALSE`, ignore generic functions.

dumpMethods: If `signature` is supplied only the methods matching this initial signature are dumped. (This feature is not found in S-Plus: don't use it if you want compatibility.)

signature: The advantage of using `signature` is to provide a check on which arguments you meant, as well as clearer documentation in your method specification. In addition, `signature` checks that each of the elements is a single character string.

removeMethods: Returns TRUE if `f` was a generic function, FALSE (silently) otherwise.

If there is a default method, the function will be re-assigned as a simple function with this definition. Otherwise, the generic function remains but with no methods (so any call to it will generate an error). In either case, a following call to `setMethod` will consistently re-establish the same generic function as before.

Examples

```
require(stats) # for lm

## get the function "myFun" -- throw an error if 0 or > 1 versions visible:
findFuncStrict <- function(fName) {
  allF <- findFunction(fName)
  if(length(allF) == 0)
    stop("No versions of ", fName, " visible")
  else if(length(allF) > 1)
    stop(fName, " is ambiguous: ", length(allF), " versions")
  else
    get(fName, allF[[1]])
}

try(findFuncStrict("myFun"))# Error: no version
lm <- function(x) x+1
try(findFuncStrict("lm"))# Error: 2 versions
findFuncStrict("findFuncStrict")# just 1 version
rm(lm)

## method dumping -----

setClass("A", representation(a="numeric"))
setMethod("plot", "A", function(x,y,...){ cat("A meth\n") })
dumpMethod("plot","A", file="")
## Not run:
setMethod("plot", "A",
function (x, y, ...)
{
  cat("AAAAA\n")
}
)
## End(Not run)
tmp <- tempfile()
dumpMethod("plot","A", file=tmp)
## now remove, and see if we can parse the dump
stopifnot(removeMethod("plot", "A"))
```

```

source(tmp)
stopifnot(is(getMethod("plot", "A"), "MethodDefinition"))

## same with dumpMethods() :
setClass("B", contains="A")
setMethod("plot", "B", function(x,y,...){ cat("B ...\\n") })
dumpMethods("plot", file=tmp)
stopifnot(removeMethod("plot", "A"),
           removeMethod("plot", "B"))
source(tmp)
stopifnot(is(getMethod("plot", "A"), "MethodDefinition"),
          is(getMethod("plot", "B"), "MethodDefinition"))

```

getClass

Get Class Definition

Description

Get the definition of a class.

Usage

```

getClass(Class, .Force = FALSE, where)
getClassDef(Class, where, package)

```

Arguments

Class	the character-string name of the class.
.Force	if TRUE, return NULL if the class is undefined; otherwise, an undefined class results in an error.
where	environment from which to begin the search for the definition; by default, start at the top-level (global) environment and proceed through the search list.
package	the name of the package asserted to hold the definition. Supplied instead of <i>where</i> , with the distinction that the package need not be currently attached.

Details

A call to `getClass` returns the complete definition of the class supplied as a string, including all slots, etc. in classes that this class extends. A call to `getClassDef` returns the definition of the class from the environment *where*, unadorned. It's usually `getClass` you want.

If you really want to know whether a class is formally defined, call `isClass`.

Value

The object defining the class. This is an object of class `classRepresentation`. However, *do not* deal with the contents of the object directly unless you are very sure you know what you're doing. Even then, it is nearly always better practice to use functions such as `setClass` and `setIs`. Messing up a class object will cause great confusion.

getClass("numeric") ## a built in class

cld <- getClass("thisIsAnUndefinedClass", .Force = TRUE)
cld ## a NULL prototype
## If you are really curious:
utils::str(cld)
## Whereas these generate errors:
try(getClass("thisIsAnUndefinedClass"))
try(getClassDef("thisIsAnUndefinedClass"))
```

getMethod

Get or Test for the Definition of a Method

Description

Functions to look for a method corresponding to a given generic function and signature. The functions `getMethod` and `selectMethod` return the method; the functions `existsMethod` and `hasMethod` test for its existence. In both cases the first function only gets direct definitions and the second uses inheritance. In all cases, the search is in the generic function itself or in the package/environment specified by argument `where`.

The function `findMethod` returns the package(s) in the search list (or in the packages specified by the `where` argument) that contain a method for this function and signature.

Usage

```
getMethod(f, signature=character(), where, optional = FALSE,
          mlist, fdef)

existsMethod(f, signature = character(), where)

findMethod(f, signature, where)

selectMethod(f, signature, optional = FALSE, useInherited =,
            mlist = , fdef = , verbose = )

hasMethod(f, signature=character(), where)
```

Arguments

<code>f</code>	A generic function or the character-string name of one.
<code>signature</code>	the signature of classes to match to the arguments of <code>f</code> . See the details below.
<code>where</code>	The position or environment in which to look for the method(s): by default, the table of methods defined in the generic function itself is used.
<code>optional</code>	If the selection in <code>selectMethod</code> does find a valid method an error is generated, unless this argument is <code>TRUE</code> . In that case, the value returned is <code>NULL</code> if no method matches.
<code>mlist, fdef, useInherited, verbose</code>	Optional arguments to <code>getMethod</code> and <code>selectMethod</code> . Avoid these: some will work and others will not, and none of them is required for normal use of the functions.

Details

The `signature` argument specifies classes, corresponding to formal arguments of the generic function; to be precise, to the `signature` slot of the generic function object. The argument may be a vector of strings identifying classes, and may be named or not. Names, if supplied, match the names of those formal arguments included in the signature of the generic. That signature is normally all the arguments except `...`. However, generic functions can be specified with only a subset of the arguments permitted, or with the signature taking the arguments in a different order.

It's a good idea to name the arguments in the signature to avoid confusion, if you're dealing with a generic that does something special with its signature. In any case, the elements of the signature are matched to the formal signature by the same rules used in matching arguments in function calls (see `match.call`).

The strings in the signature may be class names, "missing" or "ANY". See [Methods](#) for the meaning of these in method selection. Arguments not supplied in the signature implicitly correspond to class "ANY"; in particular, giving an empty signature means to look for the default method.

A call to `getMethod` returns the method for a particular function and signature. As with other `get` functions, argument `where` controls where the function looks (by default anywhere in the search list) and argument `optional` controls whether the function returns `NULL` or generates an error if the method is not found. The search for the method makes no use of inheritance.

The function `selectMethod` also looks for a method given the function and signature, but makes full use of the method dispatch mechanism; i.e., inherited methods and group generics are taken into account just as they would be in dispatching a method for the corresponding signature, with the one exception that conditional inheritance is not used. Like `getMethod`, `selectMethod` returns `NULL` or generates an error if the method is not found, depending on the argument `optional`.

The functions `existsMethod` and `hasMethod` return `TRUE` or `FALSE` according to whether a method is found, the first corresponding to `getMethod` (no inheritance) and the second to `selectMethod`.

Value

The call to `selectMethod` or `getMethod` returns the selected method, if one is found. (This class extends `function`, so you can use the result directly as a function if that is what you want.) Otherwise an error is thrown if `optional` is `FALSE` and `NULL` is returned if `optional` is `TRUE`.

The returned method object is a `MethodDefinition` object, *except* that the default method for a primitive function is required to be the primitive itself. Note therefore that the only reliable test that the search failed is `is.null()`.

Examples

```
setGeneric("testFun", function(x) standardGeneric("testFun"))
setMethod("testFun", "numeric", function(x) x+1)
hasMethod("testFun", "numeric")
## Not run: [1] TRUE
hasMethod("testFun", "integer") #inherited
## Not run: [1] TRUE
existsMethod("testFun", "integer")
## Not run: [1] FALSE
hasMethod("testFun") # default method
## Not run: [1] FALSE
hasMethod("testFun", "ANY")
## Not run: [1] FALSE
```

getPackageName	<i>The Name associated with a Given Package</i>
----------------	---

Description

The functions below produce the package associated with a particular environment or position on the search list, or of the package containing a particular function. They are primarily used to support computations that need to differentiate objects on multiple packages.

Usage

```
getPackageName(where, create = TRUE)
setPackageName(pkg, env)

packageSlot(object)
packageSlot(object) <- value
```

Arguments

- | | |
|--------|---|
| where | the environment or position on the search list associated with the desired package. |
| object | object providing a character string name, plus the package in which this object is to be found. |
| value | the name of the package. |

<code>create</code>	flag, should a package name be created if none can be inferred? If <code>TRUE</code> and no non-empty package name is found, the current date and time are used as a package name, and a warning is issued. The created name is stored in the environment if that environment is not locked.
<code>pkg, env</code>	make the string in <code>pkg</code> the internal package name for all computations that set class and method definitions in environment <code>env</code> .

Details

Package names are normally installed during loading of the package, by the `INSTALL` script or by the `library` function. (Currently, the name is stored as the object `.packageName` but don't trust this for the future.)

Value

`packageName` returns the character-string name of the package (without the extraneous "package:" found in the search list).

`packageSlot` returns or sets the package name slot (currently an attribute, not a formal slot, but this may change someday).

`setPackageName` can be used to establish a package name in an environment that would otherwise not have one. This allows you to create classes and/or methods in an arbitrary environment, but it is usually preferable to create packages by the standard R programming tools (`package.skeleton`, etc.)

See Also

[search](#)

Examples

```
## all the following usually return "base"
getPackageName(length(search()))
getPackageName(baseenv())
getPackageName(asNamespace("base"))
getPackageName("package:base")
```

hasArg

Look for an Argument in the Call

Description

Returns `TRUE` if `name` corresponds to an argument in the call, either a formal argument to the function, or a component of `...`, and `FALSE` otherwise.

Usage

```
hasArg(name)
```

Arguments

`name` The unquoted name of a potential argument.

Details

The expression `hasArg(x)`, for example, is similar to `!missing(x)`, with two exceptions. First, `hasArg` will look for an argument named `x` in the call if `x` is not a formal argument to the calling function, but `...` is. Second, `hasArg` never generates an error if given a name as an argument, whereas `missing(x)` generates an error if `x` is not a formal argument.

Value

Always TRUE or FALSE as described above.

See Also

[missing](#)

Examples

```
fctest <- function(x1, ...) c(hasArg(x1), hasArg(y2))

fctest(1) ## c(TRUE, FALSE)
fctest(1, 2) ## c(TRUE, FALSE)
fctest(y2=2) ## c(FALSE, TRUE)
fctest(y=2) ## c(FALSE, FALSE) (no partial matching)
fctest(y2 = 2, x=1) ## c(TRUE, TRUE) partial match x1
```

implicitGeneric *Manage Implicit Versions of Generic Functions*

Description

Create or access implicit generic functions, used to enforce consistent generic versions of functions that are not currently generic. Function `implicitGeneric()` returns the implicit generic version, `setGenericImplicit()` turns a generic implicit, `prohibitGeneric()` prevents your function from being made generic, and `registerImplicitGenerics()` saves a set of implicit generic definitions in the cached table of the current session.

Usage

```
implicitGeneric(name, where, generic)
setGenericImplicit(name, where, restore = TRUE)
prohibitGeneric(name, where)
registerImplicitGenerics(what, where)
```

Arguments

<code>name</code>	Character string name of the function.
<code>where</code>	Package or environment in which to register the implicit generics. When using the functions from the top level of your own package source, this argument can usually be omitted (and should be).
<code>generic</code>	Optionally, the generic function definition to be cached, but usually omitted. See Details section.

restore	Should the non-generic version of the function be restored after the current.
what	For <code>registerImplicitGenerics()</code> , Optional table of the implicit generics to register, but nearly always omitted. See Details section.

Details

Multiple packages may define methods for the same function, using the version of a function stored in one package. All these methods should be marshaled and dispatched consistently when a user calls the function. For consistency, the generic version of the function must have a unique definition (the same arguments allowed in methods signatures, the same values for optional slots such as the value class, and the same standard or non-standard definition of the function itself).

If the original function is already an S4 generic, there is no problem. The implicit generic mechanism enforces consistency when the version in the package owning the function is *not* generic. If a call to `setGeneric()` attempts to turn a function in another package into a generic, the mechanism compares the proposed new generic function to the implicit generic version of that function. If the two agree, all is well. If not, and if the function belongs to another package, then the new generic will not be associated with that package. Instead, a warning is issued and a separate generic function is created, with its package slot set to the current package, not the one that owns the non-generic version of the function. The effect is that the new package can still define methods for this function, but it will not share the methods in other packages, since it is forcing a different definition of the generic function.

The right way to proceed in nearly all cases is to call `setGeneric("foo")`, giving *only* the name of the function; this will automatically use the implicit generic version. If you don't like that version, the best solution is to convince the owner of the other package to agree with you and to insert code to define the non-default properties of the function (even if the owner does not want `foo()` to be a generic by default).

For any function, the implicit generic form is a standard generic in which all formal arguments, except for `...`, are allowed in the signature of methods. If that is the suitable generic for a function, no action is needed. If not, the best mechanism is to set up the generic in the code of the package owning the function, and to then call `setGenericImplicit()` to record the implicit generic and restore the non-generic version. See the example.

Note that the package can define methods for the implicit generic as well; when the implicit generic is made a real generic, those methods will be included.

Other than predefining methods, the usual reason for having a non-default implicit generic is to provide a non-default signature, and the usual reason for *that* is to allow lazy evaluation of some arguments. See the example. All arguments in the signature of a generic function must be evaluated at the time the function needs to select a method. (But those arguments can be missing, with or without a default expression being defined; you can always examine `missing(x)` even for arguments in the signature.)

If you want to completely prohibit anyone from turning your function into a generic, call `prohibitGeneric()`.

Value

Function `implicitGeneric()` returns the implicit generic definition (and caches that definition the first time if it has to construct it).

The other functions exist for their side effect and return nothing useful.

See Also

[setGeneric](#)

Examples

```

### How we would make the function with() into a generic:

## Since the second argument, 'expr' is used literally, we want
## with() to only have "data" in the signature.

## Note that 'methods'-internal code now has already extended with()
## to do the equivalent of the following
## Not run:
setGeneric("with", signature = "data")
## Now we could predefine methods for "with" if we wanted to.

## When ready, we store the generic as implicit, and restore the original
setGenericImplicit("with")

## (This example would only work if we "owned" function with(),
## but it is in base.)## End(Not run)

implicitGeneric("with")

```

initialize-methods *Methods to Initialize New Objects from a Class*

Description

The arguments to function `new` to create an object from a particular class can be interpreted specially for that class, by the definition of a method for function `initialize` for the class. This documentation describes some existing methods, and also outlines how to write new ones.

Methods

.Object = "ANY" The default method for `initialize` takes either named or unnamed arguments. Argument names must be the names of slots in this class definition, and the corresponding arguments must be valid objects for the slot (that is, have the same class as specified for the slot, or some superclass of that class). If the object comes from a superclass, it is not coerced strictly, so normally it will retain its current class (specifically, `as(object, Class, strict = FALSE)`).

Unnamed arguments must be objects of this class, of one of its superclasses, or one of its subclasses (from the class, from a class this class extends, or from a class that extends this class). If the object is from a superclass, this normally defines some of the slots in the object. If the object is from a subclass, the new object is that argument, coerced to the current class.

Unnamed arguments are processed first, in the order they appear. Then named arguments are processed. Therefore, explicit values for slots always override any values inferred from superclass or subclass arguments.

.Object = "traceable" Objects of a class that extends `traceable` are used to implement debug tracing (see class `traceable` and `trace`).

The `initialize` method for these classes takes special arguments `def`, `tracer`, `exit`, `at`, `print`. The first of these is the object to use as the original definition (e.g., a function). The others correspond to the arguments to `trace`.

.Object = "environment" The `initialize` method for environments takes a named list of objects to be used to initialize the environment.

.Object = "signature" This is a method for internal use only. It takes an optional `functionDef` argument to provide a generic function with a `signature` slot to define the argument names. See [Methods](#) for details.

Writing Initialization Methods

Initialization methods provide a general mechanism corresponding to generator functions in other languages.

The arguments to `initialize` are `.Object` and `...`. Nearly always, `initialize` is called from `new`, not directly. The `.Object` argument is then the prototype object from the class.

Two techniques are often appropriate for `initialize` methods: special argument names and `callNextMethod`.

You may want argument names that are more natural to your users than the (default) slot names. These will be the formal arguments to your method definition, in addition to `.Object` (always) and `...` (optionally). For example, the method for class `"traceable"` documented above would be created by a call to `setMethod` of the form:

```
setMethod("initialize", "traceable",
  function(.Object, def, tracer, exit, at, print) ...
)
```

In this example, no other arguments are meaningful, and the resulting method will throw an error if other names are supplied.

When your new class extends another class, you may want to call the `initialize` method for this superclass (either a special method or the default). For example, suppose you want to define a method for your class, with special argument `x`, but you also want users to be able to set slots specifically. If you want `x` to override the slot information, the beginning of your method definition might look something like this:

```
function(.Object, x, ...) {
  Object <- callNextMethod(.Object, ...)
  if(!missing(x)) { # do something with x
```

You could also choose to have the inherited method override, by first interpreting `x`, and then calling the next method.

 is

Is an Object from a Class

Description

Functions to test inheritance relationships between an object and a class (`is`) or between two classes (`extends`), and to establish such relationships (`setIs`, an explicit alternative to the `contains=` argument to `setClass`).

Usage

```
is(object, class2)

extends(class1, class2, maybe=TRUE, fullInfo = FALSE)

setIs(class1, class2, test=NULL, coerce=NULL, replace=NULL,
      by = character(), where = topenv(parent.frame()), classDef =,
      extensionObject = NULL, doComplete = TRUE)
```

Arguments

`object` any R object.

`class1, class2` the names of the classes between which `is` relations are to be examined defined, or (more efficiently) the class definition objects for the classes.

`maybe, fullInfo` In a call to `extends`, `maybe` is the value returned if a relation is conditional. In a call with `class2` missing, `fullInfo` is a flag, which if `TRUE` causes a list of objects of class `classExtension` to be returned, rather than just the names of the classes.

`test, coerce, replace` In a call to `setIs`, functions optionally supplied to test whether the relation is defined, to coerce the object to `class2`, and to alter the object so that `is(object, class2)` is identical to `value`. See the details section below.

The remaining arguments are for internal use and/or usually omitted.

`extensionObject` alternative to the `test, coerce, replace, by` arguments; an object from class `SClassExtension` describing the relation. (Used in internal calls.)

`doComplete` when `TRUE`, the class definitions will be augmented with indirect relations as well. (Used in internal calls.)

`by` In a call to `setIs`, the name of an intermediary class. Coercion will proceed by first coercing to this class and from there to the target class. (The intermediate coercions have to be valid.)

`where` In a call to `setIs`, where to store the metadata defining the relationship. Default is the global environment for calls from the top level of the session or a source file evaluated there. When the call occurs in the top level of a file in the source of a package, the default will be the name space or environment of the package. Other uses are tricky and not usually a good idea, unless you really know what you are doing.

`classDef` Optional class definition for `class`, required internally when `setIs` is called during the initial definition of the class by a call to `setClass`. *Don't* use this argument, unless you really know why you're doing so.

Summary of Functions

is: With two arguments, tests whether `object` can be treated as from `class2`.
 With one argument, returns all the super-classes of this object's class.

extends: Does the first class extend the second class? The call returns `maybe` if the extension includes a test.

When called with one argument, the value is a vector of the superclasses of `class1`. If argument `fullInfo` is `TRUE`, the call returns a named list of objects of class `SClassExtension`; otherwise, just the names of the superclasses.

setIs: Defines `class1` to be an extension (subclass) of `class2`. If `class2` is an existing virtual class, such as a class union, then only the two classes need to be supplied in the call, if the implied inherited methods work for `class1`. See the details section below.

Alternatively, arguments `coerce` and `replace` should be supplied, defining methods to coerce to the superclass and to replace the part corresponding to the superclass. As discussed in the details and other sections below, this form is often less recommended than the corresponding call to `setAs`, to which it is an alternative.

Details

Arranging for a class to inherit from another class is a key tool in programming. In R, there are three basic techniques, the first two providing what is called “simple” inheritance, the preferred form:

1. By the `contains=` argument in a call to `setClass`. This is and should be the most common mechanism. It arranges that the new class contains all the structure of the existing class, and in particular all the slots with the same class specified. The resulting class extension is defined to be `simple`, with important implications for method definition (see the section on this topic below).
2. Making `class1` a subclass of a virtual class either by a call to `setClassUnion` to make the subclass a member of a new class union, or by a call to `setIs` to add a class to an existing class union or as a new subclass of an existing virtual class. In either case, the implication should be that methods defined for the class union or other superclass all work correctly for the subclass. This may depend on some similarity in the structure of the subclasses or simply indicate that the superclass methods are defined in terms of generic functions that apply to all the subclasses. These relationships are also generally simple.
3. Supplying `coerce` and `replace` arguments to `setAs`. R allows arbitrary inheritance relationships, using the same mechanism for defining coerce methods by a call to `setAs`. The difference between the two is simply that `setAs` will require a call to `as` for a conversion to take place, whereas after the call to `setIs`, objects will be automatically converted to the superclass.

The automatic feature is the dangerous part, mainly because it results in the subclass potentially inheriting methods that do not work. See the section on inheritance below. If the two classes involved do not actually inherit a large collection of methods, as in the first example below, the danger may be relatively slight.

If the superclass inherits methods where the subclass has only a default or remotely inherited method, problems are more likely. In this case, a general recommendation is to use the `setAs` mechanism instead, unless there is a strong counter reason. Otherwise, be prepared to override some of the methods inherited.

With this caution given, the rest of this section describes what happens when `coerce=` and `replace=` argument are supplied to `setIs`.

The `coerce` and `replace` arguments are functions that define how to coerce a `class1` object to `class2`, and how to replace the part of the subclass object that corresponds to `class2`. The first of these is a function of one argument (conventionally `from`) and the second of two arguments (`from`, `value`). For details, see the section on coerce functions below .

When `by` is specified, the `coerce` process first coerces to this class and then to `class2`. It's unlikely you would use the `by` argument directly, but it is used in defining cached information about classes. The value returned (invisibly) by `setIs` is the revised class definition of `class1`.

Coerce, replace, and test functions

The `coerce` argument is a function that turns a `class1` object into a `class2` object. The `replace` argument is a function of two arguments that modifies a `class1` object (the first argument) to replace the part of it that corresponds to `class2` (supplied as `value`, the second argument). It then returns the modified object as the value of the call. In other words, it acts as a replacement method to implement the expression `as(object, class2) <- value`.

The easiest way to think of the `coerce` and `replace` functions is by thinking of the case that `class1` contains `class2` in the usual sense, by including the slots of the second class. (To repeat, in this situation you would not call `setIs`, but the analogy shows what happens when you do.)

The `coerce` function in this case would just make a `class2` object by extracting the corresponding slots from the `class1` object. The `replace` function would replace in the `class1` object the slots corresponding to `class2`, and return the modified object as its value.

For additional discussion of these functions, see the documentation of the `setAs` function. (Unfortunately, argument `def` to that function corresponds to argument `coerce` here.)

The inheritance relationship can also be conditional, if a function is supplied as the `test` argument. This should be a function of one argument that returns `TRUE` or `FALSE` according to whether the object supplied satisfies the relation `is(object, class2)`. Conditional relations between classes are slightly deprecated because they cannot be implemented as efficiently as ordinary relations and because they sometimes can lead to confusion (in thinking about what methods are dispatched for a particular function, for example). But they can correspond to distinctions such as two classes that have the same representation, but with only one of them obeying certain additional constraints.

Inherited methods

A method written for a particular signature (classes matched to one or more formal arguments to the function) naturally assumes that the objects corresponding to the arguments can be treated as coming from the corresponding classes. The objects will have all the slots and available methods for the classes.

The code that selects and dispatches the methods ensures that this assumption is correct. If the inheritance was “simple”, that is, defined by one or more uses of the `contains=` argument in a call to `setClass`, no extra work is generally needed. Classes are inherited from the superclass, with the same definition.

When inheritance is defined by a general call to `setIs`, extra computations are required. This form of inheritance implies that the subclass does *not* just contain the slots of the superclass, but instead requires the explicit call to the `coerce` and/or `replace` method. To ensure correct computation, the inherited method is supplemented by calls to `as` before the body of the method is evaluated.

The calls to `as` generated in this case have the argument `strict = FALSE`, meaning that extra information can be left in the converted object, so long as it has all the appropriate slots. (It's this option that allows simple subclass objects to be used without any change.) When you are writing your `coerce` method, you may want to take advantage of that option.

Methods inherited through non-simple extensions can result in ambiguities or unexpected selections. If `class2` is a specialized class with just a few applicable methods, creating the inheritance relation may have little effect on the behavior of `class1`. But if `class2` is a class with many methods, you may find that you now inherit some undesirable methods for `class1`, in some cases,

fail to inherit expected methods. In the second example below, the non-simple inheritance from class "factor" might be assumed to inherit S3 methods via that class. But the S3 class is ambiguous, and in fact is "character" rather than "factor".

For some generic functions, methods inherited by non-simple extensions are either known to be invalid or sufficiently likely to be so that the generic function has been defined to exclude such inheritance. For example `initialize` methods must return an object of the target class; this is straightforward if the extension is simple, because no change is made to the argument object, but is essentially impossible. For this reason, the generic function insists on only simple extensions for inheritance. See the `simpleInheritanceOnly` argument to `setGeneric` for the mechanism. You can use this mechanism when defining new generic functions.

If you get into problems with functions that do allow non-simple inheritance, there are two basic choices. Either back off from the `setIs` call and settle for explicit coercing defined by a call to `setAs`; or, define explicit methods involving `class1` to override the bad inherited methods. The first choice is the safer, when there are serious problems.

Examples

```
## Two examples of setIs() with coerce= and replace= arguments
## The first one works fairly well, because neither class has many
## inherited methods do be disturbed by the new inheritance

## The second example does NOT work well, because the new superclass,
## "factor", causes methods to be inherited that should not be.

## First example:
## a class definition (see setClass for class "track")
setClass("trackCurve", contains = "track",
         representation( smooth = "numeric"))
## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
         representation(x="numeric", y="matrix", smooth="matrix"),
         prototype = structure(list(), x=numeric(), y=matrix(0,0,0),
                                smooth= matrix(0,0,0)))
## Automatically convert an object from class "trackCurve" into
## "trackMultiCurve", by making the y, smooth slots into 1-column matrices
setIs("trackCurve",
      "trackMultiCurve",
      coerce = function(obj) {
        new("trackMultiCurve",
            x = obj@x,
            y = as.matrix(obj@y),
            smooth = as.matrix(obj@smooth))
      },
      replace = function(obj, value) {
        obj@y <- as.matrix(value@y)
        obj@x <- value@x
        obj@smooth <- as.matrix(value@smooth)
      })
```

```

obj})

## Second Example:
## A class that adds a slot to "character"
setClass("stringsDated", contains = "character", representation(stamp="POSIXt"))

## Convert automatically to a factor by explicit coerce
setIs("stringsDated", "factor",
      coerce = function(from) {factor(from@.Data)},
      replace=function(from, value) {
        from@.Data<- as.character(value); from})

l1 <- sample(letters, 10, replace = TRUE)
ld <- new("stringsDated", l1, stamp = Sys.time())

levels(as(ld, "factor"))

levels(ld) # will be NULL--see comment in section on inheritance above.

## In contrast, a class that simply extends "factor" has no such ambiguities
setClass("factorDated", contains = "factor", representation(stamp="POSIXt"))

fd = new("factorDated", factor(l1), stamp = Sys.time())

identical(levels(fd), levels(as(fd, "factor")))

```

isSealedMethod *Check for a Sealed Method or Class*

Description

These functions check for either a method or a class that has been *sealed* when it was defined, and which therefore cannot be re-defined.

Usage

```

isSealedMethod(f, signature, fdef, where)
isSealedClass(Class, where)

```

Arguments

<code>f</code>	The quoted name of the generic function.
<code>signature</code>	The class names in the method's signature, as they would be supplied to setMethod .
<code>fdef</code>	Optional, and usually omitted: the generic function definition for <code>f</code> .
<code>Class</code>	The quoted name of the class.

where where to search for the method or class definition. By default, searches from the top environment of the call to `isSealedMethod` or `isSealedClass`, typically the global environment or the name space of a package containing a call to one of the functions.

Details

In the R implementation of classes and methods, it is possible to seal the definition of either a class or a method. The basic classes (numeric and other types of vectors, matrix and array data) are sealed. So also are the methods for the primitive functions on those data types. The effect is that programmers cannot re-define the meaning of these basic data types and computations. More precisely, for primitive functions that depend on only one data argument, methods cannot be specified for basic classes. For functions (such as the arithmetic operators) that depend on two arguments, methods can be specified if *one* of those arguments is a basic class, but not if both are.

Programmers can seal other class and method definitions by using the `sealed` argument to `setClass` or `setMethod`.

Value

The functions return `FALSE` if the method or class is not sealed (including the case that it is not defined); `TRUE` if it is.

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

Examples

```
## these are both TRUE
isSealedMethod("+", c("numeric", "character"))
isSealedClass("matrix")

setClass("track",
         representation(x="numeric", y="numeric"))
## but this is FALSE
isSealedClass("track")
## and so is this
isSealedClass("A Name for an undefined Class")
## and so are these, because only one of the two arguments is basic
isSealedMethod("+", c("track", "numeric"))
isSealedMethod("+", c("numeric", "track"))
```

language-class

Classes to Represent Unevaluated Language Objects

Description

The virtual class "language" and the specific classes that extend it represent unevaluated objects, as produced for example by the parser or by functions such as `quote`.

Usage

```
### each of these classes corresponds to an unevaluated object
### in the S language.
### The class name can appear in method signatures,
### and in a few other contexts (such as some calls to as()).

" ("
"<-"
"call"
"for"
"if"
"repeat"
"while"
"name"
"{"

### Each of the classes above extends the virtual class

"language"
```

Objects from the Class

"language" is a virtual class; no objects may be created from it.

Objects from the other classes can be generated by a call to `new(Class, ...)`, where `Class` is the quoted class name, and the `...` arguments are either empty or a *single* object that is from this class (or an extension).

Methods

coerce signature(from = "ANY", to = "call"). A method exists for `as(object, "call")`, calling `as.call()`.

```
LinearMethodsList-class
```

```
Class "LinearMethodsList"
```

Description

A version of methods lists that has been 'linearized' for producing summary information. The actual objects from class "MethodsList" used for method dispatch are defined recursively over the arguments involved.

Objects from the Class

The function `linearizeMlist` converts an ordinary methods list object into the linearized form.

Slots

methods: Object of class "list", the method definitions.

arguments: Object of class "list", the corresponding formal arguments, namely as many of the arguments in the signature of the generic function as are active in the relevant method table.

classes: Object of class "list", the corresponding classes in the signatures.

generic: Object of class "genericFunction"; the generic function to which the methods correspond.

Future Note

The current version of `linearizeMlist` does not take advantage of the `MethodDefinition` class, and therefore does more work for less effect than it could. In particular, we may move to redefine both the function and the class to take advantage of the stored signatures. Don't write code depending precisely on the present form, although all the current information will be obtainable in the future.

See Also

Function `linearizeMlist` for the computation, and class `MethodsList` for the original, recursive form.

makeClassRepresentation

Create a Class Definition

Description

Constructs an object of class `classRepresentation` to describe a particular class. Mostly a utility function, but you can call it to create a class definition without assigning it, as `setClass` would do.

Usage

```
makeClassRepresentation(name, slots=list(), superClasses=character(),
                        prototype=NULL, package, validity, access,
                        version, sealed, virtual=NA, where)
```

Arguments

name	character string name for the class
slots	named list of slot classes as would be supplied to <code>setClass</code> , but <i>without</i> the unnamed arguments for <code>superClasses</code> if any.
superClasses	what classes does this class extend
prototype	an object providing the default data for the class, e.g, the result of a call to <code>prototype</code> .
package	The character string name for the package in which the class will be stored; see <code>getPackageName</code> .

validity	Optional validity method. See validObject , and the discussion of validity methods in the reference.
access	Access information. Not currently used.
version	Optional version key for version control. Currently generated, but not used.
sealed	Is the class sealed? See setClass .
virtual	Is this known to be a virtual class?
where	The environment from which to look for class definitions needed (e.g., for slots or superclasses). See the discussion of this argument under GenericFunctions .

[setClass](#)

method.skeleton *Create a Skeleton File for a New Method*

Description

This function writes a source file containing a call to [setMethod](#) to define a method for the generic function and signature supplied. By default the method definition is in line in the call, but can be made an external (previously assigned) function.

Usage

```
method.skeleton(generic, signature, file, external = FALSE, where)
```

Arguments

generic	the character string name of the generic function, or the generic function itself. In the first case, the function need not currently be a generic, as it would not for the resulting call to setMethod .
signature	the method signature, as it would be given to setMethod
file	a character string name for the output file, or a writable connection. By default the generic function name and the classes in the signature are concatenated, with separating underscore characters. The file name should normally end in ".R".
external	flag to control whether the function definition for the method should be a separate external object assigned in the source file, or included in line in the call to setMethod . If supplied as a character string, this will be used as the name for the external function; by default the name concatenates the generic and signature names, with separating underscores.
where	The environment in which to look for the function; by default, the top-level environment of the call to <code>method.skeleton</code> .

Value

The file argument, invisibly, but the function is used for its side effect.

See Also

[setMethod](#), [package.skeleton](#)

Examples

```
setClass("track", representation(x ="numeric", y="numeric"))
method.skeleton("show", "track")          ## writes show_track.R
method.skeleton("Ops", c("track", "track")) ## writes "Ops_track_track.R"

## write multiple method skeletons to one file
con <- file("./Math_track.R", "w")
method.skeleton("Math", "track", con)
method.skeleton("exp", "track", con)
method.skeleton("log", "track", con)
close(con)
```

MethodDefinition-class

Classes to Represent Method Definitions

Description

These classes extend the basic class "function" when functions are to be stored and used as method definitions.

Details

Method definition objects are functions with additional information defining how the function is being used as a method. The `target` slot is the class signature for which the method will be dispatched, and the `defined` slot the signature for which the method was originally specified (that is, the one that appeared in some call to [setMethod](#)).

Objects from the Class

The action of setting a method by a call to [setMethod](#) creates an object of this class. It's unwise to create them directly.

The class "SealedMethodDefinition" is created by a call to [setMethod](#) with argument `sealed = TRUE`. It has the same representation as "MethodDefinition".

Slots

.Data: Object of class "function"; the data part of the definition.

target: Object of class "signature"; the signature for which the method was wanted.

defined: Object of class "signature"; the signature for which a method was found. If the method was inherited, this will not be identical to `target`.

generic: Object of class "character"; the function for which the method was created.

Extends

Class "function", from data part.
Class "PossibleMethod", directly.
Class "OptionalMethods", by class "function".

See Also

class [MethodsList](#) for the objects defining sets of methods associated with a particular generic function. The individual method definitions stored in these objects are from class [MethodDefinition](#), or an extension. Class [MethodWithNext](#) for an extension used by [callNextMethod](#).

Methods

General Information on Methods

Description

This documentation section covers some general topics on how methods work and how the **methods** package interacts with the rest of R. The information is usually not needed to get started with methods and classes, but may be helpful for moderately ambitious projects, or when something doesn't work as expected.

The section “How Methods Work” describes the underlying mechanism; “Method Selection and Dispatch” provides more details on how class definitions determine which methods are used; “Generic Functions” discusses generic functions as objects. For additional information specifically about class definitions, see [Classes](#).

How Methods Work

A generic function has associated with it a collection of other functions (the methods), all of which have the same formal arguments as the generic. See the “Generic Functions” section below for more on generic functions themselves.

Each R package will include methods metadata objects corresponding to each generic function for which methods have been defined in that package. When the package is loaded into an R session, the methods for each generic function are *cached*, that is, stored in the environment of the generic function along with the methods from previously loaded packages. This merged table of methods is used to dispatch or select methods from the generic, using class inheritance and possibly group generic functions (see [GroupGenericFunctions](#)) to find an applicable method. See the “Method Selection and Dispatch” section below. The caching computations ensure that only one version of each generic function is visible globally; although different attached packages may contain a copy of the generic function, these behave identically with respect to method selection. In contrast, it is possible for the same function name to refer to more than one generic function, when these have different `package` slots. In the latter case, R considers the functions unrelated: A generic function is defined by the combination of name and package. See the “Generic Functions” section below.

The methods for a generic are stored according to the corresponding `signature` in the call to [setMethod](#) that defined the method. The signature associates one class name with each of a subset of the formal arguments to the generic function. Which formal arguments are available, and the order in which they appear, are determined by the `"signature"` slot of the generic function itself. By default, the signature of the generic consists of all the formal arguments except `...`, in the order they appear in the function definition.

Trailing arguments in the signature of the generic will be *inactive* if no method has yet been specified that included those arguments in its signature. Inactive arguments are not needed or used in labeling the cached methods. (The distinction does not change which methods are dispatched, but ignoring inactive arguments improves the efficiency of dispatch.)

All arguments in the signature of the generic function will be evaluated when the function is called, rather than using the traditional lazy evaluation rules of S. Therefore, it's important to *exclude* from the signature any arguments that need to be dealt with symbolically (such as the first argument to function `substitute`). Note that only actual arguments are evaluated, not default expressions. A missing argument enters into the method selection as class "missing".

The cached methods are stored in an environment object. The names used for assignment are a concatenation of the class names for the active arguments in the method signature.

Method Selection and Dispatch

When a call to a generic function is evaluated, a method is selected corresponding to the classes of the actual arguments in the signature. First, the cached methods table is searched for an exact match; that is, a method stored under the signature defined by the string value of `class(x)` for each non-missing argument, and "missing" for each missing argument. If no method is found directly for the actual arguments in a call to a generic function, an attempt is made to match the available methods to the arguments by using the superclass information about the actual classes.

Each class definition may include a list of one or more *superclasses* of the new class. The simplest and most common specification is by the `contains=` argument in the call to `setClass`. Each class named in this argument is a superclass of the new class. The S language has two additional mechanisms for defining superclasses. A call to `setIs` can create an inheritance relationship that is not the simple one of containing the superclass representation in the new class. In this case, explicit methods are defined to relate the subclass and the superclass. Also, a call to `setClassUnion` creates a union class that is a superclass of each of the members of the union. All three mechanisms are treated equivalently for purposes of method selection: they define the *direct* superclasses of a particular class. For more details on the mechanisms, see [Classes](#).

The direct superclasses themselves may have superclasses, defined by any of the same mechanisms, and similarly for further generations. Putting all this information together produces the full list of superclasses for this class. The superclass list is included in the definition of the class that is cached during the R session. Each element of the list describes the nature of the relationship (see [SClassExtension](#) for details). Included in the element is a `distance` slot giving a numeric distance between the two classes. The distance currently is the path length for the relationship: 1 for direct superclasses (regardless of which mechanism defined them), then 2 for the direct superclasses of those classes, and so on. In addition, any class implicitly has class "ANY" as a superclass. The distance to "ANY" is treated as larger than the distance to any actual class. The special class "missing" corresponding to missing arguments has only "ANY" as a superclass, while "ANY" has no superclasses.

The information about superclasses is summarized when a class definition is printed.

When a method is to be selected by inheritance, a search is made in the table for all methods directly corresponding to a combination of either the direct class or one of its superclasses, for each argument in the active signature. For an example, suppose there is only one argument in the signature and that the class of the corresponding object was "dgeMatrix" (from the `Matrix` package on CRAN). This class has two direct superclasses and through these 4 additional superclasses. Method selection finds all the methods in the table of directly specified methods labeled by one of these classes, or by "ANY".

When there are multiple arguments in the signature, each argument will generate a similar list of inherited classes. The possible matches are now all the combinations of classes from each argument (think of the function `outer` generating an array of all possible combinations). The search now

finds all the methods matching any of this combination of classes. The computation of distances also has to combine distances for the individual arguments. There are many ways to combine the distances; the current implementation simply adds them. The result of the search is then a list of zero, one, or more methods, and a parallel vector of distances between the target signature and the available methods.

If the list has more than one matching method, only those corresponding to the minimum distance are considered. There may still be multiple best methods. The dispatch software considers this an ambiguous case and warns the user (only on the first call for this selection). The method occurring first in the list of superclasses is selected. By the mechanism of producing the extension information, this orders the direct superclasses by the order they appeared in the original call to `setClass`. Classes specified in `setIs` and `setClassUnion` calls, and by the superclasses of these classes. (Note that only the ordering of classes within a particular generation of superclasses counts, because only these will have the same distance). It is generally a very bad idea to count on any observed ordering, other than of the simple superclasses, since both circumstances and future changes to the computations could alter such orderings.

All this detail about selection is less important than the realization that having ambiguous method selection usually means that you need to be more specific about intentions. It is likely that some consideration other than the ordering of superclasses in the class definition is more important in determining which method *should* be selected, and the preference may well be different for different generic functions. Where ambiguities arise, the best approach is usually to provide a specific method for the subclass.

When the inherited method has been selected, the selection is cached in the generic function so that future calls with the same class will not require repeating the search. Cached inherited selections are not themselves used in future inheritance searches, since that could result in invalid selections. If you want inheritance computations to be done again (for example, because a newly loaded package has a more direct method than one that has already been used in this session), call `resetGeneric`. Because classes and methods involving them tend to come from the same package, the current implementation does not reset all generics every time a new package is loaded.

Besides being initiated through calls to the generic function, method selection can be done explicitly by calling the function `selectMethod`.

Once a method has been selected, the evaluator creates a new context in which a call to the method is evaluated. The context is initialized with the arguments from the call to the generic function. These arguments are not rematched. All the arguments in the signature of the generic will have been evaluated (including any that are currently inactive); arguments that are not in the signature will obey the usual lazy evaluation rules of the language. If an argument was missing in the call, its default expression if any will *not* have been evaluated, since method dispatch always uses class `missing` for such arguments.

A call to a generic function therefore has two contexts: one for the function and a second for the method. The argument objects will be copied to the second context, but not any local objects created in a nonstandard generic function. The other important distinction is that the parent (“enclosing”) environment of the second context is the environment of the method as a function, so that all R programming techniques using such environments apply to method definitions as ordinary functions.

For further discussion of method selection and dispatch, see the first reference.

Generic Functions

In principle, a generic function could be any function that evaluates a call to `standardGeneric()`, the internal function that selects a method and evaluates a call to the selected method. In practice, generic functions are special objects that in addition to being from a subclass of class `"function"` also extend the class `genericFunction`. Such objects

have slots to define information needed to deal with their methods. They also have specialized environments, containing the tables used in method selection.

The slots "generic" and "package" in the object are the character string names of the generic function itself and of the package from which the function is defined. As with classes, generic functions are uniquely defined in R by the combination of the two names. There can be generic functions of the same name associated with different packages (although inevitably keeping such functions cleanly distinguished is not always easy). On the other hand, R will enforce that only one definition of a generic function can be associated with a particular combination of function and package name, in the current session or other active version of R.

Tables of methods for a particular generic function, in this sense, will often be spread over several other packages. The total set of methods for a given generic function may change during a session, as additional packages are loaded. Each table must be consistent in the signature assumed for the generic function.

R distinguishes *standard* and *nonstandard* generic functions, with the former having a function body that does nothing but dispatch a method. For the most part, the distinction is just one of simplicity: knowing that a generic function only dispatches a method call allows some efficiencies and also removes some uncertainties.

In most cases, the generic function is the visible function corresponding to that name, in the corresponding package. There are two exceptions, *implicit* generic functions and the special computations required to deal with R's *primitive* functions. Packages can contain a table of implicit generic versions of functions in the package, if the package wishes to leave a function non-generic but to constrain what the function would be like if it were generic. Such implicit generic functions are created during the installation of the package, essentially by defining the generic function and possibly methods for it, and then reverting the function to its non-generic form. (See [implicitGeneric](#) for how this is done.) The mechanism is mainly used for functions in the older packages in R, which may prefer to ignore S4 methods. Even in this case, the actual mechanism is only needed if something special has to be specified. All functions have a corresponding implicit generic version defined automatically (an implicit, implicit generic function one might say). This function is a standard generic with the same arguments as the non-generic function, with the non-generic version as the default (and only) method, and with the generic signature being all the formal arguments except

The implicit generic mechanism is needed only to override some aspect of the default definition. One reason to do so would be to remove some arguments from the signature. Arguments that may need to be interpreted literally, or for which the lazy evaluation mechanism of the language is needed, must *not* be included in the signature of the generic function, since all arguments in the signature will be evaluated in order to select a method. For example, the argument `expr` to the function `with` is treated literally and must therefore be excluded from the signature.

One would also need to define an implicit generic if the existing non-generic function were not suitable as the default method. Perhaps the function only applies to some classes of objects, and the package designer prefers to have no general default method. In the other direction, the package designer might have some ideas about suitable methods for some classes, if the function were generic. With reasonably modern packages, the simple approach in all these cases is just to define the function as a generic. The implicit generic mechanism is mainly attractive for older packages that do not want to require the methods package to be available.

Generic functions will also be defined but not obviously visible for functions implemented as *primitive* functions in the base package. Primitive functions look like ordinary functions when printed but are in fact not function objects but objects of two types interpreted by the R evaluator to call underlying C code directly. Since their entire justification is efficiency, R refuses to hide primitives behind a generic function object. Methods may be defined for most primitives, and corresponding metadata objects will be created to store them. Calls to the primitive still go directly to the C code,

which will sometimes check for applicable methods. The definition of “sometimes” is that methods must have been detected for the function in some package loaded in the session and `isS4(x)` is TRUE for the first argument (or for the second argument, in the case of binary operators). You can test whether methods have been detected by calling `isGeneric` for the relevant function and you can examine the generic function by calling `getGeneric`, whether or not methods have been detected. For more on generic functions, see the first reference and also section 2 of *R Internals*.

Method Definitions

All method definitions are stored as objects from the `MethodDefinition` class. Like the class of generic functions, this class extends ordinary R functions with some additional slots: "generic", containing the name and package of the generic function, and two signature slots, "defined" and "target", the first being the signature supplied when the method was defined by a call to `setMethod`. The "target" slot starts off equal to the "defined" slot. When an inherited method is cached after being selected, as described above, a copy is made with the appropriate "target" signature. Output from `showMethods`, for example, includes both signatures.

Method definitions are required to have the same formal arguments as the generic function, since the method dispatch mechanism does not rematch arguments, for reasons of both efficiency and consistency.

MethodsList-class *Class MethodsList, Representation of Methods for a Generic Function*

Description

Objects from this class are generated and revised by the definition of methods for a generic function.

Details

Suppose a function `f` has formal arguments `x` and `y`. The methods list object for that function has the object `as.name("x")` as its `argument` slot. An element of the methods named "track" is selected if the actual argument corresponding to `x` is an object of class "track". If there is such an element, it can generally be either a function or another methods list object.

In the first case, the function defines the method to use for any call in which `x` is of class "track". In the second case, the new methods list object defines the available methods depending on the remaining formal arguments, in this example, `y`.

Each method corresponds conceptually to a *signature*; that is a named list of classes, with names corresponding to some or all of the formal arguments. In the previous example, if selecting class "track" for `x`, finding that the selection was another methods list and then selecting class

"numeric" for y would produce a method associated with the signature x = "track", y = "numeric".

You can see the methods arranged by signature by calling the function `showMethods`. A methods list can be converted into an ordinary list with the methods arranged this way (in two different forms) by calling the functions `listFromMlist` and `linearizeMlist`.

Slots

argument: Object of class "name". The name of the argument being used for dispatch at this level.

methods: A named list of the methods (and method lists) defined *explicitly* for this argument. The names are the names of classes, and the corresponding element defines the method or methods to be used if the corresponding argument has that class. See the details below.

allMethods: A named list, contains all the directly defined methods from the `methods` slot, plus any inherited methods. Ignored when methods tables are used for dispatch (see [Methods](#))

Extends

Class "OptionalMethods", directly.

MethodWithNext-class

Class MethodWithNext

Description

Class of method definitions set up for `callNextMethod`

Objects from the Class

Objects from this class are generated as a side-effect of calls to `callNextMethod`.

Slots

.Data: Object of class "function"; the actual function definition.

nextMethod: Object of class "PossibleMethod" the method to use in response to a `callNextMethod()` call.

excluded: Object of class "list"; one or more signatures excluded in finding the next method.

target: Object of class "signature", from class "MethodDefinition"

defined: Object of class "signature", from class "MethodDefinition"

generic: Object of class "character"; the function for which the method was created.

Extends

Class "MethodDefinition", directly.

Class "function", from data part.

Class "PossibleMethod", by class "MethodDefinition".

Class "OptionalMethods", by class "MethodDefinition".

Methods

findNextMethod signature (method = "MethodWithNext"): used internally by method dispatch.

loadMethod signature (method = "MethodWithNext"): used internally by method dispatch.

show signature (object = "MethodWithNext")

See Also

[callNextMethod](#), and class [MethodDefinition](#).

new

Generate an Object from a Class

Description

Given the name or the definition of a class, plus optionally data to be included in the object, `new` returns an object from that class.

Usage

```
new(Class, ...)
```

```
initialize(.Object, ...)
```

Arguments

Class	Either the name of a class (the usual case) or the object describing the class (e.g., the value returned by <code>getClass</code>).
...	Data to include in the new object. Named arguments correspond to slots in the class definition. Unnamed arguments must be objects from classes that this class extends.
.Object	An object: see the Details section.

Details

The function `new` begins by copying the prototype object from the class definition. Then information is inserted according to the `...` arguments, if any. As of version 2.4 of R, the type of the prototype object, and therefore of all objects returned by `new()`, is "S4" except for classes that extend one of the basic types, where the prototype has that basic type. User functions that depend on `typeof(object)` should be careful to handle "S4" as a possible type.

The interpretation of the `...` arguments can be specialized to particular classes, if an appropriate method has been defined for the generic function `"initialize"`. The `new` function calls `initialize` with the object generated from the prototype as the `.Object` argument to `initialize`.

By default, unnamed arguments in the `...` are interpreted as objects from a superclass, and named arguments are interpreted as objects to be assigned into the correspondingly named slots. Thus, explicit slots override inherited information for the same slot, regardless of the order in which the arguments appear.

The `initialize` methods do not have `...` as their second argument (see the examples). Initialize methods are often written when the natural parameters describing the new object are not the names of the slots. If you do define such a method, note the implications for future subclasses of your class. If these have additional slots, and your `initialize` method has `...` as a formal argument, then your method should pass such arguments along via `callNextMethod`. If your method does not have this argument, then either a subclass must have its own method or else the added slots must be specified by users in some way other than as arguments to `new`.

For examples of `initialize` methods, see [initialize-methods](#) for existing methods for classes `"traceable"` and `"environment"`, among others.

Methods for `initialize` can be inherited only by simple inheritance, since it is a requirement that the method return an object from the target class. See the `simpleInheritanceOnly` argument to `setGeneric` and the discussion in `setIs` for the general concept.

Note that the basic vector classes, `"numeric"`, etc. are implicitly defined, so one can use `new` for these classes.

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

See Also

[Classes](#) for an overview of defining class, and [setOldClass](#) for the relation to S3 classes.

Examples

```
## using the definition of class "track" from Classes

## a new object with two slots specified
t1 <- new("track", x = seq_along(ydata), y = ydata)

# a new object including an object from a superclass, plus a slot
t2 <- new("trackCurve", t1, smooth = ysmooth)

### define a method for initialize, to ensure that new objects have
### equal-length x and y slots.

setMethod("initialize",
          "track",
          function(.Object, x = numeric(0), y = numeric(0)) {
            if(nargs() > 1) {
              if(length(x) != length(y))
                stop("specified x and y of different lengths")
              .Object@x <- x
              .Object@y <- y
            }
            .Object
          })

### the next example will cause an error (x will be numeric(0)),
### because we didn't build in defaults for x,
```

```

### although we could with a more elaborate method for initialize

try(new("track", y = sort(stats::rnorm(10))))

## a better way to implement the previous initialize method.
## Why? By using callNextMethod to call the default initialize method
## we don't inhibit classes that extend "track" from using the general
## form of the new() function. In the previous version, they could only
## use x and y as arguments to new, unless they wrote their own
## initialize method.

setMethod("initialize", "track", function(.Object, ...) {
  .Object <- callNextMethod()
  if(length(.Object@x) != length(.Object@y))
    stop("specified x and y of different lengths")
  .Object
})

```

ObjectsWithPackage-class

A Vector of Object Names, with associated Package Names

Description

This class of objects is used to represent ordinary character string object names, extended with a package slot naming the package associated with each object.

Objects from the Class

The function `getGenerics` returns an object of this class.

Slots

.Data: Object of class "character": the object names.

package: Object of class "character" the package names.

Extends

Class "character", from data part.

Class "vector", by class "character".

See Also

Methods for general background.

`promptClass`*Generate a Shell for Documentation of a Formal Class*

Description

Assembles all relevant slot and method information for a class, with minimal markup for Rd processing; no QC facilities at present.

Usage

```
promptClass(clName, filename = NULL, type = "class",
            keywords = "classes", where = topev(parent.frame()))
```

Arguments

<code>clName</code>	a character string naming the class to be documented.
<code>filename</code>	usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to a file whose name is the topic name for the class documentation, followed by ".Rd". Can also be NA (see below).
<code>type</code>	the documentation type to be declared in the output file.
<code>keywords</code>	the keywords to include in the shell of the documentation. The keyword "classes" should be one of them.
<code>where</code>	where to look for the definition of the class and of methods that use it.

Details

The class definition is found on the search list. Using that definition, information about classes extended and slots is determined.

In addition, the currently available generics with methods for this class are found (using [getGenerics](#)). Note that these methods need not be in the same environment as the class definition; in particular, this part of the output may depend on which packages are currently in the search list.

As with other prompt-style functions, unless `filename` is NA, the documentation shell is written to a file, and a message about this is given. The file will need editing to give information about the *meaning* of the class. The output of `promptClass` can only contain information from the metadata about the formal definition and how it is used.

If `filename` is NA, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

Value

If `filename` is NA, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

See Also

`prompt` for documentation of functions, `promptMethods` for documentation of method definitions.

For processing of the edited documentation, either use R CMD `Rdconv`, or include the edited file in the 'man' subdirectory of a package.

Examples

```
## Not run:
> promptClass("track")
A shell of class documentation has been written to the
file "track-class.Rd".
## End(Not run)
```

promptMethods

Generate a Shell for Documentation of Formal Methods

Description

Generates a shell of documentation for the methods of a generic function.

Usage

```
promptMethods(f, filename = NULL, methods)
```

Arguments

<code>f</code>	a character string naming the generic function whose methods are to be documented.
<code>filename</code>	usually, a connection or a character string giving the name of the file to which the documentation shell should be written. The default corresponds to the coded topic name for these methods (currently, <code>f</code> followed by <code>"-methods.Rd"</code>). Can also be <code>FALSE</code> or <code>NA</code> (see below).
<code>methods</code>	Optional methods list object giving the methods to be documented. By default, the first methods object for this generic is used (for example, if the current global environment has some methods for <code>f</code> , these would be documented). If this argument is supplied, it is likely to be <code>getMethods(f, where)</code> , with <code>where</code> some package containing methods for <code>f</code> .

Details

If `filename` is `FALSE`, the text created is returned, presumably to be inserted some other documentation file, such as the documentation of the generic function itself (see [prompt](#)).

If `filename` is `NA`, a list-style representation of the documentation shell is created and returned. Writing the shell to a file amounts to `cat(unlist(x), file = filename, sep = "\n")`, where `x` is the list-style representation.

Otherwise, the documentation shell is written to the file specified by `filename`.

Value

If `filename` is `FALSE`, the text generated; if `filename` is `NA`, a list-style representation of the documentation shell. Otherwise, the name of the file written to is returned invisibly.

[prompt](#) and [promptClass](#)

representation	<i>Construct a Representation or a Prototype for a Class Definition</i>
----------------	---

Description

In calls to [setClass](#), these two functions construct, respectively, the `representation` and `prototype` arguments. They do various checks and handle special cases. You're encouraged to use them when defining classes that, for example, extend other classes as a data part or have multiple superclasses, or that combine extending a class and slots.

Usage

```
representation(...)  
prototype(...)
```

Arguments

... The call to `representation` takes arguments that are single character strings. Unnamed arguments are classes that a newly defined class extends; named arguments name the explicit slots in the new class, and specify what class each slot should have.

In the call to `prototype`, if an unnamed argument is supplied, it unconditionally forms the basis for the prototype object. Remaining arguments are taken to correspond to slots of this object. It is an error to supply more than one unnamed argument.

Details

The `representation` function applies tests for the validity of the arguments. Each must specify the name of a class.

The classes named don't have to exist when `representation` is called, but if they do, then the function will check for any duplicate slot names introduced by each of the inherited classes.

The arguments to `prototype` are usually named initial values for slots, plus an optional first argument that gives the object itself. The unnamed argument is typically useful if there is a data part to the definition (see the examples below).

Value

The value of `representation` is just the list of arguments, after these have been checked for validity.

The value of `prototype` is the object to be used as the prototype. Slots will have been set consistently with the arguments, but the construction does *not* use the class definition to test validity of the contents (it hardly can, since the prototype object is usually supplied to create the definition).

## which should be a "numeric" object, and extending class "track"
representation("track", smooth = "numeric")
```

```
setClass("Character", representation("character"))
setClass("TypedCharacter", representation("Character", type="character"),
         prototype(character(0), type="plain"))
ttt <- new("TypedCharacter", "foo", type = "character")
```

```
setClass("num1", representation(comment = "character"),
         contains = "numeric",
         prototype = prototype(pi, comment = "Start with pi"))
```

Description

Old-style (S3) classes may be registered as S4 classes (by calling `setOldClass`, and many have been. These classes can then be contained in (that is, superclasses of) regular S4 classes, allowing formal methods and slots to be added to the S3 behavior. The function `S3Part` extracts or replaces the S3 part of such an object and `S3Class` extracts or replaces the S3-style class. Most computations that need to deal with the S3 aspects can coerce the objects automatically, without direct calls to these functions. The functions also work for classes that extend basic vector or matrix object types. See the details below.

Also discussed are S3 <-> S4 coercion; see the section “S3 and S4 objects”

Usage

```
S3Part(object, strictS3 = FALSE, S3Class)

S3Part(object, strictS3 = FALSE, needClass = ) <- value

S3Class(object)

S3Class(object) <- value

isXS3Class(classDef)

slotsFromS3(object)
```

Arguments

<code>object</code>	An object from some class that extends a registered S3 class, usually because the class has as one of its superclasses an S3 class registered by a call to <code>setOldClass</code> , or from a class that extends a basic vector, matrix or array object type. See the details. For most of the functions, an S3 object can also be supplied, with the interpretation that it is its own S3 part.
<code>strictS3</code>	If <code>TRUE</code> , the value returned by <code>S3Part</code> will be an S3 object, with all the S4 slots removed. Otherwise, an S4 object will always be returned; for example, from the S4 class created by <code>setOldClass</code> as a proxy for an S3 class, rather than the underlying S3 object.
<code>S3Class</code>	The character vector to be stored as the S3 class slot in the object returned. Usually, and by default, retains the slot from <code>object</code> .
<code>needClass</code>	Require that the replacement value be this class or a subclass of it.
<code>value</code>	For <code>S3Part<-</code> , the replacement value for the S3 part of the object. This does <i>not</i> need to be an S4 object; in fact, the usual way to create objects from these classes is by giving an S3 object of the right class as an argument to <code>new</code> . For <code>S3Class<-</code> , the character vector to assign as the S3 class.
<code>classDef</code>	A class definition object, as returned by <code>getClass</code> .

Details

Classes that register S3 classes by a call to `setOldClass` have slot `".S3Class"` to hold the corresponding S3 vector of class strings. The prototype of such a class has the value for this slot determined by the argument to `setOldClass`.

As a result, new S4 classes that extend (contain) such registered S3 classes also have the same slot, and by default the prototype has the value determined by the `contains=` argument to `setClass`. Individual objects from the S4 class may have an S3 class corresponding to the value in the prototype or to an (S3) subclass of that value. See the examples below.

`S3Part()` with `strictS3 = TRUE` constructs the underlying S3 object by eliminating all the formally defined slots and turning off the S4 bit of the object. With `strictS3 = FALSE` the object returned is from the corresponding S4 class. For consistency and generality, `S3Part()` works also for classes that extend the basic vector, matrix and array classes. Since R is somewhat arbitrary about what it treats as an S3 class ("`ts`" is, but "`matrix`" is not), `S3Part()` tries to return an S3 (that is, non-S4) object whenever the S4 class has a suitable superclass, of either S3 or basic object type.

One general application that relies on this generality is to use `S3Part()` to get a superclass object that is guaranteed not to be an S4 object. If you are calling some function that checks for S4 objects, you need to be careful not to end up in a closed loop (`fooS4` calls `fooS3`, which checks for an S4 object and calls `fooS4` again, maybe indirectly). Using `S3Part()` with `strictS3 = TRUE` is a mechanism to avoid such loops.

Because the contents of S3 class objects have no definition or guarantee, the computations involving S3 parts do *not* check for slot validity. Slots are implemented internally in R as attributes, which are copied when present in the S3 part. For this reason, grave problems can occur if an S4 class extending an S3 class uses the name of an S3 attribute as the name of an S4 slot. It's tempting to "promote" an attribute to a slot, but the resulting confusion between slot and attribute is hard to handle.

Frequently, `S3Part` can and should be avoided by simply coercing objects to the desired class; methods are automatically defined to deal correctly with the slots when `as` is called to extract or replace superclass objects.

The function `slotsFromS3()` is a generic function used internally to access the slots associated with the S3 part of the object. Methods for this function are created automatically when `setOldClass` is called with the `S4Class` argument. Usually, there is only one S3 slot, containing the S3 class, but the `S4Class` argument may provide additional slots, in the case that the S3 class has some guaranteed attributes that can be used as formal S4 slots. See the corresponding section in the documentation of `setOldClass`.

Value

`S3Part`: Returns or sets the S3 information (and possibly some S4 slots as well, depending on arguments `S3Class` and `keepSlots`). See the discussion of argument `strict` above. If it is `TRUE` the value returned is an S3 object.

`S3Class`: For an object from a class extending S3 classes, returns or sets the character vector of class(es) stored in the object. Note that `S3Class` on any other object returns the value of `class`.

`isXS3Class`: Returns `TRUE` or `FALSE` according to whether the class defined by `ClassDef` extends S3 classes (specifically, whether it has the slot for holding the S3 class).

`slotsFromS3`: returns a list of the relevant slot classes, or an empty list for any other object.

S3 and S4 Objects: Conversion Mechanisms

Objects in R have an internal bit that indicates whether or not to treat the object as coming from an S4 class. This bit is tested by `isS4` and can be set on or off by `asS4`. The latter function, however, does no checking or interpretation; you should only use it if you are very certain every detail has been handled correctly.

As a friendlier alternative, methods have been defined for coercing to the virtual classes "S3" and "S4". The expressions `as(object, "S3")` and `as(object, "S4")` return S3 and S4 objects, respectively. In addition, they attempt to do conversions in a valid way, and also check validity when coercing to S4.

The expression `as(object, "S3")` can be used in two ways. For objects from one of the registered S3 classes, the expression will ensure that the class attribute is the full multi-string S3 class implied by `class(object)`. If the registered class has known attribute/slots, these will also be provided.

Another use of `as(object, "S3")` is to take an S4 object and turn it into an S3 object with corresponding attributes. This is only meaningful with S4 classes that have a data part. If you want to operate on the object without invoking S4 methods, this conversion is usually the safest way.

The expression `as(object, "S4")` will use the attributes in the object to create an object from the S4 definition of `class(object)`. This is a general mechanism to create partially defined version of S4 objects via S3 computations (not much different from invoking `new` with corresponding arguments, but usable in this form even if the S4 object has an initialize method with different arguments).

mx1 = new("MatX", m1, date = Sys.Date())
stopifnot(identical(m1, S3Part(mx1, strict = TRUE)))

```

S4groupGeneric

Group Generic Functions

Description

Methods can be defined for *group generic functions*. Each group generic function has a number of *member generic functions* associated with it.

Methods defined for a group generic function cause the same method to be defined for each member of the group, but a method explicitly defined for a member of the group takes precedence over a method defined, with the same signature, for the group generic.

The functions shown in this documentation page all reside in the **methods** package, but the mechanism is available to any programmer, by calling `setGroupGeneric`.

Usage

```

## S4 group generics:
Arith(e1, e2)
Compare(e1, e2)
Ops(e1, e2)
Logic(e1, e2)
Math(x)
Math2(x, digits)
Summary(x, ..., na.rm = FALSE)
Complex(z)

```

Arguments

`x`, `z`, `e1`, `e2` objects.

`digits` number of digits to be used in round or signif.

... further arguments passed to or from methods.
 na.rm logical: should missing values be removed?

Details

Methods can be defined for the group generic functions by calls to `setMethod` in the usual way. Note that the group generic functions should never be called directly – a suitable error message will result if they are. When metadata for a group generic is loaded, the methods defined become methods for the members of the group, but only if no method has been specified directly for the member function for the same signature. The effect is that group generic definitions are selected before inherited methods but after directly specified methods. For more on method selection, see [Methods](#).

There are also S3 groups `Math`, `Ops`, `Summary` and `Complex`, see `?S3groupGeneric`, with no corresponding R objects, but these are irrelevant for S4 group generic functions.

The members of the group defined by a particular generic can be obtained by calling `getGroupMembers`. For the group generic functions currently defined in this package the members are as follows:

Arith "+", "-", "*", "^", "%%", "%/%", "/"

Compare "==", ">", "<", "!=", "<=", ">="

Logic "&", "|".

Ops "Arith", "Compare", "Logic"

Summary "max", "min", "range", "prod", "sum", "any", "all"

Complex "Arg", "Conj", "Im", "Mod", "Re"

Note that `Ops` merely consists of three sub groups.

All the functions in these groups (other than the group generics themselves) are basic functions in R. They are not by default S4 generic functions, and many of them are defined as primitives. However, you can still define formal methods for them, both individually and via the group generics. It all works more or less as you might expect, admittedly via a bit of trickery in the background. See [Methods](#) for details.

Note that two members of the `Math` group, `log` and `trunc`, have ... as an extra formal argument. Since methods for `Math` will have only one formal argument, you must set a specific method for these functions in order to call them with the extra argument(s).

For further details about group generic functions see section 10.5 of *Software for Data Analysis*.

The function `callGeneric` is nearly always relevant when writing a method for a group generic. See the examples below and in section 10.5 of *Software for Data Analysis*.

See `S3groupGeneric` for S3 group generics.

Examples

```
setClass("testComplex", representation(zz = "complex"))
## method for whole group "Complex"
setMethod("Complex", "testComplex",
          function(z) c("groupMethod", callGeneric(z@zz)))
## exception for Arg() :
setMethod("Arg", "testComplex",
          function(z) c("ArgMethod", Arg(z@zz)))
z1 <- 1+2i
z2 <- new("testComplex", zz = z1)
stopifnot(identical(Mod(z2), c("groupMethod", Mod(z1))))
stopifnot(identical(Arg(z2), c("ArgMethod", Arg(z1))))
```

SClassExtension-class

Class to Represent Inheritance (Extension) Relations

Description

An object from this class represents a single ‘is’ relationship; lists of these objects are used to represent all the extensions (superclasses) and subclasses for a given class. The object contains information about how the relation is defined and methods to coerce, test, and replace correspondingly.

Objects from the Class

Objects from this class are generated by `setIs`, from direct calls and from the `contains=` information in a call to `setClass`, and from class unions created by `setClassUnion`. In the last case, the information is stored in defining the *subclasses* of the union class (allowing unions to contain sealed classes).

Slots

subClass, superClass: The classes being extended: corresponding to the `from`, and `to` arguments to `setIs`.

package: The package to which that class belongs.

coerce: A function to carry out the `as()` computation implied by the relation. Note that these functions should *not* be used directly. They only deal with the `strict=TRUE` calls to the `as` function, with the full method constructed from this mechanically.

test: The function that would test whether the relation holds. Except for explicitly specified `test` arguments to `setIs`, this function is trivial.

replace: The method used to implement `as(x, Class) <- value`.

simple: A "logical" flag, TRUE if this is a simple relation, either because one class is contained in the definition of another, or because a class has been explicitly stated to extend a virtual class. For simple extensions, the three methods are generated automatically.

by: If this relation has been constructed transitively, the first intermediate class from the subclass.

dataPart: A "logical" flag, TRUE if the extended class is in fact the data part of the subclass. In this case the extended class is a basic class (i.e., a type).

distance: The distance between the two classes, 1 for directly contained classes, plus the number of generations between otherwise.

Methods

No methods defined with class "SClassExtension" in the signature.

See Also

`is`, `as`, and the `classRepresentation` class.

setClass

Create a Class Definition

Description

Create a class definition, specifying the representation (the slots) and/or the classes contained in this one (the superclasses), plus other optional details.

Usage

```
setClass(Class, representation, prototype, contains=character(),
         validity, access, where, version, sealed, package)
```

Arguments

Class	character string name for the class.
representation	a named list of the slots that the new class should have, the names giving the names of the slots and the corresponding elements being the character string names of the corresponding classes. Usually a call to the <code>representation</code> function. Backward compatibility and compatibility with S-Plus allows unnamed elements for superclasses, but the recommended style is to use the <code>contains=</code> argument instead.
prototype	an object providing the default data for the slots in this class. Usually and preferably the result of a call to <code>prototype</code> .
contains	what classes does this class extend? (These are called <i>superclasses</i> in some languages.) When these classes have slots, all their slots will be contained in the new class as well.
where	the environment in which to store or remove the definition. Defaults to the top-level environment of the calling function (the global environment for ordinary computations, and the environment or name space of a package in the source code for that package).

<code>validity</code>	if supplied, should be a validity-checking method for objects from this class (a function that returns <code>TRUE</code> if its argument is a valid object of this class and one or more strings describing the failures otherwise). See <code>validObject</code> for details.
<code>access, version</code>	access and version, included for compatibility with S-Plus, but currently ignored.
<code>sealed</code>	if <code>TRUE</code> , the class definition will be sealed, so that another call to <code>setClass</code> will fail on this class name.
<code>package</code>	an optional package name for the class. By default (and usually) the name of the package in which the class definition is assigned.

Basic Use: Slots and Inheritance

The two essential arguments, other than the class name are `representation` and `contains`, defining the explicit slots and the inheritance (superclasses). Together, these arguments define all the information in an object from this class; that is, the names of all the slots and the classes required for each of them.

The name of the class determines which methods apply directly to objects from this class. The inheritance information specifies which methods apply indirectly, through inheritance. See [Methods](#).

The slots in a class definition will be the union of all the slots specified directly by `representation` and all the slots in all the contained classes. There can only be one slot with a given name; specifically, the direct and inherited slot names must be unique. That does not, however, prevent the same class from being inherited via more than one path.

One kind of element in the `contains=` argument is `special`, specifying one of the R vector types or one of a few other special R types (`matrix` and `array`). A class can contain at most one of these, directly or indirectly. When it does, that contained class determines the “data part” of the class, and objects from the new class inherit all the built in behavior of the contained type. Two direct consequences are: for any object `x` from the class, `typeof(x)` will be the contained basic type; and a special pseudo-slot, `.Data`, will be shown with the corresponding class.

For an object from any class that does *not* contain such a type, `typeof(x)` will be `"S4"` and the class will have no `.Data` slot.

Prototypes

Defining new classes that inherit from (‘extend’) other classes is a powerful technique, but has to be used carefully and not over-used. Otherwise, you will often get unintended results when you start to compute with objects from the new class.

As shown in the examples below, the simplest and safest form of inheritance is to start with an explicit class, with some slots, that does not extend anything else. It only does what we say it does.

Then extensions will add some new slots and new behavior.

Another variety of extension starts with one of the built-in objects, perhaps with the intention of modifying R’s standard behavior for that class. In this case, the new class inherits the built-in data type as its ‘data’ part. See the `"numWithId"` example below.

When such a class definition is printed, the data part shows up as a pseudo-slot named `.Data`.

Classes and Packages

Class definitions normally belong to packages (but can be defined in the global environment as well, by evaluating the expression on the command line or in a file sourced from the command line). The corresponding package name is part of the class definition; that is, part of the

classRepresentation object holding that definition. Thus, two classes with the same name can exist in different packages, for most purposes.

When a class name is supplied for a slot or a superclass, a corresponding class definition will be found, looking from the name space or environment of the current package, assuming the call to setClass in question appears directly in the source for the package. That's where it should appear, to avoid ambiguity.

In particular, if the current package has a name space then the class must be found in the current package itself, in the imports defined by that name space, or in the base package.

When this rule does not identify a class uniquely (because it appears in more than one imported package) then the `packageSlot` of the character string name needs to be supplied with the name. This should be a rare occurrence.

Note

Certain slot names are not allowed in the current implementation, as they correspond to `attributes` which are treated specially. These are `class`, `comment`, `dim`, `dimnames`, `names`, `row.names` and `tsp`.

[Classes](#) for a general discussion of classes, [Methods](#) for an analogous discussion of methods, [makeClassRepresentation](#)

Examples

```
## A simple class with two slots
setClass("track",
        representation(x="numeric", y="numeric"))
## A class extending the previous, adding one more slot
setClass("trackCurve",
        representation(smooth = "numeric"),
        contains = "track")
## A class similar to "trackCurve", but with different structure
## allowing matrices for the "y" and "smooth" slots
setClass("trackMultiCurve",
        representation(x="numeric", y="matrix", smooth="matrix"),
        prototype = list(x=numeric(), y=matrix(0,0,0),
                        smooth= matrix(0,0,0)))
##
## Suppose we want trackMultiCurve to be like trackCurve when there's
## only one column.
## First, the wrong way.
try(setIs("trackMultiCurve", "trackCurve",
        test = function(obj) {ncol(slot(obj, "y")) == 1}))

## Why didn't that work? You can only override the slots "x", "y",
## and "smooth" if you provide an explicit coerce function to correct
## any inconsistencies:
```

```

setIs("trackMultiCurve", "trackCurve",
      test = function(obj) {ncol(slot(obj, "y")) == 1},
      coerce = function(obj) {
        new("trackCurve",
            x = slot(obj, "x"),
            y = as.numeric(slot(obj, "y")),
            smooth = as.numeric(slot(obj, "smooth")))
      })

## A class that extends the built-in data type "numeric"

setClass("numWithId", representation(id = "character"),
         contains = "numeric")

new("numWithId", 1:3, id = "An Example")

```

setClassUnion

Classes Defined as the Union of Other Classes

Description

A class may be defined as the *union* of other classes; that is, as a virtual class defined as a superclass of several other classes. Class unions are useful in method signatures or as slots in other classes, when we want to allow one of several classes to be supplied.

Usage

```

setClassUnion(name, members, where)
isClassUnion(Class)

```

Arguments

name	the name for the new union class.
members	the classes that should be members of this union.
where	where to save the new class definition; by default, the environment of the package in which the <code>setClassUnion</code> call appears, or the global environment if called outside of the source of a package.
Class	the name or definition of a class.

Details

The classes in `members` must be defined before creating the union. However, members can be added later on to an existing union, as shown in the example below. Class unions can be members of other class unions.

Class unions are the only way to create a class that is extended by a class whose definition is sealed (for example, the basic datatypes or other classes defined in the base or methods package in R are sealed). You cannot say `setIs("function", "other")` unless "other" is a class union. In general, a `setIs` call of this form changes the definition of the first class mentioned (adding "other" to the list of superclasses contained in the definition of "function").

Class unions get around this by not modifying the first class definition, relying instead on storing information in the subclasses slot of the class union. In order for this technique to work, the internal computations for expressions such as `extends(class1, class2)` work differently for class unions than for regular classes; specifically, they test whether any class is in common between the superclasses of `class1` and the subclasses of `class2`.

The different behavior for class unions is made possible because the class definition object for class unions has itself a special class, "ClassUnionRepresentation", an extension of class `classRepresentation`.

Examples

```
## a class for either numeric or logical data
setClassUnion("maybeNumber", c("numeric", "logical"))

## use the union as the data part of another class
setClass("withId", representation("maybeNumber", id = "character"))

w1 <- new("withId", 1:10, id = "test 1")
w2 <- new("withId", sqrt(w1)%%1 < .01, id = "Perfect squares")

## add class "complex" to the union "maybeNumber"
setIs("complex", "maybeNumber")

w3 <- new("withId", complex(real = 1:10, imaginary = sqrt(1:10)))

## a class union containing the existing class union "OptionalFunction"
setClassUnion("maybeCode",
  c("expression", "language", "OptionalFunction"))

is(quote(sqrt(1:10)), "maybeCode") ## TRUE
```

setGeneric

Define a New Generic Function

Description

Create a new generic function of the given name, that is, a function that dispatches methods according to the classes of the arguments, from among the formal methods defined for this function.

Usage

```
setGeneric(name, def= , group=list(), valueClass=character(),
  where= , package= , signature= , useAsDefault= ,
  genericFunction= , simpleInheritanceOnly = )
```

```
setGroupGeneric(name, def= , group=list(), valueClass=character(),
               knownMembers=list(), package= , where= )
```

Arguments

name	The character string name of the generic function. The simplest (and recommended) call, <code>setGeneric(name)</code> , looks for a function with this name and creates a corresponding generic function, if the function found was not generic.
def	An optional function object, defining the generic. Don't supply this argument if you want an existing non-generic function to supply the arguments. Do supply it if there is no current function of this name, or if you want the generic function to have different arguments. In that case, the formal arguments and default values for the generic are taken from <code>def</code> . You can also supply this argument if you want the generic function to do something other than just dispatch methods. Note that <code>def</code> is <i>not</i> the default method; use argument <code>useAsDefault</code> if you want to specify the default separately.
group	Optionally, a character string giving the name of the group generic function to which this function belongs. See Methods for details of group generic functions in method selection.
valueClass	An optional character vector of one or more class names. The value returned by the generic function must have (or extend) this class, or one of the classes; otherwise, an error is generated.
package	The name of the package with which this function is associated. Usually determined automatically (as the package containing the non-generic version if there is one, or else the package where this generic is to be saved).
where	Where to store the resulting initial methods definition, and possibly the generic function; by default, stored into the top-level environment.
signature	Optionally, the vector of names, from among the formal arguments to the function, that can appear in the signature of methods for this function, in calls to setMethod . If <code>...</code> is one of the formal arguments, it is treated specially. Starting with version 2.8.0 of R, <code>...</code> may be signature of the generic function. Methods will then be selected if their signature matches all the <code>...</code> arguments. See the documentation for topic dotsMethods for details. In the present version, it is not possible to mix <code>...</code> and other arguments in the signature (this restriction may be lifted in later versions). By default, the signature is inferred from the implicit generic function corresponding to a non-generic function. If no implicit generic function has been defined, the default is all the formal arguments except <code>...</code> , in the order they appear in the function definition. In the case that <code>...</code> is the only formal argument, that is also the default signature. To use <code>...</code> as the signature in a function that has any other arguments, you must supply the signature argument explicitly. See the "Implicit Generic" section below for more details.
useAsDefault	Override the usual choice of default argument (an existing non-generic function or no default if there is no such function). Argument <code>useAsDefault</code> can be supplied, either as a function to use for the default, or as a logical value. <code>FALSE</code> says not to have a default method at all, so that an error occurs if there is not an explicit or inherited method for a call. <code>TRUE</code> says to use the existing function as default, unconditionally (hardly ever needed as an explicit argument). See the section on details.

`simpleInheritanceOnly`

Supply this argument as `TRUE` to require that methods selected be inherited through simple inheritance only; that is, from superclasses specified in the `contains=` argument to `setClass`, or by simple inheritance to a class union or other virtual class. Generic functions should require simple inheritance if they need to be assured that they get the complete original object, not one that has been transformed. Examples of functions requiring simple inheritance are `initialize`, because by definition it must return an object from the same class as its argument, and `show`, because it claims to give a full description of the object provided as its argument.

`genericFunction`

Don't use; for (possible) internal use only.

`knownMembers` (For `setGroupGeneric` only.) The names of functions that are known to be members of this group. This information is used to reset cached definitions of the member generics when information about the group generic is changed.

Value

The `setGeneric` function exists for its side effect: saving the generic function to allow methods to be specified later. It returns `name`.

Basic Use

The `setGeneric` function is called to initialize a generic function as preparation for defining some methods for that function.

The simplest and most common situation is that `name` is already an ordinary non-generic non-primitive function, and you now want to turn this function into a generic. In this case you will most often supply only `name`, for example:

```
setGeneric("colSums")
```

There must be an existing function of this name, on some attached package (in this case package `"base"`). A generic version of this function will be created in the current package (or in the global environment if the call to `setGeneric()` is from an ordinary source file or is entered on the command line). The existing function becomes the default method, and the package slot of the new generic function is set to the location of the original function (`"base"` in the example). It's an important feature that the same generic function definition is created each time, depending in the example only on the definition of `print` and where it is found. The signature of the generic function, defining which of the formal arguments can be used in specifying methods, is set by default to all the formal arguments except ...

Note that calling `setGeneric()` in this form is not strictly necessary before calling `setMethod()` for the same function. If the function specified in the call to `setMethod` is not generic, `setMethod` will execute the call to `setGeneric` itself. Declaring explicitly that you want the function to be generic can be considered better programming style; the only difference in the result, however, is that not doing so produces a message noting the creation of the generic function.

You cannot (and never need to) create an explicit generic version of the primitive functions in the base package. Those which can be treated as generic functions have methods selected and dispatched from the internal C code, to satisfy concerns for efficiency, and the others cannot be made generic. See the section on Primitive Functions below.

The description above is the effect when the package that owns the non-generic function has not created an implicit generic version. Otherwise, it is this implicit generic function that is used. See

the section on Implicit Generic Functions below. Either way, the essential result is that the *same* version of the generic function will be created each time.

The second common use of `setGeneric()` is to create a new generic function, unrelated to any existing function, and frequently having no default method. In this case, you need to supply a skeleton of the function definition, to define the arguments for the function. The body of a generic function is usually a standard form, `standardGeneric(name)` where `name` is the quoted name of the generic function. When calling `setGeneric` in this form, you would normally supply the `def` argument as a function of this form. See the second and third examples below.

The `useAsDefault` argument controls the default method for the new generic. If not told otherwise, `setGeneric` will try to find a non-generic version of the function to use as a default. So, if you do have a suitable default method, it is often simpler to first set this up as a non-generic function, and then use the one-argument call to `setGeneric` at the beginning of this section. See the first example in the Examples section below.

If you *don't* want the existing function to be taken as default, supply the argument `useAsDefault`. That argument can be the function you want to be the default method, or `FALSE` to force no default (i.e., to cause an error if there is no direct or inherited method selected for a call to the function).

Details

If you want to change the behavior of an existing function (typically, one in another package) when you create a generic version, you must supply arguments to `setGeneric` correspondingly. Whatever changes are made, the new generic function will be assigned with a package slot set to the *current* package, not the one in which the non-generic version of the function is found. This step is required because the version you are creating is no longer the same as that implied by the function in the other package. A message will be printed to indicate that this has taken place and noting one of the differences between the two functions.

The body of a generic function usually does nothing except for dispatching methods by a call to `standardGeneric`. Under some circumstances you might just want to do some additional computation in the generic function itself. As long as your function eventually calls `standardGeneric` that is permissible (though perhaps not a good idea, in that it may make the behavior of your function less easy to understand). If your explicit definition of the generic function does *not* call `standardGeneric` you are in trouble, because none of the methods for the function will ever be dispatched.

By default, the generic function can return any object. If `valueClass` is supplied, it should be a vector of class names; the value returned by a method is then required to satisfy `is(object, Class)` for one of the specified classes. An empty (i.e., zero length) vector of classes means anything is allowed. Note that more complicated requirements on the result can be specified explicitly, by defining a non-standard generic function.

The `setGroupGeneric` function behaves like `setGeneric` except that it constructs a group generic function, differing in two ways from an ordinary generic function. First, this function cannot be called directly, and the body of the function created will contain a `stop` call with this information. Second, the group generic function contains information about the known members of the group, used to keep the members up to date when the group definition changes, through changes in the search list or direct specification of methods, etc.

Implicit Generic Functions

Saying that a non-generic function “is converted to a generic” is more precisely state that the function is converted to the corresponding *implicit* generic function. If no special action has been taken, any function corresponds implicitly to a generic function with the same arguments, in which all

arguments other than ... can be used. The signature of this generic function is the vector of formal arguments, in order, except for ...

The source code for a package can define an implicit generic function version of any function in that package (see [implicitGeneric](#) for the mechanism). You can not, generally, define an implicit generic function in someone else's package. The usual reason for defining an implicit generic is to prevent certain arguments from appearing in the signature, which you must do if you want the arguments to be used literally or if you want to enforce lazy evaluation for any reason. An implicit generic can also contain some methods that you want to be predefined; in fact, the implicit generic can be any generic version of the non-generic function. The implicit generic mechanism can also be used to prohibit a generic version (see [prohibitGeneric](#)).

Whether defined or inferred automatically, the implicit generic will be compared with the generic function that `setGeneric` creates, when the implicit generic is in another package. If the two functions are identical, then the `package` slot of the created generic will have the name of the package containing the implicit generic. Otherwise, the slot will be the name of the package in which the generic is assigned.

The purpose of this rule is to ensure that all methods defined for a particular combination of generic function and package names correspond to a single, consistent version of the generic function. Calling `setGeneric` with only `name` and possibly `package` as arguments guarantees getting the implicit generic version, if one exists.

Including any of the other arguments can force a new, local version of the generic function. If you don't want to create a new version, don't use the extra arguments.

Generic Functions and Primitive Functions

A number of the basic R functions are specially implemented as primitive functions, to be evaluated directly in the underlying C code rather than by evaluating an R language definition. Most have implicit generics (see [implicitGeneric](#)), and become generic as soon as methods (including group methods) are defined on them. Others cannot be made generic.

Even when methods are defined for such functions, the generic version is not visible on the search list, in order that the C version continues to be called. Method selection will be initiated in the C code. Note, however, that the result is to restrict methods for primitive functions to signatures in which at least one of the classes in the signature is a formal S4 class.

To see the generic version of a primitive function, use `getGeneric(name)`. The function `isGeneric` will tell you whether methods are defined for the function in the current session.

Examples

```
## create a new generic function, with a default method
props <- function(object) attributes(object)
```

```

setGeneric("props")

## A new generic function with no default method
setGeneric("increment",
  function(object, step, ...)
    standardGeneric("increment")
)

### A non-standard generic function. It insists that the methods
### return a non-empty character vector (a stronger requirement than
### valueClass = "character" in the call to setGeneric)

setGeneric("authorNames",
  function(text) {
    value <- standardGeneric("authorNames")
    if(!(is(value, "character") && any(nchar(value)>0)))
      stop("authorNames methods must return non-empty strings")
    value
  })

## An example of group generic methods, using the class
## "track"; see the documentation of setClass for its definition

## define a method for the Arith group

setMethod("Arith", c("track", "numeric"),
  function(e1, e2) {
    e1@y <- callGeneric(e1@y, e2)
    e1
  })

setMethod("Arith", c("numeric", "track"),
  function(e1, e2) {
    e2@y <- callGeneric(e1, e2@y)
    e2
  })

## now arithmetic operators will dispatch methods:

t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))

t1 - 100
1/t1

```

setMethod

Create and Save a Method

Description

Create and save a formal method for a given function and list of classes.

Usage

```
setMethod(f, signature=character(), definition,
          where = topenv(parent.frame()),
          valueClass = NULL, sealed = FALSE)

removeMethod(f, signature, where)
```

Arguments

<code>f</code>	A generic function or the character-string name of the function.
<code>signature</code>	A match of formal argument names for <code>f</code> with the character-string names of corresponding classes. See the details below; however, if the signature is not trivial, you should use <code>method.skeleton</code> to generate a valid call to <code>setMethod</code> .
<code>definition</code>	A function definition, which will become the method called when the arguments in a call to <code>f</code> match the classes in <code>signature</code> , directly or through inheritance.
<code>where</code>	the environment in which to store the definition of the method. For <code>setMethod</code> , it is recommended to omit this argument and to include the call in source code that is evaluated at the top level; that is, either in an R session by something equivalent to a call to <code>source</code> , or as part of the R source code for a package. For <code>removeMethod</code> , the default is the location of the (first) instance of the method for this signature.
<code>valueClass</code>	Obsolete and unused, but see the same argument for <code>setGeneric</code> .
<code>sealed</code>	If <code>TRUE</code> , the method so defined cannot be redefined by another call to <code>setMethod</code> (although it can be removed and then re-assigned).

Details

The call to `setMethod` stores the supplied method definition in the metadata table for this generic function in the environment, typically the global environment or the name space of a package. In the case of a package, the table object becomes part of the name space or environment of the package. When the package is loaded into a later session, the methods will be merged into the table of methods in the corresponding generic function object.

Generic functions are referenced by the combination of the function name and the package name; for example, the function `"show"` from the package `"methods"`. Metadata for methods is identified by the two strings; in particular, the generic function object itself has slots containing its name and its package name. The package name of a generic is set according to the package from which it originally comes; in particular, and frequently, the package where a non-generic version of the function originated. For example, generic functions for all the functions in package `base` will have `"base"` as the package name, although none of them is an S4 generic on that package.

Multiple packages can have methods for the same generic function; that is, for the same combination of generic function name and package name. Even though the methods are stored in separate tables in separate environments, loading the corresponding packages adds the methods to the table in the generic function itself, for the duration of the session.

The class names in the signature can be any formal class, including basic classes such as `"numeric"`, `"character"`, and `"matrix"`. Two additional special class names can appear: `"ANY"`, meaning that this argument can have any class at all; and `"missing"`, meaning that this argument *must not* appear in the call in order to match this signature. Don't confuse these two: if an argument isn't mentioned in a signature, it corresponds implicitly to class `"ANY"`, not to `"missing"`. See the example below. Old-style ('S3') classes can also be used, if you need

compatibility with these, but you should definitely declare these classes by calling `setOldClass` if you want S3-style inheritance to work.

Method definitions can have default expressions for arguments, but a current limitation is that the generic function must have *some* default expression for the same argument in order for the method's defaults to be used. If so, and if the corresponding argument is missing in the call to the generic function, the default expression in the method is used. If the method definition has no default for the argument, then the expression supplied in the definition of the generic function itself is used, but note that this expression will be evaluated using the enclosing environment of the method, not of the generic function. Note also that specifying class "missing" in the signature does not require any default expressions, and method selection does not evaluate default expressions. All actual (non-missing) arguments in the signature of the generic function will be evaluated when a method is selected—when the call to `standardGeneric(f)` occurs.

It is possible to have some differences between the formal arguments to a method supplied to `setMethod` and those of the generic. Roughly, if the generic has ... as one of its arguments, then the method may have extra formal arguments, which will be matched from the arguments matching ... in the call to `f`. (What actually happens is that a local function is created inside the method, with the modified formal arguments, and the method is re-defined to call that local function.)

Method dispatch tries to match the class of the actual arguments in a call to the available methods collected for `f`. If there is a method defined for the exact same classes as in this call, that method is used. Otherwise, all possible signatures are considered corresponding to the actual classes or to superclasses of the actual classes (including "ANY"). The method having the least distance from the actual classes is chosen; if more than one method has minimal distance, one is chosen (the lexicographically first in terms of superclasses) but a warning is issued. All inherited methods chosen are stored in another table, so that the inheritance calculations only need to be done once per session per sequence of actual classes. See [Methods](#) for more details.

The function `removeMethod` removes the specified method from the metadata table in the corresponding environment. It's not a function that is used much, since one normally wants to redefine a method rather than leave no definition.

Value

These functions exist for their side-effect, in setting or removing a method in the object defining methods for the specified generic.

The value returned by `removeMethod` is TRUE if a method was found to be removed.

Examples

```

require(graphics)
## methods for plotting track objects (see the example for setClass)
##
## First, with only one object as argument:
setMethod("plot", signature(x="track", y="missing"),
  function(x, y, ...) plot(slot(x, "x"), slot(x, "y"), ...)
)
## Second, plot the data from the track on the y-axis against anything
## as the x data.
setMethod("plot", signature(y = "track"),
  function(x, y, ...) plot(x, slot(y, "y"), ...)
)
## and similarly with the track on the x-axis (using the short form of
## specification for signatures)
setMethod("plot", "track",
  function(x, y, ...) plot(slot(x, "y"), y, ...)
)
t1 <- new("track", x=1:20, y=(1:20)^2)
tc1 <- new("trackCurve", t1)
slot(tc1, "smooth") <- smooth.spline(slot(tc1, "x"), slot(tc1, "y"))$y # $
plot(t1)
plot(qnorm(ppoints(20)), t1)
## An example of inherited methods, and of conforming method arguments
## (note the dotCurve argument in the method, which will be pulled out
## of ... in the generic.
setMethod("plot", c("trackCurve", "missing"),
function(x, y, dotCurve = FALSE, ...) {
  plot(as(x, "track"))
  if(length(slot(x, "smooth") > 0))
    lines(slot(x, "x"), slot(x, "smooth"),
          lty = if(dotCurve) 2 else 1)
}
)
## the plot of tc1 alone has an added curve; other uses of tc1
## are treated as if it were a "track" object.
plot(tc1, dotCurve = TRUE)
plot(qnorm(ppoints(20)), tc1)

## defining methods for a special function.
## Although "[" and "length" are not ordinary functions
## methods can be defined for them.
setMethod("[", "track",
  function(x, i, j, ..., drop) {
    x@x <- x@x[i]; x@y <- x@y[i]
    x
  })
plot(t1[1:15])

setMethod("length", "track", function(x)length(x@y))
length(t1)

## methods can be defined for missing arguments as well
setGeneric("summary") ## make the function into a generic

```

```
## A method for summary()
## The method definition can include the arguments, but
## if they're omitted, class "missing" is assumed.

setMethod("summary", "missing", function() "<No Object>")
```

setOldClass

Register Old-Style (S3) Classes and Inheritance

Description

Register an old-style (a.k.a. ‘S3’) class as a formally defined class. The `Classes` argument is the character vector used as the `class` attribute; in particular, if there is more than one string, old-style class inheritance is mimicked. Registering via `setOldClass` allows S3 classes to appear in method signatures, as a slot in an S4 class, or as a superclass of an S4 class.

Usage

```
setOldClass(Classes, prototype, where, test = FALSE, S4Class)
```

Arguments

<code>Classes</code>	A character vector, giving the names for old-style classes, as they would appear on the right side of an assignment of the <code>class</code> attribute in S3 computations.
<code>prototype</code>	An optional object to use as the prototype. This should be provided as the default S3 object for the class. If omitted, the S4 class created to register the S3 class is <code>VIRTUAL</code> . See the details.
<code>where</code>	Where to store the class definitions, the global or top-level environment by default. (When either function is called in the source for a package, the class definitions will be included in the package’s environment by default.)
<code>test</code>	flag, if <code>TRUE</code> , arrange to test inheritance explicitly for each object, needed if the S3 class can have a different set of class strings, with the same first string. This is a different mechanism in implementation and should be specified separately for each pair of classes that have an optional inheritance. See the details below.
<code>S4Class</code>	optionally, the class definition or the class name of an S4 class. The new class will have all the slots and other properties of this class, plus its S3 inheritance as defined by the <code>Classes</code> argument. Arguments <code>prototype</code> and <code>test</code> must not be supplied in this case. See the section on “S3 classes with known attributes” below.

Details

Each of the names will be defined as an S4 class, extending the remaining classes in `Classes`, and the class `oldClass`, which is the ‘root’ of all old-style classes. S3 classes have no formal definition, and therefore no formally defined slots. If a `prototype` argument is supplied in the call to `setOldClass()`, objects from the class can be generated, by a call to `new`; however, this usually not as relevant as generating objects from subclasses (see the section on extending S3 classes below). If a prototype is not provided, the class will be created as a virtual S4 class. The

main disadvantage is that the prototype object in an S4 class that uses this class as a slot will have a `NULL` object in that slot, which can sometimes lead to confusion.

Beginning with version 2.8.0 of R, support is provided for using a (registered) S3 class as a super class of a new S4 class. See the section on extending S3 classes below, and the examples.

See [Methods](#) for the details of method dispatch and inheritance.

Some S3 classes cannot be represented as an ordinary combination of S4 classes and superclasses, because objects from the S3 class can have a variable set of strings in the class. It is still possible to register such classes as S4 classes, but now the inheritance has to be verified for each object, and you must call `setOldClass` with argument `test=TRUE` once for each superclass.

For example, ordered factors *always* have the S3 class `c("ordered", "factor")`. This is proper behavior, and maps simply into two S4 classes, with "ordered" extending "factor".

But objects whose class attribute has "POSIXt" as the first string may have either (or neither) of "POSIXct" or "POSIXlt" as the second string. This behavior can be mapped into S4 classes but now to evaluate `is(x, "POSIXlt")`, for example, requires checking the S3 class attribute on each object. Supplying the `test=TRUE` argument to `setOldClass` causes an explicit test to be included in the class definitions. It's never wrong to have this test, but since it adds significant overhead to methods defined for the inherited classes, you should only supply this argument if it's known that object-specific tests are needed.

The list `.OldClassesList` contains the old-style classes that are defined by the `methods` package. Each element of the list is an old-style list, with multiple character strings if inheritance is included. Each element of the list was passed to `setOldClass` when creating the `methods` package; therefore, these classes can be used in `setMethod` calls, with the inheritance as implied by the list.

Extending S3 classes

A call to `setOldClass` creates formal classes corresponding to S3 classes, allows these to be used as slots in other classes or in a signature in `setMethod`, and mimics the S3 inheritance.

In documentation for the initial implementation of S4 classes in R, users were warned against defining S4 classes that contained S3 classes, even if those had been registered. The warning was based mainly on two points. 1: The S3 behavior of the objects would fail because the S3 class would not be visible, for example, when S3 methods are dispatched. 2: Because S3 classes have no formal definition, nothing can be asserted in general about the S3 part of an object from such a class. (The warning was repeated as recently as the first reference below.)

Nevertheless, defining S4 classes to contain an S3 class and extend its behavior is attractive in many applications. The alternative is to be stuck with S3 programming, without the flexibility and security of formal class and method definitions.

Beginning with version 2.8.0, R provides support for extending registered S3 classes; that is, for new classes defined by a call to `setClass` in which the `contains=` argument includes an S3 class. See the examples below. The support is aimed primarily at providing the S3 class information for all classes that extend class `oldClass`, in particular by ensuring that all objects from such classes contain the S3 class in a special slot.

There are three different ways to indicate an extension to an existing S3 class: `setOldClass()`, `setClass()` and `setIs()`. In most cases, calling `setOldClass` is the best approach, but the alternatives may be preferred in the special circumstances described below.

Suppose "A" is any class extending "oldClass". then

```
setOldClass(c("B", "A"))
```

creates a new class "B" whose S3 class concatenates "B" with `S3Class("A")`. The new class is a virtual class. If "A" was defined with known attribute/slots, then "B" has these slots also;

therefore, you must believe that the corresponding S3 objects from class "B" do indeed have the claimed attributes. Notice that you can supply an S4 definition for the new class to specify additional attributes (as described in the next section.) The first alternative call produces a non-virtual class.

```
setClass("B", contains = "A")
```

This creates a non-virtual class with the same slots and superclasses as class "A". However, class "B" is not included in the S3 class slot of the new class, unless you provide it explicitly in the prototype.

```
setClass("B"); setIs("B", "A", .....)
```

This creates a virtual class that extends "A", but does not contain the slots of "A". The additional arguments to `setIs` should provide a coerce and replacement method. In order for the new class to inherit S3 methods, the coerce method must ensure that the class "A" object produced has a suitable S3 class. The only likely reason to prefer this third approach is that class "B" is not consistent with known attributes in class "A".

S3 Classes with known attributes

A further specification of an S3 class can be made *if* the class is guaranteed to have some attributes of known class (where as with slots, “known” means that the attribute is an object of a specified class, or a subclass of that class).

In this case, the call to `setOldClass()` can supply an S4 class definition representing the known structure. Since S4 slots are implemented as attributes (largely for just this reason), the known attributes can be specified in the representation of the S4 class. The usual technique will be to create an S4 class with the desired structure, and then supply the class name or definition as the argument `S4Class` to `setOldClass()`.

See the definition of class "ts" in the examples below. The call to `setClass` to create the S4 class can use the same class name, as here, so long as the class definition is not sealed. In the example, we define "ts" as a vector structure with a numeric slot for "tsp". The validity of this definition relies on an assertion that all the S3 code for this class is consistent with that definition; specifically, that all "ts" objects will behave as vector structures and will have a numeric "tsp" attribute. We believe this to be true of all the base code in R, but as always with S3 classes, no guarantee is possible.

The S4 class definition can have virtual superclasses (as in the "ts" case) if the S3 class is asserted to behave consistently with these (in the example, time-series objects are asserted to be consistent with the `structure` class).

For another example, look at the S4 class definition for "data.frame".

Be warned that failures of the S3 class to live up to its asserted behavior will usually go uncorrected, since S3 classes inherently have no definition, and the resulting invalid S4 objects can cause all sorts of grief. Many S3 classes are not candidates for known slots, either because the presence or class of the attributes are not guaranteed (e.g., `dimnames` in arrays, although these are not even S3 classes), or because the class uses named components of a list rather than attributes (e.g., "lm"). An attribute that is sometimes missing cannot be represented as a slot, not even by pretending that it is present with class "NULL", because attributes unlike slots can not have value NULL.

One irregularity that is usually tolerated, however, is to optionally add other attributes to those guaranteed to exist (for example, "terms" in "data.frame" objects returned by `model.frame`). As of version 2.8.0, validity checks by `validObject` ignore extra attributes; even if this check is tightened in the future, classes extending S3 classes would likely be exempted because extra attributes are so common.

[setClass](#), [setMethod](#)

Examples

```
require(stats)
setOldClass(c("mlm", "lm"))
setGeneric("dfResidual", function(model) standardGeneric("dfResidual"))
setMethod("dfResidual", "lm", function(model) model$df.residual)

## dfResidual will work on mlm objects as well as lm objects
myData <- data.frame(time = 1:10, y = (1:10)^.5)
myLm <- lm(cbind(y, y^3) ~ time, myData)

## two examples extending S3 class "lm", class "xlm" directly and "ylm" indirectly
setClass("xlm", representation(eps = "numeric"), contains = "lm")
setClass("ylm", representation(header = "character"), contains = "xlm")
ym1 = new("ylm", myLm, header = "Example", eps = 0.)
## for more examples, see ?S3Class.

## Examples of S3 classes with guaranteed attributes
## an S3 class "stamped" with a vector and a "date" attribute
## Here is a generator function and an S3 print method.
## NOTE: it's essential that the generator checks the attribute classes
stamped <- function(x, date = Sys.time()) {
  if(!inherits(date, "POSIXt"))
    stop("bad date argument")
  if(!is.vector(x))
    stop("x must be a vector")
  attr(x, "date") <- date
  class(x) <- "stamped"
  x
}

print.stamped <- function(x, ...) {
  print(as.vector(x))
  cat("Date: ", format(attr(x,"date")), "\n")
}

## Now, an S4 class with the same structure:
setClass("stamped4", contains = "vector", representation(date = "POSIXt"))

## We can use the S4 class to register "stamped", with its attributes:
setOldClass("stamped", S4Class = "stamped4")
selectMethod("show", "stamped")
## and then remove "stamped4" to clean up
removeClass("stamped4")
```

```

someLetters <- stamped(sample(letters, 10), ISOdatetime(2008, 10, 15, 12, 0, 0))

st <- new("stamped", someLetters)
st # show() method prints the object's class, then calls the S3 print method.

stopifnot(identical(S3Part(st, TRUE), someLetters))

# creating the S4 object directly from its data part and slots
new("stamped", 1:10, date = ISOdatetime(1976, 5, 5, 15, 10, 0))

## Not run:
## The code in R that defines "ts" as an S4 class
setClass("ts", contains = "structure",
         representation(tsp = "numeric"),
         prototype(NA, tsp = rep(1,3))) # prototype to be a legal S3 time-series
## and now registers it as an S3 class
setOldClass("ts", S4Class = "ts", where = envir)

## End(Not run)

```

show

Show an Object

Description

Display the object, by printing, plotting or whatever suits its class. This function exists to be specialized by methods. The default method calls [showDefault](#).

Formal methods for `show` will usually be invoked for automatic printing (see the details).

Usage

```
show(object)
```

Arguments

object Any R object

Details

Objects from an S4 class (a class defined by a call to [setClass](#)) will be displayed automatically if by a call to `show`. S4 objects that occur as attributes of S3 objects will also be displayed in this form; conversely, S3 objects encountered as slots in S4 objects will be printed using the S3 convention, as if by a call to [print](#).

Methods defined for `show` will only be inherited by simple inheritance, since otherwise the method would not receive the complete, original object, with misleading results. See the [simpleInheritanceOnly](#) argument to [setGeneric](#) and the discussion in [setIs](#) for the general concept.

Value

show returns an invisible NULL.

See Also

[showMethods](#) prints all the methods for one or more functions; [showMlist](#) prints individual methods lists; [showClass](#) prints class definitions. Neither of the latter two normally needs to be called directly.

Examples

```
## following the example shown in the setMethod documentation ...
setClass("track",
  representation(x="numeric", y="numeric"))
setClass("trackCurve",
  representation("track", smooth = "numeric"))

t1 <- new("track", x=1:20, y=(1:20)^2)

tc1 <- new("trackCurve", t1)

setMethod("show", "track",
  function(object)print(rbind(x = object@x, y=object@y))
)
## The method will now be used for automatic printing of t1

t1

## Not run:
  [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10] [,11] [,12]
x    1  2  3  4  5  6  7  8  9  10  11  12
y    1  4  9 16 25 36 49 64 81 100 121 144
  [,13] [,14] [,15] [,16] [,17] [,18] [,19] [,20]
x    13  14  15  16  17  18  19  20
y   169 196 225 256 289 324 361 400
## End(Not run)
## and also for tc1, an object of a class that extends "track"
tc1

## Not run:
  [,1] [,2] [,3] [,4] [,5] [,6] [,7] [,8] [,9] [,10] [,11] [,12]
x    1  2  3  4  5  6  7  8  9  10  11  12
y    1  4  9 16 25 36 49 64 81 100 121 144
  [,13] [,14] [,15] [,16] [,17] [,18] [,19] [,20]
x    13  14  15  16  17  18  19  20
y   169 196 225 256 289 324 361 400
## End(Not run)
```

showMethods

Show all the methods for the specified function(s)

Description

Show a summary of the methods for one or more generic functions, possibly restricted to those involving specified classes.

Usage

```
showMethods(f = character(), where = topenv(parent.frame()),
            classes = NULL, includeDefs = FALSE,
            inherited = !includeDefs,
            showEmpty, printTo = stdout(), fdef =)
```

Arguments

<code>f</code>	one or more function names. If omitted, all functions will be shown that match the other arguments.
<code>where</code>	Where to find the generic function, if not supplied as an argument. When <code>f</code> is missing, or length 0, this also determines which generic functions to examine. If <code>where</code> is supplied, only the generic functions returned by <code>getGenerics(where)</code> are eligible for printing. If <code>where</code> is also missing, all the cached generic functions are considered.
<code>classes</code>	If argument <code>classes</code> is supplied, it is a vector of class names that restricts the displayed results to those methods whose signatures include one or more of those classes.
<code>includeDefs</code>	If <code>includeDefs</code> is TRUE, include the definitions of the individual methods in the printout.
<code>inherited</code>	logical indicating if methods that have been found by inheritance, so far in the session, will be included and marked as inherited. Note that an inherited method will not usually appear until it has been used in this session. See selectMethod if you want to know what method would be dispatched for particular classes of arguments.
<code>showEmpty</code>	logical indicating whether methods with no defined methods matching the other criteria should be shown at all. By default, TRUE if and only if argument <code>f</code> is not missing.
<code>printTo</code>	The connection on which the information will be shown; by default, on standard output.
<code>fdef</code>	Optionally, the generic function definition to use; if missing, one is found, looking in <code>where</code> if that is specified. See also comment in ‘Details’.

Details

The name and package of the generic are followed by the list of signatures for which methods are currently defined, according to the criteria determined by the various arguments. Note that the package refers to the source of the generic function. Individual methods for that generic can come from other packages as well.

When more than one generic function is involved, either as specified or because `f` was missing, the functions are found and `showMethods` is recalled for each, including the generic as the argument `fdef`. In complicated situations, this can avoid some anomalous results.

Value

If `printTo` is FALSE, the character vector that would have been printed is returned; otherwise the value is the connection or filename, via [invisible](#).

require(graphics)

## Assuming the methods for plot
## are set up as in the example of help(setMethod),
## print (without definitions) the methods that involve class "track":
showMethods("plot", classes = "track")
## Not run:
Function "plot":
x = ANY, y = track
x = track, y = missing
x = track, y = ANY

require("Matrix")# a CRAN package with much S4 functionality
showMethods("%*%")# many!
  methods(class = "Matrix")# nothing
showMethods(class = "Matrix")# everything
## End(Not run)

not.there <- !any("package:stats4" == search())
if(not.there) library(stats4)
showMethods(classes = "mle")
if(not.there) detach("package:stats4")
```

signature-class *Class "signature" For Method Definitions*

Description

This class represents the mapping of some of the formal arguments of a function onto the names of some classes. It is used as one of two slots in the [MethodDefinition](#) class.

Objects from the Class

Objects can be created by calls of the form `new("signature", functionDef, ...)`. The `functionDef` argument, if it is supplied as a function object, defines the formal names. The other arguments define the classes.

Slots

.Data: Object of class "character" the classes.

names: Object of class "character" the corresponding argument names.

Extends

Class "character", from data part. Class "vector", by class "character".

Methods

initialize signature(object = "signature"): see the discussion of objects from the class, above.

See Also

class [MethodDefinition](#) for the use of this class.

 slot

The Slots in an Object from a Formal Class

Description

These functions return or set information about the individual slots in an object.

Usage

```
object@name
object@name <- value

slot(object, name)
slot(object, name, check = TRUE) <- value

slotNames(x)
getSlots(x)
```

Arguments

object	An object from a formally defined class.
name	The name of the slot. The operator takes a fixed name, which can be unquoted if it is syntactically a name in the language. A slot name can be any non-empty string, but if the name is not made up of letters, numbers, and <code>.</code> , it needs to be quoted (by backticks or single or double quotes). In the case of the <code>slot</code> function, <code>name</code> can be any expression that evaluates to a valid slot in the class definition. Generally, the only reason to use the functional form rather than the simpler operator is <i>because</i> the slot name has to be computed.
value	A new value for the named slot. The value must be valid for this slot in this object's class.

check	In the replacement version of <code>slot</code> , a flag. If <code>TRUE</code> , check the assigned value for validity as the value of this slot. User's coded should not set this to <code>FALSE</code> in normal use, since the resulting object can be invalid.
x	Either the name of a class or a class definition. If given an argument that is neither a character string nor a class definition, <code>slotNames</code> (only) uses <code>class(x)</code> instead.

Details

The definition of the class specifies all slots directly and indirectly defined for that class. Each slot has a name and an associated class. Extracting a slot returns an object from that class. Setting a slot first coerces the value to the specified slot and then stores it.

Unlike general attributes, slots are not partially matched, and asking for (or trying to set) a slot with an invalid name for that class generates an error.

The `@` extraction operator and `slot` function themselves do no checking against the class definition, simply matching the name in the object itself. The replacement forms do check (except for `slot` in the case `check=FALSE`). So long as slots are set without cheating, the extracted slots will be valid.

Be aware that there are two ways to cheat, both to be avoided but with no guarantees. The obvious way is to assign a slot with `check=FALSE`. Also, slots in R are implemented as attributes, for the sake of some back compatibility. The current implementation does not prevent attributes being assigned, via `attr<-`, and such assignments are not checked for legitimate slot names.

Value

The `"@"` operator and the `slot` function extract or replace the formally defined slots for the object. Functions `slotNames` and `getSlots` return respectively the names of the slots and the classes associated with the slots in the specified class definition. Except for its extended interpretation of `x` (above), `slotNames(x)` is just `names(getSlots(x))`.

slotNames(myTrack)
```

StructureClasses *Classes Corresponding to Basic Structures*

Description

The virtual class `structure` and classes that extend it are formal classes analogous to S language structures such as arrays and time-series.

Usage

```
## The following class names can appear in method signatures,
## as the class in as() and is() expressions, and, except for
## the classes commented as VIRTUAL, in calls to new()
```

```
"matrix"
"array"
"ts"

"structure" ## VIRTUAL
```

Objects from the Classes

Objects can be created by calls of the form `new(Class, ...)`, where `Class` is the quoted name of the specific class (e.g., `"matrix"`), and the other arguments, if any, are interpreted as arguments to the corresponding function, e.g., to function `matrix()`. There is no particular advantage over calling those functions directly, unless you are writing software designed to work for multiple classes, perhaps with the class name and the arguments passed in.

Objects created from the classes `"matrix"` and `"array"` are unusual, to put it mildly, and have been for some time. Although they may appear to be objects from these classes, they do not have the internal structure of either an S3 or S4 class object. In particular, they have no `"class"` attribute and are not recognized as objects with classes (that is, both `is.object` and `isS4` will return `FALSE` for such objects).

That the objects still behave as if they came from the corresponding class (most of the time, anyway) results from special code recognizing such objects being built into the base code of R. For most purposes, treating the classes in the usual way will work, fortunately. One consequence of the special treatment is that these two classes *may* be used as the data part of an S4 class; for example, you can get away with `contains = "matrix"` in a call to `setGeneric` to create an S4 class that is a subclass of `"matrix"`. There is no guarantee that everything will work perfectly, but a number of classes have been written in this form successfully.

The class `"ts"` is basically an S3 class that has been registered with S4, using the `setOldClass` mechanism. Versions of R through 2.7.0 treated this class as a pure S4 class, which was in principal a good idea, but in practice did not allow subclasses to be defined and had other intrinsic problems. (For example, setting the `"tsp"` parameters as a slot often fails because the built-in implementation does not allow the slot to be temporarily inconsistent with the length of the data. Also, the S4 class prevented the correct specification of the S3 inheritance for class `"mts"`.)

The current behavior (beginning with version 2.8.0 of R) registers `"ts"` as an S3 class, using an S4-style definition (see the documentation for `setOldClass` in the examples section for an

abbreviated listing of how this is done. The S3 inheritance of "mts" in package `stats` is also registered. These classes, as well as "matrix" and "array" should be valid in most examples as superclasses for new S4 class definitions.

Extends

The specific classes all extend class "structure", directly, and class "vector", by class "structure".

Methods

coerce Methods are defined to coerce arbitrary objects to these classes, by calling the corresponding basic function, for example, `as(x, "matrix")` calls `as.matrix(x)`.

Ops, Math Group methods (see, e.g., [S4groupGeneric](#)) are defined for combinations of structures and vectors (including special cases for array and matrix), implementing the concept of vector structures as in the reference.

References

Chambers, John M. (2008) *Software for Data Analysis: Programming with R* Springer. (For the R version.)

Chambers, John M. (1998) *Programming with Data* Springer (For the original S4 version.)

Becker, R. A., Chambers, J. M. and Wilks, A. R. (1988) *The New S Language*. Wadsworth & Brooks/Cole (for the original vector structures).

Examples

```
showClass("structure")

## explore a bit :
showClass("ts")
(ts0 <- new("ts"))
str(ts0)

showMethods("Ops") # six methods from these classes, but maybe many more
```

TraceClasses

Classes Used Internally to Control Tracing

Description

The classes described here are used by the R function `trace` to create versions of functions and methods including browser calls, etc., and also to `untrace` the same objects.

Usage

```
### Objects from the following classes are generated
### by calling trace() on an object from the corresponding
### class without the "WithTrace" in the name.

"functionWithTrace"
```

```

"MethodDefinitionWithTrace"
"MethodWithNextWithTrace"
"genericFunctionWithTrace"
"groupGenericFunctionWithTrace"

### the following is a virtual class extended by each of the
### classes above

"traceable"

```

Objects from the Class

Objects will be created from these classes by calls to `trace`. (There is an `initialize` method for class `"traceable"`, but you are unlikely to need it directly.)

Slots

.Data: The data part, which will be `"function"` for class `"functionWithTrace"`, and similarly for the other classes.

original: Object of the original class; e.g., `"function"` for class `"functionWithTrace"`.

Extends

Each of the classes extends the corresponding untraced class, from the data part; e.g., `"functionWithTrace"` extends `"function"`. Each of the specific classes extends `"traceable"`, directly, and class `"VIRTUAL"`, by class `"traceable"`.

Methods

The point of the specific classes is that objects generated from them, by function `trace()`, remain callable or dispatchable, in addition to their new trace information.

See Also

function `trace`

validObject

Test the Validity of an Object

Description

The validity of `object` related to its class definition is tested. If the object is valid, `TRUE` is returned; otherwise, either a vector of strings describing validity failures is returned, or an error is generated (according to whether `test` is `TRUE`). Optionally, all slots in the object can also be validated.

The function `setValidity` sets the validity method of a class (but more normally, this method will be supplied as the `validity` argument to `setClass`). The method should be a function of one object that returns `TRUE` or a description of the non-validity.

Usage

```
validObject(object, test = FALSE, complete = FALSE)

setValidity(Class, method, where = toplevel(parent.frame()) )

getValidity(ClassDef)
```

Arguments

object	any object, but not much will happen unless the object's class has a formal definition.
test	logical; if TRUE and validity fails, the function returns a vector of strings describing the problems. If test is FALSE (the default) validity failure generates an error.
complete	logical; if TRUE, validity methods will be applied recursively to any of the slots that have such methods.
Class	the name or class definition of the class whose validity method is to be set.
ClassDef	a class definition object, as from getClassDef .
method	a validity method; that is, either NULL or a function of one argument (object). Like validObject, the function should return TRUE if the object is valid, and one or more descriptive strings if any problems are found. Unlike validObject, it should never generate an error.
where	the modified class definition will be stored in this environment.

Note that validity methods do not have to check validity of superclasses: the logic of validObject ensures these tests are done once only. As a consequence, if one validity method wants to use another, it should extract and call the method from the other definition of the other class by calling `getValidity()`: it should *not* call `validObject`.

Details

Validity testing takes place 'bottom up': Optionally, if `complete=TRUE`, the validity of the object's slots, if any, is tested. Then, in all cases, for each of the classes that this class extends (the 'superclasses'), the explicit validity method of that class is called, if one exists. Finally, the validity method of object's class is called, if there is one.

Testing generally stops at the first stage of finding an error, except that all the slots will be examined even if a slot has failed its validity test.

The standard validity test (with `complete=FALSE`) is applied when an object is created via `new` with any optional arguments (without the extra arguments the result is just the class prototype object).

An attempt is made to fix up the definition of a validity method if its argument is not object.

Value

`validObject` returns TRUE if the object is valid. Otherwise a vector of strings describing problems found, except that if test is FALSE, validity failure generates an error, with the corresponding strings in the error message.

`setClass`; class `classRepresentation`.

Examples

```

setClass("track",
         representation(x="numeric", y = "numeric"))
t1 <- new("track", x=1:10, y=sort(stats::rnorm(10)))
## A valid "track" object has the same number of x, y values
validTrackObject <- function(object) {
  if(length(object@x) == length(object@y)) TRUE
  else paste("Unequal x,y lengths: ", length(object@x), ", ",
            length(object@y), sep="")
}
## assign the function as the validity method for the class
setValidity("track", validTrackObject)
## t1 should be a valid "track" object
validObject(t1)
## Now we do something bad
t2 <- t1
t2@x <- 1:20
## This should generate an error
## Not run: try(validObject(t2))

setClass("trackCurve",
         representation("track", smooth = "numeric"))

## all superclass validity methods are used when validObject
## is called from initialize() with arguments, so this fails
## Not run: trynew("trackCurve", t2)

setClass("twoTrack", representation(tr1 = "track", tr2 = "track"))

## validity tests are not applied recursively by default,
## so this object is created (invalidly)
tT <- new("twoTrack", tr2 = t2)

## A stricter test detects the problem
## Not run: try(validObject(tT, complete = TRUE))

.checkMFClasses

Functions to Check the Type of Variables passed to Model Frames

Description

`.checkMFClasses` checks if the variables used in a predict method agree in type with those used for fitting.

`.MFclass` categorizes variables for this purpose.

Usage

```
.checkMFClasses(cl, m, ordNotOK = FALSE)
.MFclass(x)
.getXlevels(Terms, m)
```

Arguments

<code>cl</code>	a character vector of class descriptions to match.
<code>m</code>	a model frame.
<code>x</code>	any R object.
<code>ordNotOK</code>	logical: are ordered factors different?
<code>Terms</code>	a terms object.

Details

For applications involving `model.matrix` such as linear models we do not need to differentiate between ordered factors and factors as although these affect the coding, the coding used in the fit is already recorded and imposed during prediction. However, other applications may treat ordered factors differently: `rpart` does, for example.

Value

`.MFclass` returns a character string, one of "logical", "ordered", "factor", "numeric", "nmatrix.*" (a numeric matrix with a number of columns appended) or "other".

`.getXlevels` returns a named character vector, or NULL.

 acf

Auto- and Cross- Covariance and -Correlation Function Estimation

Description

The function `acf` computes (and by default plots) estimates of the autocovariance or autocorrelation function. Function `pacf` is the function used for the partial autocorrelations. Function `ccf` computes the cross-correlation or cross-covariance of two univariate series.

Usage

```
acf(x, lag.max = NULL,
    type = c("correlation", "covariance", "partial"),
    plot = TRUE, na.action = na.fail, demean = TRUE, ...)

pacf(x, lag.max, plot, na.action, ...)

## Default S3 method:
pacf(x, lag.max = NULL, plot = TRUE, na.action = na.fail,
     ...)

ccf(x, y, lag.max = NULL, type = c("correlation", "covariance"),
    plot = TRUE, na.action = na.fail, ...)

## S3 method for class 'acf':
x[i, j]
```

Arguments

<code>x, y</code>	a univariate or multivariate (not <code>ccf</code>) numeric time series object or a numeric vector or matrix, or an "acf" object.
<code>lag.max</code>	maximum lag at which to calculate the acf. Default is $10 \log_{10}(N/m)$ where N is the number of observations and m the number of series. Will be automatically limited to one less than the number of observations in the series.
<code>type</code>	character string giving the type of acf to be computed. Allowed values are "correlation" (the default), "covariance" or "partial".
<code>plot</code>	logical. If TRUE (the default) the acf is plotted.
<code>na.action</code>	function to be called to handle missing values. <code>na.pass</code> can be used.
<code>demean</code>	logical. Should the covariances be about the sample means?
<code>...</code>	further arguments to be passed to <code>plot.acf</code> .
<code>i</code>	a set of lags (time differences) to retain.
<code>j</code>	a set of series (names or numbers) to retain.

Details

For `type = "correlation"` and `"covariance"`, the estimates are based on the sample covariance. (The lag 0 autocorrelation is fixed at 1 by convention.)

By default, no missing values are allowed. If the `na.action` function passes through missing values (as `na.pass` does), the covariances are computed from the complete cases. This means that the estimate computed may well not be a valid autocorrelation sequence, and may contain missing values. Missing values are not allowed when computing the PACF of a multivariate time series.

The partial correlation coefficient is estimated by fitting autoregressive models of successively higher orders up to `lag.max`.

The generic function `plot` has a method for objects of class "acf".

The lag is returned and plotted in units of time, and not numbers of observations.

There are `print` and subsetting methods for objects of class "acf".

Value

An object of class "acf", which is a list with the following elements:

<code>lag</code>	A three dimensional array containing the lags at which the acf is estimated.
<code>acf</code>	An array with the same dimensions as <code>lag</code> containing the estimated acf.
<code>type</code>	The type of correlation (same as the <code>type</code> argument).
<code>n.used</code>	The number of observations in the time series.
<code>series</code>	The name of the series x .
<code>snames</code>	The series names for a multivariate time series.

The lag k value returned by `ccf(x, y)` estimates the correlation between $x[t+k]$ and $y[t]$.

The result is returned invisibly if `plot` is TRUE.

require(graphics)

## Examples from Venables & Ripley
acf(lh)
acf(lh, type = "covariance")
pacf(lh)

acf(ldeaths)
acf(ldeaths, ci.type = "ma")
acf(ts.union(mdeaths, fdeaths))
ccf(mdeaths, fdeaths, ylab = "cross-correlation")
# (just the cross-correlations)

presidents # contains missing values
acf(presidents, na.action = na.pass)
pacf(presidents, na.action = na.pass)
```

acf2AR

Compute an AR Process Exactly Fitting an ACF

Description

Compute an AR process exactly fitting an autocorrelation function.

Usage

```
acf2AR(acf)
```

Arguments

`acf` An autocorrelation or autocovariance sequence.

Value

A matrix, with one row for the computed AR(p) coefficients for $1 \leq p \leq \text{length}(\text{acf})$.

See Also

[ARMAacf](#), [ar.yw](#) which does this from an empirical ACF.

Examples

```
(Acf <- ARMAacf(c(0.6, 0.3, -0.2)))
acf2AR(Acf)
```

add1

Add or Drop All Possible Single Terms to a Model

Description

Compute all the single terms in the `scope` argument that can be added to or dropped from the model, fit those models and compute a table of the changes in fit.

Usage

```
add1(object, scope, ...)

## Default S3 method:
add1(object, scope, scale = 0, test = c("none", "Chisq"),
      k = 2, trace = FALSE, ...)

## S3 method for class 'lm':
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),
      x = NULL, k = 2, ...)

## S3 method for class 'glm':
add1(object, scope, scale = 0, test = c("none", "Chisq", "F"),
      x = NULL, k = 2, ...)

drop1(object, scope, ...)

## Default S3 method:
drop1(object, scope, scale = 0, test = c("none", "Chisq"),
       k = 2, trace = FALSE, ...)

## S3 method for class 'lm':
drop1(object, scope, scale = 0, all.cols = TRUE,
       test = c("none", "Chisq", "F"), k = 2, ...)

## S3 method for class 'glm':
drop1(object, scope, scale = 0, test = c("none", "Chisq", "F"),
       k = 2, ...)
```

Arguments

<code>object</code>	a fitted model object.
<code>scope</code>	a formula giving the terms to be considered for adding or dropping.
<code>scale</code>	an estimate of the residual mean square to be used in computing C_p . Ignored if 0 or NULL.

<code>test</code>	should the results include a test statistic relative to the original model? The F test is only appropriate for <code>lm</code> and <code>aov</code> models or perhaps for <code>glm</code> fits with estimated dispersion. The χ^2 test can be an exact test (<code>lm</code> models with known scale) or a likelihood-ratio test or a test of the reduction in scaled deviance depending on the method.
<code>k</code>	the penalty constant in AIC / C_p .
<code>trace</code>	if TRUE, print out progress reports.
<code>x</code>	a model matrix containing columns for the fitted model and all terms in the upper scope. Useful if <code>add1</code> is to be called repeatedly. Warning: no checks are done on its validity.
<code>all.cols</code>	(Provided for compatibility with S.) Logical to specify whether all columns of the design matrix should be used. If FALSE then non-estimable columns are dropped, but the result is not usually statistically meaningful.
<code>...</code>	further arguments passed to or from other methods.

Details

For `drop1` methods, a missing `scope` is taken to be all terms in the model. The hierarchy is respected when considering terms to be added or dropped: all main effects contained in a second-order interaction must remain, and so on.

In a `scope` formula `.` means ‘what is already there’.

The methods for `lm` and `glm` are more efficient in that they do not recompute the model matrix and call the `fit` methods directly.

The default output table gives AIC, defined as minus twice log likelihood plus $2p$ where p is the rank of the model (the number of effective parameters). This is only defined up to an additive constant (like log-likelihoods). For linear Gaussian models with fixed scale, the constant is chosen to give Mallows’ C_p , $RSS/scale + 2p - n$. Where C_p is used, the column is labelled as C_p rather than AIC.

The F tests for the "`glm`" methods are based on analysis of deviance tests, so if the dispersion is estimated it is based on the residual deviance, unlike the F tests of `anova.glm`.

Value

An object of class "`anova`" summarizing the differences in fit between the models.

Warning

The model fitting must apply the models to the same dataset. Most methods will attempt to use a subset of the data with no missing values for any of the variables if `na.action=na.omit`, but this may give biased results. Only use these functions with data containing missing values with great care.

Note

These are not fully equivalent to the functions in S. There is no `keep` argument, and the methods used are not quite so computationally efficient.

Their authors’ definitions of Mallows’ C_p and Akaike’s AIC are used, not those of the authors of the models chapter of S.

Author(s)

The design was inspired by the S functions of the same names described in Chambers (1992).

example(glm)
drop1(glm.D93, test="Chisq")
drop1(glm.D93, test="F")
```

 addmargins

Puts Arbitrary Margins on Multidimensional Tables or Arrays

Description

For a given table one can specify which of the classifying factors to expand by one or more levels to hold margins to be calculated. One may for example form sums and means over the first dimension and medians over the second. The resulting table will then have two extra levels for the first dimension and one extra level for the second. The default is to sum over all margins in the table. Other possibilities may give results that depend on the order in which the margins are computed. This is flagged in the printed output from the function.

Usage

```
addmargins(A, margin = 1:length(dim(A)), FUN = sum, quiet = FALSE)
```

Arguments

A	table or array. The function uses the presence of the "dim" and "dimnames" attributes of A.
margin	vector of dimensions over which to form margins. Margins are formed in the order in which dimensions are specified in margin.
FUN	list of the same length as margin, each element of the list being either a function or a list of functions. Names of the list elements will appear as levels in dimnames of the result. Unnamed list elements will have names constructed: the name of a function or a constructed name based on the position in the table.
quiet	logical which suppresses the message telling the order in which the margins were computed.

Details

If the functions used to form margins are not commutative the result depends on the order in which margins are computed. Annotation of margins is done via naming the FUN list.

Value

A table or array with the same number of dimensions as A, but with extra levels of the dimensions mentioned in margin. The number of levels added to each dimension is the length of the entries in FUN. A message with the order of computation of margins is printed.

x <- sample( 1:7, 20, replace=TRUE)
y <- sample( 1:7, 20, replace=TRUE)
tx <- addmargins( table(x, y) )
print(tx, zero.print = ".")
```

 aggregate

Compute Summary Statistics of Data Subsets

Description

Splits the data into subsets, computes summary statistics for each, and returns the result in a convenient form.

Usage

```
aggregate(x, ...)

## Default S3 method:
aggregate(x, ...)

## S3 method for class 'data.frame':
aggregate(x, by, FUN, ...)

## S3 method for class 'ts':
aggregate(x, nfrequency = 1, FUN = sum, ndeltat = 1,
          ts.eps = getOption("ts.eps"), ...)
```

Arguments

<code>x</code>	an R object.
<code>by</code>	a list of grouping elements, each as long as the variables in <code>x</code> .
<code>FUN</code>	a scalar function to compute the summary statistics which can be applied to all data subsets.
<code>nfrequency</code>	new number of observations per unit of time; must be a divisor of the frequency of <code>x</code> .
<code>ndeltat</code>	new fraction of the sampling period between successive observations; must be a divisor of the sampling interval of <code>x</code> .
<code>ts.eps</code>	tolerance used to decide if <code>nfrequency</code> is a sub-multiple of the original frequency.
<code>...</code>	further arguments passed to or used by methods.

Details

`aggregate` is a generic function with methods for data frames and time series.

The default method `aggregate.default` uses the time series method if `x` is a time series, and otherwise coerces `x` to a data frame and calls the data frame method.

`aggregate.data.frame` is the data frame method. If `x` is not a data frame, it is coerced to one, which must have a non-zero number of rows. Then, each of the variables (columns) in `x` is split into subsets of cases (rows) of identical combinations of the components of `by`, and `FUN` is applied to each such subset with further arguments in `...` passed to it. (I.e., `tapply(VAR, by, FUN, ..., simplify = FALSE)` is done for each variable `VAR` in `x`, conveniently wrapped into one call to `lapply()`.) Empty subsets are removed, and the result is reformatted into a data frame containing the variables in `by` and `x`. The ones arising from `by` contain the unique combinations of grouping values used for determining the subsets, and the ones arising from `x` the corresponding

summary statistics for the subset of the respective variables in `x`. Rows with missing values in any of the `by` variables will be omitted from the result.

`aggregate.ts` is the time series method. If `x` is not a time series, it is coerced to one. Then, the variables in `x` are split into appropriate blocks of length `frequency(x) / nfrequency`, and `FUN` is applied to each such block, with further (named) arguments in `...` passed to it. The result returned is a time series with `frequency nfrequency` holding the aggregated values. Note that this make most sense for a quarterly or yearly result when the original series covers a whole number of quarters or years: in particular aggregating a monthly series to quarters starting in February does not give a conventional quarterly series.

Value

For the time series method, a time series of class `"ts"` or class `c("mts", "ts")`.

For the data frame method, a data frame with columns corresponding to the grouping variables in `by` followed by aggregated columns from `x`. If the `by` has names, the non-empty times are used to label the columns in the results, with unnamed grouping variables being named `Group.i` for `by[[i]]`.

Note: prior to R 2.6.0 the grouping variables were reported as factors with levels in alphabetical order in the current locale. Now the variable in the result is found by subsetting the original variable.

## Compute the average annual approval ratings for American presidents.
aggregate(presidents, nfrequency = 1, FUN = mean)
## Give the summer less weight.
aggregate(presidents, nfrequency = 1,
          FUN = weighted.mean, w = c(1, 1, 0.5, 1))
```

AIC

Akaike's An Information Criterion

Description

Generic function calculating the Akaike information criterion for one or several fitted model objects for which a log-likelihood value can be obtained, according to the formula $-2\log\text{-likelihood} + kn_{par}$, where n_{par} represents the number of parameters in the fitted model, and $k = 2$ for the usual AIC, or $k = \log(n)$ (n the number of observations) for the so-called BIC or SBC (Schwarz's Bayesian criterion).

Usage

```
AIC(object, ..., k = 2)
```

Arguments

object	a fitted model object, for which there exists a <code>logLik</code> method to extract the corresponding log-likelihood, or an object inheriting from class <code>logLik</code> .
...	optionally more fitted model objects.
k	numeric, the <i>penalty</i> per parameter to be used; the default $k = 2$ is the classical AIC.

Details

The default method for AIC, `AIC.default()` entirely relies on the existence of a `logLik` method computing the log-likelihood for the given class.

When comparing fitted objects, the smaller the AIC, the better the fit.

The log-likelihood and hence the AIC is only defined up to an additive constant. Different constants have conventionally be used for different purposes and so `extractAIC` and `AIC` may give different values (and do for models of class `"lm"`: see the help for `extractAIC`).

Value

If just one object is provided, returns a numeric value with the corresponding AIC (or BIC, or ..., depending on k); if multiple objects are provided, returns a `data.frame` with rows corresponding to the objects and columns representing the number of parameters in the model (`df`) and the AIC.

Author(s)

Jose Pinheiro and Douglas Bates

Examples

```
lm1 <- lm(Fertility ~ . , data = swiss)
AIC(lm1)
stopifnot(all.equal(AIC(lm1),
                    AIC(logLik(lm1))))
## a version of BIC or Schwarz' BC :
AIC(lm1, k = log(nrow(swiss)))
```

alias

Find Aliases (Dependencies) in a Model

Description

Find aliases (linearly dependent terms) in a linear model specified by a formula.

Usage

```
alias(object, ...)

## S3 method for class 'formula':
alias(object, data, ...)

## S3 method for class 'lm':
alias(object, complete = TRUE, partial = FALSE,
      partial.pattern = FALSE, ...)
```

Arguments

object	A fitted model object, for example from <code>lm</code> or <code>aov</code> , or a formula for <code>alias.formula</code> .
data	Optionally, a data frame to search for the objects in the formula.
complete	Should information on complete aliasing be included?
partial	Should information on partial aliasing be included?
partial.pattern	Should partial aliasing be presented in a schematic way? If this is done, the results are presented in a more compact way, usually giving the deciles of the coefficients.
...	further arguments passed to or from other methods.

Details

Although the main method is for class "lm", `alias` is most useful for experimental designs and so is used with fits from `aov`. Complete aliasing refers to effects in linear models that cannot be estimated independently of the terms which occur earlier in the model and so have their coefficients omitted from the fit. Partial aliasing refers to effects that can be estimated less precisely because of correlations induced by the design.

Value

A list (of class "listof") containing components

Model Description of the model; usually the formula.

Complete A matrix with columns corresponding to effects that are linearly dependent on the rows.

Partial The correlations of the estimable effects, with a zero diagonal. An object of class "mtable" which has its own `print` method.

Note

The aliasing pattern may depend on the contrasts in use: Helmert contrasts are probably most useful. The defaults are different from those in S.

Author(s)

The design was inspired by the S function of the same name described in Chambers *et al.* (1992).

Chambers, J. M., Freeny, A and Heiberger, R. M. (1992) *Analysis of variance; designed experiments*. Chapter 5 of *Statistical Models in S* eds J. M. Chambers and T. J. Hastie, Wadsworth & Brooks/Cole.

Examples

```
## From Venables and Ripley (2002) p.165.
utils::data(npk, package="MASS")

op <- options(contrasts=c("contr.helmert", "contr.poly"))
npk.aov <- aov(yield ~ block + N*P*K, npk)
alias(npk.aov)
options(op) # reset
```

anova

Anova Tables

Description

Compute analysis of variance (or deviance) tables for one or more fitted model objects.

Usage

```
anova(object, ...)
```

Arguments

`object` an object containing the results returned by a model fitting function (e.g., `lm` or `glm`).

`...` additional objects of the same type.

Value

This (generic) function returns an object of class `anova`. These objects represent analysis-of-variance and analysis-of-deviance tables. When given a single argument it produces a table which tests whether the model terms are significant.

When given a sequence of objects, `anova` tests the models against one another in the order specified.

The print method for `anova` objects prints tables in a ‘pretty’ form.

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and `R`’s default of `na.action = na.omit` is used.

anova.glm

Analysis of Deviance for Generalized Linear Model Fits

Description

Compute an analysis of deviance table for one or more generalized linear model fits.

Usage

```
## S3 method for class 'glm':
anova(object, ..., dispersion = NULL, test = NULL)
```

Arguments

`object, ...` objects of class `glm`, typically the result of a call to `glm`, or a list of objects for the `"glm.list"` method.

`dispersion` the dispersion parameter for the fitting family. By default it is obtained from the object(s).

`test` a character string, (partially) matching one of `"Chisq"`, `"F"` or `"Cp"`. See [stat.anova](#).

Details

Specifying a single object gives a sequential analysis of deviance table for that fit. That is, the reductions in the residual deviance as each term of the formula is added in turn are given in as the rows of a table, plus the residual deviances themselves.

If more than one object is specified, the table has a row for the residual degrees of freedom and deviance for each model. For all but the first model, the change in degrees of freedom and deviance is also given. (This only makes statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

The table will optionally contain test statistics (and P values) comparing the reduction in deviance for the row to the residuals. For models with known dispersion (e.g., binomial and Poisson fits) the chi-squared test is most appropriate, and for those with dispersion estimated by moments (e.g., gaussian, quasibinomial and quasipoisson fits) the F test is most appropriate. Mallows' C_p statistic is the residual deviance plus twice the estimate of σ^2 times the residual degrees of freedom, which is closely related to AIC (and a multiple of it if the dispersion is known).

The dispersion estimate will be taken from the largest model, using the value returned by [summary.glm](#). As this will in most cases use a Chisquared-based estimate, the F tests are not based on the residual deviance in the analysis of deviance table shown.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models by `anova` or `anova.glm` will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used, and `anova.glm` will detect this with an error.

See Also

[glm](#), [anova](#).

[drop1](#) for so-called 'type II' anova where each term is dropped one at a time respecting their hierarchy.

Examples

```
## --- Continuing the Example from '?glm':  
  
anova(glm.D93)  
anova(glm.D93, test = "Cp")  
anova(glm.D93, test = "Chisq")
```

 anova.lm

 ANOVA for Linear Model Fits

Description

Compute an analysis of variance table for one or more linear model fits.

Usage

```
## S3 method for class 'lm':
anova(object, ...)

anova.lmlist(object, ..., scale = 0, test = "F")
```

Arguments

`object, ...` objects of class `lm`, usually, a result of a call to `lm`.

`test` a character string specifying the test statistic to be used. Can be one of "F", "Chisq" or "Cp", with partial matching allowed, or NULL for no test.

`scale` numeric. An estimate of the noise variance σ^2 . If zero this will be estimated from the largest model considered.

Details

Specifying a single object gives a sequential analysis of variance table for that fit. That is, the reductions in the residual sum of squares as each term of the formula is added in turn are given in as the rows of a table, plus the residual sum of squares.

The table will contain F statistics (and P values) comparing the mean square for the row to the residual mean square.

If more than one object is specified, the table has a row for the residual degrees of freedom and sum of squares for each model. For all but the first model, the change in degrees of freedom and sum of squares is also given. (This only make statistical sense if the models are nested.) It is conventional to list the models from smallest to largest, but this is up to the user.

Optionally the table can include test statistics. Normally the F statistic is most appropriate, which compares the mean square for a row to the residual sum of squares for the largest model considered. If `scale` is specified chi-squared tests can be used. Mallows' C_p statistic is the residual sum of squares plus twice the estimate of σ^2 times the residual degrees of freedom.

Value

An object of class "anova" inheriting from class "data.frame".

Warning

The comparison between two or more models will only be valid if they are fitted to the same dataset. This may be a problem if there are missing values and R's default of `na.action = na.omit` is used, and `anova.lmlist` will detect this with an error.

Note

Versions of R prior to 1.2.0 based F tests on pairwise comparisons, and this behaviour can still be obtained by a direct call to `anova.list.lm`.

`drop1` for so-called ‘type II’ anova where each term is dropped one at a time respecting their hierarchy.

Examples

```
## sequential table
fit <- lm(sr ~ ., data = LifeCycleSavings)
anova(fit)

## same effect via separate models
fit0 <- lm(sr ~ 1, data = LifeCycleSavings)
fit1 <- update(fit0, . ~ . + pop15)
fit2 <- update(fit1, . ~ . + pop75)
fit3 <- update(fit2, . ~ . + dpi)
fit4 <- update(fit3, . ~ . + ddpi)
anova(fit0, fit1, fit2, fit3, fit4, test="F")

anova(fit4, fit2, fit0, test="F") # unconventional order
```

anova.mlm

Comparisons between Multivariate Linear Models

Description

Compute a (generalized) analysis of variance table for one or more multivariate linear models.

Usage

```
## S3 method for class 'mlm':
anova(object, ...,
       test =
         c("Pillai", "Wilks", "Hotelling-Lawley", "Roy", "Spherical"),
       Sigma = diag(nrow = p), T = Thin.row(proj(M) - proj(X)),
       M = diag(nrow = p), X = ~0,
       idata = data.frame(index = seq_len(p)), tol = 1e-7)
```

Arguments

object	an object of class "mlm".
...	further objects of class "mlm".
test	choice of test statistic (see below).
Sigma	(only relevant if <code>test == "Spherical"</code>). Covariance matrix assumed proportional to Sigma.
T	transformation matrix. By default computed from M and X.
M	formula or matrix describing the outer projection (see below).
X	formula or matrix describing the inner projection (see below).
idata	data frame describing intra-block design.
tol	tolerance to be used in deciding if the residuals are rank-deficient: see qr .

Details

The `anova.mlm` method uses either a multivariate test statistic for the summary table, or a test based on sphericity assumptions (i.e. that the covariance is proportional to a given matrix).

For the multivariate test, Wilks' statistic is most popular in the literature, but the default Pillai–Bartlett statistic is recommended by Hand and Taylor (1987). See [summary.manova](#) for further details.

For the "Spherical" test, proportionality is usually with the identity matrix but a different matrix can be specified using `Sigma`). Corrections for asphericity known as the Greenhouse–Geisser, respectively Huynh–Feldt, epsilons are given and adjusted F tests are performed.

It is common to transform the observations prior to testing. This typically involves transformation to intra-block differences, but more complicated within-block designs can be encountered, making more elaborate transformations necessary. A transformation matrix `T` can be given directly or specified as the difference between two projections onto the spaces spanned by `M` and `X`, which in turn can be given as matrices or as model formulas with respect to `idata` (the tests will be invariant to parametrization of the quotient space M/X).

As with `anova.lm`, all test statistics use the SSD matrix from the largest model considered as the (generalized) denominator.

Contrary to other `anova` methods, the intercept is not excluded from the display in the single-model case. When contrast transformations are involved, it often makes good sense to test for a zero intercept.

Value

An object of class "anova" inheriting from class "data.frame"

Note

The Huynh–Feldt epsilon differs from that calculated by SAS (as of v. 8.2) except when the DF is equal to the number of observations minus one. This is believed to be a bug in SAS, not in R.

      idata = idata, test="Spherical" )

f <- factor(rep(1:2,5)) # bogus, just for illustration
mlmfit2 <- update(mlmfit, ~f)
anova(mlmfit2, mlmfit, mlmfit0, X = ~1, test = "Spherical")
anova(mlmfit2, X = ~1, test = "Spherical")
# one-model form, equiv. to previous

### There seems to be a strong interaction in these data
plot(colMeans(reacttime))
```

ansari.test

Ansari-Bradley Test

Description

Performs the Ansari-Bradley two-sample test for a difference in scale parameters.

Usage

```
ansari.test(x, ...)

## Default S3 method:
ansari.test(x, y,
            alternative = c("two.sided", "less", "greater"),
            exact = NULL, conf.int = FALSE, conf.level = 0.95,
            ...)
```

```
## S3 method for class 'formula':
ansari.test(formula, data, subset, na.action, ...)
```

Arguments

<code>x</code>	numeric vector of data values.
<code>y</code>	numeric vector of data values.
<code>alternative</code>	indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter.
<code>exact</code>	a logical indicating whether an exact p-value should be computed.
<code>conf.int</code>	a logical, indicating whether a confidence interval should be computed.
<code>conf.level</code>	confidence level of the interval.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> is a numeric variable giving the data values and <code>rhs</code> a factor with two levels giving the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

Suppose that x and y are independent samples from distributions with densities $f((t - m)/s)/s$ and $f(t - m)$, respectively, where m is an unknown nuisance parameter and s , the ratio of scales, is the parameter of interest. The Ansari-Bradley test is used for testing the null that s equals 1, the two-sided alternative being that $s \neq 1$ (the distributions differ only in variance), and the one-sided alternatives being $s > 1$ (the distribution underlying x has a larger variance, "greater") or $s < 1$ ("less").

By default (if `exact` is not specified), an exact p-value is computed if both samples contain less than 50 finite values and there are no ties. Otherwise, a normal approximation is used.

Optionally, a nonparametric confidence interval and an estimator for s are computed. If exact p-values are available, an exact confidence interval is obtained by the algorithm described in Bauer (1972), and the Hodges-Lehmann estimator is employed. Otherwise, the returned confidence interval and point estimate are based on normal approximations.

Note that mid-ranks are used in the case of ties rather than average scores as employed in Hollander & Wolfe (1973). See, e.g., Hajek, Sidak and Sen (1999), pages 131ff, for more information.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value of the Ansari-Bradley test statistic.
<code>p.value</code>	the p-value of the test.
<code>null.value</code>	the ratio of scales s under the null, 1.
<code>alternative</code>	a character string describing the alternative hypothesis.

method	the string "Ansari-Bradley test".
data.name	a character string giving the names of the data.
conf.int	a confidence interval for the scale parameter. (Only present if argument conf.int = TRUE.)
estimate	an estimate of the ratio of scales. (Only present if argument conf.int = TRUE.)

Note

To compare results of the Ansari-Bradley test to those of the F test to compare two variances (under the assumption of normality), observe that s is the ratio of scales and hence s^2 is the ratio of variances (provided they exist), whereas for the F test the ratio of variances itself is the parameter of interest. In particular, confidence intervals are for s in the Ansari-Bradley test but for s^2 in the F test.

## try more points - failed in 2.4.1
ansari.test(rnorm(100), rnorm(100, 0, 2), conf.int = TRUE)
```

Description

Fit an analysis of variance model by a call to `lm` for each stratum.

Usage

```
aov(formula, data = NULL, projections = FALSE, qr = TRUE,
     contrasts = NULL, ...)
```

Arguments

<code>formula</code>	A formula specifying the model.
<code>data</code>	A data frame in which the variables specified in the formula will be found. If missing, the variables are searched for in the standard way.
<code>projections</code>	Logical flag: should the projections be returned?
<code>qr</code>	Logical flag: should the QR decomposition be returned?
<code>contrasts</code>	A list of contrasts to be used for some of the factors in the formula. These are not used for any <code>Error</code> term, and supplying contrasts for factors only in the <code>Error</code> term will give a warning.
<code>...</code>	Arguments to be passed to <code>lm</code> , such as <code>subset</code> or <code>na.action</code> .

Details

This provides a wrapper to `lm` for fitting linear models to balanced or unbalanced experimental designs.

The main difference from `lm` is in the way `print`, `summary` and so on handle the fit: this is expressed in the traditional language of the analysis of variance rather than that of linear models.

If the formula contains a single `Error` term, this is used to specify error strata, and appropriate models are fitted within each error stratum.

The formula can specify multiple responses.

Weights can be specified by a `weights` argument, but should not be used with an `Error` term, and are incompletely supported (e.g., not by `model.tables`).

Value

An object of class `c("aov", "lm")` or for multiple responses of class `c("maov", "aov", "mlm", "lm")` or for multiple error strata of class `"aovlist"`. There are `print` and `summary` methods available for these.

Note

`aov` is designed for balanced designs, and the results can be hard to interpret without balance: beware that missing values in the response(s) will likely lose the balance. If there are two or more error strata, the methods used are statistically inefficient without balance, and it may be better to use `lme`.

Balance can be checked with the [replications](#) function.

The default ‘contrasts’ in R are not orthogonal contrasts, and `aov` and its helper functions will work better with such contrasts: see the examples for how to select these.

Author(s)

The design was inspired by the S function of the same name described in Chambers *et al.* (1992).

References

npk.aovE
summary(npk.aovE)
options(op) # reset to previous
```

approxfun

Interpolation Functions

Description

Return a list of points which linearly interpolate given data points, or a function performing the linear (or constant) interpolation.

Usage

```
approx(x, y = NULL, xout, method="linear", n=50,
       yleft, yright, rule = 1, f = 0, ties = mean)

approxfun(x, y = NULL, method="linear",
          yleft, yright, rule = 1, f = 0, ties = mean)
```

Arguments

<code>x, y</code>	vectors giving the coordinates of the points to be interpolated. Alternatively a single plotting structure can be specified: see xy.coords .
<code>xout</code>	an optional set of values specifying where interpolation is to take place.
<code>method</code>	specifies the interpolation method to be used. Choices are "linear" or "constant".
<code>n</code>	If <code>xout</code> is not specified, interpolation takes place at <code>n</code> equally spaced points spanning the interval $[\min(x), \max(x)]$.
<code>yleft</code>	the value to be returned when input <code>x</code> values are less than $\min(x)$. The default is defined by the value of <code>rule</code> given below.
<code>yright</code>	the value to be returned when input <code>x</code> values are greater than $\max(x)$. The default is defined by the value of <code>rule</code> given below.
<code>rule</code>	an integer describing how interpolation is to take place outside the interval $[\min(x), \max(x)]$. If <code>rule</code> is 1 then NAs are returned for such points and if it is 2, the value at the closest data extreme is used.
<code>f</code>	For <code>method="constant"</code> a number between 0 and 1 inclusive, indicating a compromise between left- and right-continuous step functions. If <code>y0</code> and <code>y1</code> are the values to the left and right of the point then the value is $y0 * (1-f) + y1 * f$ so that <code>f=0</code> is right-continuous and <code>f=1</code> is left-continuous.
<code>ties</code>	Handling of tied <code>x</code> values. Either a function with a single vector argument returning a single number result or the string "ordered".

Details

The inputs can contain missing values which are deleted, so at least two complete (`x, y`) pairs are required (for `method = "linear"`, one otherwise). If there are duplicated (tied) `x` values and `ties` is a function it is applied to the `y` values for each distinct `x` value. Useful functions in this context include [mean](#), [min](#), and [max](#). If `ties="ordered"` the `x` values are assumed to be already ordered. The first `y` value will be used for interpolation to the left and the last one for interpolation to the right.

Value

`approx` returns a list with components `x` and `y`, containing `n` coordinates which interpolate the given data points according to the `method` (and `rule`) desired.

The function `approxfun` returns a function performing (linear or constant) interpolation of the given data points. For a given set of `x` values, this function will return the corresponding interpolated values. This is often more useful than `approx`.

approx(x,y, xout=x)$y # warning
(ay <- approx(x,y, xout=x, ties = "ordered")$y)
stopifnot(ay == c(2,2,3,6,6,6,4,4,1,1,1))
approx(x,y, xout=x, ties = min)$y
approx(x,y, xout=x, ties = max)$y

```

ar

*Fit Autoregressive Models to Time Series***Description**

Fit an autoregressive time series model to the data, by default selecting the complexity by AIC.

Usage

```

ar(x, aic = TRUE, order.max = NULL,
   method=c("yule-walker", "burg", "ols", "mle", "yw"),
   na.action, series, ...)

ar.burg(x, ...)
## Default S3 method:
ar.burg(x, aic = TRUE, order.max = NULL,
        na.action = na.fail, demean = TRUE, series,
        var.method = 1, ...)
## S3 method for class 'mts':
ar.burg(x, aic = TRUE, order.max = NULL,
        na.action = na.fail, demean = TRUE, series,
        var.method = 1, ...)

ar.yw(x, ...)
## Default S3 method:

```

```

ar.yw(x, aic = TRUE, order.max = NULL,
      na.action = na.fail, demean = TRUE, series, ...)
## S3 method for class 'mts':
ar.yw(x, aic = TRUE, order.max = NULL,
      na.action = na.fail, demean = TRUE, series,
      var.method = 1, ...)

ar.mle(x, aic = TRUE, order.max = NULL, na.action = na.fail,
       demean = TRUE, series, ...)

## S3 method for class 'ar':
predict(object, newdata, n.ahead = 1, se.fit = TRUE, ...)

```

Arguments

<code>x</code>	A univariate or multivariate time series.
<code>aic</code>	Logical flag. If <code>TRUE</code> then the Akaike Information Criterion is used to choose the order of the autoregressive model. If <code>FALSE</code> , the model of order <code>order.max</code> is fitted.
<code>order.max</code>	Maximum order (or order) of model to fit. Defaults to the smaller of $N - 1$ and $10 \log_{10}(N)$ where N is the number of observations except for <code>method="mle"</code> where it is the minimum of this quantity and 12.
<code>method</code>	Character string giving the method used to fit the model. Must be one of the strings in the default argument (the first few characters are sufficient). Defaults to "yule-walker".
<code>na.action</code>	function to be called to handle missing values.
<code>demean</code>	should a mean be estimated during fitting?
<code>series</code>	names for the series. Defaults to <code>deparse(substitute(x))</code> .
<code>var.method</code>	the method to estimate the innovations variance (see 'Details').
<code>...</code>	additional arguments for specific methods.
<code>object</code>	a fit from <code>ar</code> .
<code>newdata</code>	data to which to apply the prediction.
<code>n.ahead</code>	number of steps ahead at which to predict.
<code>se.fit</code>	logical: return estimated standard errors of the prediction error?

Details

For definiteness, note that the AR coefficients have the sign in

$$x_t - \mu = a_1(x_{t-1} - \mu) + \cdots + a_p(x_{t-p} - \mu) + e_t$$

`ar` is just a wrapper for the functions `ar.yw`, `ar.burg`, `ar.ols` and `ar.mle`.

Order selection is done by AIC if `aic` is true. This is problematic, as of the methods here only `ar.mle` performs true maximum likelihood estimation. The AIC is computed as if the variance estimate were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values. In `ar.yw` the variance matrix of the innovations is computed from the fitted coefficients and the autocovariance of `x`.

`ar.burg` allows two methods to estimate the innovations variance and hence AIC. Method 1 is to use the update given by the Levinson-Durbin recursion (Brockwell and Davis, 1991, (8.2.6) on page 242), and follows S-PLUS. Method 2 is the mean of the sum of squares of the forward and backward prediction errors (as in Brockwell and Davis, 1996, page 145). Percival and Walden (1998) discuss both. In the multivariate case the estimated coefficients will depend (slightly) on the variance estimation method.

Remember that `ar` includes by default a constant in the model, by removing the overall mean of `x` before fitting the AR model, or (`ar.mle`) estimating a constant to subtract.

Value

For `ar` and its methods a list of class "ar" with the following elements:

<code>order</code>	The order of the fitted model. This is chosen by minimizing the AIC if <code>aic=TRUE</code> , otherwise it is <code>order.max</code> .
<code>ar</code>	Estimated autoregression coefficients for the fitted model.
<code>var.pred</code>	The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
<code>x.mean</code>	The estimated mean of the series used in fitting and for use in prediction.
<code>x.intercept</code>	(<code>ar.ols</code> only.) The intercept in the model for $x - x.mean$.
<code>aic</code>	The value of the <code>aic</code> argument.
<code>n.used</code>	The number of observations in the time series.
<code>order.max</code>	The value of the <code>order.max</code> argument.
<code>partialacf</code>	The estimate of the partial autocorrelation function up to lag <code>order.max</code> .
<code>resid</code>	residuals from the fitted model, conditioning on the first <code>order</code> observations. The first <code>order</code> residuals are set to NA. If <code>x</code> is a time series, so is <code>resid</code> .
<code>method</code>	The value of the <code>method</code> argument.
<code>series</code>	The name(s) of the time series.
<code>frequency</code>	The frequency of the time series.
<code>call</code>	The matched call.
<code>asy.var.coef</code>	(univariate case, <code>order > 0</code> .) The asymptotic-theory variance matrix of the coefficient estimates.

For `predict.ar`, a time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

Note

Only the univariate case of `ar.mle` is implemented.

Fitting by `method="mle"` to long series can be very slow.

```

ar.ols

Fit Autoregressive Models to Time Series by OLS

Description

Fit an autoregressive time series model to the data by ordinary least squares, by default selecting the complexity by AIC.

Usage

```
ar.ols(x, aic = TRUE, order.max = NULL, na.action = na.fail,
       demean = TRUE, intercept = demean, series, ...)
```

Arguments

`x` A univariate or multivariate time series.

`aic` Logical flag. If TRUE then the Akaike Information Criterion is used to choose the order of the autoregressive model. If FALSE, the model of order `order.max` is fitted.

<code>order.max</code>	Maximum order (or order) of model to fit. Defaults to $10 \log_{10}(N)$ where N is the number of observations.
<code>na.action</code>	function to be called to handle missing values.
<code>demean</code>	should the AR model be for x minus its mean?
<code>intercept</code>	should a separate intercept term be fitted?
<code>series</code>	names for the series. Defaults to <code>deparse(substitute(x))</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

`ar.ols` fits the general AR model to a possibly non-stationary and/or multivariate system of series x . The resulting unconstrained least squares estimates are consistent, even if some of the series are non-stationary and/or co-integrated. For definiteness, note that the AR coefficients have the sign in

$$x_t - \mu = a_0 + a_1(x_{t-1} - \mu) + \dots + a_p(x_{t-p} - \mu) + e_t$$

where a_0 is zero unless `intercept` is true, and μ is the sample mean if `demean` is true, zero otherwise.

Order selection is done by AIC if `aic` is true. This is problematic, as `ar.ols` does not perform true maximum likelihood estimation. The AIC is computed as if the variance estimate (computed from the variance matrix of the residuals) were the MLE, omitting the determinant term from the likelihood. Note that this is not the same as the Gaussian likelihood evaluated at the estimated parameter values.

Some care is needed if `intercept` is true and `demean` is false. Only use this if the series are roughly centred on zero. Otherwise the computations may be inaccurate or fail entirely.

Value

A list of class "ar" with the following elements:

<code>order</code>	The order of the fitted model. This is chosen by minimizing the AIC if <code>aic=TRUE</code> , otherwise it is <code>order.max</code> .
<code>ar</code>	Estimated autoregression coefficients for the fitted model.
<code>var.pred</code>	The prediction variance: an estimate of the portion of the variance of the time series that is not explained by the autoregressive model.
<code>x.mean</code>	The estimated mean (or zero if <code>demean</code> is false) of the series used in fitting and for use in prediction.
<code>x.intercept</code>	The intercept in the model for $x - x.mean$, or zero if <code>intercept</code> is false.
<code>aic</code>	The value of the <code>aic</code> argument.
<code>n.used</code>	The number of observations in the time series.
<code>order.max</code>	The value of the <code>order.max</code> argument.
<code>partialacf</code>	NULL. For compatibility with <code>ar</code> .
<code>resid</code>	residuals from the fitted model, conditioning on the first <code>order</code> observations. The first <code>order</code> residuals are set to NA. If x is a time series, so is <code>resid</code> .
<code>method</code>	The character string "Unconstrained LS".
<code>series</code>	The name(s) of the time series.
<code>frequency</code>	The frequency of the time series.
<code>call</code>	The matched call.
<code>asy.se.coef</code>	The asymptotic-theory standard errors of the coefficient estimates.

arima

ARIMA Modelling of Time Series

Description

Fit an ARIMA model to a univariate time series.

Usage

```
arima(x, order = c(0, 0, 0),
      seasonal = list(order = c(0, 0, 0), period = NA),
      xreg = NULL, include.mean = TRUE,
      transform.pars = TRUE,
      fixed = NULL, init = NULL,
      method = c("CSS-ML", "ML", "CSS"),
      n.cond, optim.control = list(), kappa = 1e6)
```

Arguments

<code>x</code>	a univariate time series
<code>order</code>	A specification of the non-seasonal part of the ARIMA model: the three components (p, d, q) are the AR order, the degree of differencing, and the MA order.
<code>seasonal</code>	A specification of the seasonal part of the ARIMA model, plus the period (which defaults to <code>frequency(x)</code>). This should be a list with components <code>order</code> and <code>period</code> , but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the <code>order</code> .
<code>xreg</code>	Optionally, a vector or matrix of external regressors, which must have the same number of rows as <code>x</code> .

<code>include.mean</code>	Should the ARMA model include a mean/intercept term? The default is <code>TRUE</code> for undifferenced series, and it is ignored for ARIMA models with differencing.
<code>transform.pars</code>	Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for <code>method = "CSS"</code> .
<code>fixed</code>	optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in <code>fixed</code> will be varied. <code>transform.pars = TRUE</code> will be overridden (with a warning) if any AR parameters are fixed. It may be wise to set <code>transform.pars = FALSE</code> when fixing MA parameters, especially near non-invertibility.
<code>init</code>	optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in <code>fixed</code> will be ignored.
<code>method</code>	Fitting method: maximum likelihood or minimize conditional sum-of-squares. The default (unless there are missing values) is to use conditional-sum-of-squares to find starting values, then maximum likelihood.
<code>n.cond</code>	Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.
<code>optim.control</code>	List of control parameters for <code>optim</code> .
<code>kappa</code>	the prior variance (as a multiple of the innovations variance) for the past observations in a differenced model. Do not reduce this.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition used here has

$$X_t = a_1 X_{t-1} + \dots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \dots + b_q e_{t-q}$$

and so the MA coefficients differ in sign from those of S-PLUS. Further, if `include.mean` is true (the default for an ARMA model), this formula applies to $X - m$ rather than X . For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model. If an `xreg` term is included, a linear regression (with a constant term if `include.mean` is true and there is no differencing) is fitted with an ARMA model for the error term.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide.

Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Value

A list of class "Arima" with components:

<code>coef</code>	a vector of AR, MA and regression coefficients, which can be extracted by the <code>coef</code> method.
<code>sigma2</code>	the MLE of the innovations variance.
<code>var.coef</code>	the estimated variance matrix of the coefficients <code>coef</code> , which can be extracted by the <code>vcov</code> method.

<code>loglik</code>	the maximized log-likelihood (of the differenced data), or the approximation to it used.
<code>arma</code>	A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
<code>aic</code>	the AIC value corresponding to the log-likelihood. Only valid for <code>method = "ML"</code> fits.
<code>residuals</code>	the fitted innovations.
<code>call</code>	the matched call.
<code>series</code>	the name of the series <code>x</code> .
<code>code</code>	the convergence value returned by <code>optim</code> .
<code>n.cond</code>	the number of initial observations not used in the fitting.
<code>model</code>	A list representing the Kalman Filter used in the fitting. See KalmanLike .

Fitting methods

The exact likelihood is computed via a state-space representation of the ARIMA process, and the innovations and their variance found by a Kalman filter. The initialization of the differenced ARMA process uses stationarity and is based on Gardner *et al.* (1980). For a differenced process the non-stationary components are given a diffuse prior (controlled by `kappa`). Observations which are still controlled by the diffuse prior (determined by having a Kalman gain of at least $1e4$) are excluded from the likelihood calculations. (This gives comparable results to `arima0` in the absence of missing values, when the observations excluded are precisely those dropped by the differencing.)

Missing values are allowed, and are handled exactly in method "ML".

If `transform.pars` is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are not constrained to be invertible during optimization, but they will be converted to invertible form after optimization if `transform.pars` is true.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation `n.cond` on, (where `n.cond` is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument `n.cond` can be used to allow comparability between different fits. The 'part log-likelihood' is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

The results are likely to be different from S-PLUS's `arima.mle`, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by `arima.mle` reverses the signs of the MA coefficients.

`arima` is very similar to `arima0` for ARMA models or for differenced models without missing values, but handles differenced models with missing values exactly. It is somewhat slower than `arima0`, particularly for seasonally differenced models.

require(graphics)
(fit1 <- arima(presidents, c(1, 0, 0)))
tsdiag(fit1)
(fit3 <- arima(presidents, c(3, 0, 0))) # smaller AIC
tsdiag(fit3)
```

arima.sim

Simulate from an ARIMA Model

Description

Simulate from an ARIMA model.

Usage

```
arima.sim(model, n, rand.gen = rnorm, innov = rand.gen(n, ...),
          n.start = NA, start.innov = rand.gen(n.start, ...),
          ...)
```

Arguments

<code>model</code>	A list with component <code>ar</code> and/or <code>ma</code> giving the AR and MA coefficients respectively. Optionally a component <code>order</code> can be used. An empty list gives an ARIMA(0, 0, 0) model, that is white noise.
<code>n</code>	length of output series, before un-differencing.
<code>rand.gen</code>	optional: a function to generate the innovations.
<code>innov</code>	an optional times series of innovations. If not provided, <code>rand.gen</code> is used.
<code>n.start</code>	length of ‘burn-in’ period. If <code>NA</code> , the default, a reasonable value is computed.
<code>start.innov</code>	an optional times series of innovations to be used for the burn-in period. If supplied there must be at least <code>n.start</code> values (and <code>n.start</code> is by default computed inside the function).
<code>...</code>	additional arguments for <code>rand.gen</code> . Most usefully, the standard deviation of the innovations generated by <code>rnorm</code> can be specified by <code>sd</code> .

Details

See [arima](#) for the precise definition of an ARIMA model.

The ARMA model is checked for stationarity.

ARIMA models are specified via the `order` component of `model`, in the same way as for [arima](#). Other aspects of the `order` component are ignored, but inconsistent specifications of the MA and AR orders are detected. The un-differencing assumes previous values of zero, and to remind the user of this, those values are returned.

Random inputs for the ‘burn-in’ period are generated by calling `rand.gen`.

Value

A time-series object of class `"ts"`.

Examples

```
require(graphics)

arima.sim(n = 63, list(ar = c(0.8897, -0.4858), ma = c(-0.2279, 0.2488)),
          sd = sqrt(0.1796))
# mildly long-tailed
arima.sim(n = 63, list(ar=c(0.8897, -0.4858), ma=c(-0.2279, 0.2488)),
          rand.gen = function(n, ...) sqrt(0.1796) * rt(n, df = 5))

# An ARIMA simulation
ts.sim <- arima.sim(list(order = c(1,1,0), ar = 0.7), n = 200)
ts.plot(ts.sim)
```

Description

Fit an ARIMA model to a univariate time series, and forecast from the fitted model.

Usage

```
arima0(x, order = c(0, 0, 0),
       seasonal = list(order = c(0, 0, 0), period = NA),
       xreg = NULL, include.mean = TRUE, delta = 0.01,
       transform.pars = TRUE, fixed = NULL, init = NULL,
       method = c("ML", "CSS"), n.cond, optim.control = list())

## S3 method for class 'arima0':
predict(object, n.ahead = 1, newxreg, se.fit = TRUE, ...)
```

Arguments

<code>x</code>	a univariate time series
<code>order</code>	A specification of the non-seasonal part of the ARIMA model: the three components (p, d, q) are the AR order, the degree of differencing, and the MA order.
<code>seasonal</code>	A specification of the seasonal part of the ARIMA model, plus the period (which defaults to <code>frequency(x)</code>). This should be a list with components <code>order</code> and <code>period</code> , but a specification of just a numeric vector of length 3 will be turned into a suitable list with the specification as the <code>order</code> .
<code>xreg</code>	Optionally, a vector or matrix of external regressors, which must have the same number of rows as <code>x</code> .
<code>include.mean</code>	Should the ARIMA model include a mean term? The default is <code>TRUE</code> for undifferenced series, <code>FALSE</code> for differenced ones (where a mean would not affect the fit nor predictions).
<code>delta</code>	A value to indicate at which point ‘fast recursions’ should be used. See the ‘Details’ section.
<code>transform.pars</code>	Logical. If true, the AR parameters are transformed to ensure that they remain in the region of stationarity. Not used for <code>method = "CSS"</code> .
<code>fixed</code>	optional numeric vector of the same length as the total number of parameters. If supplied, only NA entries in <code>fixed</code> will be varied. <code>transform.pars = TRUE</code> will be overridden (with a warning) if any ARMA parameters are fixed.
<code>init</code>	optional numeric vector of initial parameter values. Missing values will be filled in, by zeroes except for regression coefficients. Values already specified in <code>fixed</code> will be ignored.
<code>method</code>	Fitting method: maximum likelihood or minimize conditional sum-of-squares.
<code>n.cond</code>	Only used if fitting by conditional-sum-of-squares: the number of initial observations to ignore. It will be ignored if less than the maximum lag of an AR term.

<code>optim.control</code>	List of control parameters for <code>optim</code> .
<code>object</code>	The result of an <code>arima0</code> fit.
<code>newxreg</code>	New values of <code>xreg</code> to be used for prediction. Must have at least <code>n.ahead</code> rows.
<code>n.ahead</code>	The number of steps ahead for which prediction is required.
<code>se.fit</code>	Logical: should standard errors of prediction be returned?
<code>...</code>	arguments passed to or from other methods.

Details

Different definitions of ARMA models have different signs for the AR and/or MA coefficients. The definition here has

$$X_t = a_1 X_{t-1} + \dots + a_p X_{t-p} + e_t + b_1 e_{t-1} + \dots + b_q e_{t-q}$$

and so the MA coefficients differ in sign from those of S-PLUS. Further, if `include.mean` is true, this formula applies to $X - m$ rather than X . For ARIMA models with differencing, the differenced series follows a zero-mean ARMA model.

The variance matrix of the estimates is found from the Hessian of the log-likelihood, and so may only be a rough guide, especially for fits close to the boundary of invertibility.

Optimization is done by `optim`. It will work best if the columns in `xreg` are roughly scaled to zero mean and unit variance, but does attempt to estimate suitable scalings.

Finite-history prediction is used. This is only statistically efficient if the MA part of the fit is invertible, so `predict.arima0` will give a warning for non-invertible MA models.

Value

For `arima0`, a list of class "arima0" with components:

<code>coef</code>	a vector of AR, MA and regression coefficients,
<code>sigma2</code>	the MLE of the innovations variance.
<code>var.coef</code>	the estimated variance matrix of the coefficients <code>coef</code> .
<code>loglik</code>	the maximized log-likelihood (of the differenced data), or the approximation to it used.
<code>arma</code>	A compact form of the specification, as a vector giving the number of AR, MA, seasonal AR and seasonal MA coefficients, plus the period and the number of non-seasonal and seasonal differences.
<code>aic</code>	the AIC value corresponding to the log-likelihood. Only valid for <code>method = "ML"</code> fits.
<code>residuals</code>	the fitted innovations.
<code>call</code>	the matched call.
<code>series</code>	the name of the series <code>x</code> .
<code>convergence</code>	the value returned by <code>optim</code> .
<code>n.cond</code>	the number of initial observations not used in the fitting.

For `predict.arima0`, a time series of predictions, or if `se.fit = TRUE`, a list with components `pred`, the predictions, and `se`, the estimated standard errors. Both components are time series.

Fitting methods

The exact likelihood is computed via a state-space representation of the ARMA process, and the innovations and their variance found by a Kalman filter based on Gardner *et al.* (1980). This has the option to switch to ‘fast recursions’ (assume an effectively infinite past) if the innovations variance is close enough to its asymptotic bound. The argument `delta` sets the tolerance: at its default value the approximation is normally negligible and the speed-up considerable. Exact computations can be ensured by setting `delta` to a negative value.

If `transform.pars` is true, the optimization is done using an alternative parametrization which is a variation on that suggested by Jones (1980) and ensures that the model is stationary. For an AR(p) model the parametrization is via the inverse tanh of the partial autocorrelations: the same procedure is applied (separately) to the AR and seasonal AR terms. The MA terms are also constrained to be invertible during optimization by the same transformation if `transform.pars` is true. Note that the MLE for MA terms does sometimes occur for MA polynomials with unit roots: such models can be fitted by using `transform.pars = FALSE` and specifying a good set of initial values (often obtainable from a fit with `transform.pars = TRUE`).

As from R 1.5.0 missing values are allowed, but any missing values will force `delta` to be ignored and full recursions used. Note that missing values will be propagated by differencing, so the procedure used in this function is not fully efficient in that case.

Conditional sum-of-squares is provided mainly for expositional purposes. This computes the sum of squares of the fitted innovations from observation `n.cond` on, (where `n.cond` is at least the maximum lag of an AR term), treating all earlier innovations to be zero. Argument `n.cond` can be used to allow comparability between different fits. The ‘part log-likelihood’ is the first term, half the log of the estimated mean square. Missing values are allowed, but will cause many of the innovations to be missing.

When regressors are specified, they are orthogonalized prior to fitting unless any of the coefficients is fixed. It can be helpful to roughly scale the regressors to zero mean and unit variance.

Note

This is a preliminary version, and will be replaced by [arima](#).

The standard errors of prediction exclude the uncertainty in the estimation of the ARMA model and the regression coefficients.

The results are likely to be different from S-PLUS’s `arima.mle`, which computes a conditional likelihood and does not include a mean in the model. Further, the convention used by `arima.mle` reverses the signs of the MA coefficients.

 ARMAacf

Compute Theoretical ACF for an ARMA Process

Description

Compute the theoretical autocorrelation function or partial autocorrelation function for an ARMA process.

Usage

```
ARMAacf(ar = numeric(0), ma = numeric(0), lag.max = r, pacf = FALSE)
```

Arguments

<code>ar</code>	numeric vector of AR coefficients
<code>ma</code>	numeric vector of MA coefficients
<code>lag.max</code>	integer. Maximum lag required. Defaults to $\max(p, q+1)$, where p , q are the numbers of AR and MA terms respectively.
<code>pacf</code>	logical. Should the partial autocorrelations be returned?

Details

The methods used follow Brockwell & Davis (1991, section 3.3). Their equations (3.3.8) are solved for the autocovariances at lags $0, \dots, \max(p, q + 1)$, and the remaining autocorrelations are given by a recursive filter.

Value

A vector of (partial) autocorrelations, named by the lags.

 ARMAtoMA

Convert ARMA Process to Infinite MA Process

Description

Convert ARMA process to infinite MA process.

Usage

```
ARMAtoMA(ar = numeric(0), ma = numeric(0), lag.max)
```

Arguments

ar	numeric vector of AR coefficients
ma	numeric vector of MA coefficients
lag.max	Largest MA(Inf) coefficient required.

Value

A vector of coefficients.

References

## answer (1 + 3*n)*2^(-n)
n <- 1:10; (1 + 3*n)*2^(-n)
```

as.hclust

Convert Objects to Class hclust

Description

Converts objects from other hierarchical clustering functions to class "hclust".

Usage

```
as.hclust(x, ...)
```

Arguments

`x` Hierarchical clustering object
`...` further arguments passed to or from other methods.

Details

Currently there is only support for converting objects of class "twins" as produced by the functions `diana` and `agnes` from the package **cluster**. The default method throws an error unless passed an "hclust" object.

Value

An object of class "hclust".

See Also

[hclust](#), [diana](#), [agnes](#)

Examples

```
x <- matrix(rnorm(30), ncol=3)
hc <- hclust(dist(x), method="complete")

if(require(cluster, quietly=TRUE)) {# is a recommended package
  ag <- agnes(x, method="complete")
  hcag <- as.hclust(ag)
  ## The dendrograms order slightly differently:
  op <- par(mfrow=c(1,2))
  plot(hc) ; mtext("hclust", side=1)
  plot(hcag); mtext("agnes", side=1)
}
```

asOneSidedFormula *Convert to One-Sided Formula*

Description

Names, expressions, numeric values, and character strings are converted to one-sided formulae. If `object` is a formula, it must be one-sided, in which case it is returned unaltered.

Usage

```
asOneSidedFormula(object)
```

Arguments

`object` a one-sided formula, an expression, a numeric value, or a character string.

Value

a one-sided formula representing `object`

Author(s)

Jose Pinheiro and Douglas Bates

See Also

[formula](#)

Examples

```
asOneSidedFormula("age")
asOneSidedFormula(~ age)
```

ave

Group Averages Over Level Combinations of Factors

Description

Subsets of `x[]` are averaged, where each subset consist of those observations with the same factor levels.

Usage

```
ave(x, ..., FUN = mean)
```

Arguments

`x` A numeric.
`...` Grouping variables, typically factors, all of the same `length` as `x`.
`FUN` Function to apply for each factor level combination.

Value

A numeric vector, say y of length $\text{length}(x)$. If ... is g_1, g_2 , e.g., $y[i]$ is equal to $\text{FUN}(x[j], \text{for all } j \text{ with } g_1[j] == g_1[i] \text{ and } g_2[j] == g_2[i])$.

See Also

[mean](#), [median](#).

Examples

```
require(graphics)

ave(1:3)# no grouping -> grand mean

attach(warpbreaks)
ave(breaks, wool)
ave(breaks, tension)
ave(breaks, tension, FUN = function(x)mean(x, trim=.1))
plot(breaks, main =
     "ave( Warpbreaks ) for wool x tension combinations")
lines(ave(breaks, wool, tension           ), type='s', col = "blue")
lines(ave(breaks, wool, tension, FUN=median), type='s', col = "green")
legend(40,70, c("mean", "median"), lty=1, col=c("blue", "green"), bg="gray90")
detach()
```

bandwidth

Bandwidth Selectors for Kernel Density Estimation

Description

Bandwidth selectors for gaussian windows in [density](#).

Usage

```
bw.nrd0(x)

bw.nrd(x)

bw.ucv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax)

bw.bcv(x, nb = 1000, lower = 0.1 * hmax, upper = hmax)

bw.SJ(x, nb = 1000, lower = 0.1 * hmax, upper = hmax,
      method = c("ste", "dpi"))
```

Arguments

<code>x</code>	A data vector.
<code>nb</code>	number of bins to use.
<code>lower, upper</code>	Range over which to minimize. The default is almost always satisfactory. <code>hmax</code> is calculated internally from a normal reference bandwidth.
<code>method</code>	Either <code>"ste"</code> ("solve-the-equation") or <code>"dpi"</code> ("direct plug-in").

Details

`bw.nrd0` implements a rule-of-thumb for choosing the bandwidth of a Gaussian kernel density estimator. It defaults to 0.9 times the minimum of the standard deviation and the interquartile range divided by 1.34 times the sample size to the negative one-fifth power (= Silverman's 'rule of thumb', Silverman (1986, page 48, eqn (3.31)) *unless* the quartiles coincide when a positive result will be guaranteed.

`bw.nrd` is the more common variation given by Scott (1992), using factor 1.06.

`bw.ucv` and `bw.bcv` implement unbiased and biased cross-validation respectively.

`bw.SJ` implements the methods of Sheather & Jones (1991) to select the bandwidth using pilot estimation of derivatives.

The algorithm solves an equation (via `uniroot`) and because of that, enlarges the interval `c(lower, upper)` when the boundaries were not user-specified and do not bracket the root.

Value

A bandwidth on a scale suitable for the `bw` argument of `density`.

plot(density(precip, n = 1000))
rug(precip)
lines(density(precip, bw="nrd"), col = 2)
lines(density(precip, bw="ucv"), col = 3)
lines(density(precip, bw="bcv"), col = 4)
lines(density(precip, bw="SJ-ste"), col = 5)
lines(density(precip, bw="SJ-dpi"), col = 6)
legend(55, 0.035,
      legend = c("nrd0", "nrd", "ucv", "bcv", "SJ-ste", "SJ-dpi"),
      col = 1:6, lty = 1)
```

bartlett.test *Bartlett Test of Homogeneity of Variances*

Description

Performs Bartlett's test of the null that the variances in each of the groups (samples) are the same.

Usage

```
bartlett.test(x, ...)

## Default S3 method:
bartlett.test(x, g, ...)

## S3 method for class 'formula':
bartlett.test(formula, data, subset, na.action, ...)
```

Arguments

<code>x</code>	a numeric vector of data values, or a list of numeric data vectors representing the respective samples, or fitted linear model objects (inheriting from class "lm").
<code>g</code>	a vector or factor object giving the group for the corresponding elements of <code>x</code> . Ignored if <code>x</code> is a list.
<code>formula</code>	a formula of the form <code>lhs ~ rhs</code> where <code>lhs</code> gives the data values and <code>rhs</code> the corresponding groups.
<code>data</code>	an optional matrix or data frame (or similar: see <code>model.frame</code>) containing the variables in the formula <code>formula</code> . By default the variables are taken from <code>environment(formula)</code> .
<code>subset</code>	an optional vector specifying a subset of observations to be used.
<code>na.action</code>	a function which indicates what should happen when the data contain NAs. Defaults to <code>getOption("na.action")</code> .
<code>...</code>	further arguments to be passed to or from methods.

Details

If `x` is a list, its elements are taken as the samples or fitted linear models to be compared for homogeneity of variances. In this case, the elements must either all be numeric data vectors or fitted linear model objects, `g` is ignored, and one can simply use `bartlett.test(x)` to perform the test. If the samples are not yet contained in a list, use `bartlett.test(list(x, ...))`.

Otherwise, `x` must be a numeric data vector, and `g` must be a vector or factor object of the same length as `x` giving the group for the corresponding elements of `x`.

Value

A list of class "htest" containing the following components:

<code>statistic</code>	Bartlett's K-squared test statistic.
<code>parameter</code>	the degrees of freedom of the approximate chi-squared distribution of the test statistic.

<code>p.value</code>	the p-value of the test.
<code>method</code>	the character string "Bartlett test of homogeneity of variances".
<code>data.name</code>	a character string giving the names of the data.

plot(count ~ spray, data = InsectSprays)
bartlett.test(InsectSprays$count, InsectSprays$spray)
bartlett.test(count ~ spray, data = InsectSprays)
```

Beta

The Beta Distribution

Description

Density, distribution function, quantile function and random generation for the Beta distribution with parameters `shape1` and `shape2` (and optional non-centrality parameter `ncp`).

Usage

```
dbeta(x, shape1, shape2, ncp = 0, log = FALSE)
pbeta(q, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
qbeta(p, shape1, shape2, ncp = 0, lower.tail = TRUE, log.p = FALSE)
rbeta(n, shape1, shape2, ncp = 0)
```

Arguments

<code>x, q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>shape1, shape2</code>	positive parameters of the Beta distribution.
<code>ncp</code>	non-centrality parameter.
<code>log, log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as $\log(p)$.
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The Beta distribution with parameters `shape1 = a` and `shape2 = b` has density

$$f(x) = \frac{\Gamma(a+b)}{\Gamma(a)\Gamma(b)} x^a (1-x)^b$$

for $a > 0$, $b > 0$ and $0 \leq x \leq 1$ where the boundary values at $x = 0$ or $x = 1$ are defined as by continuity (as limits).

The mean is $a/(a+b)$ and the variance is $ab/((a+b)^2(a+b+1))$.

`pbeta` is closely related to the incomplete beta function. As defined by Abramowitz and Stegun 6.6.1

$$B_x(a, b) = \int_0^x t^{a-1} (1-t)^{b-1} dt,$$

and 6.6.2 $I_x(a, b) = B_x(a, b)/B(a, b)$ where $B(a, b) = B_1(a, b)$ is the Beta function (`beta`).

$I_x(a, b)$ is `pbeta(x, a, b)`.

The noncentral Beta distribution (with `ncp = λ`) is defined (Johnson et al, 1995, pp. 502) as the distribution of $X/(X+Y)$ where $X \sim \chi_{2a}^2(\lambda)$ and $Y \sim \chi_{2b}^2$.

Value

`dbeta` gives the density, `pbeta` the distribution function, `qbeta` the quantile function, and `rbeta` generates random deviates.

Invalid arguments will result in return value `NaN`, with a warning.

Source

The central `dbeta` is based on a binomial probability, using code contributed by Catherine Loader (see `dbinom`) if either shape parameter is larger than one, otherwise directly from the definition. The non-central case is based on the derivation as a Poisson mixture of betas (Johnson *et al*, 1995, pp. 502–3).

The central `pbeta` uses a C translation (and enhancement for `log_p=TRUE`) of

Didonato, A. and Morris, A., Jr. (1992) Algorithm 708: Significant digit computation of the incomplete beta function ratios, *ACM Transactions on Mathematical Software*, **18**, 360–373. (See also Brown, B. and Lawrence Levy, L. (1994) Certification of algorithm 708: Significant digit computation of the incomplete beta, *ACM Transactions on Mathematical Software*, **20**, 393–397.)

The non-central `pbeta` uses a C translation of

Lenth, R. V. (1987) Algorithm AS226: Computing noncentral beta probabilities. *Appl. Statist*, **36**, 241–244, incorporating

Frick, H. (1990)'s AS R84, *Appl. Statist*, **39**, 311–2, and

Lam, M.L. (1995)'s AS R95, *Appl. Statist*, **44**, 551–2.

`qbeta` is based on a C translation of

Cran, G. W., K. J. Martin and G. E. Thomas (1977). Remark AS R19 and Algorithm AS 109, *Applied Statistics*, **26**, 111–114, and subsequent remarks (AS83 and correction).

`rbeta` is based on a C translation of

R. C. H. Cheng (1978). Generating beta variates with nonintegral shape parameters. *Communications of the ACM*, **21**, 317–322.

dbeta(x, 1, 1)
pbeta(x, 1, 1)
```

binom.test	<i>Exact Binomial Test</i>
------------	----------------------------

Description

Performs an exact test of a simple null hypothesis about the probability of success in a Bernoulli experiment.

Usage

```
binom.test(x, n, p = 0.5,
           alternative = c("two.sided", "less", "greater"),
           conf.level = 0.95)
```

Arguments

- | | |
|-------------|--|
| x | number of successes, or a vector of length 2 giving the numbers of successes and failures, respectively. |
| n | number of trials; ignored if x has length 2. |
| p | hypothesized probability of success. |
| alternative | indicates the alternative hypothesis and must be one of "two.sided", "greater" or "less". You can specify just the initial letter. |
| conf.level | confidence level for the returned confidence interval. |

Details

Confidence intervals are obtained by a procedure first given in Clopper and Pearson (1934). This guarantees that the confidence level is at least `conf.level`, but in general does not give the shortest-length confidence intervals.

Value

A list with class "htest" containing the following components:

statistic	the number of successes.
parameter	the number of trials.
p.value	the p-value of the test.
conf.int	a confidence interval for the probability of success.
estimate	the estimated probability of success.
null.value	the probability of success under the null, p_0 .
alternative	a character string describing the alternative hypothesis.
method	the character string "Exact binomial test".
data.name	a character string giving the names of the data.

See Also

[prop.test](#) for a general (approximate) test for equal or given proportions.

Examples

```
## Conover (1971), p. 97f.
## Under (the assumption of) simple Mendelian inheritance, a cross
## between plants of two particular genotypes produces progeny 1/4 of
## which are "dwarf" and 3/4 of which are "giant", respectively.
## In an experiment to determine if this assumption is reasonable, a
## cross results in progeny having 243 dwarf and 682 giant plants.
## If "giant" is taken as success, the null hypothesis is that  $p =$ 
##  $3/4$  and the alternative that  $p \neq 3/4$ .
binom.test(c(682, 243), p = 3/4)
binom.test(682, 682 + 243, p = 3/4) # The same.
## => Data are in agreement with the null hypothesis.
```

Description

Density, distribution function, quantile function and random generation for the binomial distribution with parameters `size` and `prob`.

Usage

```
dbinom(x, size, prob, log = FALSE)
pbinom(q, size, prob, lower.tail = TRUE, log.p = FALSE)
qbinom(p, size, prob, lower.tail = TRUE, log.p = FALSE)
rbinom(n, size, prob)
```

Arguments

<code>x</code> , <code>q</code>	vector of quantiles.
<code>p</code>	vector of probabilities.
<code>n</code>	number of observations. If <code>length(n) > 1</code> , the length is taken to be the number required.
<code>size</code>	number of trials (zero or more).
<code>prob</code>	probability of success on each trial.
<code>log</code> , <code>log.p</code>	logical; if TRUE, probabilities <code>p</code> are given as <code>log(p)</code> .
<code>lower.tail</code>	logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

The binomial distribution with `size = n` and `prob = p` has density

$$p(x) = \binom{n}{x} p^x (1-p)^{n-x}$$

for $x = 0, \dots, n$.

If an element of `x` is not integer, the result of `dbinom` is zero, with a warning. $p(x)$ is computed using Loader's algorithm, see the reference below.

The quantile is defined as the smallest value x such that $F(x) \geq p$, where F is the distribution function.

Value

`dbinom` gives the density, `pbinom` gives the distribution function, `qbinom` gives the quantile function and `rbinom` generates random deviates.

If `size` is not an integer, NaN is returned.

Source

For `dbinom` a saddle-point expansion is used: see

Catherine Loader (2000). *Fast and Accurate Computation of Binomial Probabilities*; available from <http://www.herine.net/stat/software/dbinom.html>.

`pbinom` uses `pbeta`.

`qbinom` uses the Cornish–Fisher Expansion to include a skewness correction to a normal approximation, followed by a search.

`rbinom` (for `size < .Machine$integer.max`) is based on

Kachitvichyanukul, V. and Schmeiser, B. W. (1988) Binomial random variate generation. *Communications of the ACM*, **31**, 216–222.

Examples

```
require(graphics)
# Compute P(45 < X < 55) for X Binomial(100,0.5)
sum(dbinom(46:54, 100, 0.5))

## Using "log = TRUE" for an extended range :
n <- 2000
k <- seq(0, n, by = 20)
plot(k, dbinom(k, n, pi/10, log=TRUE), type='l', ylab="log density",
      main = "dbinom(*, log=TRUE) is better than log(dbinom(*))")
lines(k, log(dbinom(k, n, pi/10)), col='red', lwd=2)
## extreme points are omitted since dbinom gives 0.
mtext("dbinom(k, log=TRUE)", adj=0)
mtext("extended range", adj=0, line = -1, font=4)
mtext("log(dbinom(k))", col="red", adj=1)
```

 biplot

Biplot of Multivariate Data

Description

Plot a biplot on the current graphics device.

Usage

```
biplot(x, ...)

## Default S3 method:
biplot(x, y, var.axes = TRUE, col, cex = rep(par("cex"), 2),
       xlabs = NULL, ylabs = NULL, expand = 1,
       xlim = NULL, ylim = NULL, arrow.len = 0.1,
       main = NULL, sub = NULL, xlab = NULL, ylab = NULL, ...)
```

Arguments

<code>x</code>	The biplot, a fitted object. For <code>biplot.default</code> , the first set of points (a two-column matrix), usually associated with observations.
<code>y</code>	The second set of points (a two-column matrix), usually associated with variables.
<code>var.axes</code>	If <code>TRUE</code> the second set of points have arrows representing them as (unscaled) axes.
<code>col</code>	A vector of length 2 giving the colours for the first and second set of points respectively (and the corresponding axes). If a single colour is specified it will be used for both sets. If missing the default colour is looked for in the palette : if there it and the next colour as used, otherwise the first two colours of the palette are used.

<code>cex</code>	The character expansion factor used for labelling the points. The labels can be of different sizes for the two sets by supplying a vector of length two.
<code>xlabs</code>	A vector of character strings to label the first set of points: the default is to use the row dimname of <code>x</code> , or <code>1:n</code> is the dimname is <code>NULL</code> .
<code>ylabs</code>	A vector of character strings to label the second set of points: the default is to use the row dimname of <code>y</code> , or <code>1:n</code> is the dimname is <code>NULL</code> .
<code>expand</code>	An expansion factor to apply when plotting the second set of points relative to the first. This can be used to tweak the scaling of the two sets to a physically comparable scale.
<code>arrow.len</code>	The length of the arrow heads on the axes plotted in <code>var.axes</code> is <code>true</code> . The arrow head can be suppressed by <code>arrow.len = 0</code> .
<code>xlim, ylim</code>	Limits for the <code>x</code> and <code>y</code> axes in the units of the first set of variables.
<code>main, sub, xlab, ylab, ...</code>	graphical parameters.

Details

A biplot is plot which aims to represent both the observations and variables of a matrix of multivariate data on the same plot. There are many variations on biplots (see the references) and perhaps the most widely used one is implemented by `biplot.princomp`. The function `biplot.default` merely provides the underlying code to plot two sets of variables on the same figure.

Graphical parameters can also be given to `biplot`: the size of `xlabs` and `ylabs` is controlled by `cex`.

Side Effects

a plot is produced on the current graphics device.

See Also

`biplot.princomp`, also for examples.

`biplot.princomp` *Biplot for Principal Components*

Description

Produces a biplot (in the strict sense) from the output of `princomp` or `prcomp`

Usage

```
## S3 method for class 'prcomp':
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)

## S3 method for class 'princomp':
biplot(x, choices = 1:2, scale = 1, pc.biplot = FALSE, ...)
```

Arguments

<code>x</code>	an object of class "princomp".
<code>choices</code>	length 2 vector specifying the components to plot. Only the default is a biplot in the strict sense.
<code>scale</code>	The variables are scaled by $\lambda \text{ scale}$ and the observations are scaled by $\lambda (1 - \text{scale})$ where λ are the singular values as computed by <code>princomp</code> . Normally $0 \leq \text{scale} \leq 1$, and a warning will be issued if the specified <code>scale</code> is outside this range.
<code>pc.biplot</code>	If true, use what Gabriel (1971) refers to as a "principal component biplot", with $\lambda = 1$ and observations scaled up by \sqrt{n} and variables scaled down by \sqrt{n} . Then inner products between variables approximate covariances and distances between observations approximate Mahalanobis distance.
<code>...</code>	optional arguments to be passed to <code>biplot.default</code> .

Details

This is a method for the generic function `biplot`. There is considerable confusion over the precise definitions: those of the original paper, Gabriel (1971), are followed here. Gabriel and Odoroff (1990) use the same definitions, but their plots actually correspond to `pc.biplot = TRUE`.

Side Effects

a plot is produced on the current graphics device.

Examples

```
require(graphics)
biplot(princomp(USArrests))
```

birthday	<i>Probability of coincidences</i>
----------	------------------------------------

Description

Computes approximate answers to a generalised *birthday paradox* problem. `pbirthday` computes the probability of a coincidence and `qbirthday` computes the number of observations needed to have a specified probability of coincidence.

Usage

```
qbirthday(prob = 0.5, classes = 365, coincident = 2)
pbirthday(n, classes = 365, coincident = 2)
```

Arguments

<code>classes</code>	How many distinct categories the people could fall into
<code>prob</code>	The desired probability of coincidence
<code>n</code>	The number of people
<code>coincident</code>	The number of people to fall in the same category

Details

The birthday paradox is that a very small number of people, 23, suffices to have a 50-50 chance that two of them have the same birthday. This function generalises the calculation to probabilities other than 0.5, numbers of coincident events other than 2, and numbers of classes other than 365.

This formula is approximate, as the example below shows. For `coincident=2` the exact computation is straightforward and may be preferable.

Value

<code>qbirthday</code>	Number of people needed for a probability <code>prob</code> that <code>k</code> of them have the same one out of <code>classes</code> equiprobable labels.
<code>pbirthday</code>	Probability of the specified coincidence

References

Diaconis, P. and Mosteller F. (1989) Methods for studying coincidences. J. American Statistical Association, **84**, 853-861.

Examples

```
require(graphics)

## the standard version
qbirthday()
## same 4-digit PIN number
qbirthday(classes=10^4)
## 0.9 probability of three coincident birthdays
qbirthday(coincident=3, prob=0.9)
## Chance of 4 coincident birthdays in 150 people
```

```

pbirthday(150,coincident=4)
## 100 coincident birthdays in 1000 people: *very* rare:
pbirthday(1000, coincident=100)

## Accuracy compared to exact calculation
x1<- sapply(10:100, pbirthday)
x2<- 1-sapply(10:100, function(n)prod((365:(365-n+1))/rep(365,n)))
par(mfrow=c(2,2))
plot(x1, x2, xlab="approximate", ylab="exact")
abline(0,1)
plot(x1, x1-x2, xlab="approximate", ylab="error")
abline(h=0)
plot(x1, x2, log="xy", xlab="approximate", ylab="exact")
abline(0,1)
plot(1-x1, 1-x2, log="xy", xlab="approximate", ylab="exact")
abline(0,1)

```

Box.test

Box-Pierce and Ljung-Box Tests

Description

Compute the Box–Pierce or Ljung–Box test statistic for examining the null hypothesis of independence in a given time series. These are sometimes known as ‘portmanteau’ tests.

Usage

```
Box.test(x, lag = 1, type = c("Box-Pierce", "Ljung-Box"), fitdf = 0)
```

Arguments

<code>x</code>	a numeric vector or univariate time series.
<code>lag</code>	the statistic will be based on <code>lag</code> autocorrelation coefficients.
<code>type</code>	test to be performed: partial matching is used.
<code>fitdf</code>	number of degrees of freedom to be subtracted if <code>x</code> is a series of residuals.

Details

These tests are sometimes applied to the residuals from an ARMA (p , q) fit, in which case the references suggest a better approximation to the null-hypothesis distribution is obtained by setting `fitdf = p+q`, provided of course that `lag > fitdf`.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value of the test statistic.
<code>parameter</code>	the degrees of freedom of the approximate chi-squared distribution of the test statistic.
<code>p.value</code>	the p-value of the test.
<code>method</code>	a character string indicating which type of test was performed.
<code>data.name</code>	a character string giving the name of the data.

Note

Missing values are not handled.

Box.test (x, lag = 1, type="Ljung")
```

C

Sets Contrasts for a Factor

Description

Sets the "contrasts" attribute for the factor.

Usage

```
C(object, contr, how.many, ...)
```

Arguments

object	a factor or ordered factor
contr	which contrasts to use. Can be a matrix with one row for each level of the factor or a suitable function like <code>contr.poly</code> or a character string giving the name of the function
how.many	the number of contrasts to set, by default one less than <code>nlevels(object)</code> .
...	additional arguments for the function <code>contr</code> .

Details

For compatibility with S, `contr` can be `treatment`, `helmert`, `sum` or `poly` (without quotes) as shorthand for `contr.treatment` and so on.

Value

The factor `object` with the "contrasts" attribute set.

Examples

```
## reset contrasts to defaults
options(contrasts=c("contr.treatment", "contr.poly"))
tens <- with(warpbreaks, C(tension, poly, 1))
attributes(tens)
## tension SHOULD be an ordered factor, but as it is not we can use
aov(breaks ~ wool + tens + tension, data=warpbreaks)

## show the use of ... The default contrast is contr.treatment here
summary(lm(breaks ~ wool + C(tension, base=2), data=warpbreaks))

# following on from help(esoph)
model3 <- glm(cbind(ncases, ncontrols) ~ agegp + C(tobgp, , 1) +
             C(alcgp, , 1), data = esoph, family = binomial())
summary(model3)
```

cancor

Canonical Correlations

Description

Compute the canonical correlations between two data matrices.

Usage

```
cancor(x, y, xcenter = TRUE, ycenter = TRUE)
```

Arguments

<code>x</code>	numeric matrix ($n \times p_1$), containing the x coordinates.
<code>y</code>	numeric matrix ($n \times p_2$), containing the y coordinates.
<code>xcenter</code>	logical or numeric vector of length p_1 , describing any centering to be done on the x values before the analysis. If <code>TRUE</code> (default), subtract the column means. If <code>FALSE</code> , do not adjust the columns. Otherwise, a vector of values to be subtracted from the columns.
<code>ycenter</code>	analogous to <code>xcenter</code> , but for the y values.

Details

The canonical correlation analysis seeks linear combinations of the y variables which are well explained by linear combinations of the x variables. The relationship is symmetric as ‘well explained’ is measured by correlations.

Value

A list containing the following components:

cor	correlations.
xcoef	estimated coefficients for the x variables.
ycoef	estimated coefficients for the y variables.
xcenter	the values used to adjust the x variables.
ycenter	the values used to adjust the x variables.

Examples

```
pop <- LifeCycleSavings[, 2:3]
oec <- LifeCycleSavings[, -(2:3)]
cancor(pop, oec)

x <- matrix(rnorm(150), 50, 3)
y <- matrix(rnorm(250), 50, 5)
(cxy <- cancor(x, y))
all(abs(cor(x %*% cxy$xcoef,
            y %*% cxy$ycoef)[,1:3] - diag(cxy $ cor)) < 1e-15)
all(abs(cor(x %*% cxy$xcoef) - diag(3)) < 1e-15)
all(abs(cor(y %*% cxy$ycoef) - diag(5)) < 1e-15)
```

case/variable.names

Case and Variable Names of Fitted Models

Description

Simple utilities returning (non-missing) case names, and (non-eliminated) variable names.

Usage

```
case.names(object, ...)
## S3 method for class 'lm':
case.names(object, full = FALSE, ...)

variable.names(object, ...)
## S3 method for class 'lm':
variable.names(object, full = FALSE, ...)
```

Arguments

object an R object, typically a fitted model.
 full logical; if TRUE, all names (including zero weights, ...) are returned.
 ... further arguments passed to or from other methods.

Value

A character vector.

See Also

`lm`; further, `all.names`, `all.vars` for functions with a similar name but only slightly related purpose.

Examples

```
x <- 1:20
y <- x + (x/4 - 2)^3 + rnorm(20, sd=3)
names(y) <- paste("0",x,sep=".")
ww <- rep(1,20); ww[13] <- 0
summary(lmxy <- lm(y ~ x + I(x^2)+I(x^3) + I((x-10)^2),
                 weights = ww), cor = TRUE)
variable.names(lmxy)
variable.names(lmxy, full= TRUE)# includes the last
case.names(lmxy)
case.names(lmxy, full = TRUE)# includes the 0-weight case
```

 Cauchy

The Cauchy Distribution

Description

Density, distribution function, quantile function and random generation for the Cauchy distribution with location parameter `location` and scale parameter `scale`.

Usage

```
dcauchy(x, location = 0, scale = 1, log = FALSE)
pcauchy(q, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
qcauchy(p, location = 0, scale = 1, lower.tail = TRUE, log.p = FALSE)
rcauchy(n, location = 0, scale = 1)
```

Arguments

`x`, `q` vector of quantiles.
`p` vector of probabilities.
`n` number of observations. If `length(n) > 1`, the length is taken to be the number required.
`location`, `scale` location and scale parameters.
`log`, `log.p` logical; if TRUE, probabilities `p` are given as $\log(p)$.
`lower.tail` logical; if TRUE (default), probabilities are $P[X \leq x]$, otherwise, $P[X > x]$.

Details

If `location` or `scale` are not specified, they assume the default values of 0 and 1 respectively.

The Cauchy distribution with location l and scale s has density

$$f(x) = \frac{1}{\pi s} \left(1 + \left(\frac{x-l}{s} \right)^2 \right)^{-1}$$

for all x .

Value

`dcauchy`, `pcauchy`, and `qcauchy` are respectively the density, distribution function and quantile function of the Cauchy distribution. `rcauchy` generates random deviates from the Cauchy.

Source

`dcauchy`, `pcauchy` and `qcauchy` are all calculated from numerically stable versions of the definitions.

`rcauchy` uses inversion.

chisq.test
```

Pearson's Chi-squared Test for Count Data

Description

`chisq.test` performs chi-squared contingency table tests and goodness-of-fit tests.

Usage

```
chisq.test(x, y = NULL, correct = TRUE,
           p = rep(1/length(x), length(x)), rescale.p = FALSE,
           simulate.p.value = FALSE, B = 2000)
```

Arguments

<code>x</code>	a vector or matrix.
<code>y</code>	a vector; ignored if <code>x</code> is a matrix.
<code>correct</code>	a logical indicating whether to apply continuity correction when computing the test statistic for 2x2 tables: one half is subtracted from all $ O - E $ differences. No correction is done if <code>simulate.p.value = TRUE</code> .
<code>p</code>	a vector of probabilities of the same length of <code>x</code> . An error is given if any entry of <code>p</code> is negative.
<code>rescale.p</code>	a logical scalar; if TRUE then <code>p</code> is rescaled (if necessary) to sum to 1. If <code>rescale.p</code> is FALSE, and <code>p</code> does not sum to 1, an error is given.
<code>simulate.p.value</code>	a logical indicating whether to compute p-values by Monte Carlo simulation.
<code>B</code>	an integer specifying the number of replicates used in the Monte Carlo test.

Details

If `x` is a matrix with one row or column, or if `x` is a vector and `y` is not given, then a *goodness-of-fit test* is performed (`x` is treated as a one-dimensional contingency table). The entries of `x` must be non-negative integers. In this case, the hypothesis tested is whether the population probabilities equal those in `p`, or are all equal if `p` is not given.

If `x` is a matrix with at least two rows and columns, it is taken as a two-dimensional contingency table. Again, the entries of `x` must be non-negative integers. Otherwise, `x` and `y` must be vectors or factors of the same length; incomplete cases are removed, the objects are coerced into factor objects, and the contingency table is computed from these. Then, Pearson's chi-squared test of the null hypothesis that the joint distribution of the cell counts in a 2-dimensional contingency table is the product of the row and column marginals is performed.

If `simulate.p.value` is FALSE, the p-value is computed from the asymptotic chi-squared distribution of the test statistic; continuity correction is only used in the 2-by-2 case (if `correct` is TRUE, the default). Otherwise the p-value is computed for a Monte Carlo test (Hope, 1968) with `B` replicates.

In the contingency table case simulation is done by random sampling from the set of all contingency tables with given marginals, and works only if the marginals are strictly positive. (A C translation of the algorithm of Patefield (1981) is used.) Continuity correction is never used, and the statistic is quoted without it. Note that this is not the usual sampling situation for the chi-squared test but rather that for Fisher's exact test.

In the goodness-of-fit case simulation is done by random sampling from the discrete distribution specified by `p`, each sample being of size $n = \text{sum}(x)$. This simulation is done in `R` and may be slow.

Value

A list with class "htest" containing the following components:

<code>statistic</code>	the value the chi-squared test statistic.
<code>parameter</code>	the degrees of freedom of the approximate chi-squared distribution of the test statistic, NA if the p-value is computed by Monte Carlo simulation.
<code>p.value</code>	the p-value for the test.
<code>method</code>	a character string indicating the type of test performed, and whether Monte Carlo simulation or continuity correction was used.

data.name	a character string giving the name(s) of the data.
observed	the observed counts.
expected	the expected counts under the null hypothesis.
residuals	the Pearson residuals, $(\text{observed} - \text{expected}) / \sqrt{\text{expected}}$.

Examples

```
## Not really a good example
chisq.test(InsectSprays$count > 7, InsectSprays$spray)
# Prints test summary
chisq.test(InsectSprays$count > 7, InsectSprays$spray)$observed
# Counts observed
chisq.test(InsectSprays$count > 7, InsectSprays$spray)$expected
# Counts expected under the null

## Effect of simulating p-values
x <- matrix(c(12, 5, 7, 7), ncol = 2)
chisq.test(x)$p.value # 0.4233
chisq.test(x, simulate.p.value = TRUE, B = 10000)$p.value
# around 0.29!

## Testing for population probabilities
## Case A. Tabulated data
x <- c(A = 20, B = 15, C = 25)
chisq.test(x)
chisq.test(as.table(x)) # the same
x <- c(89, 37, 30, 28, 2)
p <- c(40, 20, 20, 15, 5)
try(
  chisq.test(x, p = p) # gives an error
)
chisq.test(x, p = p, rescale.p = TRUE)
# works
p <- c(0.40, 0.20, 0.20, 0.19, 0.01)
# Expected count in category 5
# is 1.86 < 5 ==> chi square approx.
chisq.test(x, p = p) # maybe doubtful, but is ok!
chisq.test(x, p = p, simulate.p.value = TRUE)

## Case B. Raw data
x <- trunc(5 * runif(100))
chisq.test(table(x)) # NOT 'chisq.test(x)'
```
